Design and simulation of the sensing/monitoring hardware circuit has been completed in Proteus simulation software with desirable waveforms displayed on the oscilloscope in the illustration below. This circuit has been implemented on a bread board and output results are within 5% error when compared with the simulation results. Interference due to noise and ambient light are apparent in the breadboard circuit. We anticipate a smaller error margin once implemented on a PCB. The control module has also been simulated in Proteus and is yet to be implemented on a bread board and subsequently PCB.

Conclusions

Pending designs include simulation of the user interface display hardware circuit in Proteus and incorporation of LCD function coding and testing. We will also identify a charge management Integrated Circuit (IC) for the rechargeable batteries to build the power supply system.

SP168 - Health Challenges in Resource-Poor Nations

TRACK 12: MEDICAL DEVICES

SP168.2 - Challenges of introducing health technologies to low resource settings in global framework: a case study at WHO Author(s): Cai Long, Adriana Velazquez Berumen, Daniela Rodriguez Rodriguez

Essential Medicines And Health Products Department, World Health Organization, Geneva/SWITZERLAND

Asphyxia, defined as the failure to initiate and sustain breath at birth, is responsible for a quarter all neonatal deaths (around 700,000)¹. Effective neonatal resuscitation, immediate care including thorough drying, suction and stimulation after assessment, and positive-pressure ventilation can prevent a large number of these neonatal deaths.^{2,3}

The United Nations Commission on Life-Saving Commodities for Women and Children (UNCLSC) aims to increase access to life-saving commodities for people in low resource settings. In collaboration with UNICEF, United States Agency for International Development (USAID), PATH and Clinton Health Access Initiatives (CHAI), WHO has worked on developing technical specifications for neonatal resuscitation commodities, including neonatal resuscitation bag with masks, suction machine, single use and reusable suction bulb. These technical specifications provide a technical baseline for any policy-maker, manager, procurement officer, manufacturer or nongovernmental agency in low resource settings to access affordable, safe and good quality neonatal resuscitation devices.

For neonatal resuscitation bag with masks, which ventilate newborns with positive air pressure, three major technical specifications were specified: bag size, pressure relief valve maximum pressure and face mask size. Unexpected challenges and barriers were faced and solved in this process, including:

 Discrepancies among existing standards and professional association guidelines.

· Lack of international standards for certain technical specifications for life-saving essential health technologies.

· Lack of information and research for life-saving essential health technologies.

 \cdot Making unbiased optimal recommendations in a smaller market with limited vendors

• Other challenges: logistics, procurement, disinfection, decommissioning and overall safe use of neonatal resuscitation devices in low resource setting countries.

Multi-stakeholder tactics were used to solve the challenges in the process of documenting WHO technical specifications:

- · Collaborate with international associations, NGOs.
- · Consult within institution experts and external experts.
- · Gather feedback and comments from users' perspective.
- · Review current market status quo.
- · Literature review.

• Encourage research on simple, essential lifesaving health technologies.

Technical specifications were identified and submitted for further global expert review. In the future, in order to increase access to lifesaving health technologies for the world's most vulnerable people, WHO, regulatory bodies and NGOs should encourage greater attention on essential health technologies needed in low resource settings.

SP168.3 - Portable microwave based stroke and trauma diagnostics

Author(s): <u>Mikael Persson</u>¹, Mikael Elam², Andreas Fhager¹, Stefan Candefjord¹

¹Signals And Systems, Chalmers University of Technology, Gothenburg/SWEDEN, ²Dept. Of Clinical Neurophysiolog, Sahlgrenska Academy, Inst of Neuroscience and Physiology, Gothenburg/SWE-DEN

Worldwide, about 17 million people suffer a stroke each year. The human cost is horrific. Out of the sufferers 5 million die and another 5 million are permanently disabled. Among stroke survivors, 20% have serious remaining dysfunctions. A much larger proportion has less conspicuous, dysfunctions, which still seriously affect quality of life for the patient and relatives. The European yearly cost (2010) has been estimated to 64.1 billion \in for the around 800 000 stroke patients.

Here we present different brain diagnostic devices based on microwave technology and the associated proof of principle measurements that show that the systems can differentiate hemorrhagic from ischemic stroke in acute stroke patients, as well differentiate hemorrhagic patients from healthy volunteers. The system was based on microwave scattering measurements with an antenna system worn on the head. Measurement data were analyzed with a machine-learning algorithm that is based on training using data from patients with a known condition. CT images were used as reference. The detection methodology was evaluated with the leave-one-out validation method combined with a Monte Carlo based bootstrap step.

The clinical motivation for this project is that ischemic stroke patients may receive acute thrombolytic treatment at hospitals, dramatically reducing or abolishing symptoms. A microwave system is suitable for pre-hospital use, and therefore has the potential to allow significantly earlier diagnosis andtreatment than today.

The relative simplicity and potentially small size of a microwavebased diagnostic system underlines a specific aim of the project which to start the path towards implementation, in the sub-Saharan Africa, where there are very limited resources in terms of medical personnel, hospitals and medical devices, that can be used by ambulance personnel, at the scene of incident, for instance at the patients home, or at the local hospital.

Our microwave-based systems have the advantage of being com-

pletely safe and without side effects since the power levels used are only a fraction of what is transmitted by a mobile phone. This also allow the systems to operate in continues mode as a monitoring devices. The systems also have the potential of becoming quite cost effective as the component costs are driven down by the considerably larger telecom industry.

SP168.4 - Bending the cost curve: Towards a \$1000 diagnostic X-ray imager for scalable and sustainable healthcare Author(s): <u>Karim S Karim</u>, Sina Ghanbarzadeh

Electrical And Computer Engineering, University of Waterloo, Waterloo/CANADA

Cost, quality and accessibility are major barriers to disease detection globally. For an easily communicable disease like tuberculosis, diagnostic or screening tests based on sputum, blood and urine analysis have slow response, are difficult to administer in remote locations, and have relatively high transportation and storage costs. Medical-grade state-of-the-art digital x-ray imaging systems are versatile in disease detection, faster, incorporate teleradiology for remote diagnosis, but are prohibitively expensive making them affordable only by major hospitals or labs that are located mostly in urban centers with high patient volumes. Here, a value priced, high quality, digital x-ray imaging system could address many global health issues by enabling fast, accessible and inexpensive early detection of curable diseases including tuberculosis especially in rural, remote or under-populated areas.

In this research, we propose a path to achieving an inexpensive, high quality, digital X-ray system by focusing on the X-ray imager, a component that can reach 50% of the manufacturing cost of an imaging system. High manufacturing costs today are largely a function of small production volumes and various specialized fabrication processes. Our approach leverages two technologies developed in-house that leverage existing manufacturing infrastructure because they are fully compatible with older generation amorphous and poly-silicon TFT display manufacturing lines: the first is a low dark current, high quantum efficiency optical radiation sensor that rivals state-of-the-art amorphous silicon pin photodiodes and the other an amplified pixel circuit having a straightforward offset and gain correction scheme that yields higher signal-to-noise ratio than state-of-the-art passive pixels. When our sensor and pixel circuit technologies are integrated, the result is a high performance, low manufacturing cost diagnostic X-ray imager that can help achieve sustainable healthcare globally.

SP168.5 - Creating a Continental Network of Healthcare Innovation Centers: Collaborating across National Boundaries to design Devices and Best Practices

Author(s): Fred W. Hosea

Clinical Technology, Kaiser Permanente, Oakland/UNITED STATES OF AMERICA

Managing the lifecycle challenges of healthcare systems exceeds the current capacities of any country in the world, and the difficulties are only growing. Central problems are: -Unprecedented technical complexity -Demand for universal services and new service lines -Interdependence of systems -Global economic slowdown, without likelihood of recovering previous growth rates -Velocity of change -Obsolete, inadequate infrastructures -Fragmentary market mechanisms and perverse incentives -Political and economic interests that preserve a dysfunctional status quo -Obsolete professional and organizational structures -Disjointed incrementalism -Demographic pressures that exceed current and future capacity -Predicted impacts of climate change: migration of populations, infectious diseases; and economic refugees to unprepared locations A new age of integrated innovation is essential to achieve the possibilities of Health for All.

-New forms of collaboration and interdisciplinary knowledge are necessary. -Innovation must be re-defined to include innovations that effectively integrate established technologies, instead of creating a relentless treadmill of expensive high-tech point solutions that often promise more than they deliver. -National innovation centers will serve as hemispheric resources in their areas of investigation and best practices (e.g., telemedicine, tropical diseases, disaster management), and will serve as consultation centers to all other countries in the network, providing expertise oriented along the entire lifecycle of successful innovation.

We envision innovation that leverages collective resources more effectively to achieve a higher adoption rate of appropriate and interoperable technologies with less wastage of resources, less planned obsolescence, more universal coverage, lower cost, and a more rational staging of medical infrastructures as economies and service models mature.

COLLABORATIVE DESIGN FORUMS to engage key stakeholders at the trans-national level of strategy and planning

NON-PROFIT INTER-SECTORAL ALLIANCES to solve core technology challenges (e.g., The Continua Alliance)

STRATIFIED INNOVATION GOALS to re-target manufacturing, facilities and workforces more equitably to low and medium resource markets, with more local production.

STRATEGIC CONSULTATIONS with regional alliances across Ministries of Health to develop and align mid- to long-term infrastructure plans and capital budgets, within regional and multi-national planning and purchasing frameworks

COORDINATED ACADEMIC PARTNERSHIPS COORDINATED to cultivate sustained, multi-disciplinary research and professional development programs aimed at integrated healthcare planning

REGIONAL/CONTINENTAL NETWORKS OF INNOVATION CEN-TERS to distribute the enormous workload of innovation design, assessment, testing and planning

"DESIGN FOR CASCADE" – design of higher-cost systems for staged re-use in low-resource locations

Adoption of a COMMON INTEROPERABILITY MATURITY roadmap that enables co-evolution of medical devices with IT systems and clinical treatment practices. SP168.6 - Towards a WHO List of Priority Medical Devices for Cancer Care, targeting low and middle income countriess Author(s): <u>M. Mikhail Lette</u>, A. Velazquez Berumen, G. Jimenez Moyao, A. Migliore, D. Rodriguez Rodriguez; HIS/EMP/PAU/Medical Devices, World Health Organization Headquarters, Geneva/SWITZERLAND

Cancer mortality disproportionately affects low and middle income countries' populations; 70% of global deaths attributable to cancer occur in low and middle income countries. In view of an alarming trend of increased incidence and prevalence of NCDs (non-communicable diseases) and their disproportionate adverse effects upon low and middle income populations, the WHO Medical Devices team has embarked upon a promising new project to develop a Priority Medical Devices List for Cancer Care, to target low and middle income countries, in the goal of better empowering countries to develop or improve cancer healthcare capacities. During this incipient few-year endeavor, the entire spectrum of devices needed for the continuum of cancer care - screening, diagnostics, and treatment (both curative and palliative) - will be analyzed and compiled for six types of cancer: cervical, breast, prostate, lung, colorectal, and leukemia. Collaboration is being invited. Project progress is presented.

First, an extensive review of evidence-based clinical guidelines was performed to select ones which comprise the continuum of diagnostics and care and are aligned with current clinical knowledge benchmarks (with guideline database updated at regular intervals). Guidelines were chosen from several world regions and current implementation and relevance of them in low and middle income settings will continue to be assessed. Based upon guidelines, matrices of clinical interventions were developed and stratified for each type of cancer. This provided a basis to generate an extensive database of medical devices per intervention via the following algorithm: Condition\Stage of Care\Intervention\Steps of the Procedure\ Procedure\Device Category\Device Code\Name(s) of the Medical Device\Description\Level of Care.

Nomenclature of interventions was compared against and harmonized with the ICHI (International Classification of Health Interventions). Likewise interventions were segregated by level of care and the associated health care facility:

- · Community level health post
- · Health center (outpatient care)
- · District or general hospital
- · National or specialized referral hospital

This project also seeks to provide a concise clinical background and staging overview for each disease in question, to research epidemiologic data on global burden of disease, to define countries to involve in this project, and eventually to conduct in-country workshops and case studies.

Further work will include inter-agency cooperation (with other UN organizations) and with professional organizations (e.g. NGOs, collaborating centres, professional societies, academic institutions). Experts and expert groups will be sought to form relevant committees willing to contribute to this project in their respective areas of expertise, to verify the interventions and priority medical devices, and eventually to validate and support implementation of the lists.

This project has been undertaken courtesy of a grant from OFID (the OPEC Fund for International Development, Uniting against Poverty).

The ultimate goal is to have available information on technologies that are required to diagnose and treat cancer patients in low and middle income countries.

SP169 - Self Engagement, Patient Empowerment and mHealth

TRACK 13: INFORMATICS IN HEALTH CARE and PUBLIC HEALTH

SP169.1 - Empowering patients through information technologies Author(s): <u>Eleni Kaldoudi</u>

School Of Medicine, Democritus University of Thrace, Alexandroupoli/GREECE

Patient empowerment is about enabling the patients to be involved in managing disease and adopting and sustaining health promoting behaviors. Patient empowerment, although a popular concept, is rather ill defined. This lecture aims to elucidate the different meanings and perceptions, together with misconceptions, that surround this construct, and to discuss how patient empowerment relates to current medical methodologies, such as evidence based medicine, and other societal and organizational factors. Furthermore, the lecture will provide an overview of how information and communication technologies are employed to empower patients, with emphasis in chronic patients with comorbidities.

The discussion will first address the "who". This includes an overview of common health problems that call for empowered patients, the types of patients that normally engage in empowering interventions and the specifics of the stakeholders who design and support such interventions.

Then we will look at the "how". The discussion here will focus on an overview of the diverse approaches and services that have been deployed to empower patients. This will also include the span of various technologies used and, where applicable, their measured induced outcome for the patient and the health care process.

Although the "who" and "how" of patient empowerment can rather easily be discerned from a literature research, the "what" is rather more elusive. The concept of patient empowerment has emerged as a new paradigm that can help improve medical outcomes while lowering costs of treatment by facilitating self-directed behavior change. Patient empowerment has gained even more popularity since the 1990's, due to the emergent of eHealth and its focus on putting the patient in the centre of the interest. Current literature provides systematic reviews of the area, and shows that well defined areas (or dimensions) have eventually emerged in the field: education, engagement, and control. Despite such findings, current research lacks of a structured approach towards patient empowerment. In an attempt to shed more light onto the process of empowering patients, this lecture will discuss a newly proposed holistic model of patient empowerment as a cognitive process, where we acknowledge three levels of increasing complexity and importance: awareness, participation, and control.

The lecture will conclude with a proof of concept example of using this approach to develop and evaluate empowerment services for the comorbid cardiorenal patient or the patient at risk of this condition. Open issues and challenges will be presented for discussion with the audience.

SP169.2 - Distributed learning: developing a predictive model for dyspnea in lung cancer patients based on data from multiple hospitals

Author(s): Arthur T.C. Jochems, Andre Dekker, Philippe Lambin, Johan Van Soest

Radiotherapy, Maastro Clinic, Maastricht/NETHERLANDS

Purpose/Objective

Predictive models play a major role in enabling personalized medicine. Predictive models require patient data to be trained successfully. One of the major hurdles in enabling personalized medicine is obtaining sufficient patient data to feed into predictive models. Combining data originating from multiple hospitals is difficult because of ethical, legal and administrative issues. In order to avoid these issues a distributed learning approach can be used. In this approach, the model training application is sent to the hospitals. The model learns from the data in each individual hospital without the data leaving the hospital. After training, the models are sent back to a central location where they are combined into one fully trained model.

In this work, we show that it is possible to use the distributed learning approach to train a Bayesian network model on patient data originating from multiple hospitals. The model predicts dyspnea, which is a common side effect after radiotherapy treatment of lung cancer.

Material/methods

Clinical data from 170 lung cancer patients, treated with curative intent with chemoradiation (CRT) or radiotherapy (RT) alone were collected and stored in 3 different medical institutes (123 patients at Maastro, 14 at Jessa and 33 at Liege). A Bayesian network model was developed to predict dyspnea (≥ Grade 2 according to the CTCv3.0). The model used gender, WHO performance status, age and overall treatment time to make predictions. Training of the model was based on data originating from two out of the three centers. The data of the remaining center was used for validation. The model was trained and validated 3 times each time using data from two different centers as the training set. The three trained models were combined by taking the average of the learned conditional probability tables. The model's performance was expressed as the Area Under the Curve (AUC) of the Receiver Operating Characteristic (ROC). The maximum value of the AUC is 1.0; indicating a perfect prediction model. A value of 0.5 indicates that patients are correctly classified in 50% of the cases, e.g., as good as chance.

Results

Thirty-four patients (27%), 6 patients (42%) and 13 patients (39%) developed dyspnea in the Maastro, Jessa and Liege datasets respectively. The AUC of the model that was trained on data from Maastro and Jessa and validated on data from Liege was 0.66 (95%CI, 0.63–0.78). The AUC of the model that was trained on data from Maastro and Liege and validated on data from Jessa was 0.63 (95%CI, 0.49–0.72)The AUC of the model that was trained on data from Jessa and Liege and validated on data from Maastro was 0.56 (95%CI, 0.48–0.59).

Conclusion

Using a distributed learning approach, we have successfully trained and validated a Bayesian network model for dyspnea prediction in lung cancer patients on data from multiple hospitals. Future work will involve using a larger number of hospitals and higher numbers of patient data to train better predictive models using the distributed learning approach.

SP169.3 - User Centered Design to incorporate predictive models for Type 2 Diabetes screening and management into professional decision support tools: preliminary results. Author(s): Giuseppe Fico

Life Supporting Technologies, Universidad Politécnica de Madrid, Madrid/SPAIN

Type 2 Diabetes screening and risk stratification tools could benefit from the incorporation of predictive systems based on computer modelling. The adoption of User Centered Design techniques is fundamental in order to integrate these systems in an effective and successful way. The work presented in this paper describe the methodologies used in the context of a multidisciplinary research project and provides an overview of the preliminary results.

SP169.4 - Quantifying Bipolar Disorder for Technology-Assisted Self-Management

Author(s): James D. Amor¹, Martina Svobodova², Ian Jones², Christopher James¹

¹School Of Engineering, University of Warwick, Coventry/UNITED KINGDOM, ²National Centre For Mental Health, Institute Of Psychological Medicine And Clinical Neurosciences, Cardiff University, Cardiff/UNITED KINGDOM

Bipolar Disorder (BD) is a serious mental health condition that is characterized by recurring affective episodes, interspersed with periods of remission. Current treatment for BD focuses on pharmacological and therapeutic techniques to control the condition. In addition to this, a significant number of people with BD adopt self-management techniques in order to help maintain a stable life pattern and control their condition. There are two significant drawbacks to current self-management in that current systems tend to be paper based and reliant on user self-insight, which is frequently lost in the run up to an affective episode. These two shortcomings can be addressed with a technology-enabled solution. Through the use of specific sensors and an electronic mood diary, the important indicators of relapse in BD can be monitored and users alerted to potential indicators of relapse in a timely manner so that they can take appropriate action.

This paper presents work that has been carried out in the development of the Auto-Motive system on the quantification of indicator metrics in BD for use in a technology-enabled self-management system. We present the methodology and results from a series of focus groups that have been carried out with users and professionals to identify the important indicators in BD and the way in which the can be quantified for use in a decision support system.

Results from the focus groups are in line with the literature and professional insight and point to sleep (hours of sleep and sleep quality), physical activity, time at home and at work and medication compliance as being particularly important indicators to quantify and use in the Auto-Motive system.

SP169.5 - Hippocratic Protocol Design to Improve Security and Privacy in Healthcare Applications for NFC Smartphone Author(s): Jose Pirrone Puma¹, Monica Huerta²

¹Esc. Ingenieria En Telecomunicaciones, Universidad Catolica Andres Bello (UCAB), Caracas/VENEZUELA, ²Universidad Politecnica Salesiana, Cuenca/ECUADOR

Today the evolution of electronics technologies had created a lot of intelligent personnel devices, like calculators, GPS, and Smartphone for example. These terminal have lowers prices than terminals used before and are fully programmable that's why are beginning to use in all sectors for implement mobile services.

Healthcare sector is not outside of this development and some experiences have been done, using not only its connectivity but also an identification technology named NFC. This result in a series of new problems, which are being studied. One of the main problems for the use of these technologies is the maintenance of privacy and security in management of patient information when using Smartphone as a mobile terminal to read data. In previous years, there have been lot of work in these areas for the health sector, for privacy and authentication,.

NFC is an evolution of Radio Frequency Identification technology (RFID), specifically contactless smart cards, and interconnection technologies. Operates in the frequency band of 13.56 MHz, with very low power levels, which means that devices must be close (less than 10 cms.) to exchange data.

Hippocratic Databases fit the Hippocratic Oath, which makes doctors upon graduation. Its use has been gaining popularity due to privacy requirements appeared in new legislation on health of some countries, e.g. United States and arises as a need for implementing privacy in today's social networks.

Transferring the Hippocratic Database concept to design a specialized protocol for the health sector, would result requirements like Verification of the purposes of data Exchange, Authentication, Data Integrity, Encryption and modes of operation for transmitting, receiving and control, which allow the user to implement accessibility and verify the above.

A family of standards ISO 11073 *Personnel Health Device Communication*, define a communication scheme between personal health devices and an external computer. ISO standard 11073_20601 describes a common communications infrastructure, independent of the underlying transport infrastructure data due to logical connection procedure based on Agent Manager relation, and can be used to implement this protocol.

A scheme of the proposed Health Hippocratic Protocol (H²P) is shown. It is composed for two states and five procedures. The use of this protocol improves the design of health applications that use Smartphone and the use of Hippocratic Databases in healthcare sector. Given its structure, the protocol can withstand attacks of man in the middle, impersonation and unauthorized data seamlessly, as the authentication process with the Checking permissions task guarantee security. The objective is to present a protocol that includes Hippocratic principles in its structure to improve security and privacy on personnel devices that use these technologies in the healthcare sector.

The design of a Hippocratic Health Protocol, based on a standard, for use in Smartphone with NFC will improve security and privacy in personnel healthcare applications, but more work is necessary because the design of the database that permits the implementation of Hippocratic considerations is not a simple work.

SP169.6 - Extracting Intention from Web Queries- Application in eHealth Personalization

Author(s): George Drosatos¹, Avi Arampatzis², <u>Eleni Kaldoudi¹</u> ¹School Of Medicine, Democritus University of Thrace, Alexandroupoli/GREECE, ²Department Of Electrical And Computer Engineering, Democritus University of Thrace, Xanthi/GREECE

Personalizing healthcare applications requires capturing patient specific information, including medical history, health status, and mental aspects such as behaviors, intentions, and attitudes. This paper presents a privacy-friendly system to deduce patient intentions that can be used to personalized eHealth applications. In the proposed approach patient intention is deduced from web query logs via query categorization techniques. The architecture assumes a user application which conceals the user's queries from the central system, while only relevant intentions are disclosed. The paper presents a prototype implementation of the proposed architecture to extract intentions for personalizing empowerment services for the cardiorenal patient. Emphasis is placed on identifying intentions related to travel, diet and physical exercise, as these play an important role for the daily management of cardiorenal disease.

SP170 - Information Technologies in Healthcare Delivery and Management: Part 3

TRACK 14: INFORMATION TECHNOLOGIES IN HEALTHCARE DELIVERY AND MANAGEMENT

SP170.1 - Wireless equipment localization for medical environments

Author(s): <u>Daniel Laqua</u>¹, Paul Fritzsche¹, Sven Niemöller¹, Peter Husar¹, Vincenz Busch², Michael Nass³, Jörg Pospiech⁴, Kutaiba Saleh⁵, Rudi Jäger⁵, Martin Specht⁵

¹Biosignal Processing Group, Technische Universität Ilmenau, Ilmenau/GERMANY, ²CE-SYS Engineering GmbH, Ilmenau/GER-MANY, ³CE-LAB GmbH, Ilmenau/GERMANY, ⁴AVT GmbH, Ilmenau/ GERMANY, ⁵Jena University Hospital, Jena/GERMANY

Searching for medical equipment in hospitals produces high costs. However, it is necessary to check each medical device periodically. Wireless systems in a medical environment must comply with the legal limits for electromagnetic interference (EMI). This work presents a tagging system for real time localization of tagged equipment respecting that some medical devices are very sensitive for EMI. Therefor, every room is equipped with a base station and a starshaped 2.4 GHz wireless network topology, which conforms with the latest legislative requirements for the EC and US market. Considering that, the device tags consist of a compact IEEE 802.15.4 ZigBit transceiver module with an adapted and extended stack. Furthermore, the device tags are equipped with sensors for detecting manipulation and motion. The base stations are connected to the server via wired TCP/IP network with Power over Ethernet (PoE), which reduces the radio traffic and considerably simplifies communication. Virtual floor plans in the dashboard software visualize the actual positions of the medical devices. The user is able to locate either a single device by its name or a list of all devices in a ward. Using two AAA batteries the device tags have an operation time of 24 months, wherein they can be in motion for 7.75 percent. The webbased dashboard software gants the medical staff an easy access via computer or mobile device. In addition, the dashboard is able to access the SAP database of the hospital for detailed information about the medical device.

SP170.2 - Exploring Approaches to Optimise the Estimation of Preterm Birth Using Machine Learning Techniques

Author(s): <u>Monique Frize</u>¹, Daphne Ong¹, Jeff Gilchrist¹, Hasmik Martirosyan¹, Erika Bariciak²

¹Systems And Computer Engineering, Carleton University, Ottawa/ CANADA, ²Neonatology, Children's Hospital of Eastern Ontario, Ottawa/CANADA

In past work, our research group obtained a number of high quality databases of newborns and mothers in order to develop models to predict premature birth before 23 weeks gestation, using only data collected from pregnant mothers. Unfortunately, the most accurate test currently used is the fetal fibronectin, which is invasive, expensive, and is done some weeks later in the pregnancy. Our initial development succeeded in matching the accuracy of the fetal fibronectin test using data from the PRAMS (Pregnancy Risk Assessment Monitoring System) database with an accuracy of 66% sensitivity (true positive cases) and 85% specificity (true negative cases). [Catley et al, 2006]

Recent work has concentrated on exploring a number of machine learning techniques such as decision trees (DTs) and artificial neural

networks (ANNs) and the addition of new databases to optimise the performance of the models we develop to predict preterm birth (PTB). One approach is to use decision trees with the 5-by-2 cross validation method to help select the most important features to use with our ANN tool. The methodology consists of separating cases involving preterm versus full term babies, and then randomly creating ten different train and test sets to perform the prediction with decision trees. Our previous work focused on selecting the variables that had the best compromise between sensitivity and specificity when used to generate the single DT model and incorporating them as features to build an ANN model for PTB. [Frize and Yu, 2010] We are now assessing the average variable usage across all ten DT models and by eliminating the variables that have limited usage, we hope to improve the classification of preterm cases when using these variables to build the final ANN model. This new ANN was developed using the FANN (Fast Artificial Neural Network) Library as a base, on which we built many enhancements that we were using in previous work. [Frize et al. 2013] Moreover, the use of a new database collected on all newborns in Ontario (BORN= Better Outcome Registry and Network) will enable our team to determine which variables in both the PRAMS and BORN databases can optimise the classification of PTB. Preliminary results are encouraging.

SP170.3 - Smartwatch App as the Chest Compression Depth Feedback Device

Author(s): Yujin Jeong, Youngjoon Chee, Yeongtak Song, Kyo-In Koo

School Of Electrical Engineering, University of Ulsan, Ulsan/KOREA

For the high quality CPR (Cardio-Pulmonary Resuscitation), the feedback devices to show chest compression depth are used to ensure the compression depth to be over 51 mm, which is one of key factors of the 2010 American Heart Association (AHA) guidelines for adults. We propose the smartwatch based app as the chest compression depth feedback device and evaluated its accuracy. The accelerometer which is inside the smartwatch makes the signal during chest compression and the real time signal processing techniques are used to estimate the compression depth. Through the manikin study, the estimation error was 3.2 mm in average which can be acceptable for its usage. With the smartwatch app as the feedback device, the rescuer can perform the chest compression without the inconvenience of gripping the device and the visual interference with hands.

SP170.4 - Diagnosis of the corporal movement in Parkinson's Disease using Kinect Sensors

SP170.5 - A System to Support Regional Screening Programs to Identify School-age Children at Risk of Neurodevelopmental Disorders.

Author(s): <u>Elsa Santos Febles</u>¹, Vivian Reigosa-Crespo², Klaudia Garcia-Liashenko¹, Adan Echemendía-Montero¹, Gabriel Pujols-Fariñas¹, Enrique Plasencia-Montero³, Aymée Alvarez-Rivero², Eduardo Eimil-Suarez⁴

¹Software Development, Cuban Neuroscience Center, Havana/ CUBA, ²Developmental Cognitive Neuroscience Department, Cuban Neuroscience Center, Havana/CUBA, ³Cuban Neuroscience Molecular Biology Department, Cuban Neuroscience Center, HAVANA/ CUBA, ⁴Speech And Hearing Sciences Department, Cuban Neuroscience Center, Havana/CUBA

This paper describes a system to support regional screening programs to identify school-age children (6 to 12 years old) that are at risk of a neurodevelopmental disorders. The screening method is based on research carried out at the Cuban Neuroscience Center. The system is a combination of an Android application for a Tablet and a Web application. The Android app enables easy and quick exploration of learning and behavior disorders, hearing impairment, parental care and certain clinical health parameters. All the information is provided by teacher reports or direct measuring on the child. The Web application manages the screening program and organizes it by geographical regions, allowing adaptations to the local educational system. The user's access is role-based and depends on the job function and the regions assigned to the user. The Web application was developed using the PHP framework Symfony2 and stores data using a relational MySQL database. The data exchange between both applications is implemented via download and upload XML file, thereby allowing the Android app to work offline in order to use it in sites with limited communication infrastructures. The system can gather, store, access and analyze data to aid in decisionmaking. The system will clarify the need of referral for early intervention services and/or other evaluations. It will also enable longitudinal follow-up neurodevelopmental studies in large samples of children.

SP170.6 - Support plataform to decision making in research and technological development in public health: a brazilian scenario approach.

Author(s): <u>Carlos E. Rocha</u>, Yuri P. Marca Carlos Chagas Institute, Oswaldo Cruz Foundation, Curitiba/BRAZIL

The area of biosciences has promoted significant changes in national competence linked to innovation in health care by creating scientific favorable for the construction of public policies on ST & I, has also been presented as a strategic dimension of prominence in the training of human resources within areas of future patients, as well as the installation and consolidation of organizations linked to the process of Research, Development and Innovation.

Thus, the activities biotechnological processes require more accurate and consistent decision-making and consider the variables inherent in the organizational environment itself Institutions of Science and Technology. This position paper analyses the current state of affairs concerning the Brazilian health industry in strategic sectors. A brief overview of the most critical infectious diseases and the associated technologies available for their diagnosis is given, pointing out research and development opportunities for the national industry for the health sector. Therefore Decision making in the process of implementation of projects of Research and Development in Health is an important activity in Brazil, since the amount of proposed projects is incompatible with the financial resources. An estimate to ensure the success of the proposal is something that would facilitate the manager's work.

For this, it was developed an application in the programming language C++ that serves as support for the manager in decision making, where it makes the evaluation of the proposed project based on some modeling variables. Moreover, the use of this software can make it more robust and over time more effective for determining the estimated success of a proposal.

Finally, current challenges and perspectives concerning national policies for the brazilian health sector are discussed.

SP171.1 - Properties Evaluation of Gd2O3-DEG as New Contrast Agent Nanomagnetic Particles Comparing to Gd-DTPA in MRI

Author(s): Banafsheh Nikfar¹, <u>Nader Riahi-Alam</u>¹, Soheila Haghgoo², Ensiyeh Gorji², Hosein Ghenaati³, Behrooz Rafiei³, Sara -. Heydarnezhadi¹, Mohammad Khosroshahi⁴

¹Tehran University Of Medical Sciences (tums), Medical Physics & Biomedical Engineering Department, tehran/IRAN, ²Ministry Of Health, Tehran, Food & Drug Laboratory Research Center, tehran/ IRAN, ³Tehran University Of Medical Sciences (tums), Medical Imaging Center of Imam Khomeini Hospital, tehran/IRAN, ⁴Laser And Nanobiophotonics Lab., Biomaterial Group, Faculty Of Biomedical Engineering, Amirkabir University of Technology, Tehran/IRAN

Magnetic resonance imaging (MRI) is widely used for imaging purposes. However, the sensitivity and intrinsic contrast of the MRI is low. In order to improve the quality of images Gd-DTPA (commercial Magnevist) is normally. Because of some limitations of low molecular weight of gadolinium chelates, nanoparticles gadolinium based contrast agents are proposed. In this study, we synthesized Gd-DTPA and compared its effects with Gd2O3-DEG nanoparticles. The samples were prepared at concentrations of 0.3, 0.6, 0.9 and 1.2 mM respectively by adding 1.5 ml deionized water. The corresponding Gd2O3-DEG nanoparticles diameter was measured about 80 nm. An in vitro study was performed using a 1.5 T scanner with standard spin echo protocol. Clearly, the signal amplitudes in both cases were increased with the Gd concentration at constant relaxation time. Also, a linear relation between signal intensity and longitudinal relaxation rate (R1) was observed with a correlation coefficient close to 1. The values of 4.30 and 14.27 (s⁻¹.mM⁻¹) were achieved for Gd-DTPA and Gd2O3-DEG nanoparticles special relaxivity, respectively.

SP171.2 - Imaging the Schlemm's Canal using an ultrahigh resolution spectral-domain optical coherence tomography working at 1.3 micrometer center wavelength Author(s): <u>Masreshaw D. Bayleyegn</u>

Center Of Biomedical Engineering, Addis Ababa Institute of Technology, Addis Ababa/ETHIOPIA

We present an ultrahigh resolution spectral-domain optical coherence tomography imaging system that uses a broadband superluminescent diode light source emitting at a center wavelength of 1.3 micrometer. The light source consists of two spectrally shifted superluminescent diodes that are coupled together into a single mode fiber. The effective emission power spectrum has a full width at half maximum of 200 nm and the source output power reaches up to 10 mW. The imaging system has an axial resolution of 3.9 micrometer in air (< 3.0 micrometer in biological tissue), and a lateral resolution of 6.5 micrometer. The sensitivity and the maximum line rate are 95 dB and 46 kHz, respectively. Images of an infrared viewing card and a cornea from human eye suffering from glaucoma showing Schlemm's canal are presented to illustrate the performance of the system.

SP171.3 - Technology Trayectory Hybrid Tomography by Positron Emissions Author(s): <u>Victor Malvaez</u>

Management Of Technology, CIECAS IPN, Mexico/MEXICO

This work studies, by means of the technological surveillance, the origin and evolution of the hybrid tomography by positron emission, commonly known as PET-CT. This tomographic technique is currently used in the medical diagnosis of patients with tumors or neoplasias, and its efficient use in Mexico could reduce costs and increase the opportunities for more people to have access to advanced medical technologies. To this end it is necessary to make them known, together with the fields of actual and potential applications. The main providers of this technology and their core competences are detected by means of patent analysis, as well as their technological profiles, advances and future developments. Patent analysis is carried out by consulting data bases as USPTO, EPO, JPO and WIPO. The technological surveillance was accomplished with the help of the International Classification of Patents (ICP) protocol, which allows the identification of the technological fields that are related to PET-CT. Future trends in the technology and possible evolution of equipment and radioactive marker prices are also found.

SP171.4 - Myocardial perfusion imaging by low-dose CT Author(s): <u>Sabee Molloi</u>, Benjamin Ziemer, Logan Hubbard, Jerry Lipinsky, Bahman Sadeghi, Hanna Javan, Elliott Groves Radiological Sciences, University of California, Irvine/UNITED STATES OF AMERICA

Coronary heart disease remains widely prevalent and is the leading cause of mortality and morbidity in the world. It is well established that the extent of coronary artery disease and left ventricular dysfunction are predictive of future cardiac events. Several clinical trials have demonstrated that mortality and morbidity can be reduced when medical and surgical interventions are applied to selected subsets of patients stratified according to coronary anatomy and left ventricular function. Coronary CT angiography is a well-established, non-invasive imaging modality for the detection and exclusion of atherosclerosis. However, coronary CT angiography cannot accurately determine whether an intermediate severity stenosis is flow limiting that requires additional functional testing, which increases the radiation dose and cost to the patient. Furthermore, international guidelines recommend the functional assessment of stenosis severity prior to revascularization. A CT perfusion technique would provide valuable functional information, in addition to the anatomical data obtained from CT angiography. As a result, many dynamic CT perfusion techniques have been developed to provide functional assessment of coronary artery disease; however, widespread clinical implementation of such techniques has been hampered by the fact that these techniques deliver a high radiation dose. Hence, there is a need for a low-dose CT perfusion technique for noninvasive functional assessment of coronary artery disease. It is possible to measure myocardial perfusion using a low-dose first-pass analysis (FPA) technique. This technique relies on conservation of mass by making measurements in an arterial tree perfusion bed before contrast exits through the venous system. Implementation of this technique using CT requires fast, whole-heart scanning combined with ECG-gating. Therefore, the FPA technique was implemented with a prospective ECG-gated protocol using a 320-slice CT scanner. This technique can measure myocardial perfusion using a minimum of two volume scans, which can substantially reduce radiation dose as compared with existing dynamic perfusion techniques. The study was carried out in anesthetized, closed-chest swine using angioplasty balloon catheters to produce partial occlusion. After segmentation of the myocardium and extraction of the coronary arterial trees, perfusion measurements were made using the FPA technique. The perfusion measurements were validated using colored microspheres as the

reference gold standard. The perfusion measurements using FPA (PFPA) and colored microspheres (PMic) were related by PFPA = 0.97PMic + 0.12 mL/min/g (r^2 =0.92). The results show that CT perfusion measurements have excellent correlation with microsphere perfusion measurements. In conclusion, the results indicate that accurate CT perfusion can be made with a substantial reduction in radiation dose as compared with existing dynamic CT perfusion techniques. Therefore, CT can potentially be used for both anatomical and physiological assessment of coronary artery disease.

SP171.5 - Renal Dynamic Phantom for Use in SPECT

Author(s): <u>Divanizia D.N. Souza</u>¹, Fernanda C.L. Ferreira² ¹Phsysics, Federal University of Sergipe, São Cristovão/BRA-ZIL, ²Federal University of South and Southeast of Pará,, Marabá/ BRAZIL

Quality control of nuclear medicine is performed through the use of phantoms during the processes necessary for consummation of quality control tests. Ideally, a specific phantom is employed for each type of procedure. Dynamic renal scintigraphy using DTPA (diethylenetriamine pentaacetic acid) is labeled with technetium-99m. This renal radiopharmaceutical tracer allows evaluation of the dynamics of renal blood flow and its symmetry, the topography and morphology of the kidneys, and the passage of the radiopharmaceutical through the urinary tract to the bladder until arrival. The objective of this study was to develop and evaluate the performance of a renal dynamic phantom, for use in SPECT. An adult human kidney was used for making the mold, ensuring phantom geometry. It was used alginate for the manufacture of the shaped form of the kidneys. Following preparation, the acrylic kidney was connected to the top of each kidney with one injection pump connected to a reservoir. To perform the flow, the phantom is controlled with injection pumps. The electrical system controls how long each pump is in operation. Changes of the operating time of the pump at different flow rates imply elimination of the radioisotope, allowing it obtain various forms of disposal. The renal dynamic phantom was constructed of acrylic and included injection pumps to simulate renal dynamics in scintigraphy with 99mTc-DTPA. This phantom was scanned with a dynamic protocol and compared with clinical data. Using this phantom it is possible to acquire similar renal images as in clinical scintigraphy, including the response of the imaging system to the form of a renogram with normal renal scintigraphic appearance. Moreover, it is expected to perform intercomparisons between different renograms scintillation cameras and nuclear medicine clinics. Therefore, the dynamic renal phantoms can be very effective for use in the quality control of renal scintigraphy and image processing systems.

SP171.6 - Physics Plan Checking Practices

Author(s): <u>Gordon Chan</u>¹, Lee Chin², Harald Keller³, Keith Nakonechny⁴, Cathy Neath⁵, Greg Salomons⁶ ¹Medical Physics, Juravinski Cancer Centre, Hamilton/ON/ CANADA, ²Odette Cancer Centre, Toronto, Canada, Toronto/ CANADA, ³Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/ON/CANADA,⁴Simcoe Muskoka Regional Cancer Centre, Barrie/CANADA, ⁵Medical Physics Department, R.S. McLaughlin Durham Regional Cancer Centre, Oshawa/ON/CAN-ADA, ⁶Cancer Centre of Southeastern Ontario, Kingston General Hospital, Kingston/CANADA

The physics treatment plan / chart check has been shown to be a critical factor in ensuring safe high-quality radiation therapy. However, there is very little publicly available documentation on plan checking. Anecdotal evidence suggests that the practice of plan checking is highly variable even among physicists within the same centre. In order to ensure a high and uniform quality in treatment plans it is imperative that the process be standardized and documented.

In order to determine the current practice in regards to physics treatment plan checking, the Medical Physics Community of Practice Working Group in Ontario conducted a survey of the medical physics departments at all cancer centres in Ontario. The survey was intended to cover all aspects of the physics checking, including which elements of a patient's plan are being checked by the physicist, what level of documentation is being performed with the checking, and where in the planning to treatment process the physics plan checking is being performed. The survey was designed to have the physicists at each centre (typically 5-6) complete the survey together as a group and provide a single response from their centre. Answers to the questions were designed to reflect the variability in practice within a centre.

We will present the results from this survey such as the responses shown in Figure 1 below. Initial survey results suggest that often the plans are accepted as is even though they could be improved upon. Comments accompanying the question indicated that the time between a physicist receiving the plan for review and the patient's scheduled appointment, was a big factor in deciding whether to accept a sub-optimal plan or not.

The process of completing the survey also provided direct benefits to the participating centres. Initial feedback suggests that the dialogue which was generated was beneficial to the participating physicists and will hopefully increase the consistency and quality of the plan checking process in those centres. Hopefully, the dialogue generated by publishing the results of the survey will have an equally beneficial effect. It is anticipated that the results of this survey will lead to new guidelines for physics involvement in patient plan QA.

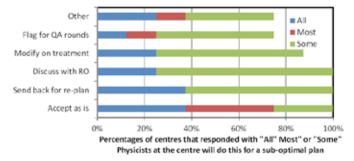

Figure 1, Responses to the question: What is done with a sub-optimal plan that meets the prescribed goals? The responses indicate the proportion of physicists who will take a certain action for a suboptimal plan. Multiple selections were allowed.

SP171.7 - Commissioning of a Flattening Filter Free Author(s): <u>Satya Ranjan Saha</u> Medical, Tradevision Limited, dhaka/BANGLADESH

Commissioning of a Flattening Filter Free (FFF) using an Anisotropic Analytical Algorithm (AAA)

Satya Ranjan Saha $^{\rm 1},$ Mohammad Amran Hossain $^{\rm 2},$ Md Safiqul Islam $^{\rm 3}$

Aim: To compare the dosimetric parameters of the flattened and flattening filter free (FFF) beam and to validate the beam data using anisotropic analytical algorithm (AAA).

Materials and Methods: All the dosimetric data's (i.e. depth dose profiles, profile curves, output factors, penumbra etc.) required for the beam modeling of AAA were acquired using the Blue Phantom RFA for 6MV, 6FFF, 10MV & 10FFF. Progressive resolution Optimizer and Dose Volume Optimizer algorithm for VMAT and IMRT were are also configured in the beam model. Beam modeling of the AAA were compared with the measured datasets.

Results: Due to the higher and lover energy component in 6FFF and 10FFF the surface doses are 10 to 15% higher compared to flattened 6MV and 10MV beams. FFF beam has a lower mean energy compared to the flattened beam and the beam quality index were 6MV 0.667, 6FFF 0.629, 10MV 0.74 and 10FFF 0.695 respectively. Gamma evaluation with 2% dose and 2mm distance criteria for the Open Beam, IMRT and VMAT plans were also performed and found a good agreement between the modeled and measured data.

Conclusion: We have successfully modeled the AAA algorithm for the flattened and FFF beams and achieved a good agreement with the calculated and measured value.

SP171.8 - Effects of 24 hour Wakefulness on Tilt Based Targeting Tasks

Author(s): Jeffrey Bolkhovsky¹, Ki Chon², Michael Qin³ ¹Biomedical Engineering, University of Connecticut, Storrs/UNITED STATES OF AMERICA, ²University of Connecticut, Storrs, CT/CT/ UNITED STATES OF AMERICA, ³Naval Submarine and Medical Research Laboratory, Groton/UNITED STATES OF AMERICA

This study investigated the effects of short term sleep deprivation while using a tilt-based control device. Accuracy and various performance parameters of subjects using tilt based devices to perform target acquisition tasks were monitored over a period of 24 hours to assess the susceptibility of performance to acute sleep deprivation. Performance was analyzed by means of the principles of Fitts' law using movement time, throughput, and time intercept as measurements. All task sessions were analyzed using movement time and difficulty correlation to determine that the tasks completed by all participants did in fact adhere to Fitts' law with an average R² of 0.99 and a standard deviation of 0.01. Accuracy was examined by looking at movement error, movement variability, and number of target reentries. These accuracy statistics were derived by comparing the subject paths for acquiring targets to the ideal paths within the task. Ten volunteers completed sets of two sets of learning tasks and then completed a set of tasks every two hours up to a time at which the subject had been awake for a consecutive 24 hours. Each

set of tasks included 240 trials over a 20 minute period in which the subject controlled a ball, with a movement gain of 25 and a size of 20 pixels (px) in order to hit a target that varied in size (40 px, 60px, 100px), distance from the start point (125 px, 250px), and location (8 cardinal directions). The control of the ball was derived using a combination of the tilt of the device and the gain. It was found that over the period of 24 hours of wakefulness there was no reliable change in movement time (p = 0.52), average throughput (p = 0.135) or average intercept (p = 0.09). The correlation between each of these measurements and time was -0.33, 0.39, and 0.52 respectively. It was also determined that the accuracy measurements of movement variability (p = 0.39), movement error (p = 0.07), and movement reentries (p = 0.72) did not change significantly over the trial period. The correlation of the three statistics over time were 0.18, 0.10 and 0.07 respectively. It was found that this particular task was not significantly affected by acute sleep deprivation over a period of 24 hours. This control setup displayed as robust in task performance and accuracy with increase wakefulness. Possible reasons for this type of result include a limited range of difficulty displayed in the task as well as lack of vigilance required to complete this task. These additions would be valuable to examine for future experiments.

This work was sponsored by the Office of Naval Research.

SP172 - Mammography and Tomosynthesis

TRACK 01: IMAGING

SP172.1 - Evaluation of automatic exposure control in digital mammography

Author(s): <u>Alessandra Tomal</u>¹, Tania A.C. Furquim², Nestor Barros² ¹Departamento De Física Aplicada, Universidade Estadual de Campinas, Campinas/BRAZIL, ²Universidade de São Paulo, São Paulo/BRAZIL

Digital mammography has been largely employed in several screening programs for detection of breast cancer. In this technique, the exposure technique is usually chosen by the automatic exposure control (AEC) in order to optimize the relation between the absorbed dose and the image quality.

In this work, we compare the contrast-to-noise ratio (CNR) and the average glandular dose (Dg) obtained for different x-ray spectra in order to evaluate the exposure techniques provided by the AEC. The study was performed in a Senographe DS equipment (GE Medical Systems) using CIRS breast phantom with different thicknesses and compositions: 4 cm - 50% glandular (model 010B), 5 cm - 30% glandular (model 010A) and 6 cm - 20% glandular (model 010C). All AEC modes available were studied: standard, contrast and dose. Additionally, using the manual exposure mode, all the different anode/filter combinations selectable on the systems (Mo/Mo, Mo/Rh and Rh/Rh) were evaluated for all tube voltages settings available. The results of CNR and Dg were combined in a Figure of Merit (FOM=CNR²/Dg) in order to study the optimal x-ray spectra for each thickness.

The results obtained using the AEC mode showed that the exposure techniques selected for the 4 cm thick phantom is the combination Mo/Rh at 27 kV, while the Rh/Rh combination at 29 kV was selected for both 5 and 6 cm phantoms. All AEC modes selects the same techniques, while the mAs values chosen by the AEC-dose mode are up to 37% and 102% greater than for the AEC-standard and AEC-contrast, respectively. The variation in relative noise (o/p) with pixel values (p) was adjusted to an allometric function ($\sigma/p=kp^{-1}$ n) and an n value equal to 0.27 was obtained, which indicates the presence of a non-neglect structural noise. Results of the FOM indicated that the optimal spectrum for the 4 cm phantom is the Mo/ Rh combination at tube voltage between 28-30 kV. For the thicker phantoms, the Rh/Rh at tube voltage between 26-28 kV showed the best performance in terms of dose saving or image guality improvement. The results obtained indicate that x-ray spectra with energies lower than those selected by the AEC mode should be used in this system, which differs of the most energetic x-ray spectra obtained in previous works. This result can be related to the high contribution of the structural noise in the detection system evaluated. Finally, our results show that the optimization studies are system dependent, instead universal, and the exposure techniques selected by the AEC should be revisited. Besides, the determination of the optimal exposure parameters also should take into account the major components for noise in image. Thus, further studies regarding optimization of mammographic techniques could evaluate other image quality parameters (i.e., image contrast and DQE) and/or include the determination of the optimal mAs.

SP172.2 - Comparing the use of force-standardized and pressure-standardized mammographic compression protocols in an Asian context

Author(s): Kwan Hoong Ng¹, Susie Lau¹, Yang Faridah Abdul Aziz¹, Ralph Highnam², Ariane Chan²

¹Department Of Biomedical Imaging, Faculty Of Medicine, University of Malaya, Kuala Lumpur/MALAYSIA, ²Volpara Solutions Limited, Wellington/NEW ZEALAND

Background: Mammographic compression is used for optimizing image quality and reducing radiation dose. Excessive compression can cause pain and discomfort to women. Current force-based compression guidelines have largely been optimized for western women and do not take breast size into account. Thus, Asian women are subjected to protocols that might not be suitable for them. Previous studies using a 10 kPa pressure-standardized protocol significantly reduced pain without compromising apparent image quality and radiation dose.

Purpose: To investigate mammographic compression practice at our center, by analyzing the variability of compression parameters between and within women in terms of both force and pressure.

Materials and Methods: We processed 18,436 digital mammograms (CC and MLO views) from 4,609 women aged 40-80 years using VolparaAnalytics and VolparaDensity to assess compression force (CF), compression pressure (CP), compressed breast thickness (CBT), breast volume (BV), volumetric breast density (VBD) and mean glandular dose (MGD) as a function of contact area (CA). Standard deviation and Wilcoxon test were used to assess variability and statistical significance between and within women, respectively.

Results: CFs were significantly different for CC (10.8 ± 2.9 daN) and MLO (13.2 ± 2.9 daN) views (p<0.001). Similarly, CPs were also significantly different for CC (21.5 ± 11.5 kPa) and MLO (13.3 ± 4.9 kPa) views (p<0.001). CBTs were significantly different between CC and MLO views (5.1 ± 1.0 cm and 5.7 ± 1.3 cm, respectively; p<0.001). Lastly, CA was significantly different between CC (0.6 ± 0.4 dm²) and MLO (1.1 ± 0.4 dm²) views (p<0.001). Compression parameters including CF, CP, CBT and CA for CC and MLO views were highly variable between and within women, as indicated by the large standard deviations and Wilcoxon test. Figure 1(a)-(f) shows the relationships of CF, CP, CBT, BV, VBD and MGD versus CA. Based on our median CA (0.8 dm²) and the proposed 10 kPa pressure-standardized protocol, the corresponding CF should be about 8.0 daN (Figure 1(a)). In comparison, our women population was subjected to about 50% higher (12.0 daN) force.

Conclusion: We observed compression parameters were highly variable between and within women. Based on the suggested CP standardized at 10 kPa, we estimated the CF should be approximately 50% lower than our current practice. We will investigate the impact of the pressure-standardized protocol on image quality and radiation dose in Asian women (who generally have smaller breasts) that is of great interest.

SP172.3 - Radiation dose of step-and-shoot digital breast tomosynthesis using an anti-scatter grid compared to full field digital mammography in a clinical population

Author(s): <u>Cecile R. Jeukens</u>¹, Leonie E. Paulis¹, Ramona W. Bouwman², Ulrich C. Lalji¹, Nicky N. Gelissen¹, Joachim E. Wildberger¹, Marc B. Lobbes³

¹Maastricht University Medical Centre+, Maastricht/NETHER-LANDS, ²Dutch Reference Center for Screening, Nijmegen/NETH-ERLANDS, ³GROW School for Oncology and Developmental Biology, Maastricht/NETHERLANDS

Background

Digital breast tomosynthesis (DBT) has emerged as a promising breast imaging modality able to improve breast cancer detection, while reducing the number of false-positive findings, which is of particular interest in breast cancer screening programs. To develop into a widely applicable breast cancer detection tool, the radiation exposure of a DBT examination should be kept as low as possible, without compromising the examination's diagnostic accuracy

Purpose

Our study aim was to assess the radiation dose of a new commercially available DBT system (Senographe Essential with a SenoClaire DBT add-on, GE Healthcare) in comparison to full field digital mammography (FFDM) in a clinical setting.

Methods and Materials

To allow a direct comparison, only patients with complementary FFDM and DBT exams on the same system were included (n=204 patients with n=236 exams). The requirement for obtaining informed consent was waived by the local ethics committee. Entrance surface air kerma (ESAK) and average glandular dose (AGD) were calculated, according to the method described in the European guidelines¹. For this, the Xray tube output and half value layer were measured for a range of spectra using an ionization chamber dosimeter (Radcal). Patient-related data and additional parameters, e.g. target/filtermaterial, tube voltage, tube load and breast thickness were retrieved

from the DICOM meta-data.

Results

The mean patient age was 55 ± 13 years (range 30-85), the mean compressed breast thickness was 55 ± 13 mm for DBT and 58 ± 13 mm for FFDM. The AGD values increase with increasing compressed breast thickness (Figure 1). The mean AGD for a single view DBT and FFDM exposure were 1.49 ± 0.36 mGy and 1.62 ± 0.55 mGy, respectively, which is a small but statistically significant difference (Wilcoxon matched-pair signed-rank test, p< 0.001). Subanalysis where patients are categorized according to breast thickness, revealed that only for breast thickness categories >50 mm the AGD of DBT was significantly lower than the AGD for FFDM, indicating that the dose reduction is most pronounced in thicker breasts.

Conclusion

On average, the radiation dose of a single view DBT exposure is comparable to a single view FFDM. For patients with thicker breast, the radiation dose of DBT is found to be slightly lower than FFDM.

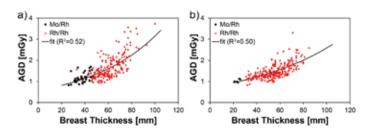

Figure 1 AGD values as a function of breast thickness for single view acquisitions for a) FFDM and b) DBT.

SP172.4 - Absorbed dose in PMMA and Equivalent Breast Phantom in a Digital Breast Tomosynthesis system: Monte Carlo Assessment

Author(s): Luis Magalhaes

Universidade do Estado do Rio de Janeiro - UERJ, Rio de Janeiro/ BRAZIL

Digital breast tomosynthesis (DBT) is a screening and diagnostic modality that acquires images of the breast at multiple angles during a short scan. The Selenia Dimensions (Hologic, Bedford, Mass) DBT system can perform both full-field digital mammography and DBT. The system acquires 15 projections over a 15° angular range (from -7.5° to +7.5°). The estimation of breast dose is an important part of mammographic quality control for x-ray mammography. Nevertheless, there are presently no standard protocols for dosimetry of breast imaging in 3D. The purpose of this work was to assess the absorbed dose by projection angle in slabs of polymethyl methacrylate (PMMA) and breast equivalent thickness using the Monte Carlo code MCNPX and typical x-ray energy range (25, 28, 31, 34, 37 and 40 kVp) recommended for breast tomosynthesis. Absorbed dose is a nearly linear function of glandularity, independently of x-ray spectra and decrease with increased PMMA thickness. Taking into account 45 mm thick PMMA and 53 mm thick equivalent breast, the difference in absorbed dose by projection angle has been up to 1.33%, 3.83% e 10.98% for x-ray energies of 25, 28 and 40 kVp, respectively. Normalized glandular dose (DgN) values may be used directly to measure the glandular dose in DBT quality control procedures.

SP173 - Ultrasound and OCT: Methods

TRACK 01: IMAGING

SP173.1 - A comparision study on shear wave velocity estimation of thin layered media using shear wave imaging

Author(s): Jun Keun Jang¹, Kengo Kondo², Makoto Yamakawa³, Tsuyoshi Shiina¹

¹Graduate School Of Medicine, Human Health Sciences, Kyoto University, Kyoto/JAPAN, ²Center For The Promotion Of Interdisciplinary Education And Research, Kyoto University, Kyoto/JAPAN, ³Ad-vanced Biomedical Engineering Research Unit, Kyoto University, Kyoto/JAPAN

Shear wave imaging allows noninvasive and quantitative evaluation of mechanical properties of human tissues. Generally, shear wave velocity (CS) can be estimated using lateral time-of-flight method (LTOFM) if a medium is unbounded. Thereafter, Young's modulus (E) is calculated directly from the estimated CS, i.e. $E=3\rho CS^2$ where p denotes density. However, shear waves propagating through a thin layered medium are influenced by strong dispersion effects. Recently, Lamb wave based method (LWBM) has been proposed to overcome this limitation. In this study, the two methods were compared to validate the effectiveness of LWBM by performing a finite element (FE) analysis and a phantom experiment for thin layered media.

Figure 1 shows the results of the FE analysis using PZFlex[®] for a thin layered model (thickness=1mm). The perpendicularly applied pressure generated shear waves propagating in the transverse direction. After obtaining axial velocity data from the FE analysis, CS was estimated using the two methods. CS_MEAN in (b) was not equal to CT in (a) and showed a non-uniform distribution, although the model was assumed to be homogeneous. On the contrary, LWBM precisely estimated CS in (C) by fitting the FE result with the theoretical curve of leaky Lamb waves.

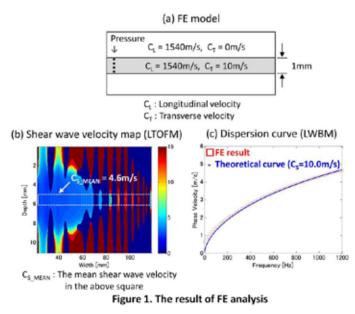

Figure 2 illustrates the results of a thin layered phantom (thickness=1.9mm). To obtain axial velocity, a 2D autocorrelator was employed to ultrasound in-phase quadrature data acquired with Aixplorer[®] and a 7.5MHz linear probe. There was a considerable discrepancy between CS_MEAN in (b) and the previously measured CS (=5.6m/s) of a bulk sample of 1.5% agar phantom. As for LWBM, no significant difference in Cs was shown between the layered phantom and the bulk phantom.

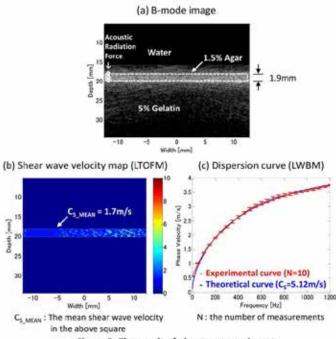

Figure 2. The result of phantom experiment

In conclusion, we showed that LWBM can be applied to accurately estimate shear wave velocity for thin layered media, while LTOFM is suitable only for unbounded media.

SP173.2 - Temperature Dependence of Nonlinear Acoustic Harmonics in Water: Measurement and Simulation

Author(s): Borna Maraghechi, Michael C. Kolios, Jahan Tavakkoli Physics, Ryerson University, Toronto/CANADA

Thermal therapeutic applications of ultrasound consist of hyperthermia and thermal ablation which are both clinically approved. In ultrasound hyperthermia, the tissue temperature increases up to 45°C through exposing it to a therapeutic ultrasound beam in order to destroy cancer cells or to sensitize them to radiotherapy or chemotherapy. A temperature monitoring technique is required to control and guide the heating during the thermal therapy.

In this study, the temperature dependence of the harmonics generated by nonlinear ultrasound beam propagation in water at a transmitting fundamental frequency of 13 MHz has been investigated both experimentally and through simulations.

The experiments were performed using a wide-band high-frequency single-element circular focused ultrasound transducer (f-number 2.1). Acoustic harmonics were generated by transmitting 15-cycle pulses at 13 MHz with focal positive peak pressures of approximately 1.3 MPa in water. The acoustic pressure signals were measured by a calibrated needle hydrophone placed at the focal point of the transducer. Water temperature was uniformly increased from 26° C to 46° C in increments of 5° C. The pressure amplitudes of the fundamental frequency (*p1*), and its harmonics (second (*p2*), third (*p3*), fourth (*p4*), fifth (*p5*) and sixth (*p6*)) generated by nonlinear ultrasound propagation were obtained by calculating the frequency spectrum of the measured acoustic pressure signals.

Nonlinear ultrasound beam simulations were performed using a time-domain numerical solution of a modified Khoklov-Zabolotskaya-Kuznetsov (KZK) nonlinear wave equation in which the temperature dependence of the medium parameters were included. Nonlinear propagation of a 15-cycle pulse at 13 MHz in water with the source pressure amplitude of 0.1 MPa from the same transducer geometry used in the experiment was simulated. This source pressure amplitude was used in simulation in order to get the same degree of nonlinear waveform distortion as to what obtained in experiment at the focus when the water was at the baseline temperature of 26°C. The changes in the *p1*, *p2*, *p3*, *p4*, *p5* and *p6* values at the focus were analysed as the water temperature increased from 26°C to 46°C.

The experimental results show that due to the temperature elevation the *p1*, *p2*, *p3*, *p4*, *p5* and *p6* values increased by $2.5\%\pm2\%$, $14\%\pm7\%$, $18\%\pm5\%$, $30\%\pm12\%$, $34\%\pm7\%$ and $63\%\pm15\%$, respectively compared to their initial value at 26° C. The results obtained from the KZK nonlinear simulations show that the *p1*, *p2*, *p3*, *p4*, *p5* and *p6* values changed by 0%, 1.6%, 3.3%, 5%, 7%, 9% as the temperature was raised from 26° C to 46° C. The simulation and experimental results show similar trend in the temperature dependence of the harmonics generated in water. However, the magnitude of the changes is lower for the simulation results and the source of the difference is currently under investigation.

The results indicate that the nonlinear harmonics generated in water from a 13-MHz transmit pulse are temperature dependent and their temperature sensitivity increases with the harmonic number. Therefore, the nonlinear harmonics generated from high-frequency ultrasound beams could potentially be used for ultrasound-based thermometry.

SP173.3 - 3D trans-rectal ultrasound for high-dose-rate prostate brachytherapy: a comparison of sagittally-reconstructed 3D image volumes with sagittally-assisted axial image sets Author(s): William T. Hrinivich¹, Douglas Hoover², Kathleen Surry², David D'Souza², Aaron Fenster³, Eugene Wong⁴ ¹Department Of Medical Biophysics, Western University, London/ CANADA, ²Department Of Oncology, Western University, London/ CANADA, ³Imaging Research Laboratories, Robarts Research Institute, London/ON/CANADA,⁴London Regional Cancer Program, London Health Science Center, London/CANADA

Background: High-dose-rate brachytherapy (HDR-BT) is a prostate cancer treatment option where hollow applicators are inserted into the gland through the perineum. Dose is delivered by indexing a high-activity source to dwell positions within the applicators based on the relative positions of applicators, the prostate, and nearby organs. Conventional HDR-BT imaging involves indexing a transrectal ultrasound (TRUS) probe in the superior/inferior (S/I) direction, typically in 5-mm intervals, using the axial crystal to produce an image set for planning. These axial images have limited spatial resolution in the applicator insertion direction (S/I), so the sagittal crystal is used to identify applicator tips, which are transferred to the axial image set through a manual registration of the axial images and live sagittal view, adding a potential source of uncertainty. Correct localization of applicators is critical for accurate dosimetry. A sagittally reconstructed 3D-TRUS image volume with high S/I spatial resolution could eliminate the need to identify applicator tips on separate images, potentially mitigating errors in applicator tip position.

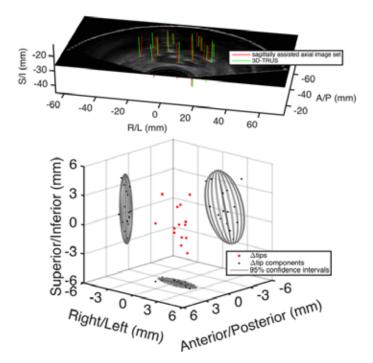

Purpose: To compare applicators localized on 3D-TRUS to those localized on sagittally assisted axial image sets, and to assess the dosimetric impact of these differences.

Methods: Our lab previously developed a mechatronic device for image-guided trans-perineal needle insertions enabling sagittally reconstructed 3D-TRUS. The device has recently been used for both axial image and 3D-TRUS acquisition. A patient underwent HDR-BT using a sagittally assisted axial image set. A 3D-TRUS image volume was acquired prior to the axial images, enabling rigid image

alignment using anatomical landmarks. Applicators were then localized on 3D-TRUS, and dwell positions were compared with those determined intra-operatively. Planned dwell times were transferred to the 3D-TRUS-localized dwell positions and changes in relevant dosimetric parameters were assessed.

Results: Mean \pm SD differences in Right/Left, Anterior/Posterior, and Superior/Inferior applicator tip positions were 0.2 \pm 1.1 mm, 0.3 \pm 0.4 mm and 0.3 \pm 1.8 mm respectively. The 3D-TRUS dwell positions resulted in reductions in prostate V100% from 97.1% to 95.5%, urethra D10% from 116.8% to 112.0%, and rectum D0.5cc from 64.4% to 63.5%.

Conclusions: Applicator localization with 3D-TRUS has the advantage of eliminating a source of uncertainty relative to sagittally assisted axial image sets. Differences in dwell positions were largest in the applicator insertion (S/I) direction. For this patient, spatial differences had little effect on dosimetric parameters. We will report on-going analysis of a larger patient cohort comparing 3D-TRUS with sagittally assisted axial image sets for HDR-BT.

SP173.4 - Understanding lung ultrasound artifacts using a phantom lung model

Author(s): Justine Shuhui Loh¹, Robin O. Cleveland², Andrew P. Walden³

¹Accident And Emergency Department, John Radcliffe Hospital, Oxford/UNITED KINGDOM, ²Old Campus Road Research Bulding, Institute of Biomedical Engineering, Oxford/UNITED KING-DOM, ³Royal Berkshire Hospital, Intensive Care Unit, Reading/ UNITED KINGDOM

Background: Fluid resuscitation as part of the early goal-directed therapy in sepsis is recommended. A conservative fluid strategy is associated with reduced risk of pulmonary oedema, highlighting the importance of limiting fluid therapy in patients at risk of pulmonary oedema. Ultrasound has been used to assess this. Diseased lungs have better ultrasound penetration and resolution, producing ultrasound artefacts known as B-lines. There is an association between

these B-lines and lung water volume. However, there is limited study in classifying and quantifying B-line artefacts as a function of lung water volume.

Objective: To recreate A-line and B-line ultrasound artifacts using a phantom lung model, and determine factors influencing changes in these artifacts, and the possibility of quantifying these changes.

Method: A phantom lung model was created from melted gel wax, which was solidified in a phantom holder over 12 hours, and placed on a layer of cling film wrapped over an air-filled plastic container. 10μ L and 200μ L pipette tips, and 0.5mL tube were embedded in the phantom model. Using a linear probe, the A-line and B-line artifacts were obtained from scanning the phantom model. Factors assessed were the different phantom thickness, different phantom surfaces, ultrasound frequency, location of meshed gel wax and weight of meshed gel wax. Data collected and analysed were based on the number of A-lines, distance between each A-line, and the average length of B-lines.

Results: Scanning empty pipette tips and tube created A-lines. B-lines were created by scanning pipette tips and tube filled with liquid (i.e. water, Gelofusin, and plasma) and semisolid (i.e. meshed gel wax) materials. The A-lines - The thickness of phantom model is directly proportional to the distance between A-lines, but inversely proportional to the number of A-lines. The ultrasound frequency is inversely proportional to the intensity of A-lines. There was no difference in the A-lines between the flat and semicurved surface phantom, or the different pipette tips and tube sizes. The B-lines -The B-lines in pipette tips filled with water showed broader distance between each B'-lines compared to pipette tips filled with meshed gel wax. The ultrasound frequency was inversely proportional to the intensity and average length of B-line. The average length of B-lines appears to increase with increasing meshed gel wax weight, although not in a progressive manner. The distance between each B'-lines appears to be shorter in water-filled and plasma-filled compared to Gelofusin-filled tubes. There was no difference in the B-line between the different pipette tips and tube sizes. There was no relationship between the average length of B-lines and the location of meshed gel wax within the pipette tips (i.e. distance between ultrasound probe and meshed gel wax).

Conclusion: We managed to recreate A-line and B-line artifacts using this model. Increasing volume of subtance was associated with ultrasound artifacts changes, confirming a potential role for ultrasound use in quantifying volume. Although there were factors with good association to ultrasound artifacts demonstrated, there were several limitations identified. Further improvement to the phantom model design is required for more accurate study.

SP173.5 - Accuracy of Tissue Elasticity Measurement using Shear Wave Ultrasound Elastography: A Comparative Phantom Study

Author(s): Chu En Ting¹, <u>Chai Hong Yeong</u>², Kwan Hoong Ng², Basri Johan Jeet Abdullah¹, Huong En Ting¹

¹Department Of Biomedical Imaging, Faculty Of Medicine, University of Malaya, Kuala Lumpur/MALAYSIA, ²University Of Malaya, University of Malaya Research Imaging Center, Kuala Lumpur/MALAYSIA

Introduction:

There is a strong correlation between tissue elasticity (Young's modulus) and pathological state. The information of tissue elasticity superimposed to any anatomical image provides great diagnostic value, hence improving treatment outcome. Shear wave elastrography (SWE) is a relatively new imaging technique using ultrafast ultrasound to measure tissue elasticity. Though studies have reported the reliability, specificity and reproducibility of SWE in elasticity quantification, the accuracy of elasticity measurements compared

to a gold standard has not been reported.

Aims and Objectives:

The objectives of this study were to verify the accuracy of tissue elasticity measured using SWE compared to the gold standard (electromechanical microtester) and to investigate several factors (size, depth and overlapping inclusions) that might affect the accuracy of SWE measurement.

Methods and Materials:

A tissue-mimicking phantom with acoustic and shear elasticity properties similar to the human breast was developed using animal hide gelatine. Elasticity values of inclusions embedded in the phantom were manipulated by varying the amount of its gelatine content. Each inclusion was made in pair, one for in vivo measurement using a commercial SWE scanner (Aix-plorer, SuperSonic Imagine, France) and the other for destructive in vitromeasurement with the microtester (Model 5848, Instron Co, USA). The measurements using both methods were compared statistically using the paired-sample t-test with 95% confidence interval. To investigate the possible factors affecting SWE measurements, the phantom was also designed to encompass inclusions with varying diameters and elasticity values, embedded at different depths in the phantom. The diameters of the inclusions were varied using pairs of hemispherical moulds with sizes ranging from 17 to 30 mm. SWE measurements were obtained for each inclusion.

Results and Discussion:

Despite a strong linear correlation, a statistically significant difference (p<0.05) was found between the elasticity values measured using SWE and the gold standard, whereby the SWE overestimated the elasticity by a mean of 22.79±15.00 kPa. This overestimation might be due to artefacts caused by wave interferences between the elasticity boundaries. Shear wave reflection at boundaries could cause either constructive or destructive interference, depending both on boundary conditions and the incoming wave, consequently causing underestimation or overestimation of the actual elasticity values. Due to shear wave reflection, an increase in contrast between elasticity boundaries was also shown to reduce reproducibility of consistent measurements. A spatio-temporal directional filter has been suggested as a means to reduce the artefacts in the reconstructed shear modulus map. Size and depth of inclusions did not affect SWE measurements; however the depth of shear wave detection was limited to 8 cm from the surface.

Conclusion:

Elastography plays a significant role in clinical diagnosis by providing useful structural and pathological information on soft tissues. This study shows that the elasticity values derived from commercial SWE system were consistently higher than the gold standard, which is likely due to wave interference at the elasticity boundary. In order for SWE to be incorporated into clinical diagnostic practice, it is vital to identify a solution to overcome these artefacts.

SP174 - Motion Management: Part 2

TRACK 04: RADIATION ONCOLOGY

SP174.1 - Assessment of lung dose in patients undergoing deep inspiration breath hold for left sided breast cancer

Author(s): <u>Peta Lonski</u>¹, David Jolly¹, Shankar Siva², David Ball², Boon Chua³, Damien Philips⁴, Maria Portillo⁴, Steven David², Amanda Philips⁴, Tomas Kron¹

¹Physical Sciences, Peter MacCallum Cancer Center, Melbourne/ AUSTRALIA, ²Department Of Radiation Oncology, Peter MacCallum Cancer Center, Melbourne/VIC/AUSTRALIA, ³Sir Peter MacCallum Department Of Oncology, University of Melbourne, Melbourne/VIC/ AUSTRALIA, ⁴Radiation Therapy Services, Peter MacCallum Cancer Center, Melbourne/AUSTRALIA

Aim: Deep inspiration breath hold (DIBH) is being used to reduce cardiac dose in patients undergoing radiotherapy for left sided breast cancer. Due to chest wall expansion there is concern that the amount of lung in the high dose region could increase. We aimed to evaluate this in a cohort of patients from a prospective trial who had both a free breathing (FB) and DIBH CT scan for planning comparison purposes.

Methods: Ten consecutive left sided breast cancer patients were enrolled in this study. Each patient underwent a FB and a DIBH CT scan in treatment position on an elevated breast board using a Philips Brilliance wide bore 16 slice CT scanner. Plans were created using 6 MV x-rays to treat the whole breast volume as marked clinically. A field in field tangential technique was used. Plans were created in Varian Eclipse version 11 using the Anisotropic Analytical Algorithm (AAA version 11.0.31). The volumes of lung receiving 5, 20 and 30 Gy (V5, V20 and V30 respectively) were assessed on the FB and DIBH scans. Lung DVH data was analysed in terms of both absolute and relative lung volumes.

Results: There was an average increase in absolute volume of lung receiving 5, 20 and 30 Gy in DIBH compared to FB. However, assessment of the same DVH parameters in terms of relative volume of lung showed an average decrease in DIBH. The difference in V5, V20 and V30 between DIBH and FB (positive values indicate a higher dose in DIBH) are shown in the table in terms of absolute and relative lung volumes.

	DIBH - volume	FB: absolute lung e (cc)	DIBH - FB: relative lung volume (%)			
	mean	standard deviation	mean	standard deviation		
V 5	+ 203	167	- 0.2	4.1		
V 20	+ 91	103	- 0.7	2.7		
V 30	+ 87	99	- 0.6	2.5		

Conclusion: DIBH resulted in an increase in the absolute volume of lung present within the target region but paradoxically reduced the evaluated DVH parameters in terms of dose to relative lung volume. Lung DVH data therefore requires careful evaluation when assessing the dosimetric consequences to lung in patients undergoing DIBH. Comparative evaluation of the clinical consequences of absolute versus relative irradiated lung volume in DIBH is warranted.

SP174.2 - Evaluation of 4D dose accumulation in CyberKnife and IMRT treatments

Author(s): <u>Vincent Cousineau Daoust</u>¹, Emily Heath², Jean-Francois Carrier¹, Stephane Bedwani³

¹Radio-oncology, CHUM/Notre-Dame Hospital - Université de Montréal, Montréal/CANADA, ²Physics, Carleton University, Ottawa/ CANADA, ³Radio-oncologie, CHUM- Notre-Dame hospital, Montreal/CANADA

Pulmonary cancer is the main cause of death amongst all cancers in Canada with a prognosis of about 15% survival rate in 5 years. The efficiency of radiotherapy treatments is lower when high displacements of the tumors are observed, mostly caused by intrafraction respiratory motion. Advanced techniques such as radiosurgery and intensity-modulated radiotherapy treatments (IMRT) are expected to provide better clinical results by delivering higher radiation doses to the tumor while sparing the surrounding healthy lung tissues. The goal of this project is to perform 4D Monte Carlo dose recalculations to assess the dosimetric impact of moving tumors in CyberKnife and IMRT treatments using dose accumulation in deforming anatomies. Scripts developed in-house were used to model both situations and to compare the Monte Carlo dose distributions with those obtained with standard clinical plans. Deformation fields are obtained from 4D CT data set and a deformable image registration (DIR) algorithm which allows a voxel-to-voxel correspondence between each respiratory phase (Figure 1). The DIR is computed by the Advanced Normalization Tools (ANTs) software and is mostly based on diffeormophisms. A modified version of DOSXYZnrc from EGSnrc software, defDOSXYZnrc, is used to transport radiation through non-linear geometries.

Current results are mostly centered toward the validation of defDOSXYZnrc with DOSXYZnrc. Theoretical affine deformations were applied to a virtual phantom and the dose distributions for both algorithms were compared using the gamma test and the Kawrakow-Fippel (KF) method. The gamma index for the two distributions is 96.7% for the 1%/1mm criterion and the KF method showed that no significant systematic differences exists between the two algorithms. A set of tools was created to link together dose calculation and DIR softwares, and also to provide the user a simple dose analysis environment. Data from patients who underwent CyberKnife or IMRT treatments with lung tumors moving at least 5 mm is used for the dose comparison. SP174.3 - Application of RADPOS System for Dose and Position Quality Assurance of 4D CyberKnife Treatments

Author(s): <u>Raanan Marants</u>¹, Eric Vandervoort², Joanna Cygler³ ¹Physics, Carleton University, Ottawa/ON/CANADA, ²Medical Physics, The Ottawa Hospital Cancer Centre, Ottawa/ON/CANADA, ³Radiology, University of Ottawa, Ottawa/ON/CANADA

Introduction

The CyberKnife robotic radiosurgery system uses Synchrony respiratory motion compensation. This complex dose delivery system needs independent performance verification to assure safe patient treatments.

In this work, we use the RADPOS 4D dosimetry system to verify CyberKnife's motion tracking and delivered dose. RADPOS motion measurements are compared with internal metal fiducials and external LED optical markers log files. Dose measurements are compared with GAFCHROMIC film and treatment planning system (TPS) calculations.

Methods

RADPOS and EBT3 GAFCHROMIC films were calibrated using an ion chamber in Solid Water (5 cm depth, 80 cm source-detector distance, 60 mm cone). A CT based treatment plan was created for a Solid Water breast phantom containing fiducials and the RADPOS detector. Dose calculations were performed using the MultiPlan TPS, Monte Carlo (MC) and ray tracing (RT) algorithms on static phantom only. Before treatment, film was inserted inside the breast phantom adjacent to the RADPOS detector. The breast phantom and LED markers were positioned on the chest platform of a Quasar Respiratory Motion Phantom. Position logging began for RADPOS and Synchrony, Quasar motion started, and irradiation commenced. A coordinate alignment algorithm was implemented, allowing all position tracking modalities to be compared within the fiducial coordinate system.

Results

Position

After LED and RADPOS position data are aligned to the fiducial coordinate system (average difference < 0.01 mm in any direction), the standard deviation of the differences between LED and RADPOS position measurements was 0.33, 0.39, and 0.56 mm along the left/ right, superior/inferior, and anterior/posterior directions, respectively.

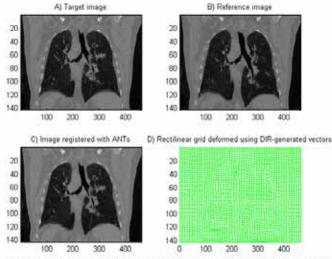

Figure 1 - A) A respiratory phase from a 4D CT acan is defined as a target image. B) Another respiratory phase is defined as a reference image () which will be deformed tenand the target image using DR algorithm. B) Vectors obtained from the DR are used to deform the grid generative. Does is computed in the deformed generaty using defDOSXV2nc and then mapped back to a restillnear grid (back to the reference image).

Dose

TPS Measured											
RT Dose (cGy)	MC Dose (cGy)	Phantom	RADPOS Dose (cGy)	% diff (RAD- POS/RT)	% diff (RAD- POS/MC)	Film Dose (cGy)	% diff (Film/RT)	% diff (Film/MC)	% diff (RAD- POS/Film)	γ-index, 3%/1 mm (RT)	γ-index, 3%/1 mm (MC)
146.7 145.	145.0.1.00/	Static	147.2±1.3%	0.3%	1.3%	147.5±1.9%	0.5%	1.5%	-0.2%	97.2	96.7
	145.3±1.0%	Dynamic	149.6±1.2%	2.0%	2.9%	145.3±1.8%	-1.0%	0.0%	3.0%	97.3	97.0

Discussion

Position

LED positions were sampled approximately 2.5 times as frequently as RADPOS positions. Also, during coordinate system alignment, the user synchronizes semi-automatically two motion signals in time. These temporal uncertainties were dealt with as follows:

 $\sigma t = \sqrt{(\sigma t, LED^2 + \sigma t, RADPOS^2)} = \sqrt{[(\frac{1}{2} \times dt LED)^2 + (\frac{1}{2} \times dt RADPOS)^2]} = 53.6$ ms

This lead to a positional uncertainty of 0.02, 0.04, and 0.19 mm along the left/right, superior/inferior, and anterior/posterior directions, respectively.

Dose

The MC and RT TPS dose values were very similar because both calculations were done for primarily homogeneous, unit-density material. RADPOS dose readings made during dynamic treatment were slightly higher than all other dose values, but still fell within two standard deviations of experimental uncertainties. Average gamma results were greater than 96% for both MC and RT dose calculation algorithms, as well as for dynamic and static treatments.

Conclusions

Our work demonstrates that RADPOS is a useful tool for independent QA of CyberKnife treatment with Synchrony respiratory compensation.

SP174.4 - Derivation of the probabilistic treatment margin for two targets with correlated motion

Author(s): Simon Van Kranen, Jan-Jakob Sonke, <u>Marcel Van Herk</u> Radiation Oncology, The Netherlands Cancer Institute, Amsterdam/ NETHERLANDS

Introduction

Margin recipes are widely used to derive PTV margins from random and systematic errors. Here we address a common situation with unknown solution: a margin that jointly covers two targets with correlated motion. E.g., primary tumor and lymph node targets in lung cancer are known to move somewhat correlated.

Material and methods

We assume two targets moving in 3D with a normal distribution with random / systematic error vectors σ and Σ . For simplicity we assume the following type of correlation: each vector component of target 1 correlates with the corresponding component of target 2 with the same and known correlation, *r*. Finally, we assume that the margin for systematic errors can be expressed as $\alpha\Sigma$, where α is function of *r*. Because the margin for **random errors** is derived from the local target motion relative to the dose distribution, correlation has no influence, and the margin remains unchanged, e.g., 0.7σ simplified. The margin for **systematic errors** needs to achieve an acceptable probability that both targets are covered together. For a single target, 90% probability is reached with $\alpha = 2.5$. For two targets with uncorrelated motion, a needs to be 2.8 to achieve 90% joint probability for both targets (0.95²). To finally derive the appropriate margin given correlation *r*, we need to establish the correlation *R* of the dichotomous (i.e. 0 or 1) variables $V1 < a \Sigma 1$, and $V2 < a \Sigma 2$, where *V* is the error vector length of a target. The probability, *P*, that $V1 < a \Sigma 1$ and $V2 < a \Sigma 2$ is given by P = p2 + p(1-p)R (equation 1), where *p* is the probability of this condition for each target independently. In this study continuous correlation *r* and dichotomous correlation *R* are linked using a simulation for a practical range of α .

Results

We first obtain *R* from *r*, then *p* from *R*, and finally α from *p*. Our simulations show that for this type of correlation, *R* fits *r4* well for 2.5 < α < 3.2. The appropriate *p* given correlation *R* is a solution of eq. 1 for *P*=0.9. Finally, α is found as the inverse of the cumulative chi-square distribution with three degrees of freedom at *p* (e.g., 2.5 for *p*=0.9). The combined equations are approximately linear with *z* = *1*-*R*, or *z* = 1-*r*4. The simplified margin recipe is given by $M = 0.7\sigma + (2.5 + 0.3z)\Sigma$, which assures with 90% probability that 2 targets are within the 95% isodose line.

Conclusions

Based on an empirical relation between a continuous and a dichotomous correlation, a practical margin recipe for two targets with correlated motion was derived. This margin formula is generic, except that z depends on the type of correlation. Because the dichotomous correlation *R* is much smaller than the underlying continuous correlation, r < 0.5 can be treated as uncorrelated. The introduced formalism opens up the way to derive analytical margin recipes for an arbitrary number of targets with correlated motion.

SP174.5 - How Truthful Is the 4D Dose Calculation?

Author(s): <u>Gang Liu</u>¹, Di Yan², Hong Quan¹ ¹School Of Physics And Technology, Wuhan University, Wuhan/ CHINA, ²Radiation Oncology, Beaumont Health System, Royal Oak/ MI/UNITED STATES OF AMERICA

Purpose: "4D dose" can be constructed using patient respiratorycorrelated 4D CT image.However, patient respiratory-induce target/ organ motion is most likely heterogeneous between breathing periods. Therefore, it is questionable if the 4D dose represents the "true dose" obtained from the entire breathing motion during the CT scanning. In this study, 4D CT scanning was simulated and used in the 4D dose calculation.The dose discrepancy between the "4D dose" and the "true dose" was evaluated and correlated to the heterogeneity of respiratory-induced motion pattern.

Method& Material:Computer simulation was performed using simulated and measured free breathing curves to generate a 4D target and an adjacent normal organ motion CT images. Two 4D dose distributions in the target and organ were constructed. The first one, named the 4D dose (D1), was calculated by tracking the point displacements in the target or organ manifested on the 4D CT images and including the physical density changes in the phase CTs, meanwhile the second one, named the true dose (D2), constructed based on the point displacements and density changes along the whole breathing motion curve. Treatment dose was generated using 6 co-planer beams aimed to the target center without using target margin. Dose discrepancy between D1 and D2 was calculated using different breathing curves with either non-uniform excursion or heterogeneous breathing period. The correlation between breathing pattern variation and dose discrepancy in the target and organ adjacent to target was determined and evaluated.

Result:The dose discrepancy in both the target and adjacent organ is highly correlated to the variation of breathing-induced target motion excursion and period. The maximum dose discrepancy in the target was on average $5\%(\pm 2.7\%)$ of one SD) to $8\%(\pm 7.3\%)$ with the standard deviation of the motion excursion variation from 1mm to 4mm, meanwhile $6\%(\pm 3.7\%)$ to $12\%(\pm 8\%)$ with the standard deviation of the motion from 0.3 sec to 0.7 sec. For the adjacent normal organ, the dose discrepancy was larger, especially for the motion period variation. When both variations appeared, the dose discrepancy could be >12\%(\pm 8.3\%) for the target, and >16\%(\pm 11.5\%) for the adjacent organ, meanwhile $10.6\%(\pm 9.8\%)$ of the target volume and $21.8\%(\pm 15.8\%)$ of the organ volume had dose discrepancy bigger than 5%.

Conclusion:The 4D dose constructed using4D CT image can have large discrepancy when patient respiratory-induced target/organ motion has a heterogeneous pattern. However, this dose discrepancy can be estimated for treatment planning evaluation using the measured breathing curve during the 4D CT scanning.

SP175 - Treatment Planning - Biology & Fractionation

TRACK 04: RADIATION ONCOLOGY

SP175.1 - Adaptive radiotherapy for bladder cancer using deformable image registration of empty and full bladder Author(s): <u>Prabhjot Juneja</u>¹, Hannah Caine², Peter Hunt², Jeremy T. Booth¹, David Thwaites¹, James O'Toole², Anen Vestergaard³, Jesper Kallehauge³, Andrew Kneebone², Thomas Eade² ¹Institute Of Medical Physics, School Of Physics, University of Sydney, Sydney/NSW/AUSTRALIA, ²Northern Sydney Cancer Centre, Royal North Shore Hospital, Sydney/NSW/AUSTRALIA, ³Department Of Medical Physics, Aarhus University Hospital, Aarhus/DENMARK

A common objective of various adaptive radiotherapy (ART) strategies for bladder cancer is to reduce irradiation of normal tissue, thereby reduce the risk of radiation induced toxicity, and maintain or improve the target coverage. Bladder radiotherapy, typically involves generous margins (up to 20 mm) for bladder planning target volume (PTV).

The goal of this retrospective study is to define, evaluate and optimize new patient-specific anisotropic PTVs (a-PTVs) using deformable image registration (DIR) between empty and full bladder computed tomography (CT) scans. This will provide an ART that incorporates the extreme deformations of the bladder, and is applicable from the first day of treatment.

Deformation vector fields (DVFs), measured from the deformable image registration between empty and full bladder CTs, were scaled and constrained to construct the a-PTVs. For each patient, four a-PTVs were constructed such that a-PTV1 was the largest and a-PTV4 was the smallest. All the a-PTVs were defined such that they covered at least the bladder volume plus 5 mm margin. These a-PTVs were retrospectively evaluated and compared to the current clinical standard (conv-PTV), with 10 mm uniform margins, using 5 bladder cancer patients and a total of 100 fractions.

It was found that the smaller a-PTV, a-PTV4 and a-PTV3, were appropriate in 87% of the fractions, while a-PTV2 and a-PTV1 were required in 12% of the fractions respectively. The use of the a-PTVs reduced the PTV volume by 32% (28-36%) as compared to conv-PTV.

In conclusion, the results of this pilot study indicate that the use of a-PTVs could result in substantial decrease in the course averaged planning target volume. This reduction in the PTV is likely to decrease the radiation related toxicity and benefit bladder cancer patients. Currently, more patients are being investigated to strengthen these findings, and also dosimetric analysis is underway.

SP175.2 - Dosimetric and clinical benefits of conformal radiotherapy combined plus volumetric modulated arc therapy in the treatment of non-small cell lung cancer Author(s): <u>Xiance Jin</u>, Congying Xie

Radiotherapy And Chemotherapy, The 1st Affiliated Hospital of Wenzhou Medical University, Wenzhou/CHINA

Background Radiation pneumonitis (RP) is one of the most common dose-limiting toxicities in conformal radiotherapy (CRT) and has a considerable impact on patient's morbidity and mortality for lung cancer patients. Intensity-modulated radiotherapy (IMRT) and volumetric modulated arc therapy (VMAT) have been applied in the treatment of lung cancer in an intent to spare the normal lung tissue and escalate dose to target. However, the use of IMRT and VMAT have been limited due to low dose dosimetric considerations. The purpose of this manuscript is to investigate the dosimetric and clinical benefits of a technique by combining conformal radiotherapy (CRT) plus VMAT in the treatment of non-small cell lung cancer (NSCLC). Materials and methods There were 200 NSCLC patients analyzed retrospectively and treated by CRT, CRT plus VMAT, and full course of VMAT, respectively. Matches were chosen based on stage, PTV size, tumor location, age, and gender. CRT scheme was planned with two parallel opposed, antero-posterior and posteroanterior (APPA) beams for 36 Gy, then followed by off-cord conformal beams for 24 Gy at 2 Gy per fraction. CRT plus VMAT was planned with initial CRT APPA beams for 36 Gy, then followed by a single-arc VMAT plan for 24 Gy. The full course VMAT plan was 60 Gy over 30 fractions with a single arc. Dosimetric differences, RP rates and their correlation were investigated. Results The number of patients analyzed in CRT, CRT plus VMAT and full course of VMAT were 42, 28, and 53, respectively. The V93 and V95 (percent volume covered by isodose line) of PTV were improved from 95.7%±2.2% and 94.5%±2.4% in CRT to 97.9%±4.6%, 98.3%±3.2% and 96.3%±5.8%, 97.1%±4.1% in CRT plus VMAT and full course of VMAT, respectively. CRT plus VMAT improved the PTV coverage compared with CRT in a cost of higher spinal cord maximum dose (p=0.02), larger lung volume receiving 5 Gy (V5, p=0.02) and mean lung dose (MLD) (p=0.04), and decreased the low dose lung volumes compared with VMAT. The RP rates were 26%, 39% and 49% for CRT, CRT plus VMAT and VMAT, respectively. V5 was significantly associated with RP and had a threshold of 60% and 65% for CRT plus VMAT and VMAT, respectively, to limit the RP rate <30%. The median three-year overall survival were 17.5, 23.2, 24.5 months for CRT, CRT plus VMAT and VMAT, respectively, without significant difference (p=0.29). Conclusions: CRT plus VMAT is a promising with increased target coverage compared with CRT and reduced low dose lung volume and RP compared with full course of VMAT in the treatment of NSCLC. V5 was significantly associated with RP and with a predicted threshold of 60% and 65% for CRT plus VMAT and VMAT, respectively, to limit the RP rate <30%. The interplay effect of chemotherapy with CRT plus VMAT on RP needs further study. Clinical trials with large population are needed to further verify the benefits of CRT plus VMAT in the treatment of NSCLC.

SP175.3 - Non-uniform spatiotemporal fractionation schemes in photon radiotherapy

Author(s): Jan Unkelbach

Radiation Oncology, Massachusetts General Hospital, Boston/MA/ UNITED STATES OF AMERICA

Fractionation decisions in radiotherapy face the tradeoff between increasing the number of fractions to spare normal tissues, and increasing the total dose to achieve the same level of tumor control. In that regard, the ideal treatment would fractionate in normal tissues while simultaneously hypofractionating in the tumor. Interestingly, this is possible to a limited degree by delivering distinct dose distributions in different fractions. The dose distributions have to be designed such that similar doses are delivered to normal tissues while delivering high single fraction doses to parts of the tumor. In this paper, proof-of-concept is provided that this concept may lead to an improved therapeutic ratio for rotation therapy treatments using conventional photon beams. An idealized model of a large tumor treated in two fractions is considered. Fractionation effects are modeled via the biologically equivalent dose model. It is shown that the optimal treatment delivers the dose to the center of the tumor in a single fraction, while the second fraction delivers dose only to the rim of the tumor. The approach may potentially be interesting for large tumors embedded in a dose-limiting organ treated with stereotactic regimens.

SP175.4 - Compressed Sensing-Based LDR Brachytherapy Inverse Treatment Planning with Biological Models Author(s): <u>Christian V. Guthier</u>¹, Katharina P. Aschenbrenner¹, Frederik Wenz², Juergen W. Hesser¹

¹Experimental Radiation Oncology, Medical Faculty Mannheim, Heidelberg University, Mannheim/GERMANY, ²Radiation Oncology, Medical Faculty Mannheim, Heidelberg University, University Medical Centre, Mannheim/GERMANY

New compressed sensing-based planning algorithms allow for fast computations of optimal planning results in low-dose-rate (LDR) brachytherapy. This enables to integrate complex models in the planning process. In this paper, we develop a new strategy for including a biological model on tumor control probability (TCP) and normal tissue complication probability (NTCP) into the objective function for plan optimization. These models were tested on clinical prostate cancer cases for their effects on the planning results relative to standard physical dose constraints for planning as reference. Interestingly, with weighting treatment risks, we observe plans using biological models assign more dose to the urethra since it is less radiation sensitive than the rectum whereby the latter is spared in order to reduce side effects. At the same time, the overall TCP is comparable. We conclude that the standard plan quality evaluation based on physical dose alone does not easily allow correctly assessing treatment risks. Hence, biological models for LDR brachytherapy treatment planning are a promising approach for an optimal management of treatment outcomes of brachytherapy.

SP175.5 - Investigation of Dosimetric and Biological Differences between Flattened and Unflattened Beams from the TrueBeam System

Author(s): Yue Yan¹, Kaifang Du², Daniel Saenz¹, Michael Bassetti², <u>Bhudatt Paliwal¹</u>, Paul Harari²

¹Medical Physics, University of Wisconsin Madison, Madison/UNIT-ED STATES OF AMERICA, ²Human Oncology, University of Wisconsin School of Medicine and Public Health, Madison/WI/UNITED STATES OF AMERICA

Purpose/Objective(s): To investigate the dosimetric and biological differences between flattened and unflattened beam plans using different anatomic cancer sites.

Materials/Methods: Flattened and unflattened beams of the True-Beam system were commissioned on the Eclipse treatment planning system (TPS). Beam energies were chosen to be 6 MV and 10 MV. Fourteen clinical cancer cases were used to simulate the clinical treatment. Static intensity modulated radiation therapy (IMRT) and volumetric modulated arc therapy (VMAT) were used to deliver the dose. Based on the dose-volume-histogram (DVH), biological effective dose (BED), equivalent uniform dose (EUD), tumor control probability (TCP) and normal tissue complication probability (NTCP) were calculated to evaluate the biological effectiveness of the treatment plan. In-house developed Matlab code was used to statistically analyze the results. Direct comparisons were made to study the dosimetric and biological differences between the flattened and the unflattened beams for both energies.

Results: Nearly the same target coverage was obtained by the unflattened beam compared with the flattened beam for all cancer cases. For organ-at-risk (OAR) with high radiation sensitivity but received low dose (e.g. lens of the eye), the unflattened beam had up to 38% mean dose reduction and 34% maximum dose reduction compared with the flattened beam, leading to 85% reduction in the NTCP value. For OARs which were closer to the treatment field and had larger dose (e.g. brainstem), the unflattened beam had up to 14% reduction in the mean dose, 10% reduction in the maximum dose and 55% reduction in the NTCP value.

Conclusion: The clinical data indicated that the unflattened beam

could provide similar target coverage as the flattened beam in all 4 types of cancer. Improved dose sparing effect was obtained by the unflattened beam, leading to lower NTCP value in general. Significant dose sparing effect of the unflattened beam was observed for the head and neck cancers with large field size (about 16x20 cm²). The maximum dose rate of the unflattened beam may not always be achievable for large treatment field size (e.g. 20x20 cm²) due to the speed limitation of the multileaf collimator (MLC).

SP176 - Characterization of Detector Systems for Therapy Dosimetry: Part 4

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP176.1 - Evaluation of surface dose distributions using ferrous benzoic xylenol orange translucent PVA cryogel radiochromic dosimeters

Author(s): <u>Molham Eyadeh</u>, Marcin Wierzbicki, Kevin Diamond McMaster University and Juravinski Cancer Centre, Hamilton/ CANADA

Purpose

The purpose of this study is to evaluate the ability of a radiosensitive bolus material to monitor the surface dose distribution. Poly-(vinyl alcohol) cryogels (PVA-C) are flexible and can be fit snugly against skin over large, curved regions, where it may be challenging to achieve the same coverage with film or TLDs. We propose a method to use ferrous benzoic xylenol orange (FBX) in translucent PVA-C in place of bolus to perform *in vivo* dosimetry in regions where surface dose is important.

Materials and Methods

In this study, a series of open fields with gantry angles ranging from 0° to 90° were delivered to a radiochromic bolus and film stack on the surface of a polystyrene phantom. These measurements established the relationship between surface dose (estimated using Gafchromic EBT-2 film) and the dose measured in a 5 mm thick piece of radiochromic bolus. This calibration was then applied to clinical head and neck IMRT treatment plans that were delivered to a RANDO phantom. Radiochromic bolus was added electronically to the CT scan of the RANDO phantom to approximate the conditions of the actual patient treatments. The radiochromic bolus was imaged pre- and post-irradiation using a charge coupled device (CCD) camera, illuminated using a uniform, red LED array. All radiation treatment plans were developed using Pinnacle 9.2.

Results

The ratio between surface dose and the dose measured in the radiochromic bolus increased with increasing gantry angle, ranging from 0.745 ± 0.005 at 0° to 0.890 ± 0.017 at 67.5° . The average ratio of 0.799 ± 0.009 was used as the calibration factor. The calibration factor was applied to the radiochromic bolus dose measurements of the IMRT treatments delivered to the RANDO phantom. A gamma comparison between the radiochromic bolus and film was performed, using 3%/3mm criteria and a 10% threshold. The pass rate ranged from 95.1% to 97.7%.

Conclusion

A comparison of film and FBX-PVA translucent cryogel suggests that the radiochromic bolus provides an accurate estimate of surface dose using a simple correction factor. It may be possible to improve agreement using a more complex, angle dependent correction scheme, but this may over-complicate the dose estimation process.

SP176.2 - Suitability of Diodes for Point Dose Measurements in IMRT/VMAT Beams

Author(s): <u>Tanya Kairn</u>¹, Salma Ibrahim², Emma Inness², Scott Crowe³, Jamie Trapp⁴

¹Physics, Genesis CancerCare Queensland, Auchenflower/QLD/ AUSTRALIA, ²Radiation Oncology, Princess Alexandra Hospital, Woolloongabba/QLD/AUSTRALIA, ³Radiation Oncology, Royal Brisbane and Women's Hospital, Herston/QLD/AUSTRALIA, ⁴Science And Engineering Faculty, Queensland University of Technology, Brisbane/AUSTRALIA

Recent advances in diode dosimetry analysis techniques, and resulting improvements in the accuracy of diode measurements of small field dose, have led to renewed interest in the use of diodes to measure point doses in modulated radiation fields. This study investigated one potential source of inaccuracy for diode measurements in modulated beams; the effect of diode housing asymmetry on measurement results.

Point dose measurements in modulated beams are used to augment dose plane measurements, for both system commissioning and treatment verification, and small-volume dosimeters have the potential to minimise volume averaging across dose gradients. For this reason, diodes are an attractive option for the measurement of intensity modulated radiotherapy (IMRT) and volumetric modulated arc therapy (VMAT) point doses. However, use a non-water-equivalent (silicon) active volume with a variable field size dependence, which is often embedded in epoxy resin and surrounded by highdensity shielding and electrical contacts. The longitudinal asymmetry of cylindrical diode construction is expected to lead to inaccurate or unpredictable results when the diode positioned parallel to the beam (usually horizontally) in a solid phantom, for IMRT/VMAT point dose measurements.

In this study, the possible effects of diode housing asymmetry on the measurement of steep dose gradients were evaluated by measuring beam profiles, for a 5x5 cm2 static field, with three cylindrical diodes and two commonly used ionisation chambers, with each dosimeter positioned in a 3D scanning water tank with its stem perpendicular to the beam axis (horizontal) and parallel to the direction of scanning. The resulting profiles were used to compare the penumbrae measured with the diode stem pointing into (equivalent to a "stem-first" setup) and out of the field (equivalent to a "stemlast" setup) in order to evaluate the effects of dosimeter alignment and thereby identify the effects of dosimeter asymmetry.

Small but noticeable differences between the penumbrae measured in the stem-first and stem-last directions, for all five dosimeters used in this study. The different orientations resulted in differences of up to 0.2 mm in the measured 20-80% penumbra widths and differences of up to 0.4 mm in the off-axis position of the 90% isodose. These differences, which are smaller than previously reported for older model dosimeters, were apparent in the profile results for both diodes and small-volume ionisation chambers.

As an extension to this study, the practical use of all five dosimeters was exemplified by measuring point doses in IMRT test beams. These measurements showed good agreement (within 2%) between the diodes and the small volume ionisation chamber, with all of these dosimeters being able to identify a region 3% under-dosage which was not identified by a larger volume (6 mm diameter) ionisation chamber.

This study does not attempt to resolve the issue of diode overresponse to the small beam segments delivered during modulated treatments, however the results of this work should help to remove some of the barriers to the use of diodes for modulated radiotherapy dosimetry in the future. SP176.3 - Development of a boron distribution monitor using prompt gamma-rays for boron neutron capture therapy Author(s): <u>Hiroki Tanaka</u>, Yoshinori Sakurai, Takushi Takata, Minoru Suzuki, Shinichiro Masunaga, Akira Maruhashi, Koji Ono Radiation Life Science And Radiation Medical Science, Kyoto University Research Reactor Institute, Osaka/JAPAN

At Kyoto University Research Reactor Institute, over 500 clinical studies of Boron Neutron Capture Therapy (BNCT) have been performed as of January 2015 using research reactor. On the other hand, clinical trials using accelerator-based epithermal neutron source were started on December 2012. The information of neutron and boron concentration is needed to perform BNCT. Boron concentration is measured by prompt gamma-ray analysis or an Inductively Coupled Plasma (ICP). Blood sample containing with boron is taken before the irradiation. During the irradiation, boron concentration is keeping by using the method of continuous injection of boron compound. However, the real-time information of not only neutron flux but boron concentration is needed to perform the precise dose estimation. We already developed the real-time neutron flux monitor using tiny scintillator combination with the quartz fiber. It is necessary to develop a monitor of boron distribution during the irradiation. In this presentation, we report the developed real-time boron distribution monitor using the information of prompt gamma-rays.

During the BNCT irradiation, prompt gamma-rays with the energy of 478 keV are emitted by the reaction between thermal neutron and boron-10. Boron concentration can be estimated using the measured counts of prompt gamma-rays and thermal neutron flux. We developed the system for measuring prompt gamma-rays using 8x8 Gd3Al2Ga3O12 (Ce:GAGG) scintillator array combination with multianode photomultiplier. Ce:GAGG scintillator was manufactured by FURUKAWA Corporation LTD. This scintillator has the characteristics such as higher light output, shorter decay time, better energy resolution compared with BGO scintillator that is usually used for the imaging of gamma-rays. Each scintillator with the size of 5mm x 5mm x 10mm^t is isolated with the light reflector. Scintillator array is coupled with multi-anode photomultiplier of H8500C. Each readout signal of photomultiplier is shaped and amplified by multi-channel amplifier and converted to digital signal to obtain energy spectrum of prompt gamma-rays. The gamma-ray collimator is set in front of detection head. This system is surrounded by lead and LiF to shield back ground gamma-rays and thermal neutrons, respectively. Performance test using ¹³⁷Cs gamma-ray source was performed. It was confirmed that gamma-rays of 662 keV was measured at each readout channel with the energy resolution of less than 12%. The gamma-ray image from ¹³⁷Cs source was measured by using the region of interest around 662 keV of energy spectrum for each scintillator. It was shown that this system was able to detect the image of prompt gamma-ray emitted from the reaction between thermal neutron and boron-10. In the future, this system will be applied to BNCT irradiation field to detect boron distribution.

SP176.4 - Study of potential effects of a strong magnetic field on radiation dosimeters (TLD, OSLD, EBT3 film, PRESAGE) Author(s): Zhifei Wen¹, Michelle V.P. Mathis¹, Gabriel O. Sawakuchi², David Flint², Ramesh Tailor², <u>Geoffrey S. Ibbott¹</u>, Sam Beddar¹ ¹Radiation Physics, The University of Texas MD Anderson Cancer Center, Houston/UNITED STATES OF AMERICA, ²Radiation Physics, MD Anderson Cancer Center, Houston/UNITED STATES OF AMERICA

Introduction: Accurate dosimetry in the presence of a strong magnetic field (B) is essential to the use of a magnetic resonance image-guided linear acclerator (MRI-linac) system. In particular, it is important to characterize the response of dosimeters in a B field to determine which types of dosimeters may be used for beam quality assurance and in-vivo dosimetry in a MRI-linac system. In

this study, four types of radiation dosimeters were investigated, including thermoluminescent dosimeters (TLDs), optically stimulated luminescence detectors (OSLDs), EBT3 radiochromic films, and PRESAGE® dosimeters.

Method: All four types of dosimeters were separated into two categories which were either exposed or not exposed (control) to a strong B field. In each category a group of dosimeters was irradiated with a dose of 0, 2, 4, or 6 Gy. In the first part of the experiment, dosimeters were exposed to a B field inside a small animal MR scanner in a B field slightly greater than 2.5 T for at least 1 hour pre-irradiation and at least 1 hour post-irradiation. Results were compared with irradiated control groups without exposure to a B field. In the second part of the study, dosimeters were irradiated inside an MR-linac prototype where the B field was 1.5 T, and the control groups were irradiated with a conventional Linac without a B field.

Results: For dosimeters exposed to a B field before and after irradiation, small difference (<2%) was observed in comparison to the control groups for all four types of dosimeters. For dosimeters with simultaneous exposure to a B field and radiation, OSLDs had the best agreement with the control groups (~1%). For TLDs and films, the agreement was about 5%, which was within experiment uncertainty (~6%). However, larger disagreement in PRESAGE dosimeters was observed (10-12%).

Conclusion: Exposure to a strong B field before and after irradiation does not appear to change the dosimetric properties of TLDs, OSLDs, EBT3 films or PRESAGE dosimeters. With simultaneous exposure to both the B field and radiation, TLDs, OSLDs, and films seem not significantly affected by the B field within the experimental uncertainty (6%). The cause of disagreement in PRESAGE dosimeter data has not been fully determined. Further study is ongoing to test reproducibility and reduce experiment uncertainty.

SP177 - Radiation Shielding - Design and Outcomes

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP177.1 - Simple expression of x-ray doses below 1 MeV grazing incident on shields of concrete and iron backed by lead Author(s): <u>Nobuteru Nariyama</u>

Light Source And Optics Division, Japan Synchrotron Radiation Research Institute, Hyogo/JAPAN

For an x-ray beam, metal pipes are sometimes used to transport the beam, in which the scattering x-rays are grazing incident on the inner surface of the pipe. Moreover, for targets in medical accelerator facilities, a thick shield is necessary near the target; however, far from the source, a thinner shield is sufficient. For such a tapered shield, the x-rays can be incident on the thin part at a small angle. With increasing incident angle, the contribution of almost vertically scattered x-rays will be dominant owing to the shortest travelling path in the shield, as shown in Fig. 1. In this study, the doses for broad x-rays grazing incident on slabs of concrete and iron backed by lead were calculated using Monte Carlo codes. The results showed that the dose transmission in concrete can be expressed as $D = D0 e - \mu' t$ at $\cos \theta = 0.01$ and 0.1 between 0.2 and 1 MeV as shown in Fig. 2; D0 is the assumed source strength at the scattering point, and t is the shield thickness. The parameter μ ' was found to be almost equal to the attenuation coefficient for the nearly vertically scattered x-rays. The values of D0 were dependent on θ . For iron backed by lead between 0.08 and 1 MeV when θ was 88°, the attenuation slope gradually changed and converged to the rate corresponding to the energies of the nearly vertically scattered x-rays in lead. The same experiment was also performed for a stainless steel pipe wrapped with lead slabs of 0-2 mm thickness and white narrow x-rays with a peak energy of 0.09 MeV incident at 85°. The results reproduced the doses predicted by the Monte Carlo calculations.

SP177.2 - Evaluation of conversion coefficients from Air Kerma to Ambient Dose Equivalent for secondary barriers in diagnostic radiological facilities

Author(s): Paulo R. Costa1, Alejandro H..L. Gonzales2

¹Nuclear Physics, Radiation Dosimetry and Medical Physics Group, Physics Institute, São Paulo/BRAZIL, ²Radiation Dosimetry and Medical Physics Group, Physics Institute, University of São Paulo, São Paulo, Brazil, São Paulo/BRAZIL

Introduction: The ambient dose equivalent operational quantity is used in many countries for planning purposes of the physical barriers in a radiographic installation. Therefore, it is important to use a conversion coefficient, which turns this dosimetric quantity into a recommended operational quantity [1]. Brazilian regulation establishes that a conversion coefficient (1.14 Sv/Gy) must be used in area monitoring.

Methods: An experimental method was developed for measurement of secondary spectra using a spectroscopic system with CdTe detector [2] and an 1800 cm³ ionization chamber. The thoracic region of an anthropomorphic phantom, RANDO[®] Man, was used as a scatter region. The voltages used began 40 kV up to 150 kV in displacements of 10 kV, the scattering angles were 30°, 60°, 90° 120° and 150° with respect to the axis of the primary beam. The mean conversion coefficients are calculated using the equation [3]:

$$\overline{C}_{k} = \frac{\int_{0}^{E_{max}} C_{k}(E) \cdot \Phi(E) \cdot E \cdot \left(\frac{\mu_{en}(E)}{\rho}\right)_{ar} \cdot \exp(-\mu(E) \cdot x) \cdot dE}{\int_{0}^{E_{max}} \Phi(E) \cdot E \cdot \left(\frac{\mu_{en}(E)}{\rho}\right)_{ar} \cdot \exp(-\mu(E) \cdot x) \cdot dE}$$

Results and Discussion: The Figure 1 shows the mean conversion coefficient as a function of the mean energy of the spectra for secondary beams scattered in angles of 30° , 60° , 90° , 120° and 150° degrees. The blue line corresponds to the constant value of 1.14 Sv/Gy.

Conclusions: In a typical example of radiometric survey, the estimated ambient dose equivalent using the conversion coefficient calculated from the evaluated spectra, is 40% higher compared to the value obtained using the coefficient recommended in Brazil.

Acknowledgments: The authors thank FAPESP for financial sup-

port under project 2010/12237-7 and CNPq/FAPESP INCT Rad Metrology in Medicine.

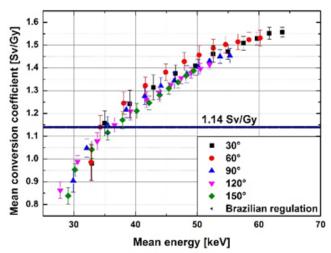

Figure 1 - Mean conversion coefficient as a function of the mean energy of the spectra for secondary beams scattered in angles of 30°, 60°, 90°, 120° and 150° degrees. The blue line corresponds to the constant value of 1.14 Sv/Gy

SP177.3 - Shielding photon beams to account for adjacent, underground building of a radiation therapy facility Author(s): Dario E. Sanz

Radiation Therapy, Fundación Escuela de Medicina Nuclear, Mendoza/ARGENTINA

Introduction

Adjacent buildings may impose not obvious conditions to shield the floor of radiotherapy treatment rooms. Even when a full occupation is considered in lateral places, potential underground, adjacent sites can be of concern due to oblique transmission through the floor.

Method

We consider a barrier wall (primary or secondary), buried underground to a certain depth *H*, without a concrete slab floor (figure 1). With the same use and occupation factors of the points P1 and any P2, the line *p* will be sufficiently protected when the broad beam transmission factor corresponding to the path length between the source and P2 is less or equal to that of *T*, which in turn accounts for any possible position of the source. The variation of the distance from the source to the points on *p* is neglected, a fact that makes

the model analytically tractable and conservative.

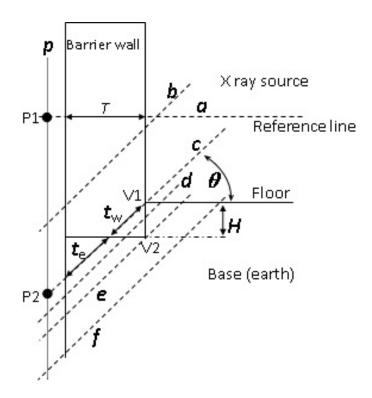

Figure 1: Shielding barrier of material w and thickness *T*. The lines *a*, *b*, *c*, *d*, *e* and *f* represent different ray trajectories. *t*w and *t*e represents the wall and earth thickness traversed by the line *c*.

Let define the scaling factor from the first tenth value layers: fw,e = TVLw /TVLe.

If $fw,e \ge 1/2$ (standard density wall) then the transmission factor corresponding to the line *c* passing through vertex V1 is greater than those of other parallel lines. The same holds for the line *e* if fw,e<1/2 (high density wall). Interestingly, a compact expression was obtained:

 $Hmax/T = \sin^3\theta max/(1 - \cos^3\theta max)$ for $fw, e \ge 1/2$ and

 $Hmax/T=sin^3\theta max/cos^3\theta max$ for fw, e< 1/2,

where $\cos^3\theta$ max=*fw,e* and *H*max is the maximum wall depth necessary to shield the line *p* for any ray trajectory and the given beam energy.

Results

For earth and ordinary concrete (1.5 and 2.35 g/cm³) we have *fw*,*e* = 0.638, θ max= 30.6° and *H*max/*T*=0.364 for any beam energy and type of barrier. In case of high density walls, deeper wall penetration is needed.

Conclusions

The critical angles θ max are compatible with typical source positions. The effect of distance has little effect on the accuracy, i.e. it is of the order of cos² θ max.

Unless there is a basement under the floor, a full concrete slab is not necessary to shield nearby underground areas. Similar, compact expressions were obtained when bending the wall inwards a certain horizontal length to shield the floor in laminated, primary barriers. In these cases, the approach can also be extended to account for groundshine radiation in a nearby floor.

SP177.4 - Vectorization of the time-dependent Boltzmann transport equation for photon beams: applications in radiation shielding

Author(s): Agustin C. Cobos¹, Ana L. Poma², Guillermo D. Alvarez³, <u>Dario E. Sanz³</u>

¹CONICET, Mendoza/ARGENTINA, ²FAMAF, Cordoba/ARGEN-TINA, ³Radiation Therapy, Fundación Escuela de Medicina Nuclear, Mendoza/ARGENTINA

Purpose

We introduce a method to evaluate the steady state solution of the angular photon flux after numerical evolution with the timedependent Boltzman transport equation (TE). The Penelope Monte Carlo (MC) method was used to test the convergence and accuracy for different time, energy, direction and spatial mesh sizes. Benchmarking was performed by calculation of radiation transmission in primary barriers of radiotherapy treatment rooms for different wall materials, beam energies and angles of incidence. Laminated barriers where simulated to assess the effect that different positions of a lead layer within a concrete slab has on the overall transmission factor and beam energy spectra.

Formalism

We applied our model on a semi-infinite slab, yet preserving the main phase space data details. The TE was converted into a system of ordinary differential equations by integration over a number of spatial mesh intervals, keeping only the temporal derivative. A weighted diamond difference scheme was used to ensure positive solutions. Flux vectorization in angle and energy was carried out using discrete ordinates and the multi-group approach, respectively. The system was expressed as $d\Phi(t) / cdt = A\Phi(t) + b$, where Φ is the vectorized flux, *c* is the speed of the particles, **A** is a time independent, square matrix that contains physical and numerical parameters like cross sections and spatial mesh sizes. The vector b accounts for the boundary conditions.

We found that under proper numerical conditions the matrix **A** is strictly diagonally dominant by columns. As such, it is non singular and the steady state can be calculated from $\Phi(t=\infty) = -\mathbf{A}^{-1}\mathbf{b}$. Also, all the elements of b are non negative and the matrix $-\mathbf{A}$ is a non singular, M matrix. As such, all the elements of its inverse are non negative. Thus, the former product always yields positive values.

Jacobi and Gauss Seidel methods can be used by discretization of the time variable in intervals Δt . For a spatial mesh size Δz , the former properties of **A** and numerical convergence are attained if $\Delta z^{-1} + \sum T < (c\Delta t)^{-1}$, where $\sum T$ is the maximum total, macroscopic cross section for the given mesh size and energy spectrum under consideration.

Results and conclusions

Numerical simulations agreed well with MC simulations and published data of transmission factors for different barriers and incident beam angles were accurately predicted. Interestingly, it was found that the position of a lead layer within a concrete slab significantly affects the overall transmission factor of the laminated barrier when irradiated with Co^{60} beams. We note that beam softening in the concrete part improves the lead absorption capability when placed in the distal part of the shield. This could be relevant when lead is used to increase the shielding of a Co^{60} high dose rate brachytherapy room.

Spatial integration and matricial theoretical treatment of the transport equation allowed for the numerical conditions for convergence, positivity and speed of the approach, without the need of explicit construction of the matrix **A**.

Despite the algorithm was tested for a 1D geometry, the concept could be extended to 2D and 3D situations.

SP177.5 - The use of FLUKA Monte Code in the re-design of radiotherapy mazes with the use of lead cladding of a few mm thickness

Author(s): <u>Ihsan A.M. Al-Affan</u>¹, Richard P. Hugtenburg¹, Simon Evans²

¹College Of Medicine, Swansea University, Swansea/UNITED KING-DOM, ²Department Of Medical Physics And Clinical Engineering, Singleton Hospital, S/UNITED KINGDOM

Abstract

A novel proposal of covering part or the whole of the maze concrete walls with a few mm of lead will be presented. The findings have direct implications for new designs of mazes for radiotherapy rooms and can help with upgrades, especially when space is limited [1]. Covering part or all of the maze walls with lead was studied in situations where extending the maze length or changing its shape would be not possible because of space restriction.

FLUKA

Monte Carlo simulations were used to examine the reduction of the dose from scattered photons at the maze entrance of radiotherapy room facilities. A pilot study at Singleton Hospital in Swansea, UK, has pioneered the use of lead sheets of various thicknesses to absorb scattered low energy photons in the maze of radiotherapy room. The Figure shows the new shape of the maze incorporating this feature. The FLUKA computations have shown that there was a noticeable reduction in the dose when lead sheet of a 2 mm thickness was added to certain walls and floor in the maze (Table). One explanation for this finding is that the reduction was due to the strong effect of the photoelectric interaction of the lead, in effect trapping the back scattered photons. The results showed that adding 1 to 4 mm lead to walls and floor of the maze reduced the dose at the maze entrance by up to 90%. However, certain walls contributed more

than others for the dose reduction. The floor was found to contribute about 8% in the dose reduction when it was covered with 2 mm lead. Other scenarios were simulated where the reduction was most cost effective. By comparing the dose reduction from the FLUKA calculations with measurements it is concluded that FLUKA Monte Carlo Code was found a very useful tool for maze design, supporting

modifications that offer better access for patient and machine maintenance without sacrificing radiation protection.

¹Rehabilitation Engineering Lab, Toronto Rehabilitation Institute, University Health Network, Toronto/ON/CANADA, ²Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA, ³Division Of Fundamental Neurobiology, Toronto Western Hospital Research Institute, Toronto/CANADA

A fundamental challenge in understanding mechanisms behind functional and pathologic states of the brain is to describe the functional and effective connectivity within the brain. This knowledge is a key step towards developing neuromodulatory strategies to control cortical circuits in the treatment or prevention of neurological disorders. In humans large scale functional networks obtained from electroencephalography, intracranial EEG, or functional magnetic resonance imaging cannot describe cortical processing at the microcircuit level, the result being that to date this aspect of human neocortex remains largely unexplored. A high throughput approach is required to elucidate connectivity principles between different neuron phenotypes in the human brain and link cellular activities to physiological signatures such as cortical rhythms and how these rhythms modulate cognition and behavior.

We have recently described that human cortical tissue, which is maintained in vitro, can be induced to generate coordinated population activity (oscillations) similar to those observed in vivo. Both narrow and broad band power increases were observed with narrowband activity being dominated by theta oscillations and which modulated high gamma (broadband) activity. Theta oscillations were coherent between cortical laminae with deep layer theta leading superficial layer activity. By further exploring the cellular basis of these findings, we have described laminar specific cellular specializations: deep layer putative pyramidal neurons have features that promote theta generation in deep layers (h-current, higher input resistance).

To extend these results, and investigate large scale cellular activities in the human cortex, we have performed in vitro multi-electrode array recording. Data were obtained from 500 µm thick temporal neocortical slices (tangential to pia) using a submerged 64-channel multi electrode array (MEA) system USB-MEA60 (Multi Channel 151 Systems, Germany) on a TiN array with inter electrode spacing of 200 µm. The data was acquired at 25 KHz and then split into local field potential (LFP; 1-300 Hz) and multiunit activity (MUA; 300-3000 Hz) using band pass filters. Individual spikes were detected in the MUA time series using a negative threshold defined to be 4 times the average background noise level. Slices were ultimately processed histologically to localize the electrodes and confirm the units' depth in the cortical laminae. Unit activity was characterized during a 10 minutes baseline period, during bath application of 50 nM kainate (10-15 min), and then addition of 50 µM of carbachol condition during which we have observed theta oscillations.

This protocol induced theta oscillations and gamma activity observed as increases in spectral power in LFP signals. Preliminary analyses on MUA signals revealed that we can sort units into narrow-spiking and broad spiking units, and these units display distinct patterns in their inter-spike intervals, which appears to be layer specific. Overall our results suggest that there are laminar specific specializations at the cellular level that may underlie the coherent theta oscillations observed between superficial and deep laminae.

SP178.2 - Astrocytes enhance neuronal long term potentiation in a biophysical model of epilepsy

Author(s): <u>Vasily Grigorovsky</u>, Berj L. Bardakjian Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/ON/CANADA

While originally astrocytes have been thought to only act as support to neurons, recent studies have implicated them in multiple active roles. In particular they have been shown to be able to moderate and alter neuronal firing patterns both in normal and epileptic conditions. Astrocytes can perform this using several mechanisms, including potassium clearance from the extracellular space as well as through the formation of tripartite synapse with both pre- and post-synaptic terminals. It has been shown that astrocytes exhibit impaired potassium clearance in epileptic models, which leads to hyperexcitable conditions in the network. Additionally, astrocytes react to glutamate release into the synaptic cleft triggering a signalling pathway that culminates in the increase of intracellular calcium concentration in postsynaptic neurons. In addition to being involved in the hyperexcitability of epileptic networks, intracellular calcium increase is also key in long term potentiation (LTP) of neuronal connections which is mediated both through NMDA-receptor channels and via the formation of new AMPA channels. Coincidentally, ripple high frequency oscillations (HFO; ~100 Hz) which have been experimentally shown to invoke LTP under normal conditions, have also been suggested as one of the potential biomarkers for epilepsy in patients. Despite these findings and general interest in the deeper insight into the biophysiological mechanisms behind epileptic seizures, computational modelling efforts have been focused more on complex neural networks without the significant inclusion of astrocytes.

Methods

In this study we introduce a computational model of CA3 region of hippocampus, consisting of a network of an astrocyte and a pyramidal cell with a feedback inhibitory interneuron. We use it to investigate the effects of astrocytic ion homeostasis moderation and calcium dynamics on long term potentiation as one of the factors in the onset and cessation of seizure like events. In addition to phenomenological feature assessment, frequency analysis is used to determine frequency dynamics during long term potentiation and depression.

Results

Preliminary results of the model show that astrocytes respond to seizure-like conditions with (a) increased calcium release, (b) reduced rates of potassium clearance mechanisms, and (c) enhancement of long term potentiation of pyramidal cell-interneuron connection following 100 Hz stimulation of the pyramidal cell.

SP178.3 - Influence of the 'sympathetic slump' on biomechanics of the sympathetic trunk

Author(s): Liesbeth Van Hauwermeiren, Laura Bekaert, Tom Van Hoof

Basic Medical Sciences, Ghent University, Ghent/BELGIUM

Introduction

Several sources show a correlation between altered peripheral nerve biomechanics and disturbed nerve function. Some clinical studies suggest that mechanical strain on the sympathetic trunk (ST), a small autonomous nerve bundle in front of the spine, could play a role in chronical disorders like sympathetically maintained pain. A clinical test, the 'sympathetic slump', consisting of full spinal flexion combined with contralateral lateral flexion and rotation in a long sitting position, was proposed to maximally lengthen the ST and thus evoke symptoms. However, biomechanical data is lacking. Investigation of the ST is challenging both through dissection and medical imaging due to its position, size and numerous side branches.

Therefore, the aim of this study is to a develop technique to visualize and quantify ST motion in the sympathetic slump position.

Methods

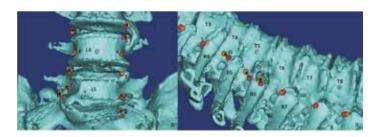

The ST's of a cadaver specimen were dissected from an anterolateral angle, until there was sufficient visualization for bilateral insertion of 30 metal markers without detaching the ST from its environment. CT scans were performed in supine position, neutral long sitting position, and sympathetic slump position to the left and right. A second supine CT scan was used to assess possible marker migration. Markers and vertebrae were segmented and 3D-rendered. Displacement of markers from the neutral to each experimental position were calculated and adjusted for vertebral movement using custom Matlab code. Furthermore, inter marker distances between adjacent markers (along a mathematical spline curve drawn between the markers to approximate the course of the ST) were calculated for each position to measure ST changes in length. Only marker movements larger than the combined errors of segmentation, registration and marker migration were taken into account (4.22mm for long sitting position, 4.51mm for slump positions and 2.18mm for inter marker distances).

Results

Overall, marker movement and inter marker movement were consistent. Only the lower lumbar markers showed significant cranial movement in both sympathetic slump positions (fig1.A), and significant movement was noted around two osteophytes during contralateral sympathetic slump (fig1.B). The traditional slump showed no significant movement of the ST.

Conclusion

Despite the limitations in motion quantification (strain could not be calculated since only markers and not the entire nerve structure was visualized), the results of this study suggest that the sympathetic slump inflicts most ST movement in the lower lumbar region and around structural pathological changes like osteophytes. Larger datasets could confirm these findings and further increase insight into ST biomechanics.

SP178.4 - Superparamagnetic Nanoparticles for Epilepsy Detection

Author(s): Maysam Pedram¹, Amir Shamloo², Aria Alasti², <u>Ebrahim</u> <u>Ghafar-Zadeh¹</u>

¹Dept. Of Electrical Engineering And Computer Science, York University, Toronto/ON/CANADA, ²Sharif University of Technology, Tehran/IRAN

Epilepsy is the most common neurological disorder that is known with uncontrolled seizure. Around 30% of patients with epilepsy

resist to all forms of medical treatments and therefore, the removal of epileptic tissue is the only solution to get these patients free from chronical seizures. The precise detection of an epileptic zone is the key to its treatment. In this paper, we propose a method of epilepsy detection using brain magnetic field. The application of superparamagnetic nanoparticles (SPMNs) as nanoprobes for the detection of the epileptic area inside the brain is investigated in this new reaserch approach. The aggregation of nanoparticles in the weak magnetic field of epileptic brain is modeled using potential energy minimization technique. The results prove the aggragation of nanoparticles influenced by weak magnetic field in the range of pT.

SP178.5 - Automatic detection of epileptic seizures in scalp EEG

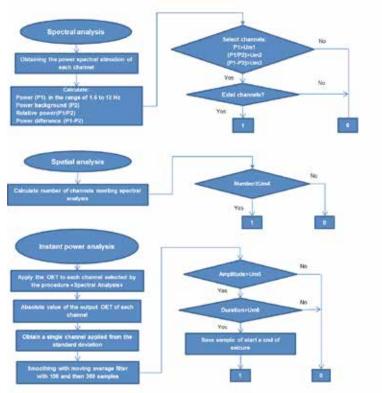

Author(s): Yasser Pérez

Bioengineering, Polytechnic José Antonio Echeverría, Havana/ CUBA

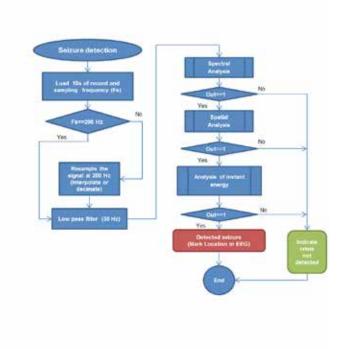

The study and clinical diagnosis of epilepsy is performed by a specialist with years of experience through simple visual inspection of the EEG record with the aim of identifying areas where seizures that characterize this condition occur. However, given the variability of the morphology of epileptic seizures and their similarity to other events as various artifacts, alpha spindles and paroxysmal activity detection work is hindered greatly. In addition, long-term records, due to the volume of information, the time used specialist study is considerable. For this reason the automatic detection of epileptic seizures has become a vital tool for the specialist.

This research proposed design and development of an algorithm for automatic detection of epileptic seizures by using simple statistics measurements, the Teager Energy Operator and power spectral analysis techniques for features extraction from a data set of reference seizure events. The database used for this project belongs to Cuba Neuroscience Center (CNEURO) it contains non-invasive EEG recordings of 20 patients of both sexes, aged between 4 and 37 years, of which 15 had may generalized seizures and 5 partial seizures, further data were recorded in the various states of wakefulness and sleep. EEG signals were acquired using the equipment MEDICID 5 at a sampling frequency of 200 Hz and an A / D converter of 16 bits. For the record signal an array of 19 electrodes with international Positioning System 10-20 and referential mount was used. The implementation of the algorithm was performed in the MATLAB tool, and then scored as a result of quantitative evaluation of the sensitivity of 94.5% and a selectivity of 87.6%.

The results of the quantitative evaluation of the algorithm show that could be used as a tool to support the specialized medical staff.

Seizure Detection Algorithm

SP178.6 - Beta/Theta Neurofeedback Training Effects in Physical Balance of Healthy People

Author(s): <u>Wenya Nan</u>¹, Xiaoting Qu¹, Limin Yang¹, Feng Wan¹, Yong Hu², Pedro Mou¹, Pui-In Mak¹, Peng Un Mak¹, Mang I Vai¹, Agostinho Rosa³

¹University of Macau, Macau/CHINA, ²University of Hong Kong, Hong Kong/CHINA, ³University of Lisbon, Lisbon/PORTUGAL

This study aimed to investigate beta/theta ratio (BTR) neurofeedback training (NFT) effects in physical balance of healthy individuals. Thirty-one healthy volunteers were randomly assigned to NFT group (n=15) and non-NFT control group (n=16). The NFT group completed 25 sessions in consecutive five days with five sessions per day. Before and after NFT, physical balance was measured by Wii Balance Board (WBB). The non-NFT control group only performed the physical balance test on the first day and the fifth day without any training. The results showed no significant improvement in physical balance in the NFT group compared to the non-NFT control group. The reason of the failure will be further studied in our future work.

SP178.7 - Potential Benefits in Comparing the Neural Control Networks Studies Between the Oculomotor and Cardiac Pacing Systems

Author(s): Alireza Ghahari¹, Michael Cheng²

¹University of Connecticut, Mansfield/CT/UNITED STATES OF AMERICA, ²Biomedical Engineer, ottawa/ON/CANADA

Clinical evidence has reported cases of acquired ocular motor apraxia after aortic surgery [1]. This paper draws attentions to potential insights gained by comparing neural control network studies between the oculomotor and cardiac pacing systems.

Both authors independently did original research on the oculomotor system, but no experience in the cardiac pacing system. In view of the rapidly increasing health problems of cardiac arrhythmia particularly among aging populations, we report our findings in the oculomotor system and suggest implications for the cardiac pacing system. It is not unusual for the biological systems to share common mechanisms for their operations.

In 1974, Cheng, Outerbridge performed inter-saccadic interval analysis of nystagmus eye movements of vestibular and optokinetic [2] origins. Optokinetic nystagmus from healthy human subjects were recorded at different intensity levels elicited by different speeds of the optokinetic stimulus. The time intervals between the onset of consecutive saccadic components, which appear random, were analyzed statistically. Resulting interval histograms showed multimodal form in which the higher order modes were approximately integral multiples of the basic mode. Now, the inter heart beat intervals (RR intervals) during cardiac arrhythmia appears also to be random, and if the histograms of the RR intervals also exhibit multi-modal behavior, it would imply that during heart-beat pauses in some "sick sinus syndrome", there is high probability that ensuing pauses between hear beats could suddenly take on twice or three times as long, thus greatly raising the risks of syncopal episodes.

Recently, Ghahari, Enderle used advanced computational modeling to demonstrate an integrative systems approach to address the challenges involved in the implementation of the saccade dynamics from the local neural circuit computations in the midbrain [3]. A biophysically-realistic neural network model was developed to examine the saccade dynamics. To explore the synaptic network function and characteristics in post-saccade oscillations, computational neural modeling of the glissades was investigated as a deficiency in the oculomotor control mechanism. In conclusion, comparison of the glissades with normal saccades confirmed that glissades were observed because of anomalies in saccade neuronal programming. They theorized that such deficits are due to unplanned post-inhibitory rebound burst firing in the antagonist motoneurons, as a coordination error in returning to tonic firing rates.

The brainstem has neural sites in the medulla oblongata responsible for controlling heart rates. Potential research are: First, explore more evidence to answer a vital question: "could glissades in eye movement be compared with the sick sinus syndrome of cardiac arrhythmia?" Second, search details on neuroconnectivity structure and underlying neural control processes important for driving the cardiac sinus pacemaker. The answers are hoped to have farreaching proportions in benefiting patients dealing with arrhythmia disturbances.

SP179 - Brain, Head/Neck, Spine: Part 2

TRACK 12: MEDICAL DEVICES

SP179.1 - Acceptance Test of the first Hospital Cyclotron for Production of PET tracers in Iran

Author(s): <u>Pardis Ghafarian</u>¹, Seyedeh Masoumeh Khamesi¹, Mohammadrasa Golrokh Nodehi¹, Mohammad Reza Ay² ¹Chronic Respiratory Diseases Research Center, National Research Institute Of Tuberculosis And Lung Diseases (nritld), Shahid Beheshti University of Medical Sciences, tehran/IRAN, ²Research Center For Molecular And Cellular Imaging, Tehran University of Medical Sciences, Tehran/IRAN

Introduction: The first fixed-energy hospital isochronous cyclotron (GE PETtrace 700) installed in Masih Daneshvari hospital can accelerate the negative hydrogen ions (H⁻) up to 9.6 MeV energy. This cyclotron equipped with six targets for production of the most common radioisotopes used for PET/CT scanners. It is well known that the acceptance tests should be done by physicist when a cyclotron installed in order to measure the performance claimed by manufacturer. This study reports the results of acceptance tests in our GE PETtrace 700 after installation for all targets.

Material and methods. Production of ¹⁸F⁻ is done using the fluorine-18 silver body target with 1.7 ml volume by bombardment of enriched ¹⁸O-water in 120 minutes irradiation time and using 50 μ A target current and high-pressurized helium. Whereas by bombardment of ¹⁶O-water with 35 μ A target current, the ¹³N-NH3 is produced after 25 minutes. The ¹³N-NH3 target consists of a silver container with 0.8 ml volume which over pressure methane is used to the target for direct production of ¹³N-NH3. Production of ¹¹C-¹¹CO2 is performed by the gaseous target with aluminum target body and volume of 23 ml. The¹¹C-¹¹CO2 is produced by the bombardment of Nitrogen-14 using 30 μ A target current in 30 minutes. After bombardment the activities were transferred to the dispenser unit and measured by dose calibrator separately (ATOMLAB 500).

Results: The yield performance of 2858.32, 138.15 and 1047.5 mCi has been observed for ¹⁸F⁻,¹³N-¹³NH3 and ¹¹C-¹¹CO2 after 120, 25 and 30 minutes irradiation time with target current 50, 35 and 30 μ A respectively. It is clear that product yield that measured in factory were 2500, 75 and 900 mCi, respectively using the mentioned standard situation.

Conclusion: during our acceptance test, the measured yield for all tracers was higher than the value reported by manufacturer

SP179.2 - HiFEM - An Integrated Approach for Human Centered Risk Management for Medical Devices

Author(s): Armin Janss¹, Klaus Radermacher²

¹Chair Of Medical Engineering, RWTH Aachen University, Aachen/ GERMANY, ²Chair Of Medical Engineering, RWTH Aachen, Aachen/ GERMANY

The implementation of appropriate processes for risk management and usability engineering are mandatory for the approval and application of medical devices (s. ISO 14971:2006 & IEC 62366:2007). As the complexity and speed of development of medical devices is increasing together with the incidents of human error in medicine [1-3], more sophisticated tools for interlinking usability engineering and risk management, i.e. human error risk analysis and human risk control respectively seem to be mandatory. The HIFEM methodology and the corresponding software tool mAIXuse developed in our lab, supports medical device manufacturers and developers by a model based human risk analysis approach. Based on a two-folded approach, HiFEM provides a task-type-sensitive modelling structure with integrated temporal relations based on [4] combined with a subsequent analysis of critical resources allocation and related potential errors adopted from and related error taxonomies. The approach can be used in an early developmental stage as well as for product validation. In a comparative study the HiFEM method outperformed a classical process-FMEA related the detection of critical errors of a surgical planning and navigation systems. These positive results have been confirmed in further applications. Moreover, we implemented a new method for systematic human risk control (mAIXcontrol) as part of the HiFEM methodology. Accessing information from the method's knowledge base enables the operator to detect the most suitable countermeasures for a respective risk. 41 approved generic countermeasure principles have been indexed as a resulting combination of root causes and failures in a matrix. The methodology has been tested in comparison to a conventional approach as well. Evaluation of the matrix and the reassessment of the risk priority numbers by a blind expert demonstrate a substantial benefit of the new mAIXcontrol method vs. classical methods. Concerning the number of appropriate counter measures for risk control, the mAIXcontrol method shows predominance compared to classical brainstorming approach, although the required time for application of the method is slightly higher than for brainstorming. Evaluation showed, that the use of the method requires a certain learning curve. The test subjects needed a learning time of more or less 15 minutes before a working routine had been adopted. This presumes a learning effect that increases time efficiency for experienced users.

SP179.3 - Ultrasonic Microscanning for Digital Dental Impressioning

Author(s): Thorsten Vollborn¹, Daniel Habor¹, Fabrice Chuembou Pekam¹, Juliana Marotti², Joachim Tinschert², Stefan Wolfart², Stefan Heger¹, <u>Klaus Radermacher¹</u>

¹Chair Of Medical Engineering, RWTH Aachen, Aachen/GERMA-NY, ²Department Of Prosthodontics And Biomaterials, University Hospital Aachen, Aachen/GERMANY

Introduction

Silicone based impression-taking of prepared teeth is well-established but potentially less reliable, error-prone and inefficient for computer aided design and manufacturing (CAD/CAM) of dental prosthetics. Intraoral optical scanners have been introduced to increase efficiency of CAM but no breakthrough occurred so far. An accurate impression of the tooth preparation is highly important for the final fit of the prosthesis. Therefore, retraction cords or electrosurgery are commonly used to invasively uncover subgingival margins prior to the impression. These methods may lead to inflammation or permanent damage of the gum. In addition, bleeding from inflamed gingiva, saliva, air bubbles or other particles can decrease the accuracy outcome of both the conventional and optical impression. Digitizing a gingiva-covered margin is an infeasible task due to the fact that optical waves can hardly penetrate gingival tissue.

Concept

High frequency ultrasound (HFUS) has been recently introduced as an alternative to optical scanning [1]. HFUS is less sensitive against oral fluids and in principal able to penetrate gingiva non-invasively. Although HFUS-systems have been introduced in other medical fields, none of them suits the challenging requirements and high accuracy demands for dental impressioning. Hence, our goals are to develop a new ultrasonic technology, which is able to scan supraand subgingival dental hard- as well as soft-tissue structures and to integrate it into the CAD/CAM-process for dental restorations. Whereas in case of optical digitization the dentist usually has to wait until bleeding and swelling subside, an HFUS-based impression can be performed within the same session.

Results

We conceived a miniaturized device based on HFUS-technology and a coupling adapter for impedance matching during intraoral application [1]. Therefore, we have integrated a HFUS transducer (>50 MHz) into an intraoral scanner in order to achieve the necessary spatial resolution for impressioning. A multi-axis kinematic has been developed and successfully tested for accurate positioning of the HFUS-probe. In-vitro surveys using comparable transducers have already proved the applicability of the concept [2]. In a recent study Marotti et al. show a potentially good fitting accuracy of metallic copings for single tooth crowns planned with HFUS-Scans [3].

Discussion and Conclusion

Ultrasound-based impressions have been able to compete with optical systems concerning the accuracy and the final fit. Subsequent to the completion of the technical development the evaluation of the presented system in clinical surveys remains.

SP179.4 - A study on prefrontal blood flow in patients with moderate dementia and severe dementia using near -infra-redinfrared

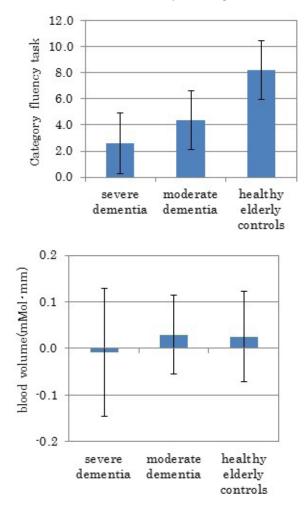

Author(s): <u>Shingo Takahashi</u>¹, Naoki Kodama² ¹Department Of Healthcare Informatics, Takasaki University of health and welfare, takasaki/JAPAN, ²Department Of Healthcare Informatics, Takasaki University of Health and Welfare, Takasaki/ JAPAN

Recently, near-infrared spectroscopy (NIRS) is one of the most im-

portant measurement tools of brain function. In this study we have used a NIRS to examine the prefrontal blood volume of the brain by performing a category fluency task function test to determine with severe dementia and moderate dementia, health elderly controls if this method can be used to determination for severity of dementia. Recently, NIRS is one of the most important measurement tools of brain function. In this study we have used a NIRS to examine the prefrontal blood volume of the brain by performing a category fluency task function test to determine with severe dementia and moderate dementia, health elderly controls if this method can be used to determination for severity of dementia.

We examined 30 patients with severe dementia (age 83.7 ± 6.6 , 7 male, 23 female,MMSE:1-14) and 20 moderate dementia (age 82.7 ± 7.1 , 5 male, 15 female,MMSE:15-23), 16 health elderly controls (age 80.5 ± 4.6 , 2 males, 14 females, MMSE:24-30). Activation with the subtasks starts at 0, 15 and 45 second in the category fluency task, 45 and 75 second subtasks again.

The average number of category fuluency task is shown in Fig.1. Severe dementia patients achieved an average score of 2.7 ± 2.3 in the category fluency task. On the other hand, moderate dementia achieved score of 4.4 ± 2.3 , health elderly controls score were 8.2 ± 2.2 . Figure.2 shows increase volume of prefrontal blood in Fp1. Our results have shown that health elderly controls show an increase in the blood volume during the category fluency task while those with severe dementia patients did not show any relevant increase of blood volume while performing the same task.

The results obtained suggest that category fluency tasks and nearinfrared spectroscopy may be useful to determination for severity of dementia.

SP180 - Information Technologies in Healthcare Delivery and Management: Part 4

TRACK 14: INFORMATION TECHNOLOGIES IN HEALTHCARE DELIVERY AND MANAGEMENT

SP180.1 - Increasing efficiency of data transfer in WBANs Author(s): Luka Celic, Ratko Magjarevic

Department Of Electronic Systems And Information Processing, University of Zagreb Faculty of Electrical Engineering and Computing, Zagreb/CROATIA

Due to aging of the society and subsequent increase of incidence of chronic diseases, use of wireless technologies in patients monitoring had large growth in latest years. After initial relatively simple point to point telemetry applications, today there is a large number of wireless devices for patients' physiological data monitoring, mobility tracking and exercising evaluation etc. These new applications are due to development of low power and inexpensive wireless communication technologies and they are mainly realized as a wireless body area network (WBAN). In health care today there is a need for more complex patient monitoring with trend predictions which cause increasing quantities of data for their transfer from the patient, but also increase current consumption drawn from the battery. It is crucial to obtain high efficiency of all segments in WBAN communication, so the device can maintain reduced battery size and keep continuance. For user acceptance, it is crucial to make the wireless sensor nodes of the WBAN sensor node inconspicuous, enabling that they do not interfere with measurements. In this paper we present a solution for direct database access from microcontrollers in WBANs, which is power and code efficient. It provides standard powerful way of using microcontroller based WBANs with classic SQL database. This reduce development time and lower power consumption.

SP180.2 - Decision support system for no common emergency in a big city with intelligent routing algorithm and attention quality parameters evaluation.

Author(s): <u>Lupe N. Toscano</u>¹, M.J.F De Oliveira² ¹Ingeniería Electrica Y Electrónica, Universidad Nacional de Ingeniería, Lima/PERU, ²Universidade Federal do Rio de Janeiro, Rio de Janeiro/BRAZIL

The latest news on no common emergencies or disasters occurred in the world show us the necessity to develop tools in order to support a rapid and efficient response. The arrival time and the first attention to the patient in the emergency place is the golden time of the response. The objective of this paper is to support decisions in a disaster for a big city focus on decrease arrival time and improve attention quality in the place of the emergency. It is important to notice that the model is for a no common emergency like earthquake, flood, tsunami or terrorism and specific when we don't know what is happening on the route of the emergency and the scope of the tragedy so for the first reaction. The first instants of the response have been modelated to have two important details, the routing of the emergency vehicle and the primary attention in the place of the emergency. A specific routing algorithm for states of not common emergency was developed. The algorithm has been implemented in language C, having being defined two interactive knowledge bases for the information network and an intelligent search with a specific heuristic for no common emergency. Besides, a discreet event simulation model is used to support decisions of the rescue teams

on the place of the emergency. This model is a good tool to be implemented inside the rescue vehicles in order to support recues, it could be used without capacitation time if the rescues manage interactive computers tools. Finally we can conclude that rescues could use this tool for the first reaction to the emergency and this gold time could be supported.

SP180.3 - Development of a Multi-Center Clinical Trial Data Archiving and Analysis Platform

Author(s): <u>Brandon Driscoll</u>¹, Ivan Yeung², Catherine Coolens², Gavin Disney², Igor Svistoun², David Jaffray² ¹Techna Institute, University Health Network, Toronto/ON/CAN-ADA, ²Radiation Medicine Program, Princess Margaret Cancer Center, Toronto/ON/CANADA

Quality results from multi-center clinical trials require consistent and robust trial protocols capable of quantifying or eliminating differences across participating institutions. The vision of the Quantitative Imaging for Personalized Cancer Medicine (QIPCM) program is to provide end to end testing and analysis support for clinical trials to achieve improved consistency and reliability in clinical trial data.

Methods: The QIPCM clinical trial data archiving and analysis platform consists of a customizable image anonymizer and secure transport pipeline (RSNAs Clinical Trial Processor, CTP), a dedicated remote analysis platform, and a dedicated server for the archival and storage of medical images.

The anonymized images received from the remote sites are held in a secure drop box where there are subjected to a quality assurance check. This check ensures both that no patient health information remains and that the image set is complete before it is then subsequently forwarded to the clinical trial PACS at which point trial based permission controls are enforced. The images can then be analyzed either by QIPCMs dedicated team of imaging experts or remotely by the trial investigators.

In addition to the platform infrastructure, a set of customized image analysis tools has been developed which are available for use on the remote analysis workstations. These tools range from quantitative functional imaging tools for 4D kinetic modeling of dynamic contrast enhanced-CT and MR and hypoxic fraction analysis in PET; to simple 1D RECIST. Alternatively remote users can choose to utilize their own custom applications on the virtual environment while still making use of the central data storage and powerful remote analysis servers.

Results: The QIPCM team has established infrastructure and support services to sustain an ever growing number of multi-centre clinical trials. The platform currently serves 15 internal and 6 multi-center clinical trials spanning 9 hospitals and imaging centers in Canada and the United States, with more trials to be added over the upcoming months. The image store currently holds in excess 1.8 million individual tomographic slices comprising more than 510 individual imaging studies from over 145 patients. The QIPCM team has also provided PET QA services for 3 different multi-center trials at 10 different sites across North America.

Conclusions: The current QIPCM platform is a fully functional commercial system with robust backup, storage and processing capacity. Within the next two months a further 50 TB of storage and 2 more high powered computational servers will further enhance performance.

SP180.4 - Global Health Catalyst: A systematic Space-time compression platform for catalyzing global health collaborations in Radiation Oncology Author(s): Michele Moreau¹, <u>Wilfred Ngwa²</u>

¹University of Massachusetts, Lowell/UNITED STATES OF AMER-ICA, ²Radiation Oncology, Dana Farber/Harvard Cancer Center, Boston/UNITED STATES OF AMERICA

The benefits of global health collaborations in cancer Care, Research and Education (CaRE), are already well established, and there is growing consensus that our ability to address the growing global burden of cancer will increasingly depend on concerted international collaborations. Such collaborations could benefit from a major recent upsurge of interest in radiation onclology global health highlighted in recent Red Journal articles. However, appurtenant to this upsurge, a common issue evident at global health summits, seminars, or symposia is that SPACE-TIME is a major barrier to many who really want to participate/collaborate in global health CaRE. Given the increasing disproportionate global burden of disease in Low and Middle Income countries (reported in the recent World Health Organization report), there is growing urgency for strategies that can reduce this space-time barrier, make it easier for people to collaborate. Systematic Space-time compression represents one such strategy. Here space-time compression refers to the use of advanced Information and Communication Technologies (ICTs) that condense or elide spatial and temporal distances. In this work a catalogue of ICTs for space-time compression to enhance global health collaborations in Radiation Oncology (RadOnc) including Medical Physics is presented. A new platform, Global Health Catalyst, being developed at Harvard Medical School to integrate these ICTs for concerted high impact global health CaRE collaborations is presented. Preliminary projections show that this systematic approach could convert the huge upsurge in global health interest into coordinated high impact global health collaborations in RadOnc CaRE, and enhance the effectiveness of other global health initiatives. Figure 1 highlights some of these ICTs for Radiation Oncology Global health integrated in the Global Health Catalyst platform.

PS01.001 - A discontinuity artefact at the isocenter of on-board CBCT images

Author(s): Elsayed S.M. Ali¹, Paul C. Johns², Balazs J. Nyiri¹ ¹Medical Physics Department, The Ottawa Hospital Cancer Centre, Ottawa/CANADA, ²Physics Department, Carleton University, Ottawa/CANADA

In our recent investigation [Ali et al PMB 60 1461 (2015)], rotational artefacts in the Elekta XVI cone beam computed tomography system were identified and corrected for. However, a residual discontinuity artefact remained at the isocenter. It was dependent on the scan direction but only slightly on its speed. In the present study, we have identified the cause of this discontinuity artefact. A 1-cm air gap is introduced between the two halves of a 30-cm diameter Solid Water phantom to accentuate the artefact, which is manifested as fading stripes in the scan direction (figure 1a,b). The artefact remains when the phantom is rotated to place the gap at an arbitrary angle relative to the horizontal. As the gap thickness is increased, a semicircular dark streak appears around the isocenter. In the sinograms (figure 1c,d), the artefact does not follow a sinusoidal path; instead, it is a fading remnant of the gap at a fixed detector location. This indicates that the artefact is caused by detector lag due to the incomplete readout of the flat-panel imager, which leads to ghost signals after high intensity irradiation. The lag blurs the edges by a few pixels, which leads to the discontinuity at the isocenter (figure 2). Analysis of the sinogram profiles (figure 1c,d) shows that the lag decay can be described by a double exponential, which agrees with the literature. The variation of the lag with the mA yields different decay time constants. Previous studies have characterized and/or corrected for the radial increase and the azimuthal decrease of the lag, but have not identified the presence of a discontinuity at the isocenter as a manifestation of detector lag.

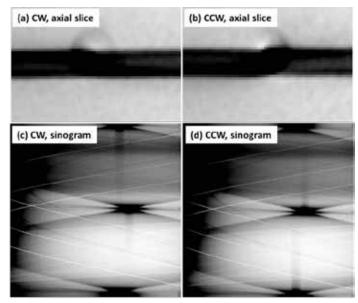

Figure 1: (a,b) Discontinuity artefact at the isocenter for clockwise (CW) and counterclockwise (CCW) scans. (c,d) Lag effect, demonstrated as a fading remnant of the gap at a fixed detector location. Time is flowing downwards in the CW sinogram and upwards in the CCW signogram.

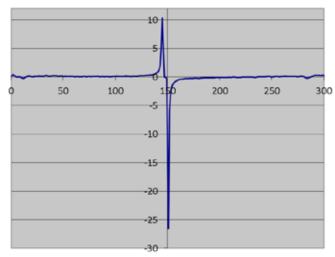

Figure 2: A vertical profile from the difference of the sinograms, CW minus CCW. The abscissa is the index of the projections. The ordinate is the pixel value in thousands. The discontinuity is around the projections that pass through the air gap.

PS01.002 - Correction of Metal Artefacts Induced from Pacemaker and ICD Leads in CT-Based Attenuation Correction of Cardiac SPECT data

Author(s): Mohammad Reza Ay¹, Zahra Etemadi², Ahmad Bitarafan-Rajabi³, Hadi Malek³, Navid Zeraatkar², Pardis Ghafarian⁴ ¹Department Of Medical Physics & Biomedical Engineering, Tehran University of Medical Sciences, Tehran/IRAN, ²Research Center For Molecular And Cellular Imaging, Tehran University of Medical Sciences, Tehran/IRAN, ³Cardiovascular Interventional Research Center, Department of Nuclear Medicine, Rajaei Cardiovascular, Medical, and Research Center, Iran University of Medical Sciences,Tehran, Iran., tehran/IRAN, ⁴Pet/ct And Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, tehran/IRAN

Objective: In CT-based attenuation correction (CTAC) of myocardial perfusion SPECT data, the metallic artefacts due to pacemaker and ICD leads attached to the myocardial wall can induce overestimation or underestimation of activity in some segments of the myocardium. In the present study, the impact of the application of metal artefact reduction (MAR) algorithm for generation of artifact free attenuation map (μ -maps) during CTAC process of SPECT data was assessed and quantified.

Methods: A cardiac phantom with the capability of inserting pacemaker and ICD leads was used. The CTAC was performed using the μ -maps without and with MAR. The volume-of-interest (VOI)-based quantitative comparison was performed between the actual activity and the activity concentration in the SPECT images, and also attenuation-corrected (AC) SPECT images without and with MAR. In addition to the phantom study, the SPECT data of 5 patients with ICD and 4 patients with pacemaker were used for clinical validation and quantification.

Results: The findings show that after applying the MAR, relative error can reduce about 4% and 6% on overestimated segments and about 2% and 2% on underestimated segments in the images of the phantom with pacemaker and ICD, respectively. In clinical evaluation, the Bland-Altman plots show no significant difference between two reconstructed SPECT images on overestimated segments for the patients with pacemaker and ICD.

Conclusion: Although the study shows improvement in SPECT image quantification and generated μ -maps after correction of metallic artifacts, it has no effect on the clinical interpretation of cardiac images corrected for attenuation with and without artifactual μ -maps.

It should be noted that due to low spatial resolution of SPECT images and considering the CT-based attenuation correction process which smoothes the CT images, the impact of metallic leads in SPECT images that corrected for attenuation using artifactual CT images is not clinically significant.

PS01.003 - Anthropomorphic Phantom of the Pancreas for Scintillation Camera Tests

Author(s): Halaine C.M. Silva¹, Fernanda C.L. Ferreira², <u>Lourdes M.</u> <u>Brasil¹</u>, Glécia V.D.S. Luz¹, Leandro X. Cardoso² ¹University of Brasilia at Gama, Brasília/BRAZIL, ²Federal University of South and Southeast of Pará,, Marabá/BRAZIL

It is well known that several medical procedures involving the use of ionizing radiation has made the radiation physics indispensable in modern medicine. The nuclear medicine, for example, is a medical specialty that uses the known radiopharmaceuticals. The radiopharmaceuticals, also known as radioactive tracers, have radionuclides associated with drugs in their composition and are administered to the patient for diagnosis and treatment of various diseases. For diagnostic purposes, particularly, it is important that the images reveal, more accurately possible, the relevant details of any present anomaly. Therefore, to ensure the quality of the equipment used in nuclear medicine services, it is important that quality control tests be performed frequently. In this context, organizations such as the International Atomic Energy Agency (IAEA) recommend periodic testing of quality control of scintillation cameras. However, it is unacceptable that such tests be performed directly on patients, since the use of ionizing radiation can damage your health. In this regard, the use of physical and anthropomorphic phantoms becomes indispensable for quality control tests be performed more safely and efficiently. Therefore, the objective of this work was the development of the phantom of the pancreas for guality control optimization in scintillation cameras, and hence obtaining images more reliable for diagnosis in addition to controlling the dose of the radiation is used in efficiently to the quality and definition in image processing. The studies performed showed that the anthropomorphic phantom of the pancreas can be used to optimize image acquisition devices, in particular for spatial resolution tests. Besides the nuclear medicine test equipment, it is important to mention that the simulations with phantom of the pancreas can contribute to the continuing education of professionals in nuclear medicine, improving its ability in the identification of cold nodules and/or hot nodules.

PS01.004 - Comparing two image processing techniques, Wavelet and Segmentation by threshold, for detecting microcalcifications in an image mammographic.

Author(s): Rubens V. Souza Sales¹, <u>Lourdes M. Brasil</u>², Fatima Elpidio¹, Janice Lamas¹

¹Gama, University of Brasilia (UnB), Gama-DF/BRAZIL, ²Fga, UnB, Brasília/BRAZIL

According to the, World Cancer Research Fund, breast cancer is currently the second most common cancer in women worldwide. Many breast cancers are characterized by the presence of calcifications which are calcium accumulation in breast regions, which can be benign or malignant. Among the calcifications stand out microcalcifications, are generally smaller than five millimeters, these are more suspicious of malignancy making early diagnosis essential.

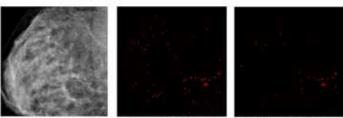

Due to the size, microcalcifications are more difficult to detect directly in an image of mammography, requiring image processing techniques, to assist the health professionals in the diagnosis. The techniques used for comparison in the detection of microcalcifications are: one based on Transformed Wavelet and another in segmentation by threshold.

Prior to the comparison, it is necessary to perform the detection of microcalcifications using each technique separately from the same image. In Figure 1.a has the original image of mammogram used in both techniques for microcalcifications detection. After the implementation of the two techniques, we can compare the results of both based on the number and position of the detected microcalcifications. The platform and language for development of algorithms is the Software Maltab, while that mammography images used are provided by Radiology Clinic Janice Lamas of Brasilia, Brazil.

In the wavelet technique, the image is decomposed into three directions (horizontal, vertical and diagonal), and the sum of these produces the resulting decomposition, it performed using two levels of decomposition and the Haar mother wavelet. After the decomposition occurs thresholding and binarization. In segmentation, an initial thresholding is used to define the points of interest, the dilatation of these points is then performed, and then the image are thresholded and binarized to indicate the detected microcalcifications. For your hit rating and detection performance, is needed help of specialist.

The Figure 1.b shows the microcalcifications detected using wavelet

technique, while Figure 1.c shows the detected microcalcifications using a technique segmentation by threshold. Note that by Wavelets could be detected more calcifications compared with segmentation (2.1 times more). This shows the advantage of using wavelet due to the fact that we can work on multiresolution for different frequencies. The Segmentation there is more information losses in steps thresholding and dilation. The main challenges of this work was to detect efficiently and reliably microcalcifications, set values for thresholds which often are not in the medical literature.

PS01.005 - Measuring red blood cell velocity in capillary using video and image processing

Author(s): Siwa Suwanmanee¹, Pedro Cabrales², <u>Surapong Chat-</u> pun¹

¹Institute Of Biomedical Engineering, Faculty Of Medicine, Prince of Songkla University, Hatyai, Songkhla/THAILAND, ²Bioengineerng, University of California, San Diego, La Jolla/CA/UNITED STATES OF AMERICA

Microvascular blood flow velocity is important in physiological health monitoring and it is essential in oxygen supply, nutrient transportation and waste removal. Blood flow is relevant to the occurrence of many diseases such as Raynaud's phenomenon, diabetes, hypertension, sepsis and cardiac diseases. Red blood cells (RBCs) velocity can represent microvascular blood flow. In capillaries, it is an important parameter in clinical hemorheology and microcirculation. For both in vitro and in vivo studies, RBCs velocity can be determined by using video image processing. Therefore, this study aimed to determine RBCs velocity from the videos recorded. The capillary blood flow videos were recorded from an animal dorsal skin window chamber model. The computer algorithm was developed to estimate the RBCs velocity. The proposed algorithm applied a digital image processing method to provide quantitative assessment of video signal to determine RBCs velocity. There were four steps to preform image processing of video images: i) image improvement, ii) image binarization, iii) image segmentation and iv) RBCs centroid estimation. In order to estimate the velocity of RBCs, it can be calculated by using the moving distance of centroid of RBCs between frames. Each frame was stored and used to calculate the RBCs velocity by dividing the frame rate of the video. Moreover, to make this algorithm more useful and efficient, the graphic user interface (GUI) was developed and tested. The final outcome of this study provided the in-house software for the velocity of RBCs in a capillary.

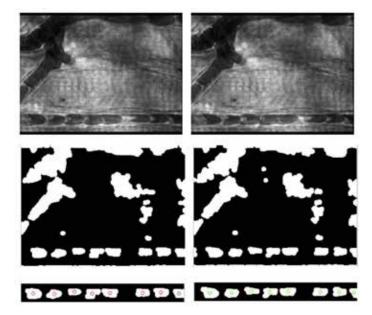

Figure Steps to determine RBCs centroids from capillary blood flow video images: (a) and (b) image improvement of image frames #195 and #196; (c) and (d) image binarization; (e) and (f) image segmentation and RBCs centroids estimation.

PS01.006 - Development of a Quantitative PET QA Procedure for Multi-Center Clinical Trials

Author(s): <u>Brandon Driscoll</u>¹, Ivan Yeung², Doug Vines³, Harald Keller³

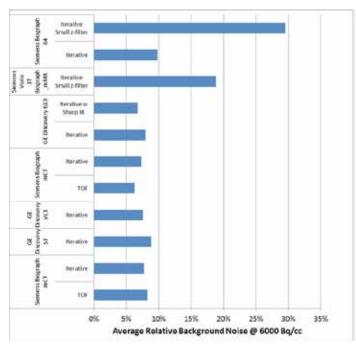

¹Techna Institute, University Health Network, Toronto/ON/CANA-DA, ²Dept Of Radiation Oncology, University of Toronto, Toronto/ ON/CANADA, ³Radiation Physics, Princess Margaret Cancer Center, Toronto/CANADA

Purpose: To develop an inter-institutional PET QA procedure especially tailored to the increasing requirement for quantitative (as opposed to qualitative) image analysis. Such a QA procedure should allow for harmonization of image acquisition and reconstruction such that images can be pooled across institutions.

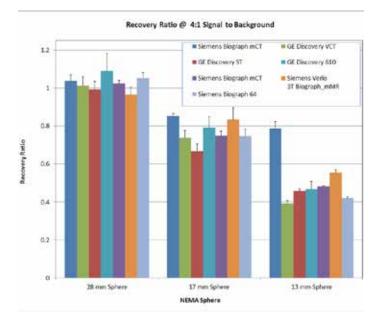

Methods: The PET QA procedure utilizes the NEMA IEC Body Phantom which contains a set of 6 spheres and a torso shaped background reservoir. The phantom is filled at two background levels (2:1 and 4:1) and imaged three times at each level. Well counter readings from the signal and background compartments are collected for absolute quantification. The sites were each asked to select the protocol they would utilize for a full body PET scan with a time per bed position of 5 minutes.

At this stage, 7 different scanners have been tested across 4 institutions. For each scanner a number of quantitative measures were analyzed such as dose calibrator to well counter cross-calibration, absolute agreement with well counter, recovery ratios, and background noise levels.

Results: The protocols utilized by individual sites varied considerably in terms of reconstruction and image acquisition parameters. Two PET scanners had Time-of-Flight acquisition capability contributing to the variability.

The relative average background noise at 6000 Bq/cc activity level was 9.6% with a substantial variation between the scanners (7.6-18.9%).

Variations of the recovery ratio were equally severe especially for the smaller spheres. The average recovery ratio for the 13mm sphere was 0.51 with relative standard deviation of 26%.

Conclusions: There is a large variation in noise and sensitivity of the PET images across the different institutions. Some PET metrics such as tumour hypoxic fraction rely on local quantification of image noise and are therefore especially prone to variations. Reliability of such metrics for multi-center clinical trials requires harmonization of PET image acquisition and reconstruction.

PS01.007 - Unwrapping highly wrapped phase using Nonlinear Multi-Echo phase unwrapping

Author(s): <u>Chemseddine Fatnassi</u>¹, Rachid Boucenna¹, Habib Zaidi² ¹Radio-oncology Department, Hirslanden, Lausanne/SWITZER-LAND, ²Department Of Nuclear Medicine And Molecular Imaging, Geneva University Hospital, Geneva/SWITZERLAND

Introduction: The unwrapping problem has been a major topic of research for more than a decade. A variety of algorithms have been proposed to overcome this problem, although a correct solution is by no means guaranteed, and many of the proposed approaches are time-consuming. In this work, we propose a simple and fast method, which combines conventional temporal unwrapping with the nonlinear phase model to unwrap multi-echo data (nonlinear multi-echo (NME) unwrapping). The approach was tested on simulated and *in vivo* brain data acquired from 10 subjects at 3 Tesla. The accuracy of the proposed method was evaluated against 2D and 3D spatial unwrapping methods and also against conventional temporal unwrapping.

Materials and Methods: The proposed method to unwrap highly wrapped phase NME requires a minimum of 2 echoes. The first echo is acquired with an echo time TE smaller than the maximum velocity encoding. Therefore, the echo difference between the two acquisitions TE can be selected on the basis of knowledge of the typical range of the field map B0 values encountered at the field strength in question to avoid unintentional phase wrapping. The second echo is acquired at long echo time TE (>20ms) to get a high wrapped phase. In the presence of large susceptibility artifacts, the linear assumption of the phase evolution is broken. To overcome this problem, we propose a model to account for this nonlinearity using a 1D random walk theory when the images are acquired at long TE. Finally, we combine the nonlinear approach to describe the temporal phase evolution and the conventional temporal phase unwrapping to correct for high phase aliasing. To assess the accuracy of our approach in presence of high phase wraps at long echo time; we used simulated wrapped phase with different wraps complexity and different noise levels. In vivo MRI scans were performed on a 3T Magnetom Trio (Siemens Healthcare, Erlangen, Germany). Data were acquired with a 3D bi-polar multi gradient echo sequence. NME was compared with 2D conventional Matlab unwrapping, 2D and 3D spatial phase-unwrapping.

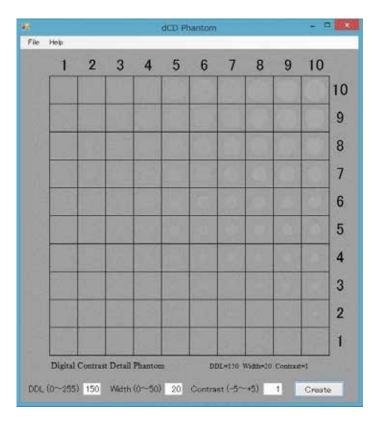

Results and Discussion: Both simulated and *in vivo* results showed that NME provides a good phase unwrapping with high accuracy (>90%) in the presence of high phase topography complexity and noise level, which reflects the real image quality at long echo time TE. Therefore, 2D, 3D spatial unwrapping and conventional temporal unwrapping present some limitations especially when phase wraps complexity and noise level are high. NME requires 2 echoes acquired at different TE; the method removes with success phase wraps occur near brain edges and paranasal sinus where the field gradient inhomogeneity is large. NME accounts for the nonlinear phase model which reduces significantly regions over-unwrapped with the conventional temporal unwrapping.

Conclusion: In this work, we proposed a simple and fast method to unwrap highly wrapped phase; the method combines conventional temporal unwrapping and nonlinear phase model to overcome phase aliasing even in the presence of high field gradient artifacts. PS01.008 - Investigation of optimal display size for viewing MRI images using a digital contrast-detail phantom Author(s): <u>Hideki Fujita</u>, Nao Kuwahata, Hiroyuki Hattori, Hiroshi

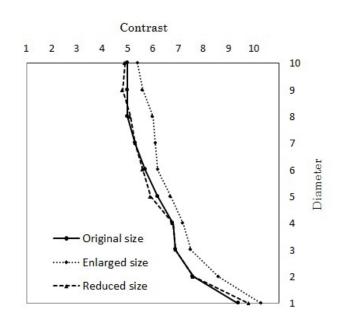

Kinoshita, Haruyuki Fukuda

Radiation Oncology, Osaka Saiseikai Nakatsu Hospital, Osaka/JA-PAN

In this study, we clarified the relationship between the display size of MRI images and observer performance using a digital contrastdetail (d-CD) phantom. The d-CD phantom was developed using Microsoft Visual Basic 2010 Express (Figure 1). It had a 512 × 512 matrix in size and a total of 100 holes, whose diameter increased stepwise from 4 to 40 pixels with a 4-pixel interval in the vertical direction; the contrast varied stepwise in the horizontal direction. The digital driving level (DDL) of the background, the width of the DDL, and the contrast were adjustable. These parameters were determined on the basis of the actual T1-weighted magnetic resonance (MR) images of the brain. In this study, the DDL, width, and contrast were set to 85, 20, and 1, respectively. The observer performance study was performed for three different display sizes (30 cm × 30 cm as the enlarged size, 13 cm × 13 cm as the original size, and 7 cm × 7 cm as the reduced size) using a 2-megapixel color liquid crystal display monitor and the results were analyzed using the Friedman and Wilcoxon statistical tests. The observer performance for the original display (P < 0.01) and the reduced display sizes (P < 0.01) 0.01) was superior to that for the enlarged size, whereas there was no significant difference between the original display and reduced display sizes (P = 0.7) (Figure 2). Evaluation with the digital phantom simulating MR imaging also revealed that the original and reduced display sizes were superior to the enlarged display size in observer performance. The d-CD phantom enables a short-term evaluation of observer performance and is useful in analyzing the relationship between display size and observer performance.

The appearance of the developed d-CD phantom.

PS01.009 - Investigation of presampled MTF using a slit device with slightly wider aperture

Author(s): Yasuyuki Kawaji¹, Tatsuhiro Gotanda¹, Tetsunori Shimono¹, Shinichi J. Nakayama¹, Miki Hisamoto¹, Sae Matsumoto², Ayato Misago², <u>Rumi Gotanda³</u>

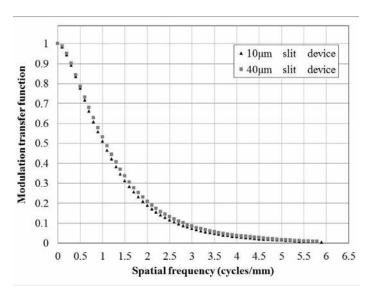

¹Department Of Radiological Science, Faculty Of Health Sciences, Junshin Gakuen University, Fukuoka/JAPAN, ²Department Of Radiological Science, Faculty Of Health Sciences, Junshin Gakuen University, fukuoka/JAPAN, ³Department Of Radiological Sciences, Ibaraki Prefectural University of Health Sciences, Inashiki-gun, Ibaraki/JAPAN

The resolution properties of an imaging system are commonly described by its modulation transfer function. The slit and edge methods are the two most commonly used and accepted techniques for measuring the MTF. The use of a slit requires very precise fabrication and alignment of the device in the radiation beam, a high radiation exposure to allow sufficient transmission through the narrow slit (aperture 10 μ m). We took notice of the slit aperture and a new slit device with slightly wider aperture (40 μ m) was made for the im-provement of the conventional slit device. The aim of this work was to show the properties such as the X-ray tube loading, the alignment and the MTF using the new slit device with slightly wider aperture. Imaging plates in the CR system were employed in this measurement.

The use of the 40 μ m aperture slit device can decrease one-fourth of the X-ray tube loading compared to the conventional device (Table 1). The use of the 40 μ m aperture slit device can improve the alignment for the slit device rotation and the incidence X-ray offset.The MTF using the 40 μ m aperture slit device is higher than that using the conventional device (Fig. 1). The maximum difference was 0.025 (at 1.3 cycles/mm). The exposure condition of the 40 mm aperture slit device is near to clinical conditions and the MTF indicates the resolution property under clinical conditions.

Our results showed that the use of 40 μ m aperture slit device allows easy acquisition of a slit image on the detector without precise alignment and ensures an appropriate MTF for the CR system under near-clinical exposure conditions.

PS01.010 - 3D Tumor delineation in Positron Emission Tomography reconstructed images restored by the use of Lucy Richardson blind deconvolution method

Author(s): Alpaslan Koc, Albert Guvenis

Institute Of Biomedical Engineering, Bogazici University, Istanbul/ TURKEY

Background Positron Emission Tomography (PET) can give the metabolically active tumor volumes necessary for radiotherapy planning and the therapeutic management of cancer patients. However, the automated edge finding algorithms and the partial volume effect due to the limited resolution of the camera can be a challenge. Pur**pose** To evaluate the gain obtained in tumor volume estimation by making use of the image restotation Lucy-Richardson blind deconvolution method for 3D active contour based delineation strategies. Method and Materials Three 3D active contour methods have been used for delineation: Active contour with 50% threshold, active contour with edge attraction, and active contour with clustering. We have used a set of simulated 3D [18F]FDG PET oncology images including spheres of diameters 37, 28, 22, 17, 13 and 10 mm in a NEMA cylindrical phantom which were reconstructed using a 3D filtered backprojection algorithm. Data were obtained from the NCI database. The images were deconvolved by using the Lucy-Richardson blind deconvolution method. The deconvolution parameters were adjusted for best accuracy. The number of iterations was set to 7. Results First results showed that none of the three 3D active contour methods showed a consistently better accuracy for all spheres. The errors increased with smaller spheres. Significant improvements were obtained for all three delineation algorithms for the first four largest spheres between by deblurring the images. The improvements ranged between 98% and 25%. Conclusion The accuracy of 3D Active Contour delineation of tumors for estimating metabolically active tumor volumes is higher when images are deblurred with the Lucy-Richardson blind deconvolution. Work is underway for improving the accuracy of delineation of the smaller spheres.

PS01.011 - Different options for stimulation intensity in mapping cortical motor area in navigated transcranial magnetic stimulation

Author(s): Petro Julkunen, Elisa Kallioniemi

Department Of Clinical Neurophysiology, Kuopio University Hospital, Kuopio/FINLAND

Background: Navigated transcranial magnetic stimulation (nTMS) is a modern technique used for mapping cortical motor areas in presurgical planning and stereotactic radiosurgery. One of its drawbacks is that it is sensitive to the selection of an appropriate stimulation intensity (SI) used in the procedure. Too low SI does not produce responses with good confidence and too high SI cannot perform focal stimulation. The SIs are determined based on resting motor threshold (rMT) prior to mapping. Commonly suprathreshold SI of 110% or 120% of rMT is used. Intuitively, a method able to determine an SI for the mapping procedure should be based on the lowest possible SI that maximizes the occurrence rate of motor responses. This can be accomplished via the use of the upper motor threshold (UT) determined with Mills-Nithi method [1] as it assumes 100% occurrence rate instead of the 50% assumed by the rMT [2].

Methods: 9 right-handed volunteers (6 males, age 24–61 years) were studied. The primary motor cortex on the left hemisphere was mapped for the extent of cortical area producing motor evoked potentials (MEPs) in three resting hand muscles using controlled suprathreshold stimulation intensity of 110% and 120% of the rMT as well as using UT. Stimulus locations and corresponding responses were used to evaluate the size of the excitable cortical motor area [3].

Results: UT was higher than 110%rMT (p=0.026) and lower than 120% of rMT (p=0.011). The representation sizes followed a similar trend. Comparison of size variations between the subjects revealed that the range of the resulting motor representation sizes was lowest with UT, while the size with UT and 110% rMT were significantly smaller compared to 120% rMT (Figure). The representation size determined with UT demonstrated best inter-subject repeatability based on confidence interval width with 2.0cm², while the confidence interval width of 2.2cm² and 2.8cm² were observed with 110% and 120% rMT, respectively.

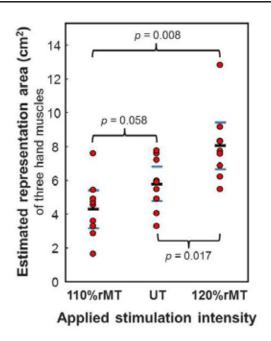

Figure: Estimates of motor cortical muscle representation area of three hand muscles determined for all subjects applying three stimulation intensities. The red dots represent area of each individual subject. The blue lines represent the 95% confidence intervals and black line indicates the mean. Non-parametric paired-samples comparisons are indicated.

Conclusions: The highest repeatability in representation size was observed with UT as compared to the commonly used 110% and 120% rMT SIs. Then the UT appears as an appropriate choice to be used with motor mapping applications to outline functional motor areas on the cortex when using nTMS in presurgical applications and radiosurgery planning to base the mapping SI to UT.

PS01.012 - Software Breast Phantom for Phase Contrast Imaging Applications

Author(s): Anastasia Daskalaki, Kristina Bliznakova, <u>Nicolas Pal-</u> likarakis

Biomedical Technology Unit, Dept. Of Medical Physics, University of Patras, Patras/GREECE

Breast cancer is the most common cancer in women worldwide. Although mammographic screening techniques have considerably reduced breast cancer mortality, the rate of missed lesions and false positives remain crucial. Phase Contrast Imaging is an emerging technique based on X-ray phase change arising from diffraction and refraction effects that take place at the boundaries of different refractive materials, producing images with strong edge enhancement. There are no phantoms for phase contrast breast imaging applications available today. The goal of this work is to develop a software phantom that mimics the refractive properties (indexes) of breast tissues, specialized for phase contrast applications. Such a phantom will enable simulated image quality evaluations and dose analysis in the case of phase contrast imaging. For this reason 17 different compounds were investigated in order to find the optimum materials to represent fibroglandular tissue, adipose tissue, skin,

lymph, microcalcifications and breast masses for an energy range between 18keV and 40keV. A comparison of the δ values between these breast tissues and the mimicking materials has been calculated according to the equation $\delta_{\text{Diff}} = (|\delta_{\text{BT}} - \delta_{\text{M}}| / \delta_{\text{BT}})^* 100$. Where δ_{BT} represents the refractive index of the breast tissue and $\delta_{_{\rm M}}$ the refractive index of the mimicking material. The XRAYImagingSimulator, an in-house developed software platform used for novel investigations in x-ray imaging, has been used for image acquisition. Simulation modules have been adapted to analytically simulate physical interactions taking place in Phase Contrast imaging based on Fresnel-Kirchoff diffraction theory. A breast like semi-cylindrical phantom of 18mm radius and 45mm thickness filled with polystyrene as background material has been modeled. In this background five cuboids of nylon, polyethylene, paraffin wax, polystyrene and silicone gel, two spheres of water of 1mm and 2mm radius and two clusters of Al of 0.098mm and 0.115mm respectively were inserted. Subsequently, x-ray planar images were produced with coherent radiation emerging from a point monochromatic source in both Phase Contrast and Absorption mode. The two images of the phantom were obtained at 20keV, with SID 23m and ODD 400mm and 5µm resolution. The two planar images were compared in terms of contrast and edge enhancement using four different line profiles. Results from the evaluation of the line profiles showed an important edge enhancement of the details embedded in the phantom. Especially for the adjacent materials polyethylene and paraffin wax that cannot be differentiated in the absorption mode, phase contrast image was able to clearly reveal their borders. Simulation images acquired show a significant edge improvement when the phase contrast effect was taken into account. For further investigation we are planning to verify the presenting results with synchrotron experimental data.

PS01.013 - Actions for Implementation Program of Image Quality of Mammography

Author(s): Rianne B. Venancio¹, Leticia S. Oliveira¹, <u>Ana Cláudia</u> <u>Patrocinio²</u>, Rodolfo D.S. Ribeiro¹, Cecilia L. Debs³ ¹College Of Electrical Engineering, Federal University of Uberlandia, Uberlandia/BRAZIL, ²Laboratory Of Biomedical Engineering, Federal University of Uberlândia, Uberlândia/BRAZIL, ³Institute Of Radiology - College Of Medicine, University of Sao Paulo, Sao Paulo/BRAZIL

Globally were established many quality programs that have proven effective in early detection of the breast cancer. In Brazil was instituted, by the Department of Health, the ordinance 531/2012 that establish the basic guidelines for the implementation of the National Program for Quality in Mammography (PNQM) to ensure the quality of digital mammography exams . But in November 2013 it was updated by the ordinance nº2898 added which the role of public and private agencies to fulfillment this ordinance, not adding any technique process. This work has the aims to implement the ordinance 531/2012 with a principal focus on training and periodic retraining of health professionals. As methodology was proposed a set of actions for hospitals and clinics regularize the conditions imposed by the law, always seeking quality mammographic images. The result was the creation of seminars and specific courses for radiologists and radiology technician, with the aim to resolve such failures always prioritizing the quality in the image digital mammography. Other tender, for comply the ordinance, is the establish a committee that will go assess the insertion of PNQM, regularly sending reports to health authorities regarding the implementation of the program and regiment and still taking providences in case of non-compliance with the quality criteria.

PS01.014 - Evaluating Techniques of Transformation Intensity for Contrast Enhancement in Mammographic Images Author(s): <u>Ana Cláudia Patrocinio</u>¹, Raquel J.P.D. Lima¹, Michele F. Angelo²

¹Faculty Of Electrical Engineering, Federal University of Uberlândia, Uberlândia/BRAZIL, ²Department Of Technology, State University of Feira de Santana, Feira de Santana/BRAZIL

Mammography has a high sensitivity, but the interpretation of the images may be affected by factors such as the density breast and the limitations of mammography equipment. Thus, it is of great importance the use of image pre-processing techniques to enhance contrast and consequently the present structures in the image are interpreted correctly. This work is dedicated to the study of the performance of intensity transformation techniques for contrast enhancement of mammographic structures. Initially, five different techniques (logarithmic, exponential, gamma, sigmoid and stretching linear function) were applied in regions of interest containing microcalcifications. Subsequently, the signal/noise ratio and the contrast/noise ratio of the images were calculated to evaluate the performance of the techniques. According to the results, the sigmoid function presented the better performance.

PS01.015 - Influence of Contrast Enhancement to Breast Density Classification by Using Sigmoid Function

Author(s): Michele F. Angelo¹, Pedro Cunha Carneiro², Talita C. Granado², <u>Ana Cláudia Patrocinio²</u>

¹Department Of Technology, State University of Feira de Santana, Feira de Santana/BRAZIL, ²Faculty Of Electrical Engineering, Federal University of Uberlândia, Uberlândia/BRAZIL

The classification of breast density is very subjective even for the experts, the categories 2 and 3, in many cases are confused. Thus, the objective of this study is to evaluate the influence of the sigmoid function in the density classification of images with lesions by using texture attributes. It was used 28 images with lesion, 19 belong to the category 2 (P2 - partially fat) and 9 to category 3 (P3 - dense). The sigmoid function was implemented and applied to all images to contrast windowing. A set of 14 Haralick descriptors were implemented. After the attributes extraction step it used the clustering technique K-Means to classify the category images of breast densitv 2 and 3. Seven of the 14 Haralick descriptors (energy/uniformity. contrast, vari-ance/homogeneity, average sum, variance of the sum, entropy difference and maximum correlation coefficient) showed higher success rate when used images processed with sigmoid function. However, five attributes (correlation, entropy sum, difference variance, correlation information measured 1 and 2) presented classification results below those that results by using the original images, and two attributes (inverse differ-ence moment and entropy) obtained the same results, for clas-sification of both images (images with sigmoid function and original images). The attributes combination used to classify images with sigmoid function were better and the combination that had the best classification accuracy rate was the contrast and variance attributes. The use of the sigmoid function direct-ly influenced the results of classification in the categories 2 and 3, however, when it was used by only one attribute in the classification, not all attributes showed great correct response rates, as happened to the results obtained using attributes combination.

PS01.016 - Evaluation of the difficulties of the learning process of mammographic readings

Author(s): Pedro Cunha Carneiro¹, Letícia Oliveira Mamere², <u>Ana</u> <u>Cláudia Patrocinio¹</u>

¹Laboratory Of Biomedical Engineering, Federal University of Uberlândia, Uberlândia/BRAZIL, ²Faculty Of Medicine, Federal University of Uberlândia, Uberlândia/BRAZIL

Breast cancer is the second most frequent type of cancer in the world, being the most common among Brazilian women. Thus, the best way to prevent from such disease is by having mammographic exams regularly. However, the mammographic report does not depend exclusively on the analysis of the physiological factors of the visualized structures and the technical characteristics of the image aquisition and storage system, but also on the interpretation of the images by the specialist. The aim of this paper is to identify and evaluate the parameters used to elaborate the mammographic reports which show a higher level of difficulty from the quantification of mistakes of the residents when reporting mammographic exams.

On this paper, 346 mammographic images were analyzed by radiology residents using a questionnaire elaborated on a previous work and it is based on BI-RADS[™] to characterize the mammographic lesions found. The collected and analyzed data are: the positive and negative cases of the BI-RADS[™] classification, the pattern of density and complexity of the image, the capacity of identifying nodules, calcifications of the vascular/parallel type, calcification of benign aspect and axillar and intramammary lymph nodes. In order to broaden the evaluation of the results some statistical methods we used, such as: sensitivity (Se), specificity (Sp), Kappa coefficient (K) and area under ROC curve (AUC).

Later, these reports were compared to the reports provided by the staff (specialized physicians), aiming at identifying the level of difficulty of the radiology residents in reporting mammographic exams. Out of the 321 negative reports defined by the staff, the residents matched 292 of them (91%). On the 25 positive cases defined by the staff, the residents matched 13 of them. Regarding the level of complexity of the lesions, the highest percentage of mistakes is found in cases considered of very high complexity. Table 1 presents a summary of the results obtained to each one of the parameters evaluated.

Table 1. Results obtained

Collected data	Se (%)	Sp (%)	AUC	Kappa
(+) and (-) BI-RADS™ Reports	68	95.6	0.852	0.57
Presence of nodules	74	99.3	0.89	0.79
Presence of vascular calcifications	84	99.6	0.931	0.88
Presence of calcifications of benign aspect	92.2	96.3	0.951	0.89
Presence of axillar lymph nodes	92	98	0.959	0.91
Presence of intramammary lymph nodes	91	98.7	0.959	0.88
(+) and (-) BI-RADS™ Reports	68	95.6	0.852	0.57
Presence of nodules	74	99.3	0.89	0.79

This study made it possible to identify which is the pattern of breast that presents the highest difficulty in being analyzed by the residents. It was noticed that the detection of positive reports was a failed process, suggesting the little familiarity of the residents to the malign lesions. The results highlight the necessity to implement a training method which provides the resident with a better learning method when characterizing mammographic lesions, favoring the early detection of breast cancer.

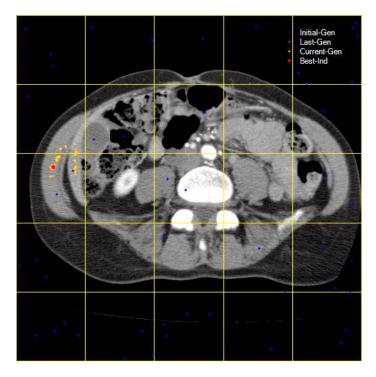

PS01.017 - Non-deterministic optimization using Differential Evolution algorithm to launch seeds for liver segmentation in MDCT

Author(s): Ricardo L. Thomaz¹, Rogério Anastácio¹, Tulio A.A. Macedo², <u>Ana Cláudia Patrocinio</u>¹, Alcimar B. Soares¹ ¹Faculty Of Electrical Engineering, Federal University of Uberlândia, Uberlândia/BRAZIL, ²Faculty Of Medicine, Federal University of Uberlândia, Uberlândia/BRAZIL

The automatic segmentation of liver in Multi Detector Computed Tomography (MDCT) is considered a complex task due to the similarity and proximity of the liver with other soft tissues. Although some techniques already achieve good results, their deterministic characteristic might prevent the feasibility of the algorithm in complex situations. Thus, this paper purpose the use of Differential Evolution (DE) as a non-deterministic evolutionary algorithm in order to optimize the launching of seeds for region growing segmentation algorithms. In order to achieve this goal, a fitness function, based on intensity, contrast, morphology and localization features of the liver, along with a full exam analysis methodology were developed. Ten MDCT exams were then submitted to the method, resulting in 7 exams with at least 85% of correctly seeded liver, as shown in the table below.

	Non-deterministic seed launching results								
Exams [#]	Slices [#]	Seeded [#]	False- Negative	False- Positive	Correctly Seeded				
1	118	072	0.00%	39.83%	60.17%				
2	376	158	0.26%	02.92%	96.82%				
3	210	163	5.24%	00.00%	94.76%				
4	366	172	0.55%	02.73%	96.72%				
5	611	386	0.00%	38.29%	61.71%				
6	385	385	0.00%	63.64%	36.36%				
7	521	191	1.15%	00.00%	98.85%				
8	501	260	0.20%	12.57%	87.23%				
9	476	193	1.47%	00.00%	98.53%				
10	094	067	7.44%	00.00%	92.56%				
Total	3658	2047	1.63%	15.99%	82.37%				

However, some exams presented high false-positive seeding due to the complexity of the images, such as the proximity of abdominal muscles near the end of the liver, as depicted in Fig. 1. In conclusion, the purposed use of DE has shown promising results on launching seeds inside the liver on MDCT images.

PS01.018 - Influence of ROI pattern on segmentation in lung lesions

Author(s): Marcelo L.N. Franco¹, Lara M. Nunes², Ana Paula P. Froner³, Ana M. Marques Da Silva³, <u>Ana Cláudia Patrocinio¹</u> ¹Laboratory Of Biomedical Engineering / Faculty Of Electrical Engineering, Federal University of Uberlândia, Uberlândia/BRA-ZIL, ²Biomedical Engineering Department / Faculty Of Electrical And Computer Engineering, State University of Campinas, Campinas/ BRAZIL, ³Graduate Program Of Electrical Engineering, Pontifical Catholic University, Porto Alegre/BRAZIL

The early diagnosis of lung cancer is critical in determining the chances of recovery and survival of patients. Sometimes the differences between malignant and benign tissues can be imperceptible to not trained human eyes, thus, a good diagnosis depends on radiologists ability.

Because of these facts, CAD systems have been designed to get features of lesions in digital images to report the probability of malignancy nodule. An important step of developing these systems is the nodule image segmentation. If segmentation does not provide satisfactory results, the descriptors used cannot describe the real features of lung tissue.

Considering the significance of segmentation step, this project aims to compare the results obtained by two segmentation algorithms: the first one consists basically in a selection of rectangular region of interest (ROI) followed by Otsu segmentation technique and the other added an elliptical ROI after applying Otsu technique, eliminating possible structures adjacent of lesion.

The images used in this project are from 22 CT exams (5088 slices) acquired at São Lucas Hospital (PCU-RS), all containing radiological report. All exams were analyzed to determine the extent of each lesion, reducing the number of images to be processed.

Then, the ROI was selected by 2 mouse clicks on the image: each one at one vertex of main diagonal of the desired rectangular region (ROI_R). Afterward, the one-threshold Otsu method was applied, segmenting the lesion. Finally, the elliptical region (ROI_c) is created

based on ROI_{R} shape and the location to cut the ROI is replicated for all slices on the even exam.

A planar morphological transformation with disc structuring element is applied on the image to define the extent of the lesion and all structure which had associated pixels less of 25% of all white pixels in the segmented image were eliminated.

On the segmented image, 11 geometric features have been extracted: area, perimeter, compactness, irregularity and 1 to 7 invariant moments of HU.

The difference between the two ways of ROI selection is shown by Fig. 1: on the left, there's a neighbor tissue seg-mented as part of lesion and on the right the lesion was completely separated from neighbor structures. Some of the descriptors showed statistical differences between measures made from nodules segmented with or without an elliptical ROI.

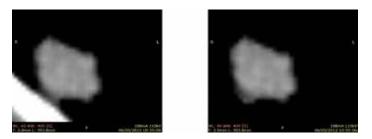

Fig. 1 Example of segmentation with ROI_{R} on the left and on the right the respective segmentation with ROI_{E}

PS01.019 - Comparison between Elliptical and Squared ROI to Launch an Automatic Seed to Region Growing Algorithm on Hepatic Segmentation using CT images

Author(s): Rogério Anastácio¹, Ricardo L. Thomaz¹, Cecília R. Moraes¹, Giulia C.M. Almeida¹, Taissa O. Ferreira¹, Murilo R. Cândido², Tulio A.A. Macedo³, <u>Ana Cláudia Patrocinio¹</u> ¹Faculty Of Electrical Engineering, Federal University of Uberlândia, Uberlândia/BRAZIL, ²Faculty Of Mathematics, Federal University of Uberlândia, Uberlândia/BRAZIL, ³Faculty Of Medicine, Federal University of Uberlândia, Uberlândia/BRAZIL

Early detection of liver cancer increases the survival rate by 60-70% in five years. As part of CAD development for the liver, two automatic seed selection techniques (for automatic liver segmentation using region growing technique) are compared, using the calculation of Mean Squared Error (MSE), to analyze which one has the lowest error when compared with manual segmentation.

It was used 2631 liver computer tomography slices, the first step is make the preprocess of these slices, that were submitted in the windowing CT and after it is applied a mean filter with the gamma transformation.

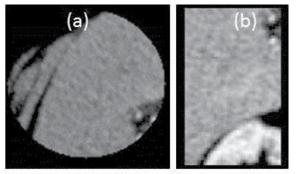

Figure 1 - ROI by two techniques: (a) SLEA, (b) SLSA.

The first technique defines the Seed Launch on Elliptical Area (SLEA), Figure 1(a), for find the seed point, and the second technique defines the Seed Launch into Square Area (SLSA), Figure 1(b), for find the seed point.

And the seed points that were found with each one of these techniques are used to perform the liver segmentation with the region growing algorithm, and from the liver segmented is performed the entire exam volume and the MSE calculation for each technique, and these results compared with the manual segmentation.

Thus the results of this process are in the Table 1, then the average liver volume measured manually was of 1,369.99cm³, and with SLEA technique the average liver volume measured automatically was of 1.625,62cm³ and the average MSE was of 65.49±94.12cm³, and for the SLSA technique the average liver volume measured automatically was of 1,643.23cm³ and the average MSE was of 181.48±281.39cm³. The smallest MSE SLEA was of 2.04cm³ and the bigger was of 391.82cm³, and for the SLSA the smallest MSE was of 2.122cm³ and the bigger was of 1,110.82cm³. It was observed that both techniques have the average volume similar, but the SLEA technique has the smallest values and averages of the MSE.

Table 1 - Volumes and MSE of exams, in cubic centimeter (cm²).

	Man. Segmentation		Automatic S	egmentation	
Exam	Volume	Group 1 (?	SLEA)	Group 2	(SLSA)
	volume	Volume	MSE	Volume	MSE

PS01.020 - Gd-based Nanoparticles Mediated Magnetic Field Enhancement Inside Homogenous Tissue: Simulation using Finite Element Method

Author(s): Sahar Rezaei¹, <u>Nader Riyahi-Alama¹</u>, Mohsen Ostovari² ¹Medical Physics And Biomedical Engineering Department, Tehran University of Medical Science, Tehran/IRAN, ²Medical Physics Department, Ahvaz Jundishapur University of Medical Science, Ahvaz, Iran, Tehran/IRAN

Tumor detection in the early stages is of outmost importance in cancer diagnosis and treatment. Magnetic resonance molecular imaging (MRMI) is a considerable medical imaging method to distinguish normal cells from cancerous cells initiating metastasis. Current MRI contrast agents are required to prevent adverse chemical activity in the body. Therefore, in conventional form of Gd-DTPA due to their relatively large size and coverage can be used only in extracellular spaces. Meanwhile, nanoparticles, because of their small size relative to the body cells, are capable of intrusion inside the cells. These materials can be used for molecular imaging; Gd based paramagnetic nanoparticles are the most widely used agents. In this paper, variation in external magnetic field as a result of using Gd-based nanoparticles in homogenous tissue was investigated with finite element method. To this end, simulations have been carried out in the presence of Gd nanoparticles and without them. This study indicated that magnitude of external magnetic field increases due to the presence of nanoparticles, and we compared the results with Vibrating Sample Magnetometer (VSM) results. In addition, Gd nanoparticles showed sigmoidal (superparamagnetic) behavior in both data set of simulation and VSM, applicable to normal cell uptake and so tumor cell tracking for cancer detection.

PS01.022 - Linear tomosynthesis with flat-panel detector for image guided radiation therapy

Author(s): Dong-Su Kim¹, Tae Ho Kim¹, Seong-Hee Kang¹, Kyeong-Hyeon Kim¹, Min-Seok Cho¹, Siyong Kim², <u>Tae-Suk Suh¹</u> ¹Biomedical Engineering And Research Institute Of Biomedical Engineering, College Of Medicine, The Catholic University of Korea, Seoul/KOREA, ²Radiation Oncology, College Of Medicine, Virginia Commonwealth University, Richmond/UNITED STATES OF AMERICA

In this study, we propose a novel imaging technique using linear tomosynthesis with flat-panel detector that can product tomographic images at arbitrary anterior-posterior depth position for image guided radiation therapy. To verify the usefulness of the imaging performance, we performed systematic simulation studies for simple linear movement of a couch with digital phantoms in several layers along the coronal direction. Projections were acquired at specific position through the calculated proper shift amounts for particular or multi-focal level imaging. The linear tomosynthesis images were reconstructed by shift-and-add (SAA) method. Furthermore, to increase blurring effect of out-focal objects in the image, we investigated a subsidiary technique that used sections of extra detector pixels along the anatomical axis. According to our preliminary results, a designed specific coronal plane was well focused with good image sharpness and multi-focal image layers were realized with the proposed method. We have also derived the thicknesses of the focused image layer as functions of the number of pixels used in focal or out-focal section of the pixel array. Our results showed that defined plane-of-interests were well focused with image sharpness and the position of image layer center was adjusted precisely with proper shift amounts in the linear motion tomosythesis. We expect that the proposed method will be very useful for accurate localization with less dose than other imaging modality such as cone-beam computed tomography.

PS01.023 - Evaluation of image quality and dose for digital breast tomosynthesis (DBT) using a semi-analytical model Author(s): <u>Alessandra Tomal</u>¹, Martin E. Poletti²

¹Departamento De Física Aplicada, Universidade Estadual de Campinas, Campinas/BRAZIL, ²Universidade de São Paulo, Ribeirão Preto/BRAZIL

Digital breast tomosynthesis (DBT) is a 3-D imaging technique that has higher sensitivity and specificity, compared to mammography, for early diagnostic of breast cancer, with a similar radiation dose. The risks associated with the DBT examination is evaluated with respect to the mean glandular dose (MGD), determined from air kerma measurements and specific normalized glandular dose factors. The image quality can be evaluated by means of the contrast-to noise ratio (CNR) and artifact spread function (ASF) In this work, we describe semianalytical models, which were developed to study the MGD, CNR and ASF in DBT, by determining the deposited energy in single and double interactions and the intensity of transmitted radiation. The semi-analytical model was used to study the dependence of these quantities with different projection angle, different breast thicknesses and glandularities. The anode/filter combinations evaluated were: Mo/ Mo, Mo/Rh and Rh/Rh, and a W anode combined with K-edge filters (Zr, Mo, Nb, Ru, Rh, Pd, Ag, Cd, In and Sn), for tube potential between 23 and 35 kV. Results demonstrate that the normalized glandular dose decreases up to 25%, as the projection angle increases, being this decrease most pronounced for thicker and denser breasts. A decreasing in the CNR and ASF values was observed as the angular range decreases. Besides, it was observed variations up to 70% on the MGD and CNR with the x-ray spectra and breast characteristics (composition and thickness). The ASF is almost independent on the x-ray spectra. Finally, it was verified that the semianalytical models developed in this work provided results of image quality and dose parameters in DBT in a fast and simple way, with a good agreement with those or by MC simulation (discrepancies lower than 10%).

PS01.024 - Optimization of acquisition parameters of the test of an overall SPECT/CT system performance.

Author(s): <u>Piotr Tulik</u>¹, Monika Tomaszuk², Paulina Wojcik¹, Alicja Hubalewska-Dydejczyk³, Anna Sowa-Staszczak²

¹Institute Of Metrology And Biomedical Engineering, Warsaw University of Technology, Faculty of Mechatronics, Warsaw/POLAND, ²Nuclear Medicine Unit, Department Of Endocrinology, University Hospital in Krakow, Krakow/POLAND, ³Department Of Endocrinology, Jagiellonian University Medical College, Krakow/POLAND

An overall SPECT/CT system performance test provides the most comprehensive information about a long term stability of an uniformity and resolution of gamma camera installed in a clinic, but its conducting is time consuming. The recommended frequency of the test and manner of its implementation varies between different countries and nuclear medicine departments. Different acquisition parameters for this purpose are proposed by NEAM, IAEA report #6 and AAPM report #22. The question arises how to get an image with the best quality, in the least amount of time. Is it possible to decrease the time needed for an overall SPECT/CT system performance test execution and in consequence being able to perform it more often in the clinic, but not to compromise with the requirements of recommendations on the quality of the observed image? The purpose of this study was to present the process of optimizing of acquisition parameters of an overall SPECT/CT system performance test, which could be implemented in each nuclear medicine department.

All measurements were performed with the use of Symbia T16 SPECT/CT (2010, Siemens). The Jaszczak SPECT phantom with cold spheres provided for high-resolution gamma cameras filled with 740MBq of ^{99m}Tc was used.

The influence of the duration of a single projection (10, 15, 20, 25, 30, 45, versus 60 sec per projection), the number of projection (64, 96 versus 128 projections in a full 360-degree rotation) and the size of acquisition matrix (64x64 versus 128x128) on the quality of the resulting image were analyzed. The scans for each combination of the parameters were performed three times with two exceptions. The study with 30 sec per projection, 128 projections and 128x128 matrix were chosen to be a reference (in accordance with IAEA recommendations and additionally a standard protocol for clinical applications in the Department). All images were subjected to visual evaluation (uniformity and spatial resolution) by 2 experienced medical physicists. Quantitative evaluation of image contrast was performed with the use of Mann-Whitney nonparametric test. Each SPECT image was evaluated with and without attenuation correction, but always with scatter correction.

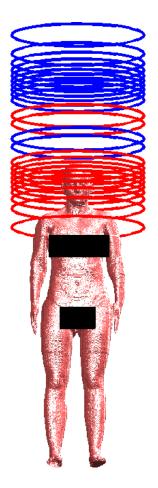

The proposed process of an evaluation of the parameters that are crucial for the image quality in nuclear medicine gave a possibility to identify the optimal acquisition parameters for considered test. Image, indistinguishable from proposed reference, but acquired in the half of time (decrease from 32 min for 16 min, respectively), was obtained with the following parameters: 30 sec per projection, 64 projections and 128x128 matrix size, with the use of attenuation correction. Reduction of the duration of a single projection, and especially the size of the matrix, or lack of AC, deteriorated image quality. An increase of the duration of a single projection over 30 sec did not bring a significant improvement of image quality, but increased the duration of the test.

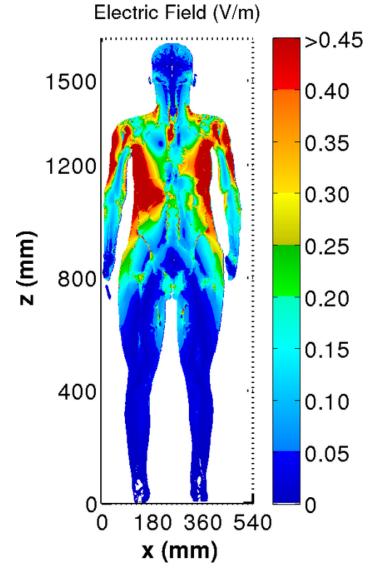

The methodology of optimization of acquisition parameters for an overall SPECT/CT system performance test has been presented for Symbia T16 SPECT/CT system in terms of time of a single acquisition and quality of acquired images.

PS01.025 - Dosimetric Analysis of Patient to a Z-Gradient Coil in Head Magnetic Resonance Imaging Author(s): Mai Lu¹, Shoogo Ueno²

¹Key Lab. Of Opt-electronic Technology And Intelligent Control Of Ministry Of Education, Lanzhou Jiaotong University, Lanzhou/CHI-NA, ²Department Of Applied Quantum Physics, Graduate School Of Engineering, Kyushu University, Fukuoka/JAPAN

In magnetic resonance imaging (MRI), magnetic field gradient coils are commonly switched at low frequency of around 1 kHz or so. Time-varied gradient magnetic fields may stimulate nerves and muscles by inducing electric fields and currents in patients, which may potentially cause health problem. The International Commission on Non-Ionizing Radiation Protection (ICNIRP) has set international guidelines for limiting the exposure. For the working frequency of 1 kHz, the ICNIRP guidelines define the reference level (RL) as 80 µT, and the basic restriction in both CNS and body tissues as 0.4 V/m. The guidelines require that the basic restrictions are not exceeded at any time. In this study, a 3D human body model i.e. the patient as shown in Fig.1 was placed in a z-gradient coil for simulating the head MRI exam. A realistic cylindrical z-gradient coil with 24 circular rings has been numerically designed. The time variation of the applied magnetic field causes induced electric fields in the body through Faraday's induction mechanism, and can be calculated by the impedance method. The electrical properties are modeled using the 4-Cole-Cole method and can be obtained by fitting to experimental measurements. The induced electric fields in all CNS tissues have been averaged over a volume of 2mm x 2mm x 2 mm , and the 99th percentile value of the averaged field strength were compared with the ICNIRP basic restrictions. Fig. 2 shows the typical slice of the induced electric fields within the coronal plane. The spatially averaged magnetic flux density was found to be approximately 9.49 times the ICNIRP reference level, and the maximum value of the induced electric fields in CNS was found to be 5.95 times the ICNIRP basic restriction.

PS01.026 - A Novel Optical System for Contrast Enhancement in Histological Plates to Be Processed Digitally

Author(s): <u>Rubiel Vargas-Canas</u>¹, Jorge Cortez¹, Jairo A. Vasquez-Lopez²

¹Physics, Universidad del Cauca, Popayan/COLOMBIA, ²Morphological Sciences, Universidad del Cauca, Popayan/COLOMBIA

For many decades, visualization of histological samples was performed using a contrast media (stain) in order to visually enhance relevant details of tissue structures that characterize a histological tissue. However, so far, there is no perfect dye or staining technique that allows visualization of all relevant details in a histological preparation because it depends on the type of dye and chemical affinity with tissue. Additionally, chromatic changes such as low contrast resolution or excess dye in the tissue are presented as a result of the misuse of the staining technique. On the other hand, nowadays, histological images can be digitally processed to obtain a variety of information, including: classifying textures, glands segmentation and identification, and nuclei and cell counting. Nevertheless, in order to perform digital processing in an efficient manner and to obtain reliable results, images must have high quality and meet certain conditions, such as uniform colouring and a good difference in contrast.

In this paper, a novel methodology to improve visualization of histological samples is presented. It uses previously calculated colour lighting to illuminate the sample. Colour is calculated using feature lighting and a physical-mathematical model based on RGB and HSI colour spaces; this lighting differs from the white light conventionally used in optical microscopes. Because of the aim is to increase contrast in the area of interest, this development is based on the complementary colour theory, which states the following: "Each colour which allowed the painters' primaries (red, yellow, blue) to be arranged opposite their complementary colours (e.g. red opposite green), as a way of denoting that each complementary would enhance the other's effect through optical contrast. ", or expressed in other words, complementary colours enhance contrast to maximum each other, which is ultimately what we want to observe in a histological preparation.

The proposed technique was tested subjectively and quantitatively, first, by measuring intra- and inter-observer variations after observing morphological patterns by the histologist and pathologists, second, quantitative assessment of histological image after segmenting areas of essential interest for establishing diagnosis more objectively. With the development of the proposed digital optical system, contrast, within different areas of interest in a tissue sample, both visually and through computer vision techniques, is automatically increased, so digital images can be processed more comfortably. The implementation of this technique will reduce time and cost of examinations such as tissue biopsies, facilitate diagnostic evaluation by pathologists and will reduce the waste of histological material; which will end in to benefit the most important person in the process of health care: the patient.

PS01.027 - Pixel-based dynamic contrast-enhanced CT study with low temporal resolution

Author(s): Sun Mo Kim¹, Michael Milosevic², Masoom A. Haider³, Ivan Yeung⁴, David Jaffray¹

¹Radiation Physics, Princess Margaret Cancer Centre, Toronto/ON/ CANADA, ²Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/ON/CANADA, ³Medical Imaging, Sunnybrook Health Sciences Centre, Toronto/ON/CANADA, ⁴Radiation Physics, Princess Margaret Cancer Centre, Toronto/CANADA

Purpose: In dynamic contrast enhanced CT (DCE-CT) study, a CT scanning with high temporal resolution is necessary to obtain accurate kinetic parameter values, but such scanning scheme substantially increases the radiation dose to the patient. A method of principal component analysis (PCA) filtering combined with the arterial input function (AIF) estimation technique is proposed to reduce patient radiation dose, while maintaining high accuracy of kinetic parameter estimates in a pixel-by-pixel analysis of DCE-CT data acquired at a low scanning frequency.

Methods: With the coarsely sampled AIF of a patient, an AIF in high temporal resolution can be generated by using the previously published technique which uses the orthonormal bases of the arterial impulse responses (AIR) extracted from a cohort of 34 patients with cervical cancer. In addition, principal component analysis (PCA) filtering was applied to the tissue curves of all the pixels in a region of interest to increase their signal to noise ratios (SNR). The proposed method was applied to each DCE-CT data set of a cohort of 14 patients at varying levels of down sampling schemes between intervals from 2 to 15 s. Subsequently, the kinetic analyses using the modified Tofts' model and singular value decomposition (SVD) method were performed for each of the down-sampling schemes. The results were compared with analyses done with the measured data in high temporal resolution (i.e. original scanning frequency) as the reference.

Results: The results of kinetic analyses using the proposed method compared with down sampling alone showed that the method is superior in maintaining the accuracy in the quantitative histo-

gram parameters of volume transfer constant (standard deviation (SD), 98th percentile, and range), blood volume fraction (mean, SD, 98th percentile, and range), and blood flow (mean and median) for longer sampling intervals between 10 and 15 s. The preliminary results suggest that the method is able to support the longer scanning intervals at a cost of 8.4%–20.5% loss in accuracy of the histogram parameters for volume transfer constant and 6.9%–18.2% for blood volume fraction, and 5.9%–8.7% for blood flow.

Conclusion: The radiation dose to patient during a DCE-CT study can be reduced by up to a factor of 15 with the proposed method of PCA filtering combined with the AIF estimation technique. The results indicate that the method is useful for pixel-by-pixel kinetic analysis of DCE-CT data for patients with cervical cancer.

PS01.028 - Method for restoring CT images obtained at low doses.

Author(s): David Adame Brooks¹, Rafael A. Miller-Clemente¹, <u>Marlen</u> <u>Perez-Diaz²</u>

¹Group Of Radiation Medical Physics, Biofísica Médica, Santiago de Cuba/CUBA, ²Study Center On Electronic And Information Technologies, Universidad Central "Marta Abreu"de las Villas, Santa clara/ CUBA

The advent of computed tomography (CT) has revolutionized diagnostic radiology. Since its inception in the seventies, its use has grown rapidly and has become the technique of choice for a wide range of indications, due to the timely and reliable diagnostic information it provides. However, despite clear evidence that CT provides valuable information for the diagnosis and treatment of the patient, there is a potential risk for the use of ionizing radiation. The benefit of an accurate diagnosis and timely justifies the use of this technique. Despite this, it's important to reduce radiation doses particularly in children and young patients that if they are exposed to these multiple times radiation during their lives may accumulate a significant dose of ionizing radiation, which in turn could lead to an increased risk. In TC, there is a compromise between image quality and dose of ionizing radiation. The problem is that by reducing the radiation dose in CT, the amount of noise in the images is increased. This is because the scanner detectors are fewer photons, which decreases the signal to noise ratio.As consequence, the noise can hide anatomical detail and decrease the detection of lesions with low contrasts. At very low doses, can also exacerbate undesirable effects on images, such as artifacts. To reduce the noise in images have been proposed different algorithms and mathematical methods. Among these are algorithms that directly filtered X-ray projections or reconstructed images. Process the reconstructed images instead of the projections has practical advantages: the images are available to any user, the methods are applicable to any type of scanner regardless of the manufacturer and usually do not demand high performance computing capacity. We proposes a method , which takes as a basis the bilateral filter theory with some changes to improve efficiency and add a component, the separation in frequency bands; to combine the images of high and low frequency after being filtered by the bilateral filter. In our case we use three filter functions most used in the image processing in the domain of the frequencies, the ideal, Butterworth and Gaussian filter, also add the use of an edge operator to improve contrast and highlight the edges of the anatomical structures. Our preliminary results suggest that it is possible to reduce the noise in at least one 30 to 50%. The studies with mathematical observers revealed that our method can decrease the noise of images and even guarantee a diagnostic quality suitable for the diagnosis that could result in the reduction of the dose of radiation.

PS02 - TRACK 02: BIOMATERIALS AND REGENERATIVE MEDICINE

PS02.001 - Chitosan: A Chitinous Biopolymer For The Treatment Of Crude Oil Polluted Water

Author(s): <u>Eillen E.C. Agoha</u>, C Atowa, Fatima Okafor, C.A. Ozodigwe

Food Sciences And Technology, Abia State University, Uturu,, Uturu/NIGERIA

The level of crude oil pollution of Taabaa village stream in Ogoni, Rivers State, Nigeria and the effectiveness of snail shells waste chitosan in the treatment of crude oil polluted water were investigated. Triplicate samples of crude oil polluted water were treated with varying concentrations (0.1,02 and 0.3 mg/L) of chitosan. Results indicated that untreated crude oil polluted water samples had a brown colour, hydrocarbon taste and odour and a high turbidity value of 17.00 units Hazen. The water also contained high levels of lead (0.10mg/L), arsenic (0.34mg/L), and iron (0.84mg/L), and had a total plate count of 31OCfU/mL, coliform count of 150CFU/mL and E. coli count of 25CFU/mL, Chitosan treated water sample was clear, colourless, tasteless and odourless with a 100% reduction in turbidity. Chitosan treatment at 0.1, 0.2 and 0.3mg/L concentrations produced 80 and 90% reductions in lead and reduced the arsenic content from 0.34mg/L to 0.04mg/L. Similarly, chitosan treatment produced

100% reduction in *E. coli*, while the total plate and coliform counts were reduced to WHO acceptable levels. The results showed that the Taabaa village stream was highly contaminated with crude oil and also indicated the potential use of chitosam in the treatment of crude oil polluted water

PS02.002 - Temperature of ice formation affects integrity of alginate 3D constructs after cryopreservation

Author(s): Oleksandr Gryshkov, Lothar Lauterboeck, Nicola S. Hofmann, <u>Birgit Glasmacher</u>

Leibniz University Hannover, Institute for Multiphase Processes, Hannover/GERMANY

Introduction

Cryopreservation is the one available method for long-term preservation of rare cell types. Application of alginate encapsulation may improve cell viability by protecting the encapsulated cells from the ice re- crystallization and osmotic stresses upon freezing and thawing. This work explores the effect of the temperature of extra-cellular ice formation on the integrity of alginate beads.

Methods

The alginate beads with a diameter of 300 μ m were generated using the high voltage encapsulation method [1]. After encapsulation and cross-linking for 15 min or 45 min, the alginate beads were re-suspended in cold culture medium (0.5 ml, 4°C). The double-concentrated cryomedium containing 5/10/15/20% (v/v) dimethyl sulfoxide and 20% (v/v) fetal bovine serum was added (0.5 ml) and the beads were equilibrated at 4°C on ice for 15 min or 45 min. Afterwards, the sample was transferred onto a quartz dish, covered with a cover slip and placed into the Linkam cryostage (FDCS 196, Linkam, UK). The following protocol with no active control over the temperature of ice formation was used: cooling rate -1 K/min from 4°C to -20°C, equilibration at -20°C for 5 min with further thawing from -20°C to 4°C with 100 K/min.

Results

The cryomicroscopy results showed that the application of 2.5%, 5%, 7.5% and 10% DMSO with pre-freezing DMSO loading intervals (15 min, 45 min) influenced differently the integrity of alginate beads post-thawing (Figure 1). The temperature of ice formation also affected the integrity of the alginate beads after thawing. The formation and further growth of specific ice crystals at higher temperatures (-12.8°C) caused mechanical rupture of alginate beads. In addition, the temperature of spontaneous ice formation varied from -12.8°C to -19.2°C.

Figure 1. Analysis of freezing/thawing of alginate beads via cryomicroscopy for 10% (v/v) DMSO and 15 min of pre-freeze loading interval. Scale bar is 100 μ m.

Conclusions and outlook

In this study it was found that the temperature of ice formation is one of the main factors affecting integrity of alginate beads after thawing. Further work will be performed to study the effect of ice formation temperature on the encapsulated cells functionalities after thawing.

PS02.003 - Influence of proteins on magnesium in vitro degradation

Author(s): Ana Silva¹, Florian Evertz¹, Sara Knigge¹, Muhammad I. Rahim², Peter P. Mueller², Hans J. Maier³, <u>Birgit Glasmacher¹</u> ¹Leibniz University Hannover, Institute for Multiphase Processes, Hannover/GERMANY, ²Helmholz Centre For Infection Research, Helmholz Centre for Infection Research, Braunschweig/GERMA-NY, ³Leibniz University Hannover, Institute of Material Science, Garbsen/GERMANY

Introduction

Magnesium is studied as a biomaterial for nonpermanent biomedical implants. Our study is focused on magnesium *in vitro* degradation. Extensive *in vitro* experiments in a simulated physiological environment have been carried out to investigate the influence of proteins on the degradation rate in order to create a protein coating that prevents the fast initial corrosion and decreases the whole corrosion rate during the implantation period, which is the major problem of the use of magnesium and its alloys as biomedical implants.

Methods

Pure magnesium samples and samples of pure magnesium coated with bovine serum albumin were analyzed. In our experiments we used porcine plasma and a simulated body fluid (r-SBF) as corrosion fluids, to test the influence of proteins. Thus, we want to be able to compare the results with the *in vivo* experiments. The *in vitro* degradation studies were done in static conditions and therefore the samples were immersed in each model fluid in 6-well-plates and placed in the incubator in a 5% CO₂ atmosphere at a temperature of 37° C. The magnesium concentration released in the fluid test during the experiment was measured photometrically and the pH was

controlled regularly. The mass loss was also calculated and for that the samples were treated with chromic acid, following the ASTM-Standard G1-03 protocol, in order to remove the oxide layer and weighted after that. SEM/EDX-Analyses were also performed.

Results

Our results show that the degradation rate depends directly on the composition of the fluid which is used we revealed that the coating and the addition of proteins have a significant influence on the degradation rate. An increase on magnesium concentration can be seen in all cases for the initial days. However, a lower initial corrosion has been observed for the coated samples, either in plasma and r-SBF.

Conclusion

The value of the degradation rate for pure magnesium in plasma is much lower than in SBF's. However in the case of the r-SBF when the samples are coated with proteins the degradation rate decreases. These studies show a slower and decreased degradation of magnesium coated samples, leading to a positive influence from proteins on corrosion prevention.

PS02.004 - Electrospinning of vascular prostheses with antikinking properties

Author(s): Michael Bode, Marc Mueller, Holger Zernetsch, <u>Birgit</u> <u>Glasmacher</u>

Leibniz University Hannover, Institute for Multiphase Processes, Hannover/GERMANY

Introduction

One of the major challenges in developing appropriate vascular substitutes is to produce a graft that adapts to the biological and mechanical conditions at the graft site. One approach is the use of electrospun grafts pre-seeded with autologous cells using methods of tissue engineering. When transplanted in a graft site with high deformation, stiffness of the graft leads to kinking which may result in vascular obliteration. The aim of this study was to develop an electrospun vascular graft consisting of biodegradable polymers which additionally possesses a high flexibility to avoid kinking.

Methods

In order to improve the bendability of the grafts, various collectors with different geometries were structured using six different patterns (30°-, 60°-, 90°-, 120° V-thread, knuckle thread and acme thread). Subsequently, the grafts were examined with regard to fiber deposition, mechanical strength and bendability.

Results

It was shown that using a collector structured with a V-shaped thread (flank angle of 120°) leads to a homogenous and reproduceable fiber depostion. The results of the tensile tests were comparable to the unstructured reference sample, proving the first observation. Studies on bendability were performed using a custom made flow-bending test setup. It was shown that the flow through the V-shaped grafts reduced to less than 45 % of the reference value even after bending the graft to an angle of 140° (Figure 1). Compared to this, the flow through an unstructured graft reduced to more than 50% after bending to an angle of 55°.

Conclusion

The presented data, which were obtained with the developed flowbending test setup demonstrate the need for optimizing the bendability of the commonly used electrospun vascular grafts. In this regard a macroscopic v-shaped engineered collector seems to be a promising method to overcome the issue of graft kinking.

Figure 1 Comparison of two samples with diffent surface structures. Unstructured reference sample at 40° bending (A). Pleated sample with 120° V-thread at 90° bending (B).

PS02.005 - Electrospinning of polycaprolactone/chitosan polymeric fibrous membranes as scaffolds for cardiovascular tissue engineering applications

Author(s): Alexandros Repanas, Fedaa Al Halabi, Marc Mueller, Holger Zernetsch, <u>Birgit Glasmacher</u> Leibniz University Hannover, Institute for Multiphase Processes, Hannover/GERMANY

Introduction

Cardiovascular diseases only in the USA account for more than 30% of all deaths with costs exceeding 300 billion dollars, according to the 2013 American Heart Association report [1]. While heart transplantation is the only cure for end-stage heart failure there is need for new strategies to develop materials that can support cell repopulation and functionality recovery. Electrospinning is a facile and cost-effective technique that can produce biocompatible structures to serve as extracellular matrix (ECM)-like scaffolds where cells can be seeded and proliferate eventually forming a hybrid bio-artificial tissue [2]. Fibrous mats, tubes and more complex 3D shapes can be successfully engineered not only to induce cell proliferation but also to release in a controllable manner biomolecules (e.g. proteins, growth factors) that can further support tissue formation [3].

Materials & methods

Polycaprolactone (PCL) and chitosan (CS) were dissolved in 99,8 % 2,2,2-Trifluoroethanol (TFE) at concentrations of 190 mg/ml and 10 mg/ml respectively. The solution was stirred at room temperature for 24 hours. Electrospinning was performed at a custom made apparatus with flow rate of 4 mL/h and electrical field of 1 kV/cm. Morphology of the fibrous scaffolds was examined by scanning electron microscopy (SEM) having previously been sputter-coated with gold. Cyclic sinusoidal uniaxial mechanical tests were performed with an electroforce tensile testing instrument by BOSE, equipped with a 200 N load cell. Rectangular, 15x10 mm strips were cut and tested at 0-20% strain, 1 cycle/sec, RT, dry conditions. Young's modulus was calculated from the linear phase of the stress-strain plot and hysteresis ratio from the area between the loading and unloading steps of each cycle. Static water contact angle experiments were performed to study the physical behavior of the fibers' surface. Chemical characterization including Fourier-Transformed Infrared Spectroscopy (FTIR) and X-rays diffraction (XRD) was carried out in order to determine the physicochemical state of the polymers in the fibers.

Results and Discussion

Structural and morphological analysis indicated that the created fibers have a smooth, "spaghetti-like" shape with an average diameter of 1.098 $\pm 0.52 \mu m$ and random orientation. The average value of Young's modulus was 10 ± 5 MPa and the hysteresis ratio 0.35

 ± 0.07 revealing the viscoelastic nature of the fibers. The surface of the fiber-mats can be considered relatively hydrophilic as the static water contact angle was 70 \pm 5 °. FTIR and XRD data lead to the conclusion that PCL and CS interact in the blend, possibly forming non-covalent bonds with PCL being in a semi-crystalline state and CS in an amorphous form in the fibers.

PS02.006 - Coaxial electrospinning of piezoelectric PVDF/PCL scaffolds for nerve regeneration

Author(s): Fedaa Al Halabi, Alexandros Repanas, Sara Knigge, Birgit Glasmacher

Leibniz University Hannover, Institute for Multiphase Processes, Hannover/GERMANY

Introduction

In neural tissue engineering piezoelectric polymers are being investigated as potential scaffolds for supporting nerve regeneration processes. A promising material is Polyvinylidinefluoride (PVDF) because of its proven biocompatibility and piezoelectric properties, which can possibly stimulate cell ingrowth with its electrical activity upon mechanical deformation [1]. This work reports the coaxial electrospinning of Polyvinylidinefluoride (PVDF) and Polycaprolactone (PCL) core/sheath nanofiber mats in order to enhance the mechanical and physical properties of the PVDF fibers.

Experimental methods

Coaxial electrospun scaffolds were produced from PVDF 20% dissolved in N,N-dimethylformamide and acetone (4:1) as a core and PCL 170 mg/ml dissolved in Tetrafluoroethylene as a sheath. In the electrospinning process flow rates of 0.5 ml/h for the core and 1 ml/h for the sheath and voltages of 22 kV were applied to produce defined fibers. The structures of the PVDF/PCL scaffolds were observed and analyzed with SEM to determine their morphology and fiber diameter. The mechanical properties of the scaffolds were tested using a tensile testing machine (BOSE-Electroforce-LM1-Test-Bench). To determine the configuration of the core/sheath structure in the coaxially electrospun scaffolds and their piezoelectric properties the scaffolds were compared with untreated/raw PVDF pellets with respect to the presence of the nonpolar a-phase and piezoelectric polar β-phase by using FTIR and DSC. The contact angles of the scaffolds surfaces were measured using deionized water. Subsequently All results were analyzed and evaluated comparing with single-jet electrospun PVDF scaffolds.

Results

Coaxial electrospun PVDF/PCL Scaffolds exhibited a higher tensile strength of 1.9 MPa and strain at break of 130 % as compared with the maximum tensile strength of the single-jet electrospun scaffolds of 138 kPa with 75 % elongation at break. The PCL layer increases the hydrophilic property of the coaxial PVDF/PCL scaffolds, which could enhance the adhesion and proliferation of the neural cells on

the scaffolds. Similar to single-get Electrospinning of PVDF scaffolds, the coaxial PVDF/PCL scaffolds resulted in a polar β -phase formation, which is relevant for the piezoelectric effect, and showed a β -phase adsorption ratio of 53% at 841 and 1277 cm⁻¹ in the FTIR-spectrum.

Conclusion

This study shows the ability to produce coaxial nanofibers of PVDF and PCL with better mechanical and physical properties. The FTIR and DSC results demonstrate the piezoelectric effect of the coaxial PVDF/PCL scaffolds. Next steps will be carrying out in vitro and in vivo experiments to evaluate the cytotoxicity of the coaxial scaffolds and to investigate the neural cells culturing on the piezoelectric PVDF/PCL scaffolds.

PS02.007 - Bio rapid prototyping project: Evaluation of spheroid formation for cells construct

Author(s): <u>Takeshi Shimoto</u>¹, Satoru Ikebe², Atsushi Ishikawa², Hidehiko Higaki², Shizuka Akieda³, Koichi Nakayama⁴, Shuichi Matsuda⁵, Hiromasa Miura⁶, Yukihide Iwamoto⁷ ¹Fukuoka Institute of Technology, Fukuoka/JAPAN, ²Kyushu Sangyo University, Fukuoka/JAPAN, ³Cyfuse Biomedical K.K, Tokyo/JA-PAN, ⁴Saga University, Saga/JAPAN, ⁵Kyoto University, Kyoto/JA-

PAN, *Saga University, Saga/JAPAN, *Kyoto University, Kyoto/JA-PAN, [®]Ehime University, Ehime/JAPAN, ⁷Kyushu University, Fukuoka/ JAPAN

In the field of regenerative medicine, 3-D tissue engineering, which intends to regenerate lost tissues and organs, is mainly focused. Formation of a 3-D construct outside the body has already been attempted by using combination of three elements, cells, growth factors or genes, and scaffold. We have already established a technique to make a 3-D construct only with cells. However, these constructs are usually made by skilled technicians who are familiar with cells, reagents, and cells culture methods. Therefore, we are developing a cell processing robot for regenerative medicine.

Cells construct is made by spheroid-culturing the cells and neatly arrange the spheroids. Therefore, quality of spheroids is important. The spheroids are manufactured by dispensing cell turbid liquid into a special multiwell plate. If there is a difference in the number of cells when dispensing the cells turbid liquid, spheroids in different sizes are generated. Moreover, spheroids are not generated if the number of cells is extremely small, and if large, spheroids in distorted shapes are generated. Therefore, this study was aimed to evaluate spheroids formation.

In this study, operations was performed by non-skilled technician and skilled technician. We used MSC (Mesenchymal Stem Cell) harvested from a Japanese white rabbit. Cultures of MSC were carried out on the culture dishes (Φ 150 mm, H25 mm, FALCON). Upon reaching the required number of cells, they were dispensed into the special multiwell plate for forming spheroids can generate 96 spheroids per plate. Cell number of a spheroids was set at $2*10^4$, $3*10^4$, $4*10^4$, $5*10^4$, $6*10^4$ and $7*10^4$, were taken by the camera every 24 hours. We analyzed the quantitative evaluation, i.e., area, diameter and degree of circularity, with the images of spheroid.

The result of the experiment was that there are difference in the spheroids created by non-skilled technician and skilled technician. The handwork was conducted by a skilled technician and there was no failure in the spheroid generation. However, when it was conducted by a non-skilled technician, sometimes resulted in failure. This case could have happened because the cells were exposed to the external air for a long time or the pipettes were erroneously operated and resulted in the occurrence of contamination, death cells, or no uniform works. Incidentally, the size of spheroids formed by the number of cells was different. In particular, it was found that there is a range of cell number to form spheroids with high degree of circularity. Therefore, by adjusting the number of cells, it may be possible to control the size of the spheroids.

We are performing the development of a spheroid building system. In spheroid exfoliation by pipetting or stirring of cells turbid liquid, it is necessary to reconstruct the motions of skilled technicians with specialist knowledge and technique so as not to damage the cells. Therefore, by the system reproduces techniques of the skilled technicians, we can obtain the spheroids uniformity, and can adjust the size of the spheroids.

PS02.008 - Scaffold Prototype for Heart Valve Tissue Engineering: Design and Material Analyses

Author(s): <u>Marcia M.O. Simbara</u>, Ronny C. Carbonari, Sônia M. Malmonge

Biomedical Engineering, Universidade Federal do ABC, Santo Andre/BRAZIL

Cardiac valves are specialized structures that ensure unidirectional flow through the heart. The aortic valve is the most frequently diseased and substituted. The current alternatives have reached a satisfactory level, but they still have their limitations, the most relevant one being the inability to remodel and grow, a critical problem especially for pediatric patients. Tissue engineering is expected to be the ultimate solu-tion to this, for it creates viable structures. The aim of this work is to propose a scaffold prototype for heart valve tissue engineering using bioresorbable polymers and analyze its design and materials through computational analyses. The scaffold design was based on existent biological valves and a 3D model was build using SolidWorks 2008. Poli(3hydroxybutyrate-co-valerate) (P3HBV), poli(L-lactic acid) (PLLA) and poli(ɛ-caprolactone) (PCL) were submitted to tensile tests in order to obtain their mechanical properties. The data collected was used to perform the computational simulation using ANSYS. The parts of the prototype were built using compression molding and airbrushing techniques. Results show that the designed geometry and the materials chosen allow the scaffold to withstand the stresses which they are subjected to. Also, the techniques chosen were indeed adequate for the manufacturing of the prototype, resulting in a very resistant structure. Some adjustments can and will be made in order to optimize mechanical behavior, but generally the scaffold seems to be adequate for heart valve tissue engineering.

PS02.009 - Unidirectionally-frozen silk/gelatin scaffolds for cardiac tissue engineering

Author(s): Maria Christine T. Asuncion, James Cho-Hong Goh, <u>Siew-Lok Toh</u>

Biomedical Engineering, National University of Singapore, Singapore/SINGAPORE

On a global scale, cardiovascular diseases (CVDs) remain to be the leading cause of death. Not only a pathological problem for the patient, CVDs are also an economic burden due to the prescribed maintenance medication and resulting decrease in physical productivity of the patients. One of the most common CVDs is the narrowing of the coronary artery that leads to ischaemia and tissue necrosis. Due to the heart's limited capacity to regenerate, heart transplants have long been the gold standard if a full functional restoration of the organ is desired. However, organ donor shortage and transplant rejection remain as challenges faced by heart transplants, making a tissue engineering strategy a more promising alternative. In this study, unidirectional freezing was achieved using a custom mold, and together with freeze-drying to fabricate a silk fibroin/gelatin-based scaffold with an aligned structure in an effort to mimic the natural anisotropy of cardiac tissue. Silk fibroin was chosen for its biocompatibility, biodegradability, low immunogenicity and good mechanical strength. Gelatin was added to enhance cell attachment to the scaffold. Scaffold morphology transitioned from an isotropic structure to an aligned structure as the freezing temperature was decreased, whereas pore morphology transitioned from an elliptical shape to a lamellar shape. Average pore size for the aligned scaffolds decreased as the freezing temperature decreased. All scaffolds exhibited a high degree of swelling with magnitudes of 656-700%. Cell viability and attachment was also investigated. The application of the aligned silk/gelatin scaffold as a cardiac patch is the objective of future studies. Although unidirectional freezing has been explored in previous investigations, its application as a cardiac patch has received little attention as of yet. It is hypothesized that the structural anisotropy of the scaffold will help promote differentiation of stem cells into a cardiomyogenic lineage without further external stimuli.

PS02.010 - Engineering Mesenchymal Stromal Cells (MSCs) to be More Immunoevasive by Altering Cell Culture Conditions Author(s): Shashank Bhatt¹, Armand Keating², <u>Sowmya Viswana-</u> than¹

¹Cell Therapy Program - Dmoh, University Health Network, Toronto/ CANADA, ²Dmoh, University Health Network, Toronto/ON/CANADA

We demonstrate that by minimally altering culture conditions for adult human bone marrow (BM) mesenchymal stromal cells (MSCs) to serum-free, cytokine-supplemented, non-adherent conditions, we can change the expression of adhesion molecules and human leucocyte antigens (HLA-ABC). This change is not accompanied by any other phenotypic changes; cells maintain the expression of minimal MSC cell surface antigens (CD90 (99.9%), CD105 (98%), CD73 (99.9%), CD14 (0.2%), HLA-DR (0.1%), CD34 (0.1%) and retain their ability to undergo trilineage differentiation. However, these cells show a decrease in HLA-ABC expression (d7: 47%, vs 99.9% d14: 10.4% vs 95.9%, and d21: 3.8% vs 90%), vascular cell adhesion protein-1 (VCAM-1) expression (d7: 14.6% vs 95.2%, d14: 1.4% vs 88%, and d21: 0.1% vs 80%) and Intercellular adhesion molecule-1 (ICAM-1) expression (d7: 13% vs 78.2%, d14: 0.5% vs 70%, and d21: 2.6% vs 62.3%). A standard ⁵¹Cr cytotoxicity assay showed that MSCs cultured in suspension, under serum-free, cytokine-supplemented conditions had reduced susceptibility to cytotoxicity from NK-92, a permanent allogeneic NK cell line under clinical investigation for treating hematopoietic malignancies (9.08% ±1.86% killing vs. 59.17% ±3.66% killing at a 40:1 NK-92:MSC ratio). Cytotoxicity at lower effector-to-target ratios (20:1, 10:1, and 5:1) was effectively 0% (SD <2%) for MSCs grown in altered conditions, compared to

approximately 30% (SD <3%) for traditional, adherent-grown MSCs. In vivo experiments in an acute inflammatory (lipopolysaccharide (LPS) paw edema) murine model are ongoing to examine effects on modified homing and anti-inflammatory properties when MSCs are grown in altered, suspension cultures vs. traditional cultures. We conclude that by subtly changing culture conditions we can alter adhesion molecules and HLA-ABC expression, which in turn affects immunoevasion, homing and migration of MSCs, equipping the cells for potentially more potent therapeutic effects in treating immunerelated disorders.

PS02.011 - Novel zwitterionic polypeptides for improving resistance to non-specific protein adsorption

Author(s): <u>Xiaojuan Wang</u>¹, Kemei Shi¹, Hanqing Gu² ¹Pain Management Center, The Second Hospitial of Tianjin Medical University, Tianjin/CHINA, ²Tianjin Institute Of Urology, Tianjin Medical University, Tianjin/CHINA

In the past three decades, because of the potential applications in biomedical fields, numerous biomaterials have been widely studied, such as medical implants, drug delivery carriers, and biosensors. Protein adsorption is the first response from human body to foreign materials exposed to physical environment. However, non-specific protein adsorption often induces biological incompatibility, thus, it's very urgent to explore new surface modification of different materials in medicine. Herein, we developed a good candidate coating material, zwitterionic dimethyl aminopropyl amine-grafted poly (α , β -L-aspartic acid) s (DMAP-PASP), by performing the aminolysis of poly (succinimide) (PSI) with different amount of a cationic monomer dimethyl aminopropyl amine, followed by hydrolysis of the residual PSI.

The modified polypeptide derivatives composed of certain negatively carboxylic acid and positively charged aminopropyl amine, and this is why DMAP-PASP could be considered as random zwitterionic copolymers. The ¹H NMR spectrums were uses to demonstrate the ratio of successful conjugated cationic units. A novel turbidity and zeta potential measurements were used to study the dilute solution behaviors of DMAP-PASP under different pH values. Each of the synthesized zwitterionic copolymer exhibited an isoelectric point (IEP) and showed opposite charges below and above the IEP. Compared to our previously reported zwitterionic polypeptide derivative, synthesized by amidation of Poly (α , β -L-aspartic acid) with L-histidine methyl ester, this synthesis route is more convenient and the number of dimethyl aminopropyl amine functionalitie could be controlled in a quantitative way. Therefore, the isoelectric point of the zwitterionic polypeptides could be easily tuned from pH 3.8 to 9.5.

There the fibrinogen, a blood protein resulting in the blood coagulation cascade, was used as a model protein. Therefore the zwitterionic polymer with an IEP of 5.3 was firstly pre-coated on the positive silica surface $\rm NH_2$ -SWs for the purpose of evaluating its protein-resistant characteristics. The amount of protein adsorbed to each sample was quantized and compared with those on the $\rm NH_2$ -SWs without polymer modification. In compared with the unmodified surface, fibrinogen protein adsorption on surfaces was eliminated effectively by DMAP-PASP polymer film. Furthermore, the anti-biofouling behavior through electrostatic interactions was affected by the surface charge density, which means in a dose-dependent manner.

Due to the good biodegradability and superior anti-protein-fouling property, this series of pH-responsive zwitterionic polypeptides are promising candidates for serving as an anti-biofouling material for in vivo applications, including medical implants, drug delivery carriers, and biosensors.

PS02.012 - Study on preparation and mechanical properties of polyurethane foam with negative Poisson's ratio Author(s): Lizhen Wang¹, Yifan Liu², Yubo Fan³

¹School Of Biological Science And Medical Engineering, Beihang University, Beijing/CHINA, ²School Of Biological Science And Medical Engineering, Key Laboratory For Biomechanics And Mechanobiology Of Ministry Of Education, National Key Lab Of Virtual Reality Technology, Beijing, China, Beihang University, Beijing/CHINA, ³National Research Center for Rehabilitation Technical Aids, Beijing/ CHINA

Auxetic foam was a new kind of material which exhibit negative Poisson's ratio effect. It has a wide application prospect. However, auxetic foam would gradually expand to its original volume with time increasing, and the negative Poisson's ratio effect will disappear. The practical use of the auxetic foam has been limited, and it becomes an urgent problem to be solved before its application. The preparation conditions and the recovery ability of auxetic foam, the 60 ppi open cell polyurethane (PU) foam was used as the parent material. The PU foams were compressed in three dimensions and been heat treated at setting temperatures. After cooling down, the auxetic foams were made. In this study, all samples were set with the same radial compression ratio, but three different axial compression ratios. During the heat treatment process, the setting temperatures were 140°C, 150°C and 160°C respectively. It was found that the setting temperature in the condition of this study should be heated until 150°Cto obtain the re-entrant structure.

PS02.013 - Proliferation of cardiomyocytes in neonatal, furture implication in heart regeneration

Author(s): Lincai Ye¹, Lishen Qiu², Haibo Zhang², Huiwen Chen², Chuan Jiang¹, Haifa Hong¹, Jinfen Liu¹

¹Pediatric Congenital Heart Disease Institute, Shanghai Children's Medical Center, Shanghai/CHINA, ²Department Of Thoracic And Cardiovascular Surgery, Shanghai Children's Medical Center, Shanghai/CHINA

Background- Human heart is a limited-mitotic organ that responds to injury with limited cell renewal. In young infants, study of the regenerative capacity of cardiomyocytes may provide an important approach for heart regeneration.

Methods and results- Human right atrial specimens were obtained during routine surgery for ventricle septal defect(VSD) and were divided into two groups: Young infant group (age, 1-3 months) and Old infant group (age, 4-6 months). Results showed that Ki67 is expressed in proliferating cardiac myocytes, and that the number of Ki67-positive cells in young infant group is significantly higher than old group. The Notch pathway was found to regulate cardiomyocyte proliferation and apoptosis during development. Current data showed that NICD expression is significantly higher in young age group and NICD was mainly expressed in cardiomyocyte nuclei.

Conclusions- Proliferating cardiac myocytes are more abundant in the young infant period (<3 months) and the Notch pathway is conserved in humans. Further understanding of their proliferative ability at different ages may provide novel therapeutic targets that can be used to enhance cardiovascular regenerative capacity.

PS02.014 - Synergetic effects of released ions from CaO-MgO-SiO2-based multiphase bioceramics on osteogenic proliferation and differentiation

Author(s): Meng J. Zhang, Xian C. Chen, Xi M. Pu, Xiao M. Liao, Zhong B. Huang, Guang F. Yin

College of Materials Science and Engineering, Sichuan University, chengdu/CHINA

Bioceramics have great potential for bone regeneration and tissue engineering applications. A novel CaO-MgO-SiO,-based multiphase glass-ceramic, composed of akermanite (Ca,MgŠi,O,), wollastonite (CaSiO₂), and dicalcium silicate (Ca₂SiO₄) crystalline phases, was designed and synthesized by sol-gel method. As reported, this glass-ceramic could induce the formation of bonelike-CHA layer when soaked in simulated body fluid (SBF), and obviously promote cell proliferation and differentiation of human osteoblasts. Further research confirmed that the ionic products released from this CaO-MgO-SiO₂-based ceramic played an important role in the modulation of cell proliferation and differentiation. In this research, the synergistic effects of its released ions (calcium ions, magnesium ions, and silicic acid radical ions, simply marked as Ca, Mg, and Si ions) on MG63 cell behaviors and their effective ion concentrations were systematically and thoroughly investigated. Original extract was prepared according to International Standard Organization (ISO/EN 10993-5), and then times diluted into 1/2, 1/4, 1/8, 1/16, and 1/160. The corresponding concentrations of Ca, Mg, and Si ions in different diluted extracts were detected by inductively coupled plasma optical emission spectroscopy (ICP-OES), and the diluted extracts were used for cellular experiments. All the results showed that released ions from CaO-MgO-SiO₂-based bioceramic could stimulate cell proliferation and osteogenic differentiation of MG63 cells at certain concentrations. Such effects were concentration-dependent, and 1/4 diluted extract (Ca 104.69 ppm, Mg 13.13 ppm, Si 33.36 ppm) was the most significant. Moreover, even 1/160 diluted extract also stimulated osteogenic proliferation and differentiation, which might be caused by additional trace amounts of Si ions (Si 0.92 ppm). It is suggested that trace amounts of Si ions could work accompanied with certain concentrations of Ca and Mg ions. Above results inferred that synergetic Ca, Mg, and Si ions played an important role in osteogenic proliferation and differentiation. However, results of MTT and FCM revealed that 1/2 diluted extract (Ca 119.15 ppm, Mg 10.99 ppm, Si 45.08 ppm) slightly inhibited MG63 proliferation by hindering the transition of cell cycle from G, to S phase in the first day. This phenomenon indicated that excessive concentration of Ca and Si ions could result in inhibiting effect on cell proliferation, and with the presence of Mg ions, the effective combination concentrations of Ca and Si ions can not exceed 119.15 and 45.08 ppm, respectively. In general, synergistic effect of various ions is crucial for cell proliferation and differentiation. To merely investigate the ion concentration range of single ion would be of lesser significance, because the beneficial ion concentrations with the existence of various ions are certainly not as the same as that with single ion. This research displayed the synergistic effects of Ca, Mg, and Si ions on the regulation of osteogenic proliferation and differentiation, and investigated the effective concentrations of Ca and Si ions released from bioceramics with the presence of Mg ions. It would be the basis to investigate the biological function of these bioceramics, and would be of great importance to design CaO-MgO-SiO₂-based bioceramics applied as bone tissue engineering scaffolds.

PS02.015 - Cooling Rate Effects on the Microstructure Evolutions of Biodegradable Mg2Ca Potential Medical Implant Alloy Author(s): Li Li Zhou, Yang Yang, Xiao Hui Qiu, You Lin Peng Department Of Information Engineering, Gannan Medical University, Ganzhou/CHINA

The molecular dynamics simulation calculations have been performed to investigate the cooling rate effects on the microstructure evolutions of biodegradable potential medical implant alloy Mg₂Ca result from rapid solidification with four cooling rates by using the generalized nonlocal model pseudopotential (GNMP) theory. Results indicate that cooling rate plays important role in the formation of icosahedron local structure, the lower the cooling rate, the more icosahedron micro-cluster forms in the system. It is also found that cooling rate is also have important effects on the glass transition, the higher the cooling rate, the higher the temperature the glass transition happens at.

PS03 - TRACK 03: BIOMECHANICS AND ARTIFICIAL ORGANS

PS03.001 - Musculoskeletal and Finite Element Simulation of Archery

Author(s): Yahia M. Al-Smadi

Mechanical Engineering, Texas A&M University - Kingsville, Kingsville/UNITED STATES OF AMERICA

In practice the behavior of the Bow-Arrow-Archer system termed 'interior ballistics' and the arrow in flight termed 'exterior ballistics' are complicated. In order to understand the mechanics of archery computer models are required. The musculoskeletal simulation is becoming a popular method in the research field of biomechanics to estimate muscle activity from body motion. The objective of this study is to conduct biomechanical simulation for a musculoskeletal of archery. This simulation aims to find the movement patterns in several working postures, stress induced on muscles and the amount of elongation of different muscles responsible for performing archery.

The work presented discusses the anatomical body arrangements and conducts biomechanically correct simulation. A design of experiment technique was utilized to find the optimum parameters such as muscle effort , angle, stress, strain etc to eliminate excessive stresses on glenohumeral, sternoclavicular & cromioclavicular joints. Initially a three dimensional model of bow and arrow is generated in Solidworks. Next stage of the experiment was performing musculoskeletal simulation using AnyBody software using "Anyscript" language which is similar like other existing programming languages. During this simulation of archery, all the programming codes were taken care thoroughly to reduce errors.

The anatomy of the shoulder is unique – it has a relatively shallow socket which results in amazing

flexibility and range of motion to the glenohumeral joint which is unparalleled elsewhere in the body. The dynamic forces and stress of arm shoulder using lagrangian mechanics approach which is verified using simulation in AnyBody software. The stresses found in the deltoid, trapezious and bisceps and tricep muscles are analyzed along with the range of elongation is shown in Figure

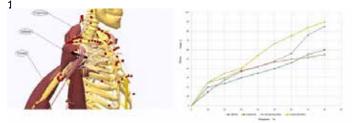

Figure1: AnyBody Simulation and Stress vs Elongation

By simulating the model one can analyze the causes for most common shoulder pain observed in archer. For each analysis, the system stores the maximum stress of muscle at any point of the movement. The simulation estimates the optimum parameters to eliminate stress overloading on the muscles and investigates muscle efforts and joint forces depending on postures.

PS03.002 - Dysfunction Screening in Experimental Arteriovenous Grafts for Hemodialysis Using Inflow and Outflow Hemodynamic Game Analysis

Author(s): <u>Wei-Ling Chen</u>¹, Chung-Dann Kan², Chia-Hung Lin³ ¹Department Of Engineering And Maintenance, Kaohsiung Veterans General Hospital, Kaohsiung/TAIWAN, ²Department Of Surgery, National Cheng Kung University Hospital, Taiana/TAIWAN, ³Department Of Electrical Engineering, Kao-Yuan University,, Kaohsiung City/TAIWAN

This study proposes inflow and outflow hemo-dynamic game analysis for early evaluation of the risk of arteriovenous access dysfunction during hemodialysis (HD) treatment. In physical examinations, inflow and outflow pressure drops and the resistive (Rsc) index reflects pulslatile flow and changes in flow volume resulting from changes in pressure, in terms of the degree of stenosis (DOS). Using static differential pressure sensors, the measured pressure drop is used to estimate the injection velocities and Res indexes through an in vitro access in on-line analysis. A less parameterized cooperative game (CG) based decision-making model is then utilized to evaluate the risk of an access dysfunction. As a simulator of the cardiovascular system and hemodialysis circulation system, the findings indicate that the proposed measurement method and decision-making model can be used in practical examinations during HD treatment.

PS03.003 - The Effects of Limb Dominance, Sex, and Gait Speed on Multisegment Foot Kinematics During Gait Author(s): <u>Victoria Chester</u>¹, Usha Kuruganti¹, Jeffrey Grant² ¹Kinesiology, university of new brunswick, fredericton/CANADA, ²Kinesiology, University of New Brunswick, Fredericton/CANADA

While the foot plays a critical role in support and propulsion during gait, multisegment foot research is still in its infancy. Most gait research has modeled the foot as a single rigid segment consisting of two rotational degrees of freedom. With advances in motion capture technology, there has been a recent increase in the number of studies using multisegment mechanical models. These models divide the foot into multiple compartments or segments allowing the relative motion between segments to be measured (e.g. forefoot vs hindfoot). Currently, we know little about the factors that may affect multisegment foot motion. Therefore, the purpose of the present study was to examine the effects of speed, gender, and limb dominance on multisegment foot kinematics during gait. Such studies will lead to an improved understanding of foot mechanics in typical and atypical gait.

Twenty-one adults (11 female, 12 male) aged 18 to 28 years were recruited to participate in the study (age = 23.0 ± 2.6 years; height = 1.73 ± 0.1 m; weight = 72.1 ± 10.1 kg). Participants were asked to perform gait trials at 5 different walking. A 12-camera Vicon T160 motion capture system (Oxford Metrics Group, Oxford, UK), sampling at 100 Hz, was used to track the three-dimensional trajectories of 34 reflective markers placed on the participant. The rigid body model consisted of five segments: 1) the shank, 2) the total foot (single rigid segment), 3) the calcaneus, 4) the midfoot, and 5) the forefoot. The hallux and metatarsal bones were modeled as line segments for the computation of planar angles. Euler angle data was analyzed using custom software created in Matlab (Mathworks, Inc). A MANOVA and post hoc analyses were used in SPSS to test for significant differences in maximum joint angles between sex and dominant and non-dominant limbs across the 5 walking speeds.

No significant differences (p>0.05) in mean maximum joint angle data were found between limbs and sex during gait. Significant differences (p < 0.002) in the mean values of temporal-spatial variables between speed groups were found for stride length, toe-off, percentage of time spent in single leg stance, and cadence. Significant differences (p < 0.002) in mean maximum joint angle data

were found in the sagittal plane only. Changes in speed altered the angular kinematics of the calcaneus vs tibia, midfoot vs calcaneus, and forefoot vs calcaneus. In addition, planar angles of the hallux, metatarsals, and medial longitudinal arch also varied with speed.

Similar to the results of simple foot models, the results of this work suggest that walking speed has an effect on multisegment foot kinematics. The relative angles between foot subsegments changed as a function of gait speed. The midfoot segment, which is often ignored in multisegment studies, showed significant changes in angular data with respect to the calcaneus. Therefore, multisegment foot studies of clinical populations should use speed-matched control data for comparative purposes. This would facilitate the identification of pathological gait from speed-mediated effects. Future studies will examine the effects of walking speed on multisegment foot kinematics in varying age groups.

PS03.004 - Investigation of transfibular locking plate to treat open extra-articular distal tibia fractures

Author(s): Ryan Normore¹, <u>Helena Greene¹</u>, Allison Delong¹, Andrew Furey², Amy Hsiao³, Stephanie Atkinson¹

¹Faculty Of Medicine, Memorial University of Newfoundland, St. John's/NL/CANADA, ²Faculty Of Medicine, Memorial University of Newfoundland, St. John's/CANADA, ³Mechanical Engineering, Memorial University of Newfoundland, St. John's/CANADA

The current surgical treatments for extra-articular distal tibia fractures have significant limitations; therefore the structural stability of a novel trans-fibular method of fixation was investigated. The fracture site was secured using a locking plate attached to the lateral side of the fibula by threaded locking screws projecting through the fibula and securing into the tibia. Synthetic sawbone specimens, that have been shown to behave similar to human bone, were chosen for this initial construct testing because of their anatomic consistency. The specimens have had osteotomies to simulate distal tibia fractures and have undergone trans-fibular fixation. The specimens were then tested using a hydraulic load frame under three different axial loading conditions; linear loading to 700N, cyclic loading of 700N for 10,000 cycles, and a specimen load to failure. Failure was defined as vertical displacement of the fracture site greater than 5mm or an angular displacement greater then 5°. Vertical displacement, applied load, and angular displacement of the specimen were recorded and a preliminary analysis was completed, including a comparison of the stability of this novel construct with that of previously investigated method of fixation.

PS03.005 - Kinematic analysis after total hip arthroplasty during weight-bearing activities

Author(s): <u>Satoru Ikebe</u>¹, Hidehiko Higaki¹, Yoshitaka Shiraishi², Takeshi Shimoto³, Yoshitaka Nakanishi⁴, Daisuke Hara⁵, Satoshi Hamai⁵, Yasuharu Nakashima⁵, Yukihide Iwamoto⁵ ¹Kyushu Sangyo University, Fukuoka/JAPAN, ²Ehime University, Ehime/JAPAN, ³Fukuoka Institute of Technology, Fukuoka/JA-PAN, ⁴Kumamoto University, Kumamoto/JAPAN, ⁵Kyushu University, Fukuoka/JAPAN

The hip joint has a wide range of motion. It achieves various daily activities. In the field of biomechanics, kinematic analysis of the hip osteoarthritis (OA) and total hip arthroplasty (THA) is important. Motion capture system has been widely used as kinematic analysis *in vivo*. However, external markers attached to the skin would be affected by soft tissue artifact with substantial errors. There is 2D-3D registration method as the kinematic analysis technique of high accuracy. There are reported of kinematic analysis technique of the natural knee and artificial knee joint using window analysis technique and single plane X-ray images. This study was aimed to analyze weight-bearing activities before and after THA. It was

confirmed to be utility of this technique by kinematic analysis during squatting and chair-rising.

In this report, the subject was one female before and after THA. Kinematic analysis at pelvis after THA was used image correlation between X-ray images and the computational simulating image. The image matching of the cup and stem was matched shape of implant in X-ray images and simulating image of 3D shape data. The accuracy of this analysis method is within 0.28 mm and 0.30 degree. We evaluated the hip joint, femoral and pelvic rotational motion. The rotational motion of the hip joint evaluates the relative motion of the femur for the pelvis, and femoral and pelvic rotational motion evaluates the tilt of the each bone for the vertical plane.

In flexion angle of the hip joint during squatting, difference between normal hip and a subject was about 23.3-32.0 degree at initial position. In femoral flexion angle during squatting, we confirmed difference of about 15.3-21.0 degree between normal hip and a subject. The posterior tilt of pelvis at a subject (16.9 degree at OA, 17.2 degree at THA) was larger than that of normal hip (10.0 degree) during squatting. In flexion angle of hip joint during chair-rising, we confirmed difference of about 6.0-12.7 degrees between normal hip and a subject. In femoral flexion angle during chair-rising, difference between normal hip and a subject was about 1.7-7.0 degrees at initial position. The posterior tilt of pelvis at a subject (16.0 degree at OA, 3.4 degree at THA) was larger than that of normal hip (9.1 degree) during chair-rising. The OA was limited range of motion in hip joints. And, range of motion became widely after THA. The pelvic posterior tilt at the OA permitted high-flexion of the femur.

In this report, we analyzed movement of the normal, OA and THA hip joints during squatting and chair-rising. The results of the study demonstrated that limited range of motion in OA hip joints was compensated by pelvic tilt. The limited range of motion in OA hip joint was become widely by THA. From these results, we were able to analyze movement of the hip joint in vivo using window analysis technique.

PS03.006 - Estimation of Compressive and Shear Forces on Lumbar Spine during Lifting by Wii Balance Board

Author(s): <u>Hieyong Jeong</u>¹, Kenji Yamada¹, Soichiro Watanabe², Moe Yokoyama¹, Michiko Kido³, Taishin Nomura⁴, Yuko Ohno³ ¹Robotics & Design For Innovative Healthcare, Graduate School of Medicine, Osaka University, Suita/JAPAN, ²Konoike Institute Of Technology, KONOIKE Transport CO., LTD., Osaka/JAPAN, ³Division Of Health Sciences, Graduate School of Medicine, Osaka University, Suita/JAPAN, ⁴Mechanical Science And Bioengineering, Graduate School of Engineering Science, Osaka University, toyonaka/JAPAN

[Background]

Compressive and shear forces on lumbar spine are recognized as a risk factor for low back pain. Previous studies of forces have shown how injurious stresses on the low back can be predicted by such biomechanical models of the torso during the early phases of designing materials handling tasks in industry, but there are little studies on posture analysis with measurement of combined center of mass between a worker and an object during lifting under realistic field conditions.

[Purpose]

The purpose of this study is to propose the evaluating method to estimate compressive and shear forces on lumbar spine during lifting by using the Wii Balance Board under realistic field conditions.

[Methods]

The Wii Balance Board is able to measure both the position and

weight of combined center of mass between a worker and an object, and also to estimate trunk kinematics through two-degreeof-freedom link model. The proposed method is to calculate compressive and shear forces on lumbar spine during lifting with measured results of the position and weight of combined center of mass and estimated results of trunk kinematics. To compare with the conventional method, we let the center of balance of posture in the conventional method correspond with the center of pressure in the Wii Balance Board. The system for estimating is portable and inexpensive because the system is composed of the Wii Balance Board and the laptop computer.

[Results]

Through comparison, we found that results of proposed method were familiar with results of conventional method during bending forward or unbending backward, however, there was the difference between two estimated results just before bending forward or unbending backward. We considered that this came from the difference between the measurement and the assumption for combined center of mass.

[Conclusions]

We propose the evaluating method to estimate compressive and shear forces on lumbar spine by using the Wii Balance Board under realistic field conditions, and our method shows the effectiveness through comparison with results of conventional method. Additionally, the proposed method shows the possibility to be used to let participants know whether the current own lifting posture is proper or not in order to prevent workers in industry from worsening low back pain under realistic field conditions.

PS03.007 - A biomechanical evaluation of a novel pedicle screw-based interspinous device used to stabilize the lumbar spine

Author(s): <u>Yu-Shu Lai</u>¹, Hsin-Chang Chen², Chi-Wei Chou¹, Cheng-Kung Cheng¹

¹Orthopaedic Device Research Center, National Yang-Ming University, Taipei/TAIWAN, ²Orthopaedic Department, Taipei City Hospital, Heping Fuyou Branch, Taipei/TAIWAN

Interspinous spacers alters the load to be transferred through the spinous process instead of anterior column and the consequent fractures of the spinous process would be raised for patients with poor bone quality. In order to reduce the risk of spinous process failure, this study developed a novel pedicle screw-based supporting system with an "M" geometry, which was designed to overcome the previous disadvantages from spinal fusion, artificial disc replacement, and traditional interspinous devices.

The first part of this study was to evaluate the mechanical strength of the novel device by using a material testing machine (MTS Bionix 370.02). Six sets of titanium alloy-made devices were tested with a fixator referred to ASTM F2624 and ASTMI2790. The second part was to design a spine simulator for evaluating the range of motion in porcine lumbar spines (Fig. 1). Total of 24 sets of spine were tested (6 intact, 6 L3-L4 implanted with the new devices, 6 L3-L4 implanted with the posterior fixation).

The results of mechanical strength showed that there was no failure occurred in the new devices under the maximal loading of 15 Nm in the backward bending test. The new device group demonstrated a similar range of motion in forward bending (0.3°) and lateral bending (2.3°) compared to the X-Stop group and a higher of that compared to the posterior fixation group. As for backward bending, the new device was proved to possess a higher stiffness compared to X-Stop and posterior fixation.

In conclusion, the novel interspinous device has enough mechanical strength, and it constraint the spinal extension to avoid nerve root/spinal cord compression, unconstrained spinal flexion, and the lowered influence on adjacent levels.

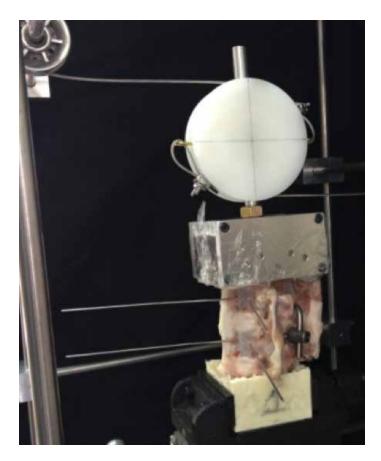

Figure 1

PS03.008 - Hematological, Biochemical, and End-organ effects of the CH-VAD in Ovine Model

Author(s): Changyan Lin

Biomedical Engineering, Beijing Anzhen Hospital, Capital Medical University, Beijing/CHINA

Background The CH-VAD is an implantable, fully magnetically suspended ventricular assist device developed by CH Biomedical Corporation for full cardiac support. This study was performed to evaluate the short-term (35 days) hematological, biochemical, and end-organ effects of the CH-VAD left ventricular assist device (LVAD) in a sheep model trial. Methods Six sheep underwent CH-VAD implantation without the use of cardiopulmonary bypass. The pump inflow was inserted into the left ventricle and the outflow graft was anastomosed to the descending aorta. Data on pump function and the health condition of the animals, including hematologic and biochemical tests, were collected during the study period. When each study was determined to termination, the sheep were humanely euthanized and the end organs were examined macroscopically and histopathologically. Hemolysis was evaluated based on the amount of free hemoglobin in the plasma. Results Except for one device that stopped operation on the 25th postoperative day because of thrombus formation, the planned date of termination (35 days) was reached in all the animals without complication and device failure. Gross examination of the pump interiors, inflow and outflow, and of the arterial anastomosis sites showed no significant abnormalities. Hematologic and biochemical test results were within normal limits during the study period. Elevations observed in the levels of white blood cell count, and decreases in hematocrit, hemoglobin, and red blood cell count were of short duration, these parameters returned to normal within 20days of surgery. Serum urea nitrogen, creatinine, SGPT(ALT), SGOT(AST), and lactate dehydrogenase levels showed transient increases within the first five days of surgery. Other biochemical parameters were within normal limits. Macroscopic and histopathologic examinations of the explanted organs revealed no evidence of ischemia or infarction associated with the device implantation, except for small foci of infarction in the kidneys of two sheep. The free hemoglobin level in plasma peaked at 9.5 mg/dL on the fifth postoperative day. Conclusions Hematological, biochemical, and end-organ functions were not adversely affected by short-term CH-VAD system.

PS03.009 - Novel Low-Profile External Fixator with Simple Locking Mechanism Compared with Commercial Available External Device Could Provide Better Stability in Multicycle Dynamic Loadings

Author(s): Kun-Jhih Lin¹, Chih-Hui Chen², Wen-Chuan Chen¹, Hung-Wen Wei¹, Jeu-Ying Li¹, Cheng-Lun Tsai³, <u>Kang-Ping Lin¹</u> ¹Technology Translation Center For Medical Device, Chung Yuan Christian University, Taoyuan/TAIWAN, ²Department Of Orthopaedic Surgery, Taichung Veterans General Hospital, Taichung/ TAIWAN, ³Department Of Biomedical Engineering, Chung Yuan Christian University, Taoyuan/TAIWAN

Recently, the standard locking compression plate (LCP) as an external fixator was introduced and coined the term supercutaneous plating. However, there are some limitations of LCP external fixation, such as limited screw holes available and insufficient strength compared with traditional fixator. We developed a LCP-like large plate to provide more screw numbers and higher strength to withstand the force during walking. Conceptually, the novel plate fixator was based on a tibial locking plate (A Plus Biotechnology Co., Ltd., New Taipei City, Taiwan) which acts for internal fracture fixation. The plate fixator is featured as thinner, wider and proximally arced shape, and can be positioned close to the skin (Fig. 1).

Fig. 1. Model of a novel plate external fixation with simulated tibia fragments apart.

We performed a repetitive loading test (200N to 200N, 1Hz, 50,000) (N=5) for the novel plate external fixator and compared with a commercialized traditional external fixator (Synthes GmbH, Oberdorf, Switzerland). The plate was fixed on polyacetal cylinder models simulating tibia with a 20 mm gap. Axial displacement of the bone fragment was recorded during testing. Statistical analysis was performed using t-test with significance set at P<0.05.

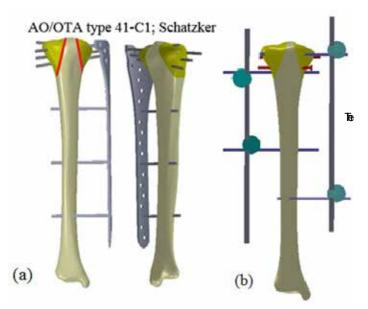

No specimen failure was found for the two fixators after 50,000 dynamic loading cycles. The novel fixator had smaller displacement than that of the Synthes fixator despite no significant difference was seen (Table 1).

Table 1. Bone fragment movements from experimental mea- surements						
Displacement (mm): mean±standard deviation Novel fix- ator Synthes fixator P value						
Tensile	1.54±0.13	2.21±0.22	0.48			
Compressed	0.66±0.05	0.83±0.11	0.55			
Total	2.2±0.26	3.03±0.18	0.15			

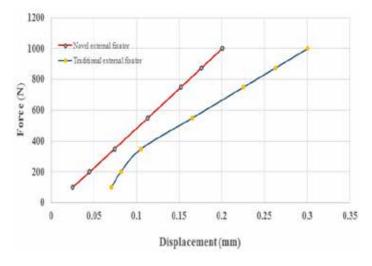

This dynamic load analysis revealed lesser fragment movement in the novel fixation. Additionally, the plate fixator was developed with low profile which is easily concealed under regular clothing and much less tendency for the frame to strike the contralateral lower leg in swing phase during ambulation. More importantly, this study demonstrated better stability in the novel fixator than traditional external fixator. The LCP-like large plate is demonstrated the ability of fragment stability. We expected this improvement may reduce the nonunion rate noted in the LCP application.

PS03.010 - A simple external fixation technique for treating bicondylar tibial plateau fracture: a finite element study Author(s): Wen-Chen Lin¹, Kun-Jhih Lin¹, Chih-Hui Chen², Bo-Hao Li³, Jeu-Ying Li¹, Wen-Chuan Chen¹, Hung-Wen Wei¹, Cheng-Lun Tsai³, Sheng-Cheng Huang¹, <u>Kang-Ping Lin¹</u> ¹Technology Translation Center For Medical Device, Chung Yuan Christian University, Taoyuan/TAIWAN, ²Department Of Orthopaedic Surgery, Taichung Veterans General Hospital, Taichung/ TAIWAN, ³Department Of Biomedical Engineering, Chung Yuan Christian University, Taoyuan/TAIWAN

Bicondylar tibial plateau fractures are difficult to treat with a high complication rate due to difficulties in achieving stable fixation. External fixation methods such as monolateral external fixator, circular external fixators, or a hybrid between a monolateral and a circular external fixator are considered to be good mechanical methods of stabilising these complex fractures. However, main disadvantages of these traditional external fixators are bulky and cumbersome for the patient during daily activities. Therefore, we developed a simple low-profile external device to overcome these drawbacks. ThisTnovel external device is characterized as arced shape proximally and multi-directional screw insertion trajectory to enhance fixation stability of fracture. This study aimed to investigate the biomechanical performence of the novel device and to compare with commercialized traditional external fixator. Finite element method was employed to carry out all biomechanical analyses. Three CAD models of a normal tibia bone, the simple low-profile external device, and a traditional monolateral external fixator were reconstructed (Fig 1). Bicondylar tibia plateau fracture was simulated according to AO classification (AO/OTA type 41-C1; Schatzker type-V). A 1000N axial compression load was applied to the tibial plateau with fully fixed distal end of the tibia. Maximum von Mises stress on bone, screws, and fixators were calculated. The construct stiffness of both groups were calculated also.

results showed that the maximum von Mises stress on implants was much lower than the yielding strength of the material for both groups. The construct stiffness of the novel device (4992.5 N/mm) was 49.8% higher than the traditional external device (3333.3 N/mm) (Fig 2). This study demonstrated that the fixation strength of the novel external device was higher than the traditional monolateral fixator. Clinical evaluation for the novel device is still necessary to further verify its usefulness.

PS03.011 - Numerical analysis of the elaborate sound amplification mechanism of the mammalian inner ear Author(s): <u>Michio Murakoshi</u>¹, Hiroshi Wada²

¹Department Of Mechanical Engineering, Kagoshima University, Kagoshima/JAPAN, ²Department Of Intelligent Information System, Tohoku Bunka Gakuen University, Sendai/JAPAN

Sounds are converted to the mechanical vibration by the tympanic membrane and this vibration is transmitted to the basilar membrane (BM) and the sensory organ of hearing named organ of Corti (OC) in the cochlea. The OC consists of one row of inner hair cells (IHCs), three rows of outer hair cells (OHCs) and other supporting cells, as shown in Fig. 1.

The process known as cochlear amplification is realized by coordinated movement of the OHCs in response to changes in their membrane potential. In this process, the displacement amplitude of the BM is thought to be increased, thereby leading to the high sensitivity, wide dynamic range and sharp frequency selectivity of our hearing.

Unfortunately, however, OHCs are vulnerable to noise exposure, ototoxic acid, aging and so on. Previous studies have shown that exposure to intense noise causes functional loss of OHCs from the innermost row (i.e., close to the modiolus) to the outermost row (i.e., close to the cochlear wall). On the contrary, by other traumatic stimuli such as ototoxic acid, aging and ischemia, such loss of OHCs has been reported to occur from the outermost row toward the innermost row. However, how the cochlear amplification changes when coordinated movement of OHCs is impaired remains unclear. Since the OC is vulnerable and sound-induced displacement amplitude of the OC is quite tiny, measurement of the dynamic behavior of the OC is difficult. Analysis using finite element method (FEM) is thus helpful.

In the present study, therefore, a finite element (FE) model of the gerbil cochlea, which takes the motility of OHCs into account, was developed based on our previous FE model. Using this model, changes in the displacement amplitude of the BM due to the functional loss of OHCs in one, two or all three rows were investigated and the effects of incoordination of the three rows of OHCs on cochlear amplification were estimated. Results showed that the displacement amplitude of the BM significantly decreased when either the innermost row or the outermost row of OHCs lost its function, suggesting that all three rows of OHCs are required for cochlear amplification.

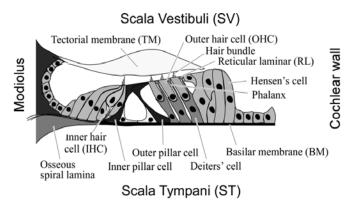

Fig. 1. Schematic of structure of the OC. The OC contains two types of sensory cells, i.e., the inner hair cells (IHCs) and the outer hair cells (OHCs), and the supporting cells. The tectorial membrane (TM) is an extracellular matrix and covers the OC.

PS04 - TRACK 04: RADIATION ONCOLOGY

PS04.001 - Image-Guided Intra-arterial Delivery of Yttrium-90 Radioactive Microspheres for the Treatment of Liver Tumors Author(s): <u>Muthana Al-Ghazi</u>¹, Varun Sehgal¹, Suhong Yu¹, Garrett Green¹, Glenn Samford², Jeffrey Kuo¹, Dayantha Fernando², David Imagawa³

¹Radiation Oncology, University of California, Irvine, Orange/UNITED STATES OF AMERICA, ²Radiological Science, University of California, Irvine, Orange/CA/UNITED STATES OF AMERICA, ³Surgery, University of California, Irvine, Orange/CA/UNITED STATES OF AMERICA

Purpose: To outline the use of yttrium-90 (Y-90) for the treatment of liver tumors.

Background: Y-90 is a β^- emitter with an energy of 2.28 MeV. It decays to Zr-90 with a half-life of 64 hours. It is produced from the decay of Sr-90; the latter in turn is produced by chemical high-purity separation from strontium-90, a fission product of uranium in nuclear reactors. The short range of the emitted β^- makes Y-90 ideal for irradiation of tumors at very short range.

Liver tumors arise as either primary tumors (e.g. hepatocellular carcinoma) or as metastases resulting from e.g. colorectal primaries. In the simplest form, these tumors destroy the local vasculature of the liver. As such, delivery of Y-90 coated microspheres through liver vessels will terminate at the tumor site enabling very high doses to be delivered locally.

Methods: Healthy liver tissue gets its blood supply from the portal vein. The hepatic artery supplies blood to the tumor. Therefore, delivery of a "radioactive drug" through the hepatic artery will lead to the site of the tumor leaving healthy liver tissue and its blood supply unaffected. A catheter is inserted intrafemorally under fluoroscopic image guidance to reach the site of the tumor via the hepatic artery. This intervention is performed under local anesthesia. In the meantime the descending gastric artery is coiled to prevent Y-90 microspheres from escaping to the gastrointestinal tract and causing untoward toxicity. The required Y-90 activity to deliver a dose in the range 100 - 150 Gy to the tumor site is calculated using a multicompartmental model that takes into consideration (a) liver volume, (b) body surface area, (c) tumor burden expressed as a percentage of liver volume and (d) the "lung shunt", the latter is the amount of the circulation from the liver to the lung. Patients with lung shunt equal or greater 10% are not candidates for this procedure due to unacceptable pulmonary toxicity.

Results: This method of image-guided brachytherapy enables safe delivery of doses in the range 100 – 150 Gy to the tumor site with minimal normal tissue toxicity due to the short range of the emitted β - particles, taking advantage of the destruction of the vasculature by the tumor and the nature of the hepatic blood circulation. There appears to be a favorable dose response associated with this minimally invasive procedure for patients who are not surgical candidates and have exhausted other treatment options.

Conclusion: Y-90 radioactive microspheres can be safely used to deliver doses in excess of 100 Gy locally to liver tumors with minimum toxicity taking advantage of the low energy (2.28 MeV) of the emitted β - particles and the nature of the hepatic blood circulation. This advantage along with the short half-life of this isotope enables this minimally invasive procedure to be performed as a same day surgery. Preliminary evidence suggests a favorable dose response at this dose range

PS04.002 - Commissioning of an ASi EPID for patient specific IMRT QA.

Author(s): <u>David N. Alonso Fernández</u>¹, Rodolfo Alfonso¹, Eduardo Larrinaga², Jose L. Alonso Samper², Rogelio Diaz Moreno² ¹Nuclear Engineering, High Institute for Applyed Technologies and Sciences (InSTEC), Havana/CUBA, ²Department Of Radiotherapy, Institute of Oncology and Radiobiology, Havana/CUBA

The use of the Electronic Portal Image Device (EPID) in an Elekta Linac for patient-specific Intensity Modulated Radiotherapy (IMRT) Quality Assurance (QA) is assessed and validated. A linac Elekta was used, with IMRT step&shoot capability using Multileave Collimator (MLC). An EPID image calibration was performed for a 6MV photon beam and a 10x10cm² field size. The EPID effective water scattering depth (d_{eff}) was assessed through the measurement of its response versus the field size variation; and compared to the output factor scatter at different depths calculated from Radiotherapy Treatment Planning System (RTPS) Elekta XiO data. A correction matrix was created from a 24x24cm² field profile padded with radial symmetry.

The EPID d_{eff} found was close to 5cm. Dose profiles and dose maps were calculated to d_{eff} with the RTPS using a collapsed beam arrangement. Also they were measured with the bidimensional (2D) ion chamber array PTW Seven29 Octavius sandwiched in PTW RW-2946 slabs for validation purpose. Point measurements with an ion chamber PTW M30013 Farmer type were carried out also. The dose maps and profiles were compared to the processed EPID images for simple cases (i.e. open fields and wedged fields) and more complex cases (Head and Neck IMRT clinical cases).

The EPID obtained dose maps were compared with the RTPS calculated dose maps and the measured with the 2D-array. Comparison was performed using the PTW VeriSoft v5.1 software. Results showed that approximately 90% of all points passed using a 3% dose/4mm Distance to Agreement (DTA) for the gamma analysis for both methods.

PS04.003 - Status of Radiotherapy Treatment in Lebanon Author(s): Ibrahim Duhaini¹, Antar Aly²

¹Radiation Oncology, Rafik Hariri University Hospital, Beirut/LEBA-NON, ²Hamad Medical corporation, Doha/QATAR

Abstract:

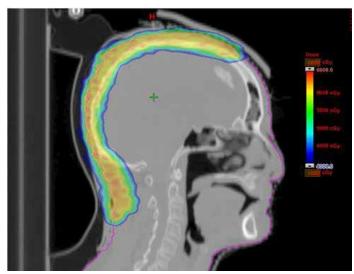

Lebanon is located in the heart of the Middle East Region with a population of 4.5 million and is considered one of the best places of Medical Hot Spot destination that attracts many of the neighboring Arab countries to seek medical treatment. This is due to the fact of the highly skilled medical professionals and advanced health infrastructure in the country. Radiotherapy started in the early 70's with Cobalt Machines and has developed tremendously thought the years to include the highly technological and advanced Linac Systems. Now, there are 10 Hospitals that offer Radiotherapy Treatment with 14 Linacs equipped with the state of the art technology using 3-D Conformal, IMRT, Stereotactic Radiosurgery, IGRT and other modalities. In this presentation, an overview of the current cancer treatment in these 10 hospitals will be revealed. Detailed information will be unwrapped for the newly opened Radiotherapy Center at Nabih Berry Governmental University Hospital (NBGUH) in South Lebanon, which covers one third of the Lebanese population in that region.

PS04.004 - Verification of VMAT Arc Radiation Therapy Technique for Full Scalp Treatment

Author(s): Cynthia Araujo, Islam Mohamed, Claude Lapointe, Dawn Gillund, Kristine Mcgee

Radiation Therapy, BC Cancer Agency - Southern Interior, Kelowna/ CANADA

A VMAT arc technique was designed to treat the full scalp for a patient with angiosarcoma of the scalp to a dose of 6000cGy in 25 fractions.

The CT of the entire head was acquired with the patient in supine treatment position with a 0.5 cm thick custom bolus-cap on the top and back of the head, an immobilization shell, and additional bolus attached to the shell.

A VMAT plan to be treated on a Varian True Beam LINAC was optimized in Eclipse using the photon dose AAA calculation version 11. Two full arcs with couch at 0° and collimator at +/- 10° where used along with two partial arcs with couch at 270° and collimator at 90°. The treatment was optimized to cover the skin, and a PTV margin, while sparing the underlying brain and limiting the dose to the optic apparatus and lacrimal glands. The dose to the brain was limited so that V20Gy, V30Gy and V40Gy were 710, 390 and 193 cm³ respectively. The mean dose to the brain was 2385 cGy.

On the 2nd treatment day, 13 TLDs where positioned on the patient's scalp. The TLDs were spaced 2cm apart, 9 along the midline sagittal plane, and 4 along an axial plane. The dose measured by the TLDs was compared to the treatment planning calculation and it showed an excellent agreement. The mean difference between the measured and calculated dose was 1% with a standard deviation of 4%.

TABLE 1: Results of the TLD dose measurements compared to the treatment planning calculation for 13 positions spaced 2 cm apart on the patient's scalp. **TLD Dose** Treatment Difference Planning (cGy) (cGy) 247 245 1% Mean Standard 5 9 4% Deviation 236 231 Minimum -6% 253 259 7% Maximum

PS04.006 - Uncertainty evaluation of radiation treatment with DIBH for left-sided breast cancer using MV cine imaging Author(s): Jae Beom Bae, Byung Chul Cho, Kyoung Jun Yoon, Young Eun Choi, Su Ssan Kim, Seung Do Ahn, Sang Wook Lee, Jung Won Kwak

Radiation Oncology, Asan Medical Center, Seoul/KOREA

Purpose/Objective: Deep inspiration breath-hold (DIBH) technique has been utilized to reduce the radiation exposure of heart for left-sided breast cancer patients during radiotherapy. Obtaining MV x-ray cine images during beam delivery, we evaluated the interand intra-fractional variations of breast cancer treatment with DIBH technique.

Materials/Methods: For five left-sided breast cancer patients treated with DIBH technique, about 15000 cine images (7.5 frame/ sec) in 209 fractions were acquired by Electronic Portal Image Device (aSi1000, Varian). The acquired DICOM image files were converted into ASCII format using ImageJ (Java image processing program, NIH). The ASCII files were imported into ROOT (Data Analysis Framework, CERN) to generate the 2D maps of local standard deviations (LSTD) calculated with each pixel and 4 neighboring pixel values. The edges of organs could be easily extracted by selecting local maximums in the 2D LSTD map. As the projected profiles from the ROI regions of the 2D LSTD maps were taken into account for fast processing, the local maximum points in the projected profiles were interpreted as the relative positions of heart boundary, chest wall, and skin from the edge of MLC. The cine images of the medial and lateral fields for each fraction were separately accumulated to obtain the representative positions in each fraction.

Results: The inter- and intra-fractional variations of each organ during DIBH breast radiotherapies for 5 breast cancer cases were evaluated using the 15000 cine images. The averages of inter-fractional variations about the skin, chest wall, and heart for 5 cases were 0.37 cm, 0.31 cm, and 0.33 cm. The averages of intra-fractional variations of the skin and chest wall positions were measured to be about 1/10 of inter-fractional variations. The results showed that inter-fractional variations were much bigger than the intra-fractional values except of the position of heart edge. For the position of heart edge, the intra-fractional variation was measured to be about the same level to the inter-fractional variation.

Conclusion: MV cine imaging was assessed as an appropriate tools to evaluate the intra- and inter-fractional variations of DIBH breast cancer treatments. The inter-fractional variations for the skin, chest wall, and heart positions were all about 3~4 mm, which were quite reasonable in patient setup with skin marks. The skin level guidance with RPM system and the cooperation of patients seemed to result in much smaller intra-fractional variation than inter-fractional variation of the anterior-left edge of heart was similar to the inter-fractional variation. For the robust conclusion, the analysis with the bigger statistics is in progress.

PS04.007 - Evaluation of the Applicability of Pinpoint ion chamber for Dosimetric Quality Assurance of SRS

Author(s): Jong Geun Baek¹, Hyun Soo Jang¹, Yong Hee Lee², Eng Chan Kim², Young Kee Oh³, Sung Kyu Kim⁴

¹Radiation Oncology, Dongguk University Gyeongju Hospital, Gyeongju/KOREA, ²Physics, Yeungnam University, Gyeongsan/ KOREA, ³Department Of Radiation Oncology, Keimyung University Dongsan Medical Center, Daegu/KOREA, ⁴Department Of Radiation Oncology, Yeungnam University College of Medicine, Daegu/ KOREA

A number of investigators demonstrated that Pinpoint chamber is not suitable for dosimetry in small field because the effect of finite detector size led to large volume averaging problems in regions of high dose gradient. However, Pinpoint chambers still have been used for the measurement of absolute dose in dosimetric quality assurance (QA) of stereotactic radiosurgery (SRS). The aim of the present study was to evaluate the applicability of Pinpoint ion chamber for the measurement of small photon beams in dosimetric QA under the actual SRS treatment circumstances.

A total 23 cases of SRS plans were used for the verification and the diameters of the target volumes were divided into two groups, the diameter of <10 mm (10 cases) and of ≥10 mm (13cases). The PTW 31014 Pinpoint chamber was used to measure the absolute dose of small beams in SRS treatment and the chamber has an active volume of 0.015 cm³. To compare the dosimetric uncertainties for Pinpoint chamber, the PTW 60003 natural diamond detector was used as a reference dosimeter. A custom-made cylindrical acrylic phantom (15 cm diameter, 15 cm length) was designed for measurement. The noncoplanar arc plan was created to deliver a prescription dose (15-25 Gy) to 80% of the maximum dose of the target in a single fraction and then the calculated plan was projected on the CT images of the phantom as inserted each detector for verification planning. All irradiations were performed using a Varian Clinac IX 6MV equipped with a micro-multileaf-collimator designed by BrainLAB. The acceptability criteria of the dose difference at our institution is less than 3%.

The dosimetric uncertainty was represented as a percentage dose difference between planed and measured. For Pinpoint chamber in the target diameters of <10 mm, the maximum dose difference was 4.85%, the mean ± standard deviation (SD) discrepancy was 2.82±1.41%, and the number of the dosimetric uncertainty of >3% was 4 of 10 cases. For diamond detector in the same diameters, the values were 2.70% and 1.51±0.74% and all measured discrepancies were <3%. Statistical analysis indicates that the dosimetric uncertainties for Pinpoint chamber in the target diameters of <10 mm were significantly different from the uncertainties for diamond detector (p<0.05). On the other hand, the maximum difference was 1.56% and mean ± SD discrepancy was 0.81±0.44% for Pinpoint chamber in the target diameters of ≥10 mm and the values were 1.79% and 1.09±0.41% for the diamond detector. The correlations between the dosimetric uncertainties and the all target diameters in our study by determining the R2 regression coefficient. A highly significant but moderate correlation was observed for Pinpoint chamber (R2=0.483, p<0.001), whereas the weak correlation was observed for diamond detector (R2=0.053, p=0.230). Based on the results of this study, Pinpoint chamber is unsuitable for the measurement of the absolute dose of SRS field designed by the target diameters of <10 mm, whereas the chamber can provide reliable and acceptable data for verifying the SRS fields created by the diameter of ≥10 mm.

PS04.008 - Development of a VARIAN 600 C/D Linear Accelerator model using MCNPX 2.6 Monte Carlo code.

Author(s): Jorge L. Batista Cancino, Clarysson A. Mello Da Silva , Rômulo Verdolin De Sousa, Claubia Pereira Departamento De Engenharia Nuclear, Universidade Federal de

Minas Gerais, Belo Horizonte/BRAZIL

In radiotherapy treatment planning, tools that improve the accuracy of patient dosimetry are valuable. The Ministry of Health of Brazil has near of 240 linear accelerators in the radiotherapy service. VARIAN is the main distribution company in the country and more than 60% are linear accelerators of low-energy (4-6 MeV). In this research work, a simple and useful model was developed for VARIAN 600 C/D linear accelerator using MCNPX 2.6 Mote Carlo (MC) code. The essentials components of VARIAN 600 C/D head was simulated for 6 MeV electron beam using MCNPX 2.6 MC code. In this study is considered a monoenergetic electron beam of 6 MeV as a source. Photons generated by Bremsstrahlung in tungsten target are transported too. Percentage depth doses (PDD) and beam profiles were calculated for different field sizes. The MC calculated results were compared against measurement and good agreement was obtained. The comparison between MC calculations and measurement of PDD showed less than 5% of error for build up region. Also, there was a high coherence in beam profiles comparison. In the flat region was less than 3% of error and near to 10% difference was seen for penumbra region. In conclusion, our study showed acceptable results according to the reference criteria. The developed model will optimize the patient dosimetry in radiotherapy treatment planning.

PS04.009 - A Comparison of Dosimetric Characteristic Between Integrated and Cine Acquisition Modes of a-Si EPID Author(s): <u>Omemh Bawazeer</u>¹, Siva Sarasanandarajah¹, Sisira Herath², Tomas Kron², Shu Hui Hsu³, Pradip Deb¹ ¹School Of Medical Radiation, RMIT University, Melbourne/AUS-TRALIA, ²Radiation Oncology, Peter MacCallum Cancer Centre, Melburone/AUSTRALIA, ³Radaition Oncology, Montefiore Medical Centre, New York City/UNITED STATES OF AMERICA

Electronic Portal Imaging Device (EPID) is currently used for the dosimtery purpose. There are two acquisition modes, integrated and cine mode [1]. The aim of this study is to compare the dosimetric characteristic between both acquisition modes. The a-Si 500 EPID that attached to Varian Synergy linear accelerator was used in this study. The comparison included the response of EPID to dose, reproducibility, field size dependence, ghosting effect, dose rate and multi-leaf collimator effect. In addition, the ionization chamber response under the identical setup was acquired to assess the dosimetric characteristic of EPID response with two acquisition modes. All acquired images were analysed using MATLAB programme. The preliminary results of comparison between acquisition modes for dose response and field size dependent represent in Figure 1and Figure 2. The results indicated that the differences between two modes is because the difference in the pixel value range for each mode, however both modes have a comparable response to dose. In each mode, the ratio between following points is varied with the increasing MU. For example the ratio between 100 to 200 MU for integrated mode is slightly different from the ratio between 200 to 300 MU. In contrast, this ratio for integrated and cine mode is equal. In clinical application, even both acquisition mode has a relatively similar response, each mode required individual calibration factor for dosimtery purpose due to the difference in the range of pixel value intensity for each mode.

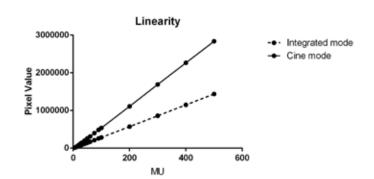

Figure 1: Response of a-Si EPID in both acquisition modes as a function of MU, error bars are too small to see.

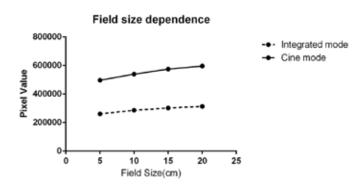

Figure 2: Response of a-Si EPID in both acquisition modes as a function of field size.

PS04.010 - Predicting clinical outcomes in locally-advanced non-small cell lung cancer using machine learning focusing on tumor and node imaging features

Author(s): Heyse Li¹, <u>Nathan Becker²</u>, Srinivas Raman³, Timothy C.Y. Chan⁴, Jean-Pierre Bissonnette³

¹Department Of Mechanical And Industrial Engineering, University of Toronto, Toronto/ON/CANADA, ²Radiation Oncology, UHN Princess Margaret Cancer Center, Toronto/ON/CANADA, ³Radiation Oncology, UHN Princess Margaret Cancer Center, Toronto/CANADA, ⁴Mechanical And Industrial Engineering, University of Toronto, Toronto/ CANADA

There is evidence that computed tomography (CT) and positron emission tomography (PET) imaging metrics are prognostic and predictive in

non-small cell lung cancer (NSCLC) treatment outcomes. We investigated the use of image features extracted from the radiotherapy target volumes to predict relapse in a cohort of NSCLC patients undergoing chemoradiation treatment (CRT). A prospective cohort of 25 patients with locally-advanced NSCLC underwent PET/CT imaging for radiation planning. Thirty-seven image features were derived from the CT-defined volumes and standard uptake values (SUV) of the PET image, for both the tumor and nodal target regions. The machine learning methods of logistic regression and repeated stratified five-fold cross-validation (CV) were used to predict local and overall relapse at two years of follow up. We selected features through an exhaustive search over all combinations of single- and two-feature classifiers. Classifiers were evaluated on their Matthew's correlation coefficient (MCC) after CV.

For local relapse, the best classifier had a mean CV MCC of 0.42. The classifier was composed of two features: (1) the volume of tumor having an SUV greater than the 95th percentile of the SUV distribution and (2) the volume of the whole tumor based on the CT scan. For overall relapse, the best classifier had a mean CV MCC of 0.51. The classifier was composed of two features: (1) the volume of tumor having an SUV greater than half of the 95th percentile SUV and (2) the volume of the nodes having an SUV greater than half of the maximum SUV.

Adding node-specific SUV information to the classifier improved the ability to predict overall relapse two years following treatment in our cohort of NSCLC patients. Also two-feature classifiers outperformed single-feature classifiers in predicting both local and overall relapse.

S04.011 - Risk estimate of second primary cancers after breast radiotherapy

Author(s): Eva Bezak¹, Alexandre Santos², Loredana Marcu³ ¹School Of Physical Sciences, University of Adelaide, Adelaide/SA/ AUSTRALIA, ²Medical Physics, Royal Adelaide Hospital, Adelaide/ AUSTRALIA, ³University of Oradea, Oradea/ROMANIA

Purpose: Induction of second primary cancers (SPCs) after breast radiotherapy (RT) has been known for some time and organs such as the lungs and the oesophagus have been identified as common sites for SPC formation¹. At present, breast cancer patients can be treated with a number of RT techniques that may have different morbidity risks. As a result, the current study investigated the risk of secondary carcinogenesis associated with particular radiotherapy techniques for breast cancer; these included 3DCRT whole breast, segmented breast, partial breast and mammosite brachytherapy.

Method: Seven breast cancer patients had all major organs contoured by a radiation oncologist on their planning CT images. Whole breast, segmented breast, accelerated partial breast irradiation (APBI) and mammosite boost treatment plans were generated for each patient using Pinnacle3 v 9.2 treatment planning system. Whole and segmented breast techniques used two tangential wedged fields: where the segmented techniques consisted of more MLC defined segments. Prescribed dose of 2 Gy for 25 fractions was used for calculations. APBI treatments were planned based on the Trans-Tasman Radiation Oncology Group (TROG) "trefoil" technique, using three non-coplanar fields. 6 MV photon beam was used for all treatment plans with a prescribed dose of 3.85 Gy for 10 fractions. Mammosite treatments consisted of a brachytherapy balloon (~35 mm diameter) inserted into the tumour bed inside a breast. Ir-192 source was positioned in the centre of the balloon to deliver the dose of 3.5 Gy for 10 fractions. Differential dose volume histograms were generated for a number of critical structures: bladder, brain and CNS, breast, colon, liver, lung, mouth and pharynx, oesopageous, ovary, salivary gland, small intestine, stomach, and uterus.

The lifetime attributed risk (LAR) of cancer induction was then estimated using the BEIR VII² and Schneider et. al ³ excess absolute risk models and calculated dose volume histograms for the above organs.

Results: The sites with the highest LAR estimates were the ipsilateral and contralateral lungs, and contralateral breast for all treatment techniques. For all sites, the LAR estimates for the segmented breast and mammosite treatments were lower than those for the whole breast and APBI treatments. For right sided target volumes the liver also resulted in high LAR estimates, with all techniques having a LAR greater than 20 per 10,000 PY, except for mammosite with a mean LAR estimate of 13.2 per 10,000 PY, as calculated by the full model ³. For left sided target volumes the stomach also resulted in high LAR estimates, with both whole breast and APBI having a LAR greater than 20 per 10,000 PY, and mammosite the lowest with a LAR of 8.3 per 10,000 PY, calculated by the full model³.

Conclusions: Whole breast, segmented breast, APBI and mammosite treatment plans were generated for seven breast cancer patients, and the DVHs were used to estimate the risk of secondary primary cancer induction. As expected from reported clinical studies; the lungs and contralateral breast showed high LAR estimates. Results show that mammosite technique results in the lowest risk estimate for SPC induction.

PS04.012 - A beam angle optimization technique for proton pencil beam scanning treatment planning of lower pelvis targets

Author(s): Janid Blanco Kiely, Benjamin M. White, Stefan Both Radiation Oncology, University of Pennsylvania, Philadelphia/UNIT-ED STATES OF AMERICA

Purpose: For deep seated targets in the lower pelvis, the highly conformal nature of proton therapy offers advantages in sparing organs at risk (OARs) located in the beam's path. A sharp distal penumbra effectively removes dose beyond the distal edge, completely sparing the OARs located beyond the distal edge. However, OARs located proximal to the beam's distal edge may receive significant dose. Selection of an optimal proton pencil beam scanning (PBS) beam angle has the potential to reduce the magnitude of dose to OARs by minimizing the integral dose. This would ensure target coverage and minimize the number of treatment beams. The purpose of this work is to investigate if a single optimal proton PBS beam angle could be quantitatively determined for lower pelvic targets.

Methods: This study employed a cohort of ten consecutively enrolled patients with high risk rectal cancer. The clinical target volume (CTV) was delineated by an attending radiation oncologist. Three plans were created for each patient where each plan had a single beam oriented in the left lateral, right lateral, and posterior directions. For each of the three beam angles, a ray-tracing approach was used to calculate the values of optimization metrics. The optimization process was based on two objectives; path length and HU homogeneity. The goal was to minimize the path length of the proton PBS beam from the patient surface to the distal edge of the CTV, relative to the entry point, while simultaneously minimizing HU inhomogeneity along the path length. The path length of a ray was calculated as a straight-line Euclidean distance from the surface of the skin to the distal edge of the CTV. HU homogeneity, which is to say inter-ray HU variation, was quantitatively defined as the standard deviation of the average intra-ray HU intensity distribution of the several hundred beamlets which comprise one beam. Both metrics were assessed for normalcy with a Kolmogorov-Smirnov test (KS test) where the criteria for a normal distribution classification was p<0.05.

Results: The KS test demonstrated that the distribution of path lengths were normally distributed in each beam angle. The average p-value was 0.03 ± 0.01 . 87.1% of the HU intensity distribution along individual rays was found to be normal where the average 90th percentile p-value was 0.04 ± 0.01 . Over the entire cohort, the beam angle with the shortest mean path length was the posterior beam at an average of 132.7±18.1mm compared to the lateral beams at average of 232.7±25.4mm. The lateral beams had less HU intensity variation on average at 31.7±4.9HU compared to an average of $36.0\pm4.5HU$ for the posterior beam. Though lateral beams had less HU intensity variation than the posterior beam, the difference in HU intensity variation was much less than the difference between path lengths. Numerically, the posterior beam's shorter path length resulted in its classification as the optimal beam angle.

Conclusion: A posterior PBS beam angle was found to be optimal for lower pelvis targets through an optimization approach that minimized the average path length and HU variation along multiple rays.

PS04.013 - Neutron-Photon mixed field dosimetry by TLD700 glow curve analysis and its implementation in dose monitoring for Boron Neutron Capture Therapy (BNCT) treatments Author(s): Esteban F. Boggio, Pablo Andres, Juan Longhino Reactor And Radiation Physics - Bariloche Atomic Center, Atomic Energy National Comission, San Carlos de Bariloche/ARGENTINA

Introduction. BNCT is a cancerous cells selective, non-conventional radiotherapy modality to treat malignant tumors such as glioblastoma, melanoma and recurrent head and neck cancer. It consists of a two-step procedure: first, the patient is injected with a tumor localizing drug containing a non-radioactive isotope (Boron-10) with high slow neutron capture cross-section. In a second step, the patient is irradiated with neutrons, which are absorbed by the Boron-10 agent with the subsequently nuclear reaction B-10(n,a)Li-7, thereby resulting in dose at cellular level due to the resulting high-LET particles. The neutron fields suitable for BNCT are characterized by high neutron fluxes and low gamma dose. Determination of each component is not an easy task, especially when the volume of measurement is quite small or inaccessible for a miniature ionization chamber. A method of measuring the photon and slow neutron doses (mainly by N-14 and B-10) from the glow curve (GC) analysis of a single 7LiF thermoluminescence detector is evaluated. This method was suggested by the group headed by Dra. Grazia Gambarini and used in the TAPIRO Research Reactor (Casaccia, Italy) and in the TRIGA MarkII of LENA Reactor (Pavia, Italy).

Material and Methods. The dosimeters used were TLD-600 (6LiF: Mg,Ti with 95.6% 6Li) and TLD-700 (7LiF:Mg,Ti with 99.9% 7LiF) from Harshaw. Photon dose measurement using the GC analysis method with TLD-700 in mixed fields requires the relation of the two main peaks of a TLD-600 GC shape obtained from an exposition to the same neutron field, and a photon calibrated GC with TLD700. The requirements for slow neutron dose measurements are similar. In order to properly apply the GC analysis method at the RA-6 Research Reactor BNCT facility, measurements were carried out in a standard water phantom, fully characterized on the BNCT beam by conventional techniques (activation detectors and paired ionization chambers technique). Next, the method was implemented in whole body dose monitoring of a patient undergoing a BNCT treatment, using a BoMAb (Bottle Manikin Absorption) phantom, with representative measuring points of critical organs. Finally, mice phantoms were constructed and irradiated in the BNCT beam using an experimental setup specifically designed for biological models experimentation. TLD-700 and activation detectors were implemented to compare with the Monte Carlo (MCNP) calculation model results, in order to evaluate the method performance.

Results. Implementation results and methodology evaluation are satisfactory.

Conclusions. The potential of GC analysis method to estimate both photon and slow neutron dose by using a single TLD-700 is shown, resulting in a dosimetric tool of great value. Using this method, whole body dosimetry results simple and precise, in contrast with the traditional method being used. Experimental validation for Monte Carlo (MCNP) calculation models of little animal irradiation setups were carried out successfully, especially when ionization chambers cannot be used because of instrument dimensions.

PS04.014 - Boron Neutron Capture Therapy (BNCT) neutron beam at **RA-6 reactor: Quality Assurance and Quality Control Author(s):** <u>Esteban F. Boggio</u>¹, Juan Longhino¹, Mariana Casal², Diana Feld³

¹Reactor And Radiation Physics - Bariloche Atomic Center, Atomic Energy National Comission, San Carlos de Bariloche/ARGENTI-NA, ²Constituyentes Atomic Center, Atomic Energy National Comission, Buenos Aires/ARGENTINA, ³Ezeiza Atomic Center, Atomic Energy National Comission, Buenos Aires/ARGENTINA

Introduction. BNCT is a cancerous cells selective, non-conventional radiotherapy modality to treat malignant tumors such as glioblastoma, melanoma and recurrent head and neck cancer. It consists of a two-step procedure: first, the patient is injected with a tumor localizing drug containing a non-radioactive isotope (Boron-10) with high slow neutron capture cross-section. In a second step, the patient is irradiated with neutrons, which are absorbed by the Boron-10 agent

with the subsequently nuclear reaction B-10(n,a)Li-7, thereby resulting in dose at cellular level due to the resulting high-LET particles. The Argentine clinical facility for superficial tumors treatment is located at the RA-6 Research Reactor (Bariloche Atomic Center). The neutron beam is defined as hyperthermal, designed as a combination of high thermal and epithermal neutron intensities, in order to provide a maximum of thermal neutron fluency at 1 cm depth. The clinical treatments were initiated in October 2003, having successfully completed 10 irradiations in 7 patients of cutaneous melanoma in extremities until 2007. In 2007, the highly-enriched fuel of the RA-6 reactor was replaced by the new low-enrichment uranium, which included a power upgrade and the reconfiguration of the core. This was the opportunity to improve the BNCT facility, mainly in terms of irradiation room size and beam port, protruding its end. Furthermore, the neutron beam was improved in specific irradiation parameters, such as an extended uniformity of the irradiation field.

Material and Method. The neutron beam and facility design process required the complete structural description for the calculation model in Monte Carlo (MCNP5). At the end of this process, the construction was executed, being completed in 2011. In order to ensure the new BNCT beam output, a Quality Assurance (QA) process was initiated by means of calculation model experimental validation. Usual activation techniques were employed to obtain thermal, epithermal and fast neutron fluxes, both with beam free-in-air and into standard water phantom. Gamma and fast neutron doses were measured in both configurations implementing the paired ionization chambers method, using tissue-equivalent and graphite miniature chambers. All measurements were carried out over the axial, parallel and transverse axis to the beam. A few modifications were performed to ensure essential parameters of the beam, and the full characterization was done and reported. Finally, the Quality Control (QC) protocol was developed and became effective before the restart of the clinical trials.

Results. QA process and its results will be shown in detail. Main beam parameters were compared and ensured with other techniques that have been implemented in the dosimetric characterization process.

Conclusions. Nowadays, under rigorous quality indicators, the Argentine BNCT Project is in conditions to restart the clinical trials in the short term.

PS04.015 - Improved Pareto navigation using a plan database with segmented plans

Author(s): <u>Rasmus Bokrantz</u>¹, Katrin Teichert², David Craft³ ¹Department Of Research, RaySearch Laboratories, Stockholm/ SWEDEN, ²Department Of Optimization, Fraunhofer Institute for Industrial Mathematics, Kaiserslautern/GERMANY, ³Department Of Radiation Oncology, Massachusetts General Hospital, Boston/MA/ UNITED STATES OF AMERICA

Background

Pareto surface navigation is a form of decision support for intensity-modulated radiation therapy that allows planners to browse through a space of possible dose distributions. This technique relies on interpolation of a number of pre-calculated plans' doses. The standard for step-and-shoot delivery is to represent Pareto surfaces by a database of fluence optimized plans. Such a representation inevitably leads to perturbations of the navigated dose when it is converted to a deliverable plan, because non-restricted fluence modulation is an idealization that cannot be matched in practice. The aim of the present work is to minimize the presence of conversion errors. To this end, we investigate navigation with respect to segmented plans, i.e., plans that take the physical limitations of the delivery system into account.

Materials

Navigation with segmented plans was assessed with respect to two head and neck cases obtained from Massachusetts General Hospital. The cases were selected because conversion errors had been a difficulty during the preparation of the clinical plan.

For comparative purposes, separate Pareto surfaces were generated with non-segmented (i.e., fluence-optimized) and segmented plans. Navigation was simulated by sampling 100 random points per surface. The associated navigated doses were converted to deliverable plans.

The magnitude of dose and dose-volume histogram (DVH) errors for organs at risk were quantified in terms of overdosage relative to the navigated dose: the error for a point that was nominally planned to receive 10 Gy but that received 11 Gy after the conversion is 1 Gy. Dose errors within targets were quantified analogously, but with underdosage also taken into account. All experiments were performed in RayStation v4.7 (RaySearch Laboratories).

Results

Figure 1 summarizes the collected error measures for one of the patients, which are representative also for the second patient. With segmented plans, the dose error in percent of the prescription was within 1.4% on average and within 6.8% at the 98th percentile level for all structures. The corresponding figures for the DVH errors are 0.9% and 3.3%. About a factor 2-3 larger errors were observed with non-segmented plans: the averages and 98thpercentiles of the dose errors were up to 3.5% and 15.9%, respectively, and up to 2.6% and 9.4% with respect to DVH. The smaller errors indicate that a representation with segmented plans has the potential to provide more informed and streamlined planning.

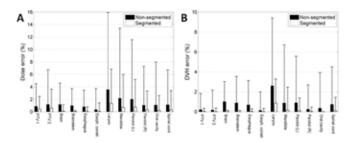

Figure 1: Averages (bars) and 98^{th} percentiles (whiskers) of the dose (A) and DVH errors (B).

PS04.016 - Automated measurement of dwell and tandem position in ring HDR applicators

Author(s): Bruno Carozza, Fabiola Vallejo

Radio-oncologie, Centre intégré de cancérologie de Laval, Laval/ QC/CANADA

Accuracy and efficacy in measuring in house dwell and tandem positions in ring applicators is very important due to steep dose gradients encountered in HDR brachytherapy.

It is suggested that measuring those offsets should take place when commissioning/replacing a ring applicator and after every source change. For each applicator, the reproducibility of these positions must also be considered.

Previous work has failed to address the inter/intra-observer variability of measurements as well as the time required to commission a ring applicator.

This work describes a new approach to determine dwell and tandem positions for ring applicators in which the ring is imaged and its dwell and tandem positions automatically measured in the ring applicator coordinate system. An image analysis computer algorithm was developed for this. It uses edge detection techniques and Hough transform for circle and ellipse detection to process axial and sagittal CT scouts of the ring applicator for each dwell position.

The algorithm performs the measurement of hundreds of dwell positions in seconds with an uncertainty below 0.2mm (CT Scout with up to 0.6mm pixel spacing) which allows us to speed up the ring applicator commissioning process along with removing inter/ intra-observer variability.

Our results showed that source dwells and tandem within Elekta's HDR CT/MR ring applicators can deviate from expected (Elekta's) positions by up to 4 millimeters. These results reinforce the importance of developing an in house technique to accurately measure dwell and tandem positions.

PS04.017 - eMU Whisperer: An application for assessing patient surface topology and its impact on monitor units in electron beam therapy.

Author(s): <u>Paule M. Charland</u>¹, Baochang Liu¹, Shane L. Lawrence², Natascha H. Van Lieshout³

¹Medical Physics, Grand River Hospital, Kitchener/ON/CANA-DA, ²Department Of Physics, University of Waterloo, Waterloo/ ON/CANADA, ³Electrical And Computer Engineering, University of Waterloo, Waterloo/ON/CANADA

Standard quality assurance protocols of patient specific radiation treatment plans require that monitor units (MUs) be verified with an independent mean. While Monte Carlo methods for electron beam treatment planning have opened up a new era where we anticipate reasonable dose accuracy in complex irradiation geometry and media composition, an independent (MU) verification is still to be performed to evaluate, within tolerance, if the Monte Carlo predicted MUs could be endorsed. The intent is to flag suspicious dose calculation that would warrant further investigation. These independent methods to verify MUs are normally based on simpler calculations consisting of empirical multiplicative functions with shortcomings such that flat geometry and straight beam incidence have to be assumed. The decoupled functions nevertheless provide insightful values. In a logical extension of current methodology for routine independent MU check, we have exploited the multiplicative property to define a correction factor, CF_{topo} , to account for topology effects. It is defined as the ratio of the dose output on the central axis at a nominal depth of maximum dose (d_{max}) of a given surface topology relative to the dose to a flat phantom, for the same irradiation conditions.

We have characterized CF_{topo} for a variety of phantoms on a True-Beam linac (Varian). Phantoms were constructed of different rounded masses of tissue equivalent material superposed to solid water slabs to create different surface topologies where the beams are incident. Point dose measurements were performed with a Markustype ionization chamber inserted into one of the solid water slabs on the central axis at nominal d_{max} for a constant source-surface-distance of 100 cm. Energies under consideration were 6, 9, 12, 16 and 20 MeV and cone sizes ranged from 6 cm x 6 cm to 25 cm x 25 cm. It was found that the magnitude of CF_{topo} could drop as low as around 80%, the lowest energies 6, 9 and 12 MeV being generally the most impacted.

This motivated the development of a methodology to provide $CF_{to.}$ from any arbitrary surface topology for our routine patient-specific plan quality assurance. We have developed the application "eMU Whisperer" in Matlab (MathWorks) which takes as input the three-dimensional patient surface topology based on the external body contour according to the CT image exported from the Eclipse treatment planning system (Varian). A cropped area in the beam's–eye-view, function of the range of the electron energy under consideration is used by the application to analyze and quantify the topology. A function for a given energy, previously determined from the aforementioned measurements, is used to map the topology parameter to the corresponding CF_{topo} .

The propounded methodology has been carried out on different clinical cases. The "eMU Whisperer" application provided CF_{topo} to help reconcile MUs. Data showed the marked impact of topology change, which if unaccounted for would lead to an unintended dosage. Detailed user evaluation demonstrates the strengths, limitations and practical value of the proposed quality assurance method.

PS04.018 - Beam modeling of the flattening filter-free beams for VMAT SBRT using the collapsed cone convolution superposition algorithm

Author(s): <u>Samju Cho</u>¹, Woonhoon Choi¹, Ho Lee¹, Kwangwoo Park¹, Jungil Lee¹, Jeongmin Yoon¹, Eungman Lee¹, Suk Lee², Sang Hoon Lee³, Juree Kim³, Jinho Choi⁴, Sangwook Lim⁵, Ki Chang Keum¹ ¹Radiation Oncology, Yonsei University, Seoul/KOREA, ²Radiation Oncology, Korea University, Seoul/KOREA, ³Radiation Oncology, Catholic Kwandong University, Seoul/KOREA, ⁴Radiation Oncology, Gachon University, Seoul/KOREA, ⁵Radiation Oncology, Kosin University College of Medicine, Busan/KOREA

Flattening filter-free(FFF) megavoltage beam has a highly forward peaked beam profile, increased dose rate from 1200 MU/min up to 2400 MU/min, less variation of off-axis beam hardening, less photon head scatter and less leakage outside of beam. In SBRT, high dose rate reduce the delivery time with benefit inpatient discomfort and with potential limitation of intra-fraction motion. The volumetric modulated arc therapy(VMAT) technique with FFF megavoltage beam have recently started to be used in the SBRT. The aim of this study is to create accurate FFF megavoltage beam model with the collapsed cone convolution superposition (CCCS) dose calculation algorithm for VMAT SBRT implementation.

The beam data sets of off-axis profiles, depth dose and relative output factor for photon 6 and 10 MV were measured in a PTW MP3 water phantom with a source to surface distance of 90 cm SSD. The off-axis profiles and depth dose were acquired with LA 48 linear chamber array at dose rate 300 MU/min from 1x1 up to 30x30 cm². The relative output factors were measured with the Farmer chamber for field size 10x10 cm² and larger, and the 0.004 mm³microDianmond detector for less than 10x10 cm² field size. Absolute calibration was performed according to IAEA TG 398 with 0.6 cm³ Farmer chamber using dose rate 1000 MU/min. Extra audit for output verification was carried out using OSLD with IORC Houston. The beam models were evaluated by making point dose measurement using cheese phantom and verifications of dose distribution using Sun Nuclear ArcCheck phantom with 3 mm/3% Gamma criteria.

The verification of CCCS beam modeling results showed that the point dose measurements were within 3% agreement between computed dose data and chees phantom measured dose data. The ArcCheck phantom evaluation results were well within the accepted clinical tolerance level. Our results show that beam modeling of CCCS algorithm could provide reliable FFF beam model for the VMAT SMRT treatment.

PS04.019 - Dependence of Collimator Angle on Prostate VMAT: A Treatment Planning Study

Author(s): M Isa¹, J Rehman¹, M Afzal¹, James Chow²

¹Islamia University of Bahawalpur, Bahawalpur/PAKISTAN, ²Princess Margaret Cancer Center, Toronto/CANADA

This study investigated the dose-volume dependences of planning target volume (PTV) and organs-at-risk (OARs) on prostate volumetric modulated arc therapy (VMAT), when the collimator angle is varied. Single-arc VMAT plans at different collimator angles (0°, 15°, 30°, 45°, 60°, 75° and 90°) were created systematically based on a Harold pelvis phantom and the 6 MV photon beams. The conformity index (CI), homogeneity index (HI), gradient index (GI), machine monitor units (MUs), dose-volume histogram and mean and maximum dose of the PTV were calculated and analyzed (Table 1). The dose-volume histogram and mean and maximum doses of OARs such as bladder, rectum and femoral heads for different collimator angles were determined from the plans (Table 2). From our dosimetric results, there was no significant difference, according to the planned dose-volume evaluation criteria, found in the VMAT optimizations for all studied collimator angles. However, a higher CI (0.53) and lower HI (0.064) resulted from the 45° collimator angle. The 15° collimator angle provided a lower value of HI similar to the 45° angle while collimator angles of 75° and 90° were found to be good for rectum sparing. In addition, collimator angles of 75° and 30° worked well for sparing the right and left femur. The PTV dose coverage for each plan was comparatively independent of the collimator angle. The dosimetric results in this study provide support and guidance in the collimator angle selection for prostate VMAT to improve the PTV coverage and OARs sparing.

PS04.020 - Dosimetry of Pacemaker in VMAT for Lung SBRT Author(s): James Chow¹, R Jiang²

¹Princess Margaret Cancer Center, Toronto/CANADA, ²Grand River Regional Cancer Center, Kitchener/CANADA

This study investigated the possibility to include the pacemaker in volumetric modulated arc therapy (VMAT) plan optimization for lung stereotactic body radiotherapy (SBRT) to reduce the pacemaker dose. Moreover, dose distributions of the planning target volume (PTV) and organs-at-risk (OARs) with and without lowering the pacemaker dose in VMAT plans were compared with the PTV close to and far away from the pacemaker. Patients with PTVs in their left and right lung were selected in lung SBRT. VMAT plans with pacemaker regarded as an OAR or not in the plan optimization were created. Dose-volume histograms (DVHs) of PTVs and OARs were determined and compared. Our results of VMAT plans (Figure 1(a): left lung and 1(b): right lung) showed that no significant deviation of dose-volume criteria of OAR was found, whether the pacemaker was or was not regarded as an OAR. This demonstrated that it is possible to achieve an acceptable PTV coverage by lowering the pacemaker dose in the VMAT plan, though larger dose-volume deviation of PTV can be found when it is closer to the pacemaker. In addition, DVH deviations for OARs were not significant when the pacemaker was regarded as an OAR in the plan. We also found that the dosimetric change is sensitive to OARs namely, trachea, bronchus, esophagus and cord when the pacemaker was included in the plan optimization. We concluded that it is possible to reduce the pacemaker dose by including it as an OAR in the VMAT plan for lung SBRT. This is especially important for patient depending seriously on the pacemaker, as VMAT beams for SBRT are directly on the device with a very high dose per fraction.

Fig. 1 DVHs of OARs for Patient (a) #1 and (b) #2 with (solid line) and without (broken line) lowering the pacemaker dose.

PS04.021 - Determination of ion chamber correction factors for small composite fields used by the CyberKnife radiosurgery system

Author(s): Eric J. Christiansen¹, Bryan R. Muir², Jason Belec³, Eric Vandervoort³

¹Medical Physics Unit, McGill University, Montreal/QC/CANA-DA, ²Measurement Science And Standards, National Research Council, Ottawa/CANADA, ³Medical Physics, Ottawa Hospital Cancer Center, Ottawa/CANADA

Purpose: A dosimetry formalism has been proposed to determine ionization chamber correction factors (CFs) for small and non-standard fields. Small field ionization chamber CFs have been shown to depend on off-axis position and source-to-axis distance (SAD). In this study, CFs were calculated using the EGSnrc user code egs_chamber for six composite fields delivered by the CyberKnife system with varying SAD and off-axis position.

Methods: Percentage depth dose (PDD) curves and output factors (OFs) for CyberKnife's largest (60 mm) and three smallest collimators (5 mm, 7.5 mm, and 10 mm) were measured with an Exradin A16

microchamber. A model of the CyberKnife G4 head was created in BEAMnrc with initial electron energy and spatial distribution tuned by matching measured PDDs and OFs to simulations performed in egs_chamber with detector response effects modelled based on manufacturer specifications.

This beam model was used to calculate dose-to-detector (D_{det}) to dose-to-water (D_w) CFs for the A16 in six different composite fields (5 isocentric, one non-isocentric) using the 5 mm collimator. The first three used all the standard beams employed by CyberKnife for skull lesions (average SAD= 800 mm), while the last three used a set of beams optimized for the treatment of trigeminal neuralgia (TN) (average SAD=700 mm). The point of intersection of the beams varied between different fields using the same beam set. The final field was a non-isocentric optimized clinical TN plan, where detector off-axis position varied between beams.

Results: Calculated and measured PDDs for the 60 mm collimator are in good agreement (root mean square deviation=1.1%) after tuning the electron energy. Figure 1 shows measured OFs and calculated D_{det} ratios used to select the beam's spatial distribution. The D_{det} to D_w CFs for the skull lesion fields were calculated to be 1.2464±0.0023, 1.2391±0.0022, and 1.2598±0.0024. The CFs for the isocentric TN fields were calculated to be 1.2565±0.0021, and 1.2495±0.0021; the CF for the non-isocentric field was 1.2103±0.0028.

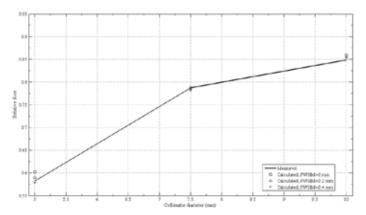

Figure 1. Comparison between measured and calculated OFs. The OFs were calculated with an electron energy of 6.7 MeV and varying full width at half maximum (FWHM).

Conclusions: CFs for the skull lesion fields varied by no more than 2% as a function of the location of the point of intersection of the beams. For "isocentric" TN fields, they varied by no more than 1%. If the non-isocentric field is included, the variation increases to 4%, demonstrating that a clinically-optimized plan requires larger CFs.

PS04.022 - One-year review of a real-time, ultrasound-based, single-fraction prostate HDR program – the Halifax experience Author(s): <u>Krista Chytyk-Praznik</u>¹, Amanda Cherpak¹, David Bowes², Nikhilesh Patil³, Mammo Yewondwossen¹

¹Medical Physics, QEII Health Sciences Centre, Halifax/NS/CANA-DA, ²Radiation Oncology, QEII Health Sciences Centre, Halifax/NS/ CANADA, ³Radiation Oncology, Dalhousie University, Halifax/NS/ CANADA

Introduction: The QEII Health Sciences Centre began a high-doserate prostate brachytherapy program in March 2014. As of January 2015, 25 prostate cancer patients have been treated under general anaesthetic using the real-time Oncentra Prostate (v. 4.2) treatment planning system (Elekta), with ultrasound imaging (BK Medical).

Materials and Methods: Two radiation oncologists and three physicists have been trained in the procedure. The patients were prescribed 15 Gy in a single fraction to the entire prostate (dose constraints listed in Table 1). The planning method for the first 10 cases involved 1) obtaining initial US image set 2) detailed contouring of the prostate, urethra and rectum 3) choosing virtual catheter positions 4) pre-plan dose optimization (using DVHO algorithm) 5) catheter insertion 6) catheter tip reconstruction 7) final imaging 8) final contouring 9) catheter reconstruction and catheter free length measurement and 10) final dose optimization. By the 11th patient, this planning flow was redesigned by replacing the first six steps with four: 1) obtaining initial US image set 2) choosing catheter positions 3) simultaneous needle insertion and preliminary contouring of prostate, urethra and rectum and 4) needle tip reconstruction. The remaining steps follow in the same order as the original planning method.

Results: Average treatment time (US probe insertion until the start of treatment delivery) was 177 ± 24 min (114 min – 216 min). Eliminating pre-planning steps for later patients increased efficiency of the treatment, with an improvement in average treatment time from 193 min for the first five patients to 155 min for the last five patients. The average prostate volume treated was $32.4 \pm 9.4 \text{ cc}$ (21.2 cc - 58.0 cc) with the average number of needles used equal to 15.1 ± 1.4 (11 – 17). A standard template for needle placement was not used, however general guidelines have been developed and are consistently followed. Prostate coverage for all patients was met, with an average V100% = 96.44% and a V90% = 99.35%, as were the constraints for the urethra and rectum (see Table 1). Comparing the dose constraints achieved for the first five patients and the last five patients, prostate coverage was consistent, but the guality of the plans improved by the last five patients (achieved lower V150% and V200% values).

Conclusion: Careful commissioning and practice runs of the procedure aided in a successful start to the program which has evolved and been refined over the initial 12 months.

	All patients	First 5	Last 5
Prostate: V100% (goal: 95-99%)	96.44%	96.28%	96.19%
Prostate: V90% (goal: 99-100%)	99.35%	99.15%	99.38%
Prostate: V150% (goal: <35%)	36.05%	39.95%	33.91%
Prostate: V200% (goal: <11%)	11.77%	14.47%	9.77%
Urethra: D10% (goal: <118%)	113.81%	114.61%	113.03%
Rectum: V80% (goal: < 0.5 cc)	0.281	0.245	0.321

Table 1: Summary of dose constraints and average results over all patients, the first five patients and the last five patients.

PS04.023 - Retrospective evaluation of visually monitored deep inspiration breath hold for breast cancer patients using edge detection

Author(s): Leigh Conroy¹, Rosanna Yeung², Sarah Quirk¹, Tien Phan², Wendy L. Smith²

¹Department Of Medical Physics, Tom Baker Cancer Centre, Calgary/AB/CANADA, ²Department Of Oncology, University of Calgary, Calgary/AB/CANADA

Purpose: Deep inspiration breath hold (DIBH) can reduce cardiac dose during left-sided breast cancer radiotherapy. This study uses cine imaging with edge detection to evaluate a visually-monitored DIBH technique (VM-DIBH).

Methods: Cine images were acquired weekly during the medial tangent field of patients treated with VM-DIBH. Edge detection was used to identify the field borders and chest wall edges in digitally reconstructed radiographs (DRRs) and cine images of 15 patients. The distance between the field border and chest wall was measured at the center of the field and used as a surrogate for patient position during breath hold. Setup uncertainties were found by comparing DRR measurements to the first cine image measurement for each fraction. Intra-beam motion during individual breath holds was assessed by comparing the first cine image measurement to all subsequent cine image measurements for each fraction.

Results: The mean setup uncertainty (M) was 1.2 mm; random (σ) and systematic (Σ) setup errors were both 2.0 mm. The chest wall position was within 5 mm of the DRR position in 92% of cine images. Intra-beam motion was within +/- 2 mm in 98% of images, and was slightly skewed in the posterior direction, indicating that patients tend to relax or exhale during breath holds.

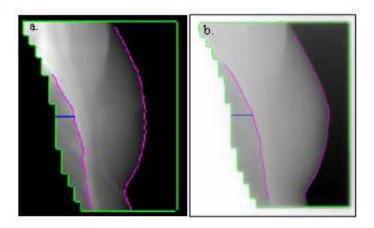

Fig. 1 Chest wall edge detection of field borders (green), chest wall (pink) and chest wall position measurement (blue) for a DRR (a) and cine image (b).

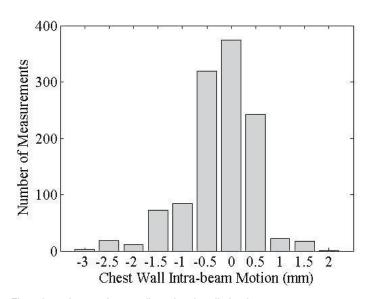

Fig. 2 Intra-beam chest wall motion for all cine images.

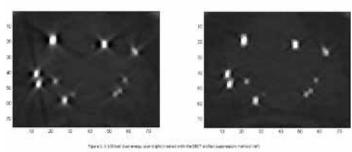

Conclusion: Edge detection of field borders and the chest wall in cine images and DRRs was successfully used to evaluate interfraction and intra-beam uncertainties for a VM-DIBH technique. Setup uncertainties and chest wall position measurements indicated adequate breath hold setup reproducibility for the majority of patients. Intra-beam motion measurements showed excellent stability of breath hold during treatment.

PS04.024 - DECT Tissue Characterisation and Artefact Suppression Method for Improved Dose Calculations in Brachytherapy Treatments.

Author(s): <u>Nicolas Cote</u>, Stephane Bedwani, Jean-Francois Carrier Radio-oncologie, CHUM- Notre-Dame hospital, Montreal/QC/ CANADA

Doses in brachytherapy, for many years now, have been evaluated using the TG-43 formalism which make use of standard equations determined from a full water based medium. However, the accuracy of these calculations, particularly in Low Dose Rate (LDR) brachytherapy, are misleading, as they are highly dependent on inter-seed attenuation and patient tissue heterogeneities due to its low energy range (20-30 keV). This Monte Carlo study allows the evaluation of the dose distribution in individual cases by encompassing patient specific tissue information with a voxel by voxel determination of the effective atomic number (EAN) and electron density (ED). Using a dual energy computed tomography (DECT), these physical parameters can be extracted using the stoichiometric calibration method. The DECT is also be used to minimize the presence of metallic artifact contributed by sealed radioactive sources containing materials of high atomic number. This new technique is quick and simple as it uses a mixture of both distinct energy scans. The concept behind the suppression is manipulating the differences in Hounsfield Units (HU) variations between different structures in order to find an image describing the artifacts alone. Thereafter, the initial image can be treated from metallic artifacts by subtracting it from the latter (Figure 1). The dose calculations have been accomplished using Brachy-Dose from the EGSnrc series. Using this software, variations in the dose have been analyzed from inter-seed attenuation and show differences ranging roughly 5.8% to 6.2% in the dose at 90 % of the target volume (D_{oo}). Also, with the stoichiometric method, the extraction of ED and EAN, using DECT suppressed artifact images, allows for a voxel-to-voxel tissue characterization depicting a better reality of patient anatomy. This would in consequence be integrated in the Monte Carlo simulation to analyze further variations from TG-43

formalism. Results currently suggest an increase in dose variations when considering these heterogeneities compared to inter-seed attenuation. Henceforth, this study would help bolster the recommendations in brachytherapy dose calculations suggested by the TG-186 report as it implements techniques that reach beyond the TG-43 formalism.

PS04.025 - Radiotherapy Planning using CEER and CADPLAN in a Prostate Cancer Patient

Author(s): Juan Alberto L. Cruz¹, Maíra Mariana C. Uchôa², Diego S. Dolci¹, Ernando S. Ferreira¹, Wilfredo G. Infante³ ¹Department Of Physics, State University of Feira de Santana, FEIRA DE SANTANA/BRAZIL, ²Radiotherapy Section, Hospital Aristides Maltez, Salvador/BRAZIL, ³Department Of Atomic Molecular And Nuclear Physics, University of Granada, Granada/SPAIN

The authors accurately reproduced 3D conformal radiotherapy treatment plan beamlet and patient configurations using Computational Environment for Radiotherapy Research (CERR) and CADPlan treatment planning system (Varian Medical Systems, Palo Alto, CA). These planning were carried out with seven radiation fields of X-ray using a Therac-20 Neptune linac. All fields were calculated with a source surface distance of 100 cm, symmetric collimators in the Xaxis and asymmetric in the Y-axis, and with a total field of 12 x 10.5 cm². The nominal energy was 18 MV except for a one field, which was chosen 6 MV. The initial parameters to perform the calculation were complemented with the inclination angles of the couch and gantry. Were used a set of Computerized Tomography images obtained of an anonymous patient with prostate cancer diagnosed and indication for radiotherapy (the prescribed dose was 58.5 Gy). Isodose contours maps, normal tissue complication probability (NTCP), and dose-volume histograms (DVHs), are shown and discussed. The results show that on the gross tumour volume (GTV), there is 99 % of its volume receiving 56.67 Gy. It is observed that approximately the GTV receive the prescribed dose. The PTVHD and PTVLD that includes the GTV with margins also show high probabilities of receiving the prescribed dose. The risk organs, bladder and rectum has a probability of 68 % and 89 % of its volume to receive an equivalent dose of 27 Gy and 36.76 Gy, respectively. Comparing the planning results obtained from two codes, it is observed that both are consistent with the established standards. The results shown that the CERR is appropriate to be use in clinical treatment planning.

PS04.026 - Impact of increasing irradiation time on the treatment of prostate cancers

Author(s): <u>Alexandru Dasu</u>¹, Iuliana Toma-Dasu² ¹Department Of Radiation Physics, Linköping University Hospital, Linköping/SWEDEN, ²Medical Radiation Physics, Stockholm University and Karolinska Institutet, Stockholm/SWEDEN

This study aimed to investigate the expected impact of intrafraction repair during increasing irradiation times for the treatment of prostate cancers. Lengthy sessions are indeed expected for some

advanced irradiation techniques capable to deliver the large fractional doses required by the increased fractionation sensitivity of the prostates. For this purpose, clinically-derived parameters characterizing repair rates and dose response curves for prostate tumors have been used to calculate the expected loss of effectiveness when increasing the irradiation time. The results have shown that treatment sessions lasting more than about 20 to 40 minutes could reduce the probability of biochemical control of prostate tumors by more than 20 to 30 percentage points. These results are in agreement with some observed clinical results and therefore they suggest that treatment durations in prostate radiation therapy should be carefully recorded in order to explicitly account for intrafraction repair, especially when irradiation techniques make use of multiple beams and imaging sessions. Failure to do so might overestimate the expected effectiveness of the treatment and could lead to disappointing clinical results precisely from the demanding treatment modalities expected to increase the therapeutic gain in prostate radiotherapy.

PS04.027 - Hemi-body Electron irradiation: Development and Verification of this new technique

Author(s): <u>Panagiotis G. Delinikolas</u>, Kalliopi Platoni, Vasilios Kouloulias, Georgios Patatoukas, Maria Dilvoi, Efstathios Efstathopoulos 2nd Department Of Radiology, Radiotherapy Unit, Attikon Hospital,medical School, National University of Athens, Greece, Chaidari -Athens/GREECE

Purpose

Half body (or Hemi body) electron irradiation aims to deal with cases of surficial skin tumors with more symptomatic density on upper or lower body (upper and lower HBI technics). Like Total Skin Electrons Beam Technique (TSEB), the spectrum of using HBI includes various deceases such as Kaposi's sarcoma and T-Cell Lymphoma plus its product diseases. As today half body irradiation technics are using photons (x radiation produced from linacs or γ radiation produced by Cobalt Units) mainly for bone metastatic cancers, the need of introducing electron beams for skin tumors was raised. The purpose of the following study is to introduce a new electron HBI technique, implementing dosimetry and standards protocol in accordance with TRS 398 (IAEA). The evaluation of the results is according to AAPM's Report No.23 and IEAE's Review of radiation Oncology Physics: A handbook for teachers and students.

Materials and Methods

A linear accelerator of the radiotherapy division of Attikon Hospital (Athens Greece), used to produce electron beams, a custom crafted chamber (used for TSEB in "Attikon" hospital) and an additional and adjustable (for Upper and Lower HBI taking patient's height into consideration) Pb shielding placed before patient are used for this new treatment. Custom standing technique is used both for lower and upper body cases. Parameters and characteristics of the beam which are measured and evaluated are: PDD on treatment plane and 2 dimensions profile of single beam (fig. 2) for both upper and lower regions, surficial and in reference depth absorbed dose in plain phantom and human like phantom. The above resulted in a calculation of the monitor units need for the delivery of the prescribed dose.

Results

The results are different especially close to the points of high dose spikes, to those extracted for the TSEB techniques driving to different homogeny of dose distribution on upper or lower extremities optimized for different metrical characteristics of patients and their clinical cases.

Conclusion

Electron HBI technique delivers the prescribed dose in the portion of the skin which needs treatment. This will minimize the dose delivered to healthy skin and allow us to handle each case differently and provide more choices for each individual.

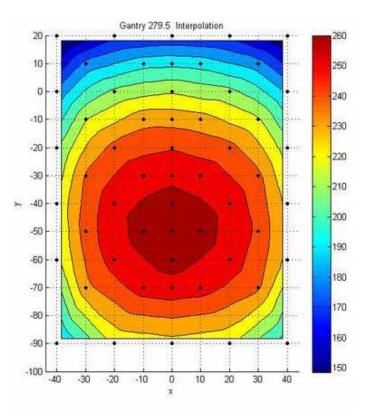

Figure 2 – 2 Dimensional Beam profile on treatment plane

PS04.028 - Deformable image registration and automatic contouring using Cone-Beam CT imaging: A study of volume statistics and similarity measures

Author(s): <u>Olivier Fillion</u>¹, Luc Gingras², Louis Archambault² ¹Centre De Recherche Sur Le Cancer, Universite Laval, Quebec/ QC/CANADA, ²Departement De Radio-oncologie, Hotel-Dieu de Quebec - CHU de Quebec, Quebec/QC/CANADA

Volume statistics and similarity measures provide useful tools for an image-guided adaptive radiotherapy protocol to evaluate the need for re-planning during treatment. The aim of this study is to assess the accuracy of such indices when calculated on contours generated by a deformable image registration algorithm and an automatic contouring tool compared to manual references.

The study was done using the OnQ rts software (Oncology Systems Limited, Shrewsbury, UK). This software includes modules to register and/or recontour image series and evaluate the automatic contours it generates. Two methods are tested to generate contours during treatment: (1) registering the planning CT onto daily CBCTs and applying the deformation map to the planning CT structures to create an adaptive plan; (2) using the automatic atlas-based contouring tool directly on the daily CBCTs. These 2 sets of deformed structures are then compared against the same 240 structures manually contoured by a physician on daily CBCTs. The 240 reference CBCT structures with the 25 reference CT structures define the ground truth for volume statistics such as Δ Volume and Dice index.

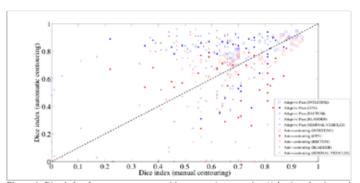

Figure 1. Dice index for structures generated by automatic contouring (Adaptive planning and Auto-contouring) with respect to the expected Dice index as given by the manually contoured structures (Intestine, GTV, Rectum, Bladder and Seminal vesicles) on the reference CT and CBCT. The dashed line y = x indicates a perfect registration, where manual Dice index = automatic Dice index.

Results in Figure 1 show the adaptive planning tends to over-estimate the Dice index for many organs, thus generating not as large a deformation as required. Figure 2 shows the ratio of Dice indexes tends to diverge from 1 if the structure shrinks during treatment. Such deformations, especially for the bladder and independent of the method, would wrongly indicate the organ had not moved or deformed during the treatment.

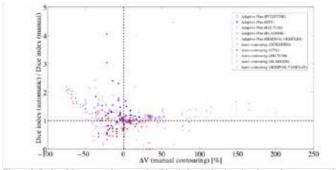

Figure 2. Ratio of the automatic contouring Dice index (Adaptive planning and Auto-contouring) on the manual contouring Dice index given by the reference CT and CBCT structures (Intestine, GTV, Rectum, Bladder and Seminal vesicles) with respect to the variation in volume of the structures between the reference CT and the reference CBCT. The vertical dashed line at x = 0 indicates no variation in volume between the reference CBCT structure and the reference CT structure. The horizontal dashed line at y = 1 corresponds to a perfect registration, where manual Dice index = automatic Dice index.

To conclude, automatic contouring on CBCTs depends on the organ, the method and the deformation. Looking at Dice indexes, organs such as the intestines show good agreement with manual contours, but the variability is larger for the seminal vesicles. Ultimately, the decision to re-plan treatments could be based on thresholds for selected indices and organs.

PS04.029 - Acceptance Modulated Radiation Intensity and Enhanced Dynamic Wedge using 2D Ion Chamber Array Author(s): Oscar J. Garcia Contreras¹, Luis D. Casas² ¹Unidad De Cancerologia, Hospital Universitario de Neiva, Neiva/ COLOMBIA, ²Radiotherapy Service, Oncologist from Occident Foundation, Pereira/COLOMBIA

Dynamic techniques for dose delivering used in external radiotherapy such as modulated radiation intensity (IMRT) and enhanced dynamic wedges (EDW) tend to be used with more frequency due to the benefits in terms of higher treatment dose to the tumor while preserving the exposure of healthy tissues and reduction in treat-

ment times needed in wedged beam techniques, respectively. In seeking to ensure accuracy in dose delivery in dynamic techniques are several the measurement methods and systems developed. One of the factors of interest to medical physicists who daily use these techniques in the clinic routine is the quick and easy configuration of measurement systems and analysis to carry out QA tests. This paper presents the results of tests of acceptance for Intensity Modulated Radiation Therapy and Enhanced Dynamic Wedge Commissioning made on a Varian iX with 6 and 10 MV energies using a 2D array ionization chamber Octavius2D. This paper presents the results of acceptance tests for IMRT and EDW commissioning made on a 6 and 10 MV Varian iX using a 2D array Octavius2D PTW ionization chamber. Acceptance factors considered were: absolute dose delivery, reproducibility and exactitude fluence patterns, dose profile and QA of specific patient. The results obtained show a good accordance with the field parameters having higher acceptance percentages to 90% in all realized tests.

PS04.030 - Dose Calculation in Gynecological Brachytherapy using Monte Carlo simulation for intracavitary treatment of Cervical Cancer

Author(s): Oscar J. Garcia Contreras¹, Luis F. Cristancho Mejia² ¹Unidad De Cancerologia, Hospital Universitario de Neiva, Neiva/ COLOMBIA, ²Physics Department, National University of Colombia, Bogota/COLOMBIA

Intracavitary brachytherapy with high dose rate (HDR) is nowadays one of the complementary specialities for the treatment of cervical cancer. This work presents results of an application for the deposited dose calculation in brachytherapy treatments for cervical cancer using distributed tools in the GAMOS and Geant4, aimed at studying the effects on dose distribution considering the variation of tissue inhomogeneities and decay characteristics for an mHDR-v1 Nucletron Classic source. The anatomy of the patient is included in the developed Monte Carlo simulation using CT images of a typical HDR brachytherapy for cervical cancer treatment defining a voxel grid which contains the composition and density information due to body tissues, extracted from CT images, and converted to material voxels through the CT Number characteristic curve. The results obtained are in agreement with values reported by the planning system used, showing a difference possibly due to overestimation due to AAPM Task Group No. 43 formalism, the effect due to variation in tissue and the noise contained in the image.

PS04.031 - An inverse treatment planning module for Gamma Knife Perfexion™ using 3D Slicer

Author(s): <u>Kimia Ghobadi</u>¹, Yago Oliveira², Kevin Wang³, Dionne Aleman⁴, David Jaffray⁵

¹Techna Institute, University Health Network, Toronto/ON/CAN-ADA, ²Computer Science, University of Toronto, Toronto/CAN-ADA, ³Radiation Oncology, Princess Margaret Cancer Centre, Toronto/CANADA, ⁴Mechanical And Industrial Engineering, University of Toronto, Toronto/ON/CANADA, ⁵Radiation Medicine Program, Princess Margaret Cancer Center, Toronto/ON/CANADA

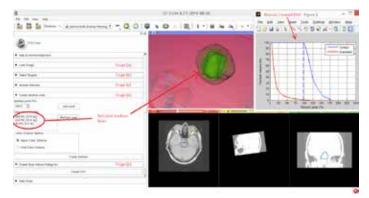

We developed an inverse treatment planning module for Leksell Gamma Knife Perfexion[™] using 3D Slicer as the interface. Perfexion[™] is a cobalt-60 system that delivers stereotactic radiosurgery treatments for head-and-neck tumours. Inverse treatment planning for Perfexion[™] has been previously shown to produce quality treatment plans [1], however, a medium to easily use and test the inverse plans does not exist. Our module provides a layout that simplifies input/output format and the result illustration process for any Perfexion[™] inverse treatment planning algorithm that is written in MATLAB.

The Gamma Knife Perfexion Inverse Treatment Planning (GK-Inverse-

Plan) module is developed in Python and MATLAB using 3D Slicer (v4.3.1 r23560) and its SlicerRT (v0.14.5) and MatlabBridge (v0.11.0.) extensions. GK-InversePlan provides the inverse planning optimization algorithm with inputs, such as, tumour volumes, organs-at-risk (OARs), and clinical prescriptions and guidelines. It also captures and illustrates the outputs including dose-volume matrices and final shots.

The GK-InversePlan module is divided into five stages of (a) Load Image, (b) Select Target, (c) Inverse Planning, (d) Isodose Illustration, and (e) Dose-Volume Histogram (DVH) Illustration (Figure 1). In Stage (a), the user can load DICOM formatted images, as well as other data including target volumes, OARs, and other organs of interest, which are all typically contoured previously in Perfexion™'s treatment planning environment (GammaPlan). Once the images and the organs are imported, the user will be prompted to Stage (b) where the target volume(s), their prescription dose, and other clinical guidelines can be specified. In Stage (c), the inverse treatment planning algorithm is performed by calling the optimization model from MATLAB. Any MATLAB figures, interfaces, and scripts that are contained in the inverse plan algorithm will be shown to the user at this point. Once the inverse treatment plan is obtained, the user can use Stages (d) and (e) to illustrate the isodose lines and DVH graphs, respectively.

GK-InversePlan is a module in 3D Slicer that provides a platform for integrating MATLAB-written inverse treatment planning tools for Perfexion[™] with clinical visual interface and easy input and output access. Figure 1 depicts a snapshot of GK-InversePlan and a conformal plan [1] (Paddick CI of 0.83) for a synthetic acoustic neuroma on a sample MRI image, and shows the obtained DVH graph and isodose volumes.

[1] Ghobadi, Ghaffari, Aleman, Jaffray, Ruschin. Automated treatment planning for a dedicated multi-source intra-cranial radiosurgery treatment unit using projected gradient and grassfire algorithms, Medical Physics, 39(6):3134-3142, 2012.

PS04.032 - Bladder and rectum DVH prediction: a statistical approach for prostate treatment

Author(s): Frédéric Girard, Martin Hinse

Département De Radio-oncologie, Centre intégré de cancérologie de Laval, Laval/CANADA

Purpose: To predict bladder and rectum DVH values for prostate treatment based on the intersection of these structures with the PTV.

Methods: DVH values for the rectum (V50, V60, V65, V70 and V75) and the bladder (V40, V65, V70 and V75) were extracted from prostate and post-operative prostatic bed treatment plan. All the planification process of these plans from the contouring of OAR and target volume to the VMAT inverse planning technique was performed using a standard procedure. For convenience, all plans

are optimized at the total treatment dose and then scaled down to the specific plan dose. Correlation of each DVH value with relative volume of bladder and rectum that are within the PTV or an 18 mm expansion of the PTV was verified using multi-linear regression. The correlation with a parameter was judged significant if the p value is inferior to 0.05. In order to improve the correlation of the regressions with the parameters, treatment plans were divided in three categories that shared common target morphology: treatment of the prostate with or without seminal vesicles (N = 191, 2 Gy per fraction, prostate receives 78 Gy, seminal vesicles receive 54 Gy); treatment of the prostate that included both seminal vesicles and the lymph nodes (N = 37, 2 Gy per fraction, lymph nodes receive 44 Gy); and post-operative prostatic bed treatment (N = 62, total dose of 66 Gy in 33 fractions). Post-operative prostatic bed treatments that included lymph nodes were removed from the analysis due to the small sample size. Outliers were removed from each distribution.

Results: DVH values that are close to the total treatment dose showed the best correlation with the intersection of bladder and rectal volume with the PTV and only marginally or not at all with the intersection of the expanded PTV. The overall regression models showed better results with tighter confidence intervals than the ones for low dose values. This is to be expected since the highest isodoses are tailored almost perfectly around the PTV. Correlation with the PTV intersection decrease gradually as the DVH dose values get further away from the total dose and the correlation with the expanded PTV intersection because more significant. Rectum V50 and bladder V40 showed the poorest correlation which suggest that there is a great variability in the optimization of these parameters due to the patient morphology and/or planner decision. The use of the statistical models in clinical practice is in the early stage but we can already see an improvement in planification time and overall better rectum and bladder sparring.

Conclusion: Building a statistical model of bladder and rectum DVH values against intersection of these structures with the PTV provides a simple mean to predict the DVH outcome of future plan, to prevent planification error and to guide beginning dosimetrist.

PS04.033 - Retrospective evaluation of applicator localization for HDR cervix brachytherapy – A comparison of MR versus CT Author(s): Lisa Glass¹, Daron Owen², Daxa Patel², Aaron Vandermeer², Cathy Neath²

¹Department Of Radiation Oncology, University of Toronto, Toronto/ON/CANADA, ²Medical Physics Department, R.S. McLaughlin Durham Regional Cancer Centre, Oshawa/ON/CANADA

The international standard for treating cervix cancer with brachytherapy is 3D volume-based planning. Currently at the Durham Regional Cancer Centre (DRCC; Oshawa, Canada) CT and MR imaging are acquired and fused for each fraction. The MR image is used to aid target contouring and the applicator is reconstructed on the CT dataset using an applicator model provided in our brachytherapy planning software.

Although MR-only planning would reduce patient transfers, thereby lowering the risk of applicator motion or uterine perforation, a limiting factor is the inferior visibility of the applicator in MR versus CT imaging. In this retrospective study, applicator placement with MR versus CT imaging using the applicator model is compared. In order to assess the relative applicator position in a single coordinate system, the applicator is contoured on the CT image set and copied to the fused MR image set. The applicator model is then placed on the MR image set first using the CT applicator contour, and then using the MR image only. Fifteen cervix cancer brachytherapy treatments at the DRCC were evaluated.

As demonstrated in Figure 1, the source dwell positions vary by an average of 1.3 ± 0.5 mm in the ring and 1.0 ± 0.3 mm in the tandem,

when comparing CT to MR. Furthermore, we investigate the dose equivalency between CT and MR-based applicator model placement. As shown in Table 1, there is no significant difference in D90 to the CTV and in D2cc to the OARs between CT and MR, varying on average by less than 3%. Other dose indicators and individual treatment DVHs also support the conclusion that doses to target volumes and OARs are comparable between applicator model placement on CT versus MR image sets.

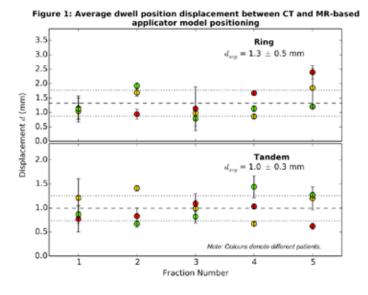

Table 1: Dose difference in MRbased applicator model placement compared to placement on CT

∆ (D90)					
CTV	$-0.5\pm1.8~\%$				
∆(D2cc)					
Bladder	$+0.6\pm2.6$ %				
Rectum	$0.0\pm2.7~\%$				
Sigmoid	$-0.2\pm2.4~\%$				

PS04.034 - A general source model for clinical linac heads in photon mode

Author(s): <u>Wilfredo González</u>, Marta Anguiano, Antonio M. Lallena Department Of Atomic Physics, Molecular And Nuclear, University of Granada, Granada/SPAIN

In this work a general source model has been developed to describe clinical linac heads when operating in photon mode. Six different linacs (three operating at 6 MV, one at 15 MV and two at 18 MV) have been studied. The construction of the model as well as its validation have been carried out on the base of the virtual linac approach in which the complete linac geometries have been simulated with the

Monte Carlo code PENELOPE. The model includes a primary and a secondary sources for photons and two sources for electron contamination whose geometrical characteristics are determined from a set of simulated fluence distributions in air. The energy distributions are obtained from the Monte Carlo energy distributions, for photons of the photons moving along the beam axis, and for electrons of electrons below the flattening filter. To verify the model, output factors, percentage depth doses and transverse profiles in water obtained from a calculation performed with the complete geometry are compared to those found with the source model. A reasonable agreement is obtained in all cases analyzed.

PS04.035 - Measurement of the beam quality TPR 20,10 of small radiotherapy fields: Comparison of experimental measurements and Monte Carlo simulations

Author(s): Eduardo A. González-Villa, Jose M. Larraga-Gutierrez Laboratorio De Física Médica, Instituto Nacional de Neurología y Neurocirugía, México city/MEXICO

Purpose. To measure the beam quality of small radiotherapy fields by using several detectors commonly used in small beam dosimetry and to verify the accuracy of these measurements by means of Monte Carlo simulations.

Material and Methods. The detectors employed in this work were a PTW-Farmer ionization chamber (to measure TPR 20.10 in reference conditions), PTW-31014, and PTW-60019 (PTW-Freiburg, Germany), and IBA-CC01 and IBA-SFD (IBA-Dosimetry, Germany). The experimental measurements were performed in a water scanning phantom MP3-XS (PTW-Freiburg, Germany). The irradiation of the detectors was carried out with a Novalis (BrainLAB, Germany) linear accelerator operating in x-ray mode at 6 MV with an exposition rate of 480 UM/min. The reading instrument used was a PTW UNIDO-Swebline electrometer. TPR 20,10 was determined as the ratio of doses at 20 and 10 cm in a parallel beam with a source to axis distance of 100 cm. The data were acquired for conventional field sizes of 10 x 10, 5 x 5, and unconventional field sizes of 3 x 3, 2 x 2 and 1 x 1 cm. The DOSRZnrc code was used for Monte Carlo simulations of photon transport through the linear accelerator and for the calculation of absorbed dose in water. Phase spaces data were used to calculate dose profiles in water for the conventional and unconventional field size (José Lárraga, Phys. Med. Biol. 60 905, 2015).

Results. For the PTW-31014 TPR 20,10's differences between Monte Carlo Simulation were 0.2 to 5.5%. For the IBA CC-01 were 0.2 to 4.0%. For the IBA-SFD were 0.2 to 2.3%, and for the synthetic diamond PTW-60019 were 0.2 to 2.3%. The uncertainty measurements for conventional fields were 0.1% and for the unconventional small fields were 0.2%. The major difference that was taken into the field 10 x 10 cm was in SFD IBA-Dosimetry, and for the field 1 x 1 cm was in PinPoint PTW-31014.

Conclusions. The best matches between Monte Carlo and measured detectors TPR 20,10 were the stereotactic field diode and the synthetic diamond detector. The high deviation present in the measurement of beam quality of small radiotherapy beams may be related to the partial volume averaging. Further research in needed to establish if this results may be applied to small beam corrections factor determination for small beams.

PS04.036 - The Effect of Assessment Criteria on Inter-rater Variability in the Evaluation of Skin Reactions following Breast Cancer Radiation Therapy

Author(s): <u>Riya Goyal</u>¹, Alexander Blood¹, Louis Potters², Ajay Kapur¹

¹Hofstra North Shore LIJ School of Medicine, Hempstead/UNITED STATES OF AMERICA, ²North Shore LIJ Cancer Institute, Lake

Success/UNITED STATES OF AMERICA

Purpose: Although the Common Terminology Criteria for Adverse Events (CTCAE) grading scales are utilized to assess adverse reactions to radiation therapy, few studies have investigated their reliability. In our previously reported image-based retrospective study, variability between caregivers (radiation oncologists, nurses) in assessing skin reactions in breast cancer radiation therapy using this scale was found to fall within a "moderate" range of concordance (Fleiss kappa score 0.43) per the Landis-Koch criteria. In this work, the potential impact of specific toxicity assessment terms documented by raters in our previous study on overall scale reliability was evaluated.

Methods: In an institutional-review board approved retro-

spective study, clinical notes documented by 8 caregivers were interpreted to assess how discordances among grades of skin lesions following radiation therapy potentially related to the use of freehand terms to describe the adverse events. 25 terms commonly used in the commentary were identified and categorized into those that were and were not outlined in the CTCAE scale. The percentage incidence and free marginal kappa scores for each term was calculated.

Results: The free marginal kappa scores for the terms stated in the CTCAE scale ranged from 0.333 to 0.565, suggesting a fair-to-moderate level of concordance between grades given by caregivers who used such terms. Certain terms not included within the CTCAE scale such as "hyperpigmentation" exhibited a higher rate of incidence (80%) and concordance (free marginal kappa score of .512) than those included explicitly in the scale.

Conclusion: The low kappa scores associated with terms in the CT-CAE scale suggest variability in caregivers' interpretation of assessment criteria. Revision of the wording of the scales may be needed to make definitions unambiguous and ensure a reliable grading scheme. The high frequency and kappa scores of terms including "hyperpigmentation" suggests revisions may also require inclusion of new clinical toxicity assessment criteria.

PS04.037 - Two-dimensional probability density function presenting the pre-treatment variability of the rectal wall integrating the variability of the motion of the rectum and the rectal wall thickness

Author(s): <u>Grigor N. Grigorov</u>, Johnson Darko, Ernest K. Osei Medical Physics Department, Grand River Hospiatl, Kitchener/ CANADA

Taking into account inter-fraction changes in anatomy and rectal content, it can be assumed that the position of the rectum (Rm) and the thickness of the rectal wall (tw) could be different for each fraction. This may cause a disagreement between the planned and the delivered dose map to the rectum. Probability density functions (PDFm) describing the organ motion uncertainties of the rectum have been reported by many authors. We further propose a probability density function describing the changes in the rectal wall thickness (PDFtw) and hence introduce a two-dimensional function PDFm&tw, incorporating the variability of Rm and tw using their PDFm and PDFtw, respectively. Our model is based on the histogram of the average tw of 587 randomly selected prostate patients. The average tw values were calculated in a treatment planning system based on the rectal structure contours drawn in the planning dataset using the initial planning CT scan of the patient. The new PDFtw was established as a mixture of a threemode distribution with specific mean value, standard deviation and weight, namely, for full (3.31, 1.82 and 77.1%), partially full (7.7, 0.809 and 15.2%) and empty state of the rectum (10.27, 0.906 and 9.4%), respectively. The PDFm&tw function was introduced as a productmixture model of the two functions PDFm and PDFtw and it has been graphically and mathematically reviewed. The *product-mixture* is an original model presenting the pre-treatment variability of the rectal wall.

Figure 1a Figure 1b

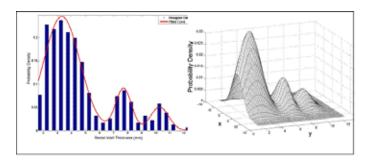

Figure 1a. Normalized histogram data with a fitted three-mode Gaussian curve.

Figure 1b. Anterior–posterior direction. A *Product-Mixture* model of the multivariate probability density function *PDFm&tw* which includes both the motion of the rectum (axis X [mm]) and the rectal wall thickness variability (axis Y [mm])

PS04.038 - Unbiased Assessment of Detail Detectability in Image Guided Radiation Therapy

Author(s): <u>Victor A. Gurvich</u>¹, Lester L. Greer², George Davydenko³ ¹Government Contractor In Radiology Clinic, Fort Belvoir Community Hospital, Fort Belvoir/VA/UNITED STATES OF AMERICA, ²Fort Belvoir Community Hospital, Fort Belvoir/VA/UNITED STATES OF AMERICA, ³Society of Euro-American Medical Physicists, Alexandria/UNITED STATES OF AMERICA

The accuracy of delineation of targets and organs at risk during radiation therapy treatment planning as well as precise verification and localization for image guided beam delivery considerably depends on detectability of small and low contrast details. The assessment of detail detectability with Las Vegas phantom, Leeds test objects and some other standard test tools recommended by vendors is very subjective because of fixed disposition of test elements known to an observer. On the other hand, physical parameters of the image obtained with instrumental tools often do not adequately reflect its clinical quality. The proposed method allows fast, simple and unbiased evaluation of detectability using standard phantoms and special StatPhan software.

An observer should estimate the likelihood of pathology simulator presence in the image of selected phantom areas. Then the results of the estimation are compared with real locations of the simulators. The number of selected areas and locations of test elements can be changed so that they are not known to the observer beforehand. StatPhan software calculates sensitivity, specificity and accuracy of test elements detection, signal-to-noise ratio, areas under receiver operating curves that define overall decision performance, and the factor of observer's tendency to overestimation or misses. For our experiments we used Las Vegas phantom, Leeds test objects, ALVIM statistical phantoms with pathology simulators in aluminum, tissue and bone equivalent materials, aluminum step-wedge with holes of different diameter, and Catphan phantom for computer tomography. The detail detectability was measured for CT simulators, electronic portal image devices with 6 MV and 16 MV photon beams, and for on-board imager system in radiographic and cone beam CT modes. The smallest test elements (pathology simulators) distinguished with Pdet \ge 0.9 was assumed as a measure of image quality.

In all experiments we selected at least 10 areas with identical test elements and equal amount of areas with and without simulators when the accuracy had the most meaningful value. Low contrast resolution of Phillips Big Bore CT simulator and Varian On-Board Imager in cone beam mode was defined as detectability of supra-slice cylinders with 1% and 0.5 % contrast, for 100 kV at the X-ray tube, narrow window width (100 or less) and appropriate window level, so that low contrast disks were distinguished as well as possible. Cylinders of 3.0 mm, 1% contrast and 6 mm, 0.5% were detected in CT-sim images. The results for CBCT systems were 6.0 mm cylinders with 1% contrast and 9 mm, 0.5%. In images taken in On-Board imager radiographic mode 16 Leeds test disks and holes with diameter 1.1 mm in aluminum, 1.2 mm in bone and 1.4 mm in tissue equivalent material respectively were distinguished. Data for contrast-detail curves were obtained with aluminum step-wedge phantom.

The suggested method and StatPhan software were used for unbiased rapid statistical evaluation of therapeutic image quality using phantoms with fixed disposition of test elements and can be helpful for acceptance testing, establishment of QA base line, maintenance of excellent image quality, teaching and training of physicians and technical staff.

PS04.039 - Assessing radiation protection of members living close to patients with implanted 125I seeds in prostate Author(s): <u>Takashi Hanada</u>¹, Atsunori Yorozu², Sachiko Shinya², Shiro Saito³, Toshio Ohashi¹, Naoyuki Shigematsu¹ ¹Department Of Radiology, Keio University School of Medicine, Tokyo/JAPAN, ²Department Of Radiology, Tokyo Medical Center, National Hospital Organization, Tokyo/JAPAN, ³Department Of Urology, Tokyo Medical Center, National Hospital Organization, Tokyo/JAPAN

Purpose/Objective(s): Permanent seed implant treatment using ¹²⁵I is currently a common procedure for localized prostate cancer. For using the isotopes, we are frequently asked for more detailed information regarding the true exposure rates and associated risk that patients pose to the members living close to patients. However, there are few data for specific measurements situations, or considering lifestyle habits. In this study, a direct measurement was performed to determine the expected lifetime exposure from the patient with ¹²⁵I seed brachytherapy prostate implant to members living close to patients.

Materials/Methods: Measurements were obtained from 25 consecutive unselected patients at Tokyo Medical Center, Japan. After a permanent brachytherapy implant with ¹²⁵I seeds, patients and their member living close to patients were provided radiation monitors to measure direct radiation exposure at lifestyle. Each patient and their members were given a monitors to hang it on the neck, continuously, 24 hours a day. Monitors were returned approximately 1 week after the started day of measurements, and lifetime exposure were calculated based on the reading from the dosimeters. In addition, same measurements were performed after approximately 4 weeks after the first measurement for correctness verification of exposure monitoring.

Results: Based on dosimeter readings, the calculated mean lifetime dose to members living close to patients was 0.19 mSv (range, 0.02-0.54). There were no correlations between the calculated mean lifetime dose from patients of 7.61 mSv (range, 0.45-20.44) and their members. The average of calculated mean lifetime dose of second/first measurement ratio was 1.05 (range, 0.44-3.18) for patients. Results for the members, on the other hand, were 1.82 (range, 0.21-7.04). Radiation exposure to the members were differ in two measurements term, even when measured under the same conditions. That is to say, spending time the members contact with patients were not always the same in a day, leading to the non-

negligible uncertainty of occupancy factors, used in calculating the lifetime dose.

Conclusions: There were no correlations between the measured radiation dose from patients and their members. However, radiation exposure to members living close to patients receiving a permanent prostate brachytherapy implant with radioactive ¹²⁵I is very low and well below the limits recommended by the general guideline.

PS04.040 - Improvement of MV planar image by elimination of Compton scattered photons and re-projection as primary photons

Author(s): <u>Masatsugu Hariu</u>, Atsushi Myojoyama, Hidetoshi Saitoh Radiological Sciences, Tokyo Metropolitan University, Tokyo/JAPAN

Introduction

For the IGRT technique of the radiation therapy, a MV planar image is acquired with an electronic portal imaging device (EPID). And displacement of patient position will be adjusted by image registration between the MV planar image and a reference image that digitally reconstructed from 3D X-CT image. Arbitrary structures, e.g. bone, soft tissue and lung, on the MV planar image are guide for image registration, therefore high image quality is required. However, density distribution of the MV planar image is deteriorated because of Compton scattered photons.

Purpose

To compute information of Compton scattered photons impinged on the EPID aiming to real time processing, an original Monte Carlo (MC) was coded. Then energy spectrum distribution of scattered photons was acquired using the MC code. Improvement of image density was attempted by eliminating contribution of scattered photons from the MV planar image and re-projecting as primary photons from Compton interaction point.

Method

The original MC code and the image-processing program were coded with the integral development environment Qt 5.0. This MC code can simulate Compton interaction within voxels that reconstructed from 3D X-CT image. Mean absorbed dose by scattered photons (D_s) , primary photons (D_r) and total photons (D_s) to the EPID were estimated using energy and fluence and mass energy absorption coefficient of the EPID. It is assumed that the pixel value (P) of the EPID is proportional to absorbed dose (D) of Gd₂O₂S:Tb scintillator. In order to process the image excluding scattered photons (P_{a}), the image by scattered photons (P_{c}) was subtracted from the raw MV planar image (P_i). The P_s image was processed by multiplying the P_r and the ratio of D_s/D_t . To improve image density of arbitrary structure, which is guide for image registration, scattered photons were back projected to interaction point and re-projected as primary photons on the assumption that Compton scatter did not take place. The image by primary photons (P,) was processed by multiplying the $P_{\rm s}$ and the ratio of $D_{\rm p}/D_{\rm s}$. Finally, corrected image density (P) was processed by adding P_{Λ} and P_{Γ} .

Result and Conclusion

A chest phantom was modeled in this study. As a result of boneweighted image, it was obvious that P_c image was easier to distinguish the spinous process of vertebra, the intervertebral disks and the ribs than the P_r image. Additionally, by the soft tissue-weighted image, the bone structure was suppressed and Bronchi were observed clearly. Consequently, usability of proposed image density processing was clarified.

PS04.041 - Determination of exit fluence by MCNP4 code for IMRT treatment fields and its validation with a conventional EPID system

Author(s): <u>Benjamin Hernandez Reyes</u>, Modesto A. Sosa Aquino Physical Engineering, University of Guanajuato campus Leon, Leon/ MEXICO

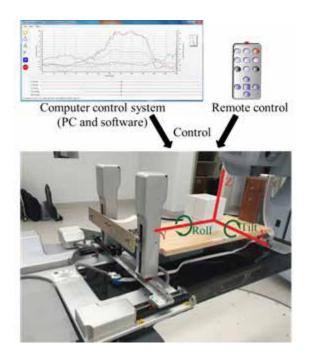

Dosimetry in intensity modulated radiotherapy (IMRT) is a fundamental process in quality control assurance. The electronic portal imaging devices (EPID) are widely used in IMRT dosimetry to measure the fluence of a radiation field and compare with the expected value calculated by a prediction algorithm. The objective of this work was to determine by Monte Carlo simulation the exit fluence of a treated patient with IMRT fields using MCNP4 code for a Varian linear accelerator Clinac iX model and then validate the simulation with fluences measures in the Varian aS1000 EPID system. Portal dosimetry configuration was previously performed by measuring output factors and dose calculation kernel. Comparisons between the simulated and the measured were made with a gamma evaluation (acceptance criterion $\Delta D=3\%$ and $\Delta r=2$ mm), finding that over 95% of the points fall within the acceptance criteria. Verification with radiochromic film was also evaluated, also found correspondence >95% of the points evaluated between the simulated and measured. This work will assist in the implementation of 3D in-vivo IMRT dosimetry.

PS04.042 - Accuracy in simulating tumor translation and rotation: Commissioning a motion platform, Hexamotion for tumor motion management QA

Author(s): <u>Chen-Yu Huang</u>¹, Jeremy T. Booth², Jin A. Ng¹, Adam Rice², Paul Keall¹

¹Radiation Physics Laboratory, Sydney Medical School, The University of Sydney, Camperdown/AUSTRALIA, ²Northern Sydney Cancer Centre, Royal North Shore Hospital, Sydney/AUSTRALIA

Purpose: The success of gating and tumor tracking requires rigorous QA and validation to meet the goal of better coverage of the target and sparing of organs at risk. The Hexamotion 5 degree-offreedom (DoF, 3 DoF translation and 2 DoF rotation) programmable motion platform uniquely uses the patient specific tumor motion trajectory and reproduces it in 5 dimensions (Fig 1). The purpose of this study is to commission the Hexamotion that to be served as an end-to-end tumor motion tracking or gating system QA device.

Methods: Three Calypso electromagnetic transponders were fixed to Hexamotion to record its real-time position. Range, velocity, acceleration were measured for each of the 5 DoF. Representative lung patient tumor motion trajectories were selected and input into the Hexamotion to measure the dynamic accuracy. The tolerances for all tests are that both the mean and standard deviation of the difference between the programmed trajectory and the measured data are <0.5 mm as the accuracy of tumor motion detection and adaptation methods reach submilimeter accuracy.

Results: Hexamotion's range, velocity and acceleration are adequate to reproduce prostate and lung tumor motion during treatment (Table 1). Hexamotion demonstrated a high mechanical accuracy of 0.5 mm. In the dynamic accuracy test, the mean and standard deviation differences between the input lung trajectory and Calypso measured continuous position are less than 0.5 mm. Hexamotion has been used in our center to perform QA for the tumor motion detection system - Kilovoltage Intrafraction Monitoring (KIM) and the tumor motion tracking system - Dynamic MLC tracking.

Table 1. Hexamotion range, velocity and acceleration meet therequirement of reproducing tumor motion.					
	Range (mm or deg)	Velocity (mm ordeg/s)	Acceleration (mm ordeg/s ²)		
X (LR)	-43 ~ 43	-30 ~ 30	Up to 100		
Y (SI)	-43 ~ 43	-30 ~ 31	Up to 100		
Z (AP)	-40 ~ 41	-37.5 ~ 22	Up to 100		
Tilt	-3.5 ~ 8	-7 ~ 7.5	Up to 100		
Roll	-11 ~ 11	-10.5 ~ 10	Up to 100		

Conclusion: The Hexamotion platform is capable of reproducing individual patient-specific tumor trajectories with a high degree of accuracy. It can be served for end-to-end tumor motion management systems QA device including 4DCT imaging, monitoring, gating and tracking.

PS04.043 - Dosimetric impact of the Acuros XB Algorithm for 25 lung SABR patients treated using the TrueBeam FFF 6MV Author(s): <u>Derek Hyde</u>¹, Tony Teke¹, Matthew Schmid² ¹Medical Physics, BC Cancer Agency - Centre for the Southern Interior, Kelowna/BC/CANADA, ²Medcial Physics, BC Cancer Agency - Southern Interior, Kelowna/BC/CANADA

Purpose:

Stereotactic Ablative Radiotherapy (SABR) requires the delivery of a high biologically effective dose in only a few fractions. The Varian Truebeam has optional Flattening Filter Free (FFF) modes which greatly increase the dose rate and reduce treatment times. We previously commissioned the 6MV FFF beam (1400 MU/min) in Eclipse using Varian's Analytical Anisotropic Algorithm (AAA), but have recently commissioned the Acuros XB algorithm (AXB). To examine the clinical significance of the new algorithm, we have retrospectively recalculated the dose distributions for the 25 patients that we have already treated.

Methods:

The standard commissioning data was acquired for Varian's AAA and AXB beam models, and then MLC-defined fields were acquired for verification. Measurements were completed with the IBA Blue Phantom, using the CC13 and CC01 ion chambers and PTW diode. Heterogeneous dose calculations were then independently verified using Monte Carlo Simulations and Gafchromic film (EBT3, Ashland), confirming that the heterogeneous dose calculations were improved with the AXB algorithm. We have treated 25 lung patients, in which we used 4D-CT to define an ITV, added a 5mm expansion for the PTV, and then forward-planned on the fast-helical image, using a 3D conformal, non-coplanar technique to deliver 48 Gy (covering 95% of the PTV) in 4 fractions. The original MU from the AAA plan was used to calculate the 'dose to medium' as well as 'the dose to water', using the new AXB algorithm. Finally, both AXB plans were rescaled to the volume-based prescription, as per clinical practice.

Results:

When the dose distribution was recalculated with same MU for the dose to <u>water</u>, the difference of the PTVmean (avg=1.1%) was statistically significant (P=0.02). Neither the difference of the PTVmin (avg=-1.0%) nor the difference of the PTVmax (avg=0.13%) were statistically significant.

When the AXB dose to <u>medium</u> was calculated (with the same MU), the difference of the PTVmean remained similar (avg=1.1%), but the difference of the PTVmin (avg=-1.3%) became significant (P=0.04) and although the difference of the PTVmax increased (avg=0.97%), it was still not significant. It should be noted that the maximum differences for the PTVmin, PTVmax and PTV mean were -10.1%, 5.6% and 4.9% respectively.

When the AXB dose calculations were renormalized with the standard prescription of 48Gy covering 95% of the PTV, on average there was almost no affect on the calculated dose to water, but some effect on the calculated dose to medium. The maximum differences for the PTVmin, PTVmax and PTV mean were -5.2%, 16.2% and 4.3% respectively, for the dose to medium.

Conclusions:

The PTVmin is typically lower with the AXB calculation. Consequently, any volume based prescription will tend to increase the PTVmean as well as the PTVmax. Although the average differences for this patient set were only about 1%, individual patients illustrated the potential for much greater differences.

PS04.044 - Dynamic resource allocation: Investigating ways to distribute resources in a patient cohort based on plan quality Author(s): Elin Hynning

Department Of Research, RaySearch Laboratories, Stockholm/ SWEDEN

Radiation therapy is a resource intensive type of treatment and resources are always limited. This study aims at investigating ways to dynamically allocate resources among a cohort of patients. The idea is to take into account the plan quality that can be achieved for the individual patients with regard to the considered resource when allocating the resources.

A cohort of 13 prostate patients has been investigated, and the considered resource is the delivery time for a treatment fraction. The delivery time for a treatment fraction was represented as the number of beams used in the treatment plan. For each patient, six SMLC plans were automatically generated, with 5, 7, 9, 11, 13 and 15 beams respectively. All plans were required to fulfill a set of clinical goals and moreover to achieve as low average dose to the rectum as possible. The average dose to the rectum was used as the measure of plan quality. The available treatment time for all patients in the cohort was 91 beams, i.e. all patients in the cohort could receive a plan with seven beams. Three different schemes to allocate the available resources were considered; equal distribution, minimax distribution and population average distribution. In the equal distribution, all patients received a plan with seven beams. In the minimax distribution,

resources were allocated to improve the plan quality for the patients with the worst plan quality. In the population average distribution, resources were allocated to achieve the best average plan quality for the cohort.

The resulting allocations of treatment time stemming from the different allocation schemes are shown in table 1.

Patient	Equal	Minimax		Population average	
	Average dose rectum	Beams	Average dose rectum	Beams	Average dose rectum
1	23.14	5	28.62	5	28.62
2	37.57	9	29.03	9	29.03
3	37.90	9	32.27	9	32.27
4	29.13	7	29.13	7	29.13
5	27.44	7	27.44	7	27.44
6	28.22	7	28.22	7	28.22
7	26.20	5	35.02	7	26.20
8	37.57	9	34.01	5	41.02
9	31.10	7	31.10	7	31.10
10	24.90	7	24.90	7	24.90
11	26.37	7	26.37	7	26.37
12	20.47	5	26.62	7	20.47
13	33.12	7	33.12	7	33.12
Average	29.47		29.68		29.06

Neither the minimax distribution nor the population average distribution allocate more than nine beams to any patient in the cohort. Thus, adding more than nine beams does not make significantly better plans for any patient in the cohort.

The minimax distribution and population average distribution lead to different resource allocations between the patients in the cohort. As expected, the population average distribution lowers the population average compared to the equal distribution, and the minimax distribution improves the plan quality to the three patients with the worst plan quality in the equal distribution. Even though no distribution dominates any other distribution in both worst case and population average measures, the results show that if there exists an objective on population basis apart from giving all patients the same resources, then dynamic resource allocation should be considered.

PS04.045 - Physical plan evaluation of Head and Neck Cancer at Square Hospital, Bangladesh.

Author(s): Md. Anwarul Islam¹, Md.Mahmudul Hasan¹, Golam Abu Zakaria²

¹Department Of Oncology & Radiotherapy Centre, Square Hospitals Ltd, Dhaka/BANGLADESH, ²Dept. Of Medical Radiation Physics, Academic Teaching Hospital Of The University Of Cologne, Gummersbach Hospital, Colongn/GERMANY

Purpose: To compare the physical parameters of Three Dimensional Conformal Radiotherapy (3DCRT) with Intensity Modulated Radiotherapy (IMRT) for Head & Neck cancer and the dose profiles of primary tumors, electively treated organ (Lymph node) and Organ at Risk (OARs).

Materials and Methods: From January 2010 to October 2014, total 473 patients were diagnoses with head and neck cancer in Square

Hospitals Ltd. Among those patients, five (5) patients treated with 3DCRT and five (5) with IMRT technique have been selected randomly for this study. All the 3DCRT and IMRT plans were done using ECLIPSE (version 8.6) treatment planning system of VARIAN Medical System. All the cases were immobilized with Head & Neck thermoplastic mask and scanned at 3.75 mm slice width with GE Light Speed CT simulator. For each case of 3DCRT (66 Gy) and IMRT (70 Gy), target volume for primary lesions and electively treated regions (50 Gy) were contoured respectively. In this study, parotid gland, spinal cord and mandible have been contoured as OARs. The beam direction of 3DCRT plans were selected laterally parallel opposed with wedge and Field in Field (FiF) technique either co-planar or non co-planar to avoid shoulder. The beam weights were adjusted in order to minimize tumors dose inhomogeneity. The beam arrangements of IMRT plans were nine and seven equispaced non-opposed coplanar beams. The same dose volume constraints were used for all IMRT plannings during inverse optimization. The physical parameters, Target Coverage (TC), Conformity Index (CI), Conformation Number (CN), Lesion Under dose Factor (LUF), Healthy Tissue Over dose Factor (HTOF), Homogeneity Index (HI) and DVHs have been calculated for each treatment plan. The 100% is the perfect TC coverage, whereas if the 95% isodose covers all of the clinical and pathologic target volume, treatment is considered to comply with the protocol. A CI equal to 1 corresponds to ideal conformation. The CN ranges from 0 to 1, where 1 is the optimal conformity and value close to 0 indicates less conformal plan. The lower the values of LUF and HTOF, the higher is the conformal plan. Smaller values of HI correspond to more homogeneity and 0 corresponds to absolute homogeneity. According to the RTOG and QUANTEC guideline, mean and maximum doses (1cc and 1%) have been considered for Organ at Risk (OARs) dose evaluation.

Results: The mean values for 3DCRT and IMRT were 95.07 and 95.33 for TC, 0.466 and 0.895 for Cl, 0.441 and 0.795 for CN, 0.045 and 0.028 for LUF, 1.115 and 0.100 for HTOF and 0.145 and 0.085 for HI respectively. The mean dose for parotid glands were 47.28 and 23.80, maximum dose for spinal cord 43.78 and 39.63 for mandible 64.20 and 59.17 Gy correspondingly for 3DCRT and IMRT.

Conclusion: IMRT is superior to 3DCRT in dose delivery and critical structure sparing for the treatment of Head & Neck cancer. The primary tumor can get higher equivalent dose by IMRT techniques.

PS04.046 - IAEA multicentre study of the methodology for advanced dosimetry audit: single IMRT field dose delivery Author(s): Barbara Bencsik, Paulina Grochowska, Joanna Izewska Nuclear Sciences And Applications, International Atomic Energy Agency, Vienna/AUSTRIA

New auditing methodology for national dosimetry audit networks is under development within an IAEA co-ordinated research project (CRP): "Development of Quality Audits for Advanced Technology in Radiotherapy Dose Delivery". It consists of four steps: (1) verification of TPS calculation of small beam output factors, (2) film dosimetry audit of MLC positional performance, (3) film audit of single clinical IMRT field dose delivery and (4) 'end-to-end' dosimetry audit (imaging, planning, dose delivery) for multiple field IMRT techniques. The current work refers to part 3 of this CRP. The purpose is to verify the audit methodology for checking the delivery of an IMRT treatment field by comparing the relative dose distributions delivered to the film and that calculated by the treatment planning system.

Sixteen research groups from 14 countries were involved in this multicentre study. Each group received a set of instructions, datasheets and a sheet of radiochromic EBT3 film from the IAEA. The participants were asked to choose a highly modulated single treatment field from a typical inverse planned IMRT head and neck treatment plan and then deliver it to the EBT3 film placed at depth in a solid phantom. Upon receipt of the irradiated films by the IAEA Dosimetry Laboratory, a comparison was performed between the TPS calculated and the measured film dose distributions using gamma analysis tool (FilmQA Pro[™], Ashland). The gamma acceptance criterion of 3%/3mm over all pixels values exceeding 20% of the maximum dose was adopted, with 90% of pixels passing the criterion. Agreement of the profiles through the maximum dose region was also checked with the criteria of 7% of the maximum dose for low gradient regions and 4 mm position error for high gradient regions.

The results are obtained for 8 different accelerator models, 6 MLC models, 4 different TPSs and 8 dose calculation algorithms. All participants achieved the minimum passing level of 90% with the actual passing rate between 95.4% and 100%. The average result of gamma analysis for Varian machines was 99.0% (12 participants) and for Elekta machines 97.7% (4 participants). Comparison of dose profiles showed that the largest differences occur in the high dose gradients regions, where precise positioning of the MLC leaves has the greatest impact on the accurate dose delivery; 4 mm error in such regions can bring more than 20% difference in the dose.

The methodology of this audit has been examined through a multicentre study and proven to work well. The study was performed smoothly; instructions and datasheets appeared to be clear and straightforward to follow. As the EBT 3 films are easy to damage in transport, it is important to handle them carefully and pack properly for mailing. The results show good agreement between the planed and the measured dose distributions, with all participants having achieved satisfactory results. The analysis criteria adopted for this study have been confirmed for future use by national dosimetry audit networks in countries participating in the CRP.

PS04.047 - Electron Density Measurements of Metallic Implants with Cobalt-60 Computed Tomography

Author(s): <u>Christopher Jechel</u>¹, Greg Salomons², L John Schreiner² ¹Physics, Engineering Physics & Astronomy, Queen's University, Kingston/ON/CANADA, ²Department Of Medical Physics, Cancer Centre of Southeastern Ontario, Kingston/ON/CANADA

Introduction: The photon starvation and beam-hardening artifacts produced by high density and atomic number objects in kilovoltage CT images are a well known phenomenon in radiation therapy planning. Metal artifacts can obscure anatomy and impact dose calculation accuracy as the quantitative information in CT images is used to provide a map of relative electron density (RED) within the patient's body. Further calculation perturbations arise when the range of allowed CT values is constrained to 12 bits. In this work we investigate the importance of these effects in treatment planning. Methods: Our group has developed a benchtop cone-beam CT system to investigate the potential for patient alignment on a cobalt-60 teletherapy unit. The high energy (~1.25 MeV) and nearly monoenergetic gamma ray spectrum of cobalt-60 reduces metalinduced artifacts, suggesting cobalt-60 CT (CoCT) may be useful for evaluating RED information derived from kVCT images acquired in the presence of metal objects. Images of metal rods of varied RED and atomic number within water phantoms were gathered via CoCT and conventional kVCT including images reconstructed using a commercial metal artifact reduction algorithm. To demonstrate the importance of accurate electron density information, large field (6MV, 25x25cm2) dose profiles were measured with an ion chamber in a water phantom containing metal rods and compared to treatment planning system calculations based on kVCT and CoCT images. Results/Conclusions: Converting images from CT number to RED and comparing with known electron density distributions shows that the starburst artifacts surrounding the metal rods in kVCT are absent from CoCT (Figure 1a-b). In kVCT images, pixels above a threshold electron density are assigned the same CT number, the maximum of the allowed range. This leads to an

ambiguous condition where different high density materials cannot be differentiated in kVCT images (Figure 1c). Reduced artifacts in regions surrounding metal objects and the lack of a limit on CT number range enable a more faithful representation of electron density information with CoCT. Compared to ion chamber measurements at a point downstream of a titanium rod, calculations based on kVCT and CoCT images differed from measurements by -12.7% and 3.2%, respectively. This result is likely attributable to the treatment planning system's assumption that threshold value kVCT pixels are approximately equivalent to stainless steel, a 76% overestimate of the true electron density of titanium. CoCT imaging enables the evaluation of metal artifact perturbations in planning CT and work assessing vendor correction algorithms is underway.

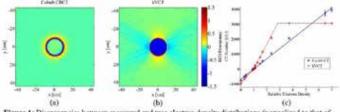

Figure 1: Discrepancies between measured and true electron density distributions (normalized to that of water) surrounding a titanium (relative electron density-3.73) cylinder for (a) cobait-60 CT and (b) conventional kVCT. RED-CT number data is shown in (c) for Co-60 CT and kVCT seamers demonstrating how the limited CT number range in kVCT images obscures the difference between high density materials.

PS04.048 - A Systematic Analysis Of The Error Sources Within The CyberKnife M6 Daily AQA Test

Author(s): <u>Kevin T. Jordan</u>, Alan Mayville, Tewfik Bichay Lacks Cancer Center -- Radiation Oncology, Mercy Health Grand Rapids, Grand Rapids/UNITED STATES OF AMERICA

Objectives: To determine and critically analyze the sources of error within the daily Automatic Quality Assurance (AQA) test used on the CyberKnife M6 system.

Methods: A systematic analysis of the inherent uncertainties involved in the CyberKnife M6 AQA test was conducted to quantify the uncertainty in each of the components making up the AQA process. The identified components included the robot positional uncertainty, film scanning precision, film response and the kV imaging system. A range of 10-20 repeat measurements were carried out for each of these identified components. A modified Winston-Lutz test with orthogonal images was carried out using GAFchromic EBT3 film. The exposure was by a dedicated AQA plan within Accuray's Multiplan Software. The images were scanned on an Epson 10000XL film scanner. The SRS profiler QA device was used to determine the robot positional accuracy and repeatability.

Results: The total film AQA uncertainty using IRIS and FIXED cone was found to be 0.349 and 0.339 millimeters (\pm 3SD) respectively. The Epson 10000XL flatbed scanner was used to scan RGB pixel intensity. The scanner uncertainty was very small; repeat measurements of the same film suggested a scanner precision of 0.015-0.025 millimeters (\pm 3SD). The act of repositioning a film contributed a small uncertainty of 0.0008-0.0014 millimeters (\pm 3SD). The largest uncertainty was due to the imaging system. The kV imaging system Fiducial tracking algorithm uncertainty was 0.150 millimeters (\pm 3SD), while the 6D skull algorithm was 0.300 millimeters (\pm 3SD). The SRS Profiler suggested a robot precision uncertainty of 0.1 mm or less.

Conclusion: The total AQA uncertainty appears to be largely due to the kV imaging system. These results suggest an uncertainty of less than 0.1 mm for the film, film scanner, and robot components of the AQA test. The kV imaging system uncertainty could reach 0.3 mm and is the main source of uncertainty. This information explains greatest weakness in daily CyberKnife QA and may be useful in establishing realistic expectations of daily AQA results.

PS04.049 - The Use of Boron Neutron Capture Therapy in the Treatment of Cancer Tumours in the Czech Republic Author(s): Veronika Burianova¹, Lubomir Sklenka², <u>Ivana Jurickova¹</u> ¹Department Of Biomedical Technology, Czech Technical University in Prague, Faculty of Biomedical Engineering, Kladno/CZECH REPUBLIC, ²Department Of Nuclear Reactors, Czech Technical University in Prague, Faculty of Nuclear Sciences and Physical Engineering, Prague/CZECH REPUBLIC

Boron neutron capture therapy is an experimental method of the treatment of malignant tumors of today. The study first gives a comprehensive overview of the state of the art both in the Czech Republic and abroad. It describes a low power research nuclear reactor which will be utilized as the radiation source used in the therapy. The feasibility study introduces the project proposal and the approximate cost of the facility construction. The feasibility study further quantifies the reactor's operating cost and summarizes the cost of treatment with neutron capture therapy. Based on the market analysis, the marketing strategy and the marketing mix are devised. The professions needed for the facility operation are defined. The study assesses the project's impact on the environment, presents the risk analysis and sensitivity analysis. Boron neutron capture therapy has a great potential to become a successful therapy in the treatment of some types of malignant tumors under certain conditions in the future.

PS04.050 - Partial Arc Breast Boost

Author(s): <u>Tania Karan</u>¹, Daria Comsa¹, Woodrow Wells², Erin Barnett¹

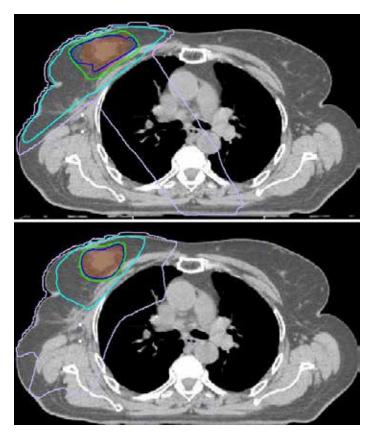

¹Medical Physics, Stronach Regional Cancer Centre, Newmarket/ ON/CANADA, ²Radiation Oncology, Princess Margaret Cancer Centre, Toronto/ON/CANADA

Adjuvant radiotherapy to the excised tumour bed following radiotherapy of the entire breast is routinely used to reduce risk of local recurrence in select patients. Boost treatments are generally delivered via conformal radiation therapy (CRT) with 2-3 fields, making use of tangential geometry. This study explores volumetric modulated arc therapy (VMAT) as an alternative to conventional CRT. A modulated partial arc was planned, spanning the angles between the tangential fields used in the initial phase of treatment to the entire breast.

The plans of 15 previously treated patients (7 left-sided, 7 right-sided, one bilateral) were retrospectively re-planned in *Pinnacle* (Phillips, v9.0). The left-sided patients were all CT simulated in a breath hold position using the *active breathing control* system. The average volume of the tumour cavity was 19 cc (range: 4-57cc). A class solution for beam geometry and optimization objectives of the arc plans was achieved, and plan comparison was based on coverage of the tumour bed by 95% of the prescription (950 cGy) and doses to the pertinent organs at risk. All plans were normalized to achieve target coverage equivalent to or better than the original plans. Robustness of the two techniques was evaluated by simulating breast contour changes in *Pinnacle*.

The arc plans achieved significant improvements in dose conformality, as exemplified in **Figure 1**. Doses to 10 cc of heart increased in the arc plans, while the volume of ipsilateral lung receiving >2 Gy did not show a consistent trend. The maximum point dose to skin (a 3mm thick rind contracted from the external contour) increased, particularly in superficial targets, however the maximum dose to 10cc of skin decreased. The low-dose exposure to the contralateral breast in the arc plans was controlled with a medial optimization structure and was equivalent with the CRT technique. The overall maximum point dose was higher in the arc plans, however the volume receiving 105% of the prescribed dose did not vary monotonically when compared with CRT plans. Arc plans were equivalent or superior in retaining target coverage following breast contour changes when compared with conformal plans. Based on the performance of arc plans in this small cohort of patients, an investigation involving a larger retrospective dataset is warranted.

Figure 1. Comparison of a conformal (above) and arc (below) breast boost plan. Target is shown in brown colourwash, along with the 100% (blue), 95% (green), 50% (cyan) and 10% (violet) isodoses

PS04.051 - Determination of the optimal phase for respiratory gated radiotherapy from statistical analysis using a visible guidance system

Author(s): Se An Oh, <u>Sung Kyu Kim</u>, Ji Woon Yea Radiation Oncology, Yeungnam University Medical Center, Daegu/ KOREA

Purpose: Respiratory gated radiation therapy (RGRT) is used to minimize the radiation dose to normal tissue in lung cancer patients. Determination of the optimal point in the respiratory phase of a patient is important in RGRT but it is not easy. The goal of the present study was to see if a visible guiding system is helpful in determining the optimal phase in respiratory gated therapy.

Materials and **methods:** The breathing signals of 23 lung cancer patients were recorded with a Real-time Position Management (RPM) respiratory gating system (Varian, USA). The patients underwent breathing training with our visible guiding system, after which their breathing signals were recorded during 5 min of free breathing and 5 min of guided breathing. The breathing signals recorded between 3 and 5 min before and after training were compared. We performed statistical analysis of the breathing signals to find the optimal duty cycle in guided breathing for RGRT.

Results: The breathing signals aided by the visible guiding system had more regular cycles over time and smaller variations in the positions of the marker block than the free breathing signals. Of the 23 lung cancer patients, 19 showed statistically significant differences

by time when the values obtained before and after breathing were compared (p < 0.05); 30% and 40% of the duty cycle, respectively, was determined to be the most effective, and the corresponding phases were 3060% (duty cycle, 30%; p < 0.05) and 3070% (duty cycle, 40%; p < 0.05).

Conclusions: Respiratory regularity was significantly improved with the use of the RPM with our visible guiding system; therefore, it would help improve the accuracy and efficiency of RGRT.

PS04.052 - Dosimetric Verifications of the Output Factors in the Small Field less than 3 cm2 using the Gafchromic EBT2 films and the Various Detectors

Author(s): Se An Oh, <u>Sung Kyu Kim</u>, Ji Woon Yea Radiation Oncology, Yeungnam University Medical Center, Daegu/ KOREA

The small field dosimetry is very important in modern radiotherapy because it has been frequently used to treat the tumor with high dose hypo-fractionated radiotherapy or high dose single fraction stereotactic radiosurgery (SRS) with small size target. But, the dosimetry of a small field ($< 3 \times 3 \text{ cm}^2$) has been great challenges in radiotherapy. Small field dosimetry is difficult because of (a) a lack of lateral electronic equilibrium, (b) steep dose gradients, and (c) partial blocking of the source. The objectives of this study were to measure and verify with the various detectors the output factors in a small field ($< 3 \square$) for the 6 MV photon beams.

Output factors were measured using the CC13, CC01, EDGE detector, thermoluminescence dosimeters (TLDs), and Gafchromic EBT2 films at the sizes of field such as 0.5×0.5 , 1×1 , 2×2 , 3×3 , 5×5 , and 10×10 \Box . The differences in the output factors with the various detectors increased with decreasing field size.

Our study demonstrates that the dosimetry for a small photon beam $(< 3 \times 3 \text{ cm}^2)$ should use CC01 or EDGE detectors with a small active volume. And also, Output factors with the EDGE detectors in a small field $(< 3 \times 3 \text{ cm}^2)$ coincided well with the Gafchromic EBT2 films.

PS04.053 - Methodology to Evaluate Combined EBRT and HDR Brachytherapy for Cervical Cancer using Equivalent Uniform Dose (EUD) and Tumor Control Probability (TCP)

Purpose: In order to predict tumor control for patients receiving both external beam radiotherapy (EBRT) and high-dose-rate (HDR) brachytherapy, we present a methodology of evaluating overall radiobiological parameters of equivalent uniform dose (EUD) and tumor control probability (TCP). The current tumor coverage metric is D90 for HDR cervical cancer by assuming the shape of DVH is reasonably same. EUD, accounting for whole DVH has potential as an additional plan quality evaluation tool.

Methods & Materials: A total of 6 biopsy proven cervical cancer patients with FIGO stage I were retrospectively analyzed. All patients received EBRT (45Gy with 1.8 Gy/fx) and Point-A based HDR plans (7Gy x 4fx or 5.5Gy x 5fx). Two patients received a parametrial boost (5.4 or 9Gy). The EBRT and HDR dose maps were converted into equivalent dose in 2Gy fraction (EQD2) dose maps with alpha/beta = 10 using an in-house tool. EUD values were measured from EQD2-DVHs using two different formulae: 1) Using alpha value = 0.15 and 2) Using survival fraction in 2 Gy (SF2) = 0.48. TCP values were calculated using Logistic and Poisson TCP models. The positional input parameters (D50) of TCP for stage I cervical cancer were modeled from long-term clinical data: D90 = 59 Gy and 75.7 Gy with gamma50 = 2 and 8, respectively.

Results: It was feasible to estimate the predicted TCP of the combined EBRT and HDR plans by combining differential EQD2-DVHs. The predicted TCP values for 6 patients were recorded as 100% when using the individual-patient based TCP (gamma50 = 8), and ranged from 88 – 100 % with the population-based TCP (gamma50 = 2). The TCP values were robust with respect to the two different TCP models with correlation coefficients of 0.99 – 1.0. EUD values were on average 124 ± 8 Gy and 110 ± 7 Gy using alpha-based and SF2-based formulae, respectively, with a correlation coefficient of 0.98. All EUD values were recorded as higher than their corresponding D90 values.

Conclusion: It was feasible to estimate the predicted TCP and overall EUD of combined EBRT and HDR plans by combining differential EQD2-DVHs. TCP values were robust regardless of Logistic or Poisson model.

Figure. Upper panel: TCP values calculated from the combined EUD

values of EBRT and HDR. Lower left: The combined EUD values compared with combined D90 and D100 values. Lower right: TCP models with gamma50 = 2 and 8.

PS04.054 - International Multi-Institutional Bench Mark Study on Dosimetric and Volumetric Modulation using Helical Tomo-Therapy Treatment Planning for Malignant Pleural Mesothelioma Tumors

Author(s): Allen Movahed, André Haraldsson, Claire Foottit, Milton Xavier Vargas Verdesoto, Thuy Lau, Thomas Lacornerie, Sharon Qi, X, Somsak Wanwilairat, Hew Choon Soong, Dale Matson, Dirk Verellen, Koen Tournel, Osama Hassad, Christine Higby, Belal Moftah, Antoine Wagner, <u>Tommy Knöös</u>

Radiation Oncology, Pomona Valley Medical Center, Pomona/UNIT-ED STATES OF AMERICA

Purpose:

To determine the most desirable and achievable target dose and organ at risk (OAR) sparing using helical TomoTherapy planning system for mesothelioma treatment plans.

Introduction:

Mesothelioma is an incurable cancer involving the lining of the lung. Treatment options currently available are chemotherapy and external radiotherapy. TomoTherapy's ability to treat unusually shaped tumors, particularly those wrapped around sensitive normal tissues (e.g.lung), enables higher doses of radiation to be delivered to the target while sparing the normal lung. This, in theory, should improve the treatment's effectiveness.

Materials and methods:

Academic and clinical participants (from US, Canada, France, Sweden, Belgium, Malaysia Thailand, Mexico and Saudi Arabia) were given CT images and structure sets of a patient having mesothelioma with mediastinal nodes. The planning target volume (PTV) was created using margins of 3 mm inner and 1cm outer and was prescribed a dose of 54Gy to 95% of the volume. Each of participants was asked to create a helical TomoTherapy IMRT plan following same planning guidelines. They were given the goal of either (1) keeping the prescribed dose to the targets while reducing the dose to the OARs or (2) escalating the target dose while maintaining the original level of healthy tissue sparing.

Results:

The resulting treatment plans in primary lesion and nodal mass varied in coverage (95-98.7%) with PTV V54Gy (90.5-96.1%) with Max dose of (57.73-63.46 Gy). Conformality index were (0.950-1.730) and homogeneity index varied from (1.087-1.217) among the participating TomoTherapy centers. The most variable OAR constraint was mean total lung dose (16.4 -98.15%). Other OAR constraints varied less; total lung V5Gy (28.4-58.5%), total lung V20Gy (15.6-33.21%), contralateral lung V5Gy (0.87-39.45%) and heart V45Gy (20.7-28.9%). A range of planning parameters were used; pitch (0.22-0.43) and delivered modulation factor of (1.143-2.084), and treatment time of (302.1 - 778.2seconds). The reviewers' ranking assessment (Ranking in Groups: 1 = Good, 2 = Above Average, 3 = Average, 4 = Poor) varied with 3/9 treatment plans rated Good (rank = 1) in at least one category by at least one reviewer. The overall rankings revealed that a plan with balanced trade-off among all planning objectives was preferred by most participants and reviewers.

Conclusion:

Helical TomoTherapy is a promising technique in the multimodality treatment of malignant pleural mesothelioma. Based on many studies on the comparison of 3DCRT, IMRT and TomoTherapy, it is has been recommended that helical TomoTherapy provide better target coverage and sparing of OARs. Other studies found low doses to the contralateral lung to be limiting. This was not the case in our study, with TomoTherapy we found the dose to contralateral lung be as low as V5Gy=0.87%. A pitch value of 0.287 or 0.43 and a delivered modulation factor of above 1.7 will be beneficial consideration in planning.

PS04.055 - Factors predicting of local relapse in irradiated patients with breast cancer: A Syrian Cohort study Author(s): Moussa Kravem

Medical Physics Department, Al Bairouni University Hospital, Damascus/SYRIA

Background: Breast cancer is the most common cause of cancer death in women. Better understanding of cell biology and behavior may lead to improvement of disease control and prolongation of both disease free and overall survival rate.

Objective: The study is aiming to determining the factors implicated in local relapse in breast cancer patients treated with radiotherapy on chest wall.

Materials and Methods: The study is retrospective one, where we collected data from 2440 Syrian women with breast cancer during the period between 2007 to 2012 at AI Bairouni University Hospital, Damascus. Syria.

Results and Discussion: Among the 2440 patients, 1213 patients experienced local relapse with median period of 14 months. Factors associated with local relapse were: Tumor volume (P. Value 0.002),lymph\\ Vascular invasion (P. Value 0.005), quadrectomy (P. Value 0.0004) and Her-2 positive status (P. Value 0.0001). Patients with total mastectomy, small tumor volume and estrogen, receptors positive did not correlated with local relapse. Data showed that the most of our locally relapsed patients presented with locally advanced disease and big tumor volume which correlates with high rates of lymph\\ vascular invasion, the thing can clarify the tendency for local relapse in this group of patients.

Conclusion: Our results showed that big tumor volume, lymph vascular invasion and Her-2 status are the main factors correlated with local relapse after radiotherapy irrespective of the dose and method of radiotherapy.

PS04.056 - Automated Routine Quality Assurance of VMAT Author(s): Bryce Cyr¹, <u>Michael Lamey</u>², Grace Zeng-Harpell² ¹Deptartment Of Physics, University of Victoria, Victoria/CANA-DA, ²Medical Physics, Trillium Health Partners, Mississauga/CANA-DA

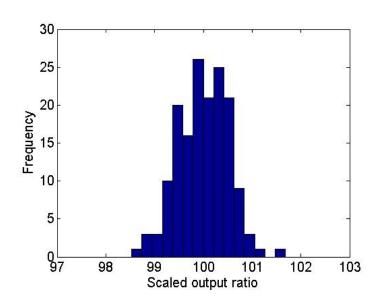

Purpose: The purpose of the work was to develop a standardized picket fence equivalent for Volumetric Modulated Arc Therapy (VMAT) QA, and to automate the analysis method such that the tests can be performed in routine fashion.

Materials & Methods: An in-house software program was developed using Matlab to automatically analyze delivery to a portal imager using VMAT with varying MLC speed, dose rate and gantry speed. The testing was separated into two cases: the first in which the dose rate and gantry speed are varied and the second in which the MLC speed is varied. For each case two files were delivered: (1) a dynamic field in which MLCs and gantry moved and (2) a static open field in which the MLCs were retracted and the gantry was stationary. A ratio of the two fields was taken in order to remove field non-uniformities (i.e. horns). The software analyzed the completely irradiated area on the portal imager.

Results: An example of a delivered MLC speed file is shown in Figure 1. The analysis was separated into two regions (the 2.5mm & 5mm MLC widths) due to higher leakage in the 2.5mm region. The image intensity ratio in the 2.5mm MLC region, between the VMAT delivered field and the open field, is shown in Figure 2. The average of the image intensity ratio was scaled to 100 for ease of visibility. The data collected over a six month time frame illustrate that the spread in image intensity ratio is less than 2.5% in all delivered cases. Approximately 95% of the points are within 1.5% of the mean image intensity ratio.

Conclusion: The work herein illustrates that automated VMAT delivery analysis can be performed in a routine fashion while generating reproducible results. The results can be tracked and obtained quickly after delivery.

PS04.057 - Evaluation of the clinical usefulness of modulated Arc treatment

Author(s): Young Kyu Lee, Young Nam Kang

Department Of Radiation Oncology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul/KOREA

To compare the dosimetric performance of three different arc treatment techniques; modulated arc (m-ARC), tomotherapy, volumetric modulated arc therapy (RapidArc, RA). The purpose of this study is to evaluate the clinical usefulness of mARC treatment techniques. The mArc treatment was selected patients with non-small cell lung cancer (NSCLC) for clinical usefulness of mARC. In order to do this, a study to find the most suitable plan condition of mARC treatment was performed and the usefulness was evaluated by comparing it with the other Arc treatment plans such as Tomotherapy and RapidArc. Three different arc treatments were performed on patients with NSCLC. In the case of mARC, to compare the dosimetric performance of three different main factors- An photon energies (6MV or 10MV), and segment number per each spacing angle were considered. The treatment plans produced using the three different techniques were compared based on the following parameters: conformity index (CI), homogeneity index (HI), target coverage, dose in the OARs, monitor units (MU), treatment time and the normal tissue complication probability (NTCP). As a result, the best dosimetric performance of mARC was observed with the main factors of 10MV photon energy and the spacing angle 6 degree, 59 segments. The target coverage was similar in three different treatment techniques. The RapidArc produced the best dose homogeneity index. However, the conformity index for RapidArc was 1.51 and 1.63 with an absolute difference of 1.07 and 1.52 than tomotherapy, 1.1 and 1.116 lower than mARC. The mARC produced the lowest V20. However, RapidArc produced the best mean lung dose. Both mARC and RapidArc plans had a shorter treatment time, compared with tomotherapy, with a relative fast of 62% and 77% in treatment time. As a result, this study has shown satisfactory result about the clinical usefulness of mARC plans.

PS04.058 - A comparison of linac-based IMRT with helical tomotherapy for craniospinal irradiation

Author(s): Cindy Tam¹, Alex Karotki², Anthony Kim², <u>Young K. Lee¹</u>, Arjun Sahgal¹

¹Department Of Radiation Oncology, University of Toronto, Toronto/ ON/CANADA, ²Department Of Medical Physics, Sunnybrook Health Sciences Centre, Odette Cancer Centre, Toronto/ON/CANADA <u>Purpose</u>: To determine if a linac-based intensity-modulated radiation therapy (IMRT) technique is comparable to helical tomotherapy (HT) for the treatment of craniospinal volumes in terms of planned dose to the planning target volume (PTV) and organs at risk (OARs).

<u>Methods and Materials</u>: A retrospective planning study was performed on 11 patients (3 female, 8 male) who received treatment at this center in the past. The IMRT plans consisted of three sets of beams (with each set having a separate isocenter) - five cranial, three upper spine, and three lower spine fields - and were inverse-planned using Pinnacle³ (v.9.2, Philips). Helical tomotherapy plans were generated with the TomoTherapy Hi-Art (v.4.0.4) planning system. All patients were prescribed 36 Gy in 20 fractions, and plans were optimized to achieve similar goals across both platforms, namely 95% volume coverage of both the brain and spinal PTVs, and reduced dose to all OARs. We compared the performance of each technique through dose-volume histogram (DVH) statistical parameters, mean and maximum doses, and conformity index, testing for significance using the Wilcoxon signed-rank test at a level of p < 0.05.

Results: We find that multi-isocentric IMRT generally produces comparable plans to those of HT in terms of PTV coverage and homogeneity. We find that $\mathrm{D}_{\mathrm{max}}$ to the optic nerves, optic chiasm, lenses and eyes and $\mathrm{D}_{\mathrm{mean}}$ to the heart are equivalent in our patient sample. Slight differences are noticeable in the larger organs. The volume of lung receiving low dose is less for IMRT (average V_{5Gy} = 27.9%) than HT (V_{5Gy} = 37.2%, p < 0.005), while the opposite is true for higher doses (V_{10Gy} = 11.4% for IMRT vs. 9.1% for HT, p < 0.005; V_{20Gy} = 3.1% for IMRT vs. 1.8% for HT, p < 0.001); this is perhaps unsurprising considering the three chosen IMRT spinal beam directions compared to the possible 360° field delivery of HT. Similarly, a decreased low-dose wash to the whole body from the linac-based IMRT is reflected in its ability to spare kidney dose, resulting in a lower mean dose and volume exposed to low dose (average D 3.2 Gy for IMRT vs. 4.4 Gy for HT, p < 0.005; $V_{_{5\mathrm{Gy}}}$ = 15.9% for IMRT vs. 26.1% for HT, p < 0.02). Further differences we observed were a marginally higher mean dose to the parotids and esophagus, as well as higher D_{max} to the esophagus in the IMRT plans.

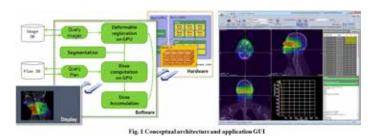

Conclusions: Based on our 11 patient sample set, the linac-based multi-isocentric IMRT treatment technique is able to produce comparable plans to helical tomotherapy in patients receiving craniospinal irradiation, with only minor tradeoffs in plan quality. This technique may provide an attractive alternative at treatment centers looking for a more conformal and homogeneous approach than conventional methods (ie. cranial lateral parallel opposed pairs with spinal posterior junctioned fields) but without access to HT.

PS04.059 - A Hardware-Accelerated Software Platform for Adaptive Radiation Therapy

Author(s): Seyoun Park¹, William Plishker², Adam Robinson¹, George Zaki², Raj Shekhar², Todd Mcnutt¹, Harry Quon¹, John Wong¹, Junghoon Lee¹

¹Radiation Oncology And Molecular Radiation Sciences, Johns Hopkins University, Baltimore/UNITED STATES OF AMERICA, ²IGI Technologies Inc., College Park/UNITED STATES OF AMERICA

A critical requirement of successful adaptive radiotherapy (ART) is the knowledge of anatomical changes as well as actual dose delivered to the patient during the course of treatment. While cone-beam CT (CBCT) is typically used to minimize the patient setup error and monitor daily anatomical changes, its poor image quality impedes accurate segmentation of the target structures and the dose computation. We developed an integrated ART software platform that combines fast and accurate image registration, segmentation, and dose computation/accumulation methods. The developed platform automatically links patient images, radiotherapy plan, beam and dosimetric parameters, and daily treatment information, thus providing and efficient ART workflow. Furthermore, to improve the accuracy of deformable image registration (DIR) between the planning CT and daily CBCTs, we iteratively correct CBCT intensities by matching local intensity histograms in conjunction with the DIR process. We tested our DIR method on six head and neck (HN) cancer cases, producing improved registration quality. Our method produced overall NMI of 0.663 and NCC of 0.987, outperforming conventional methods by 3.8% and 1.9%, respectively. The overall ART process has been validated on two HN cancer cases, showing differences between the planned and the actually delivered dose values. Both DIR and dose computation modules are accelerated by GPUs, and the computation time for DIR and dose computation at each fraction is ~1min.

PS04.060 - Predicting the Impact of Surgery on Quality of Life and Risk Management in Patients Afflicted with Glioblastoma Multiforme

Author(s): Luca Y. Li¹, David G. Gobbi², Jacob C. Easaw³, Yves P. Starreveld⁴

¹Biomedical Engineering, University of Calgary, Calgary/AB/CANA-DA, ²Calgary Image Processing and Analysis Centre, Calgary/AB/ CANADA, ³Tom Baker Cancer Centre, Calgary/AB/CANADA, ⁴Hotchkiss Brain Institute, Calgary/AB/CANADA

Introduction:

Glioblastoma multiforme (GBM) tumors are the most common brain malignancy with an average prognosis of 12-18 months with treatment. Surgical reduction of tumor volume by 78% or more increases patient life expectancy, and can be further extended by adjuvant radio/chemotherapy. However, the effect of treatment on patient Quality of Life (QOL) remains unknown. This study investigates: 1) the impact of more aggressive surgery on patient function, and 2) the utility of a tumor assessment score (TAS) to optimize treatment options by using tumor location and size to predict if the patient is healthy enough for adjuvant therapy. We hypothesize that: 1) there is a thershold between 78% and 98% resection where survival time will continue to increase but functional performance score will start to decrease, 2) a lower TAS based on anatomical location of tumour will reliably predict a lower post-operative functional score.

Methods:

Approximately 90 patients with GBM have gadolinium enhanced and non-enhanced T1 MR images taken pre- and post-surgery. Image pairs are registered and subtracted to highlight active tumor tissue and have their volume measured to calculate the extent of resection (EOR) (Figure 1). Patient QOL is measured with the Karnofsky Performance Scale (KPS) score. The TAS has a value between 1 and 10 based on: 1) which lobes the tumor infiltrates, 2) left vs. right hemisphere, and 3) the volume of tumor within each region. The impact of surgery looks at the relationship between EOR and postsurgical KPS. The predictive ability of TAS is determined by how closely it can estimate post-surgical KPS.

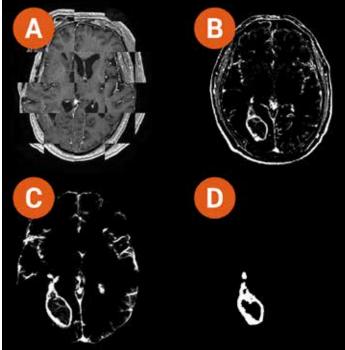

Figure 1: Tumour segmentation pipeline. (A) Registration of gadolinium contrast enhanced and non-enhanced axial T1 images. (B) Subtraction of the image pair highlights active tumour tissue. (C) Brain extraction removes skull and erosion reduces blood vessel connectivity. (D) Floodfill algorithm segments the tumour and provides a volume measurement.

Preliminary Results:

14 test patients were run with an EOR of $87.2\% \pm 5.9\%$ for gross-total resection (GTR) patients, and $63.8\% \pm 29.5\%$ for sub-total resection (STR) patients. KPS was slightly higher (p over 0.05) in STR (81±8) than GTR (75±14), supporting our first aim.

Conclusions:

Preliminary findings indicate that the pipeline can successfully segment the tumor for EOR calculation, and volumetric measurement of TAS.

PS04.061 - A memetic algorithm for body gamma knife stereotactic radiotherapy treatment planning

Author(s): <u>Bin Liang</u>¹, Bo Liu¹, Fugen Zhou¹, Bin Guo¹, Xuanang Xu¹, Jingbo Kang², Jianguo Li², Wei Liu²

¹Image Processing Center, Beihang University, Beijing/CHINA, ²Department Of Radiation Oncology, Naval General Hospital of PLA, Beijing/CHINA

Abstract—Body gamma knife stereotactic radiotherapy (SBRT) is an effective treatment for non–small-cell lung cancer (NSCLC). Treatment planning is both tedious and time-consuming due to its complexity. In order to address this issue, we present a memetic

optimization algorithm for body gamma knife SBRT treatment planning. Different from currently available methods, the memetic approach performs the optimization on relative dosimetric distribution, which results in an enlarged search space. Taking advantage of the prior knowledge about the interaction between the focuses, a heuristic initialization strategy and a set of genetic operators are developed. During optimization, the most time consuming part is accelerated by graphic processing unit (GPU). Three typical targets arising from real patient data are used to test the efficiency of this approach. Experimental results demonstrate that the memetic optimization could generate a feasible treatment plan quickly (94.6 sec for the largest case).

PS04.062 - Gamma evaluation of dose distributions from newly developed dosimetry system for helical tomotherapy Author(s): Sangwook Lim, Sangwook Lim, Sun Young Ma Radiation Oncology, Kosin University College of Medicine, Busan/ KOREA

To see the reliability of the newly developed dosimetry system using phosphor screen for arc therapy such as helical tomotherapy. The cylindrical water phantom was fabricated with the rounded phosphor screen emitting the visible light, that is phosphorescence during the exposure. Three types of virtual targets were defined, one is a small rounded target, another is C-shaped target, and the other is multiple targets. All the targets were to be irradiated at 10 Gy respectively by tomotherapy. Every frame captured from the camera was integrated and the doses were calculated in pixel by pixel. The dose distributions from the phosphorescence images were compared with the calculated dose distribution from the TPS. The discrepancies were evaluated as gamma index for each treatment. The curve for dose rate versus pixel value was not saturated until 900 MU/min. The dosimetry system with the phosphor screen and the camera is respected to be useful to verify the dose distribution of the tomotherapy if the linearity correction of the phosphor screen improved.

PS04.063 - Suitability of a Light Transparent and Electrically Conductive Glass Plate for Construction of a Beam Monitor for Radiation Therapy

Author(s): Xun Lin¹, Robert K. Heaton², Bern Norrlinger², Mohammad K. Islam²

¹Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/ON/CANADA, ²Radiation Physics, Princess Margaret Cancer Centre, Toronto/CANADA

Introduction: Due to increasing complexities in radiation therapy technology and associated processes, several real-time independent beam monitoring systems have recently been proposed to minimize treatment errors. Proposed systems utilize a large area detector system or ion chamber mounted after the final beam forming collimator on medical linear accelerators. Some of these devices block light fields, disrupting workflow as therapists are required to remove and re-install the dosimetry device before and after patient setup. In this presentation we describe the suitability of electrically conductive and light-transparent glass plates for use as electrodes in a large area ion chamber

Method: Plates' suitability was assessed based on four properties: (1) surface electrical conductivity (2) light intensity attenuation (3) light field boundary deviations due to refraction (4) stability to radiation exposure.

A commercially available 30×30 cm² conductive glass plate from Sigma Aldrich (Oakville, Canada) was investigated. The plates are 2 mm thick Soda-Lime Glass, coated with 0.5 microns thick conductive layer of Fluorine-doped Tin Oxide (FTO).

Glass surface conductivity was measured and a prototype parallel plate Ion Chamber was created using 2 such plates and tested in radiation for functionality. Light attenuation caused by the prototype was measured using the light probe accessory from the Xi system manufactured by RaySafe (Billdal, Sweden). Light field deviation was calculated using Snell's law; incident angle needed for 1 mm deviation was determined for red and green light, and experimentally confirmed with red and green lasers. Finally, plates' effect on the light field's usability and impact on equipment and patient setup in clinical settings was evaluated by an independent observer using eQA – a commercially available light field and radiation congruence validation tool by Modus Medical (London, Canada) – with and without the prototype. Exposure history is documented and periodic inspections performed to assess radiation damage.

Results: Glass surface resistance was measured to be 51.2 Ω from corner to corner. Basic performance of the prototype was satisfactory. Light field intensity from a Varian linear accelerator was reduced by 35.6% with the 2-plate prototype. According to Snell's Law a 2 mm glass plate causes 1 mm deviation in ray-line with incident angles of 61.3° and 58.6° for red and green light respectively. Experimental results confirmed calculated values. The boundary of a 40×40 cm² light field makes 15° incident angle with the prototype when mounted at the collimator; therefore only 0.74 mm deviation in field size is expected. Field congruence value comparison measureable changes to 24×24 cm² light field. No structural changes were observed after testing sessions where the prototype was exposed to radiation doses exceeding 1000 MU.

Conclusions: A commercially available electrically conductive glass plates was found to be suitable for construction of a transmission area ion chamber. The deviation in light-field boundary was found to be negligible. The reduction in light field intensity with 2 glass plates did not limit the usability.

PS04.064 - Objective assessment of skin erythema caused by radiotherapy

Author(s): <u>Hiroaki Matsubara</u>¹, Naruhiro Matsufuji¹, Hiroshi Tsuji¹, Naoyoshi Yamamoto¹, Kumiko Karasawa¹, Mio Nakajima¹, Wataru Takahashi², Masataka Karube¹

¹National Institute of Radiological Sciences, Chiba/JAPAN, ²The University of Tokyo Hospital, Tokyo/JAPAN

Skin toxicity of normal-tissue is unavoidable side effect in external-beam radiation therapy. Degree of skin toxicity has been visually categorized into discrete grades with having uncertainty owing to subjective evaluation by physicians. Skin dose irradiated in treatment is controlled for skin condition not to get worse than being erythema. This indicates that radiation-induced skin toxicity can be represented by degree of skin erythema. Skin erythema is caused by expansion of capillaries because of increase of blood flow, hemoglobin, owing to biological response for repair. The present study focuses on such physiological response in order to continuously assess skin toxicity.

Two kinds of non-invasive techniques to detect hemoglobin quantities have been developed. One is a Doppler laser flowmeter, which measures reflectance and wavelength-modulation of laser light scattered by skin. It detects skin blood flow in absolute value. The other is skin color pigments decomposition on digital image using independent component analysis (ICA) which is one of multivariate statistics methods. It decomposes a full-color skin image into color tones of hemoglobin, melanin, and others in relative value. Combined analysis of these techniques is expected to provide skin blood flow distribution in a skin image.

Six patients who had carbon beam therapy on lung cancer were treated. Prescription dose of 50 GyE were irradiated from four ports in one day. Photography and skin blood flow measurement were done at 3 h, 1 and 3 month(s) later since the irradiation for study of time series. A conventional compact digital camera was used, but special instruments and lightning condition were not prepared. A fast fixed-point algorithm was employed for ICA. Skin colors were successfully decomposed as shown in Fig. 1.

The results obtained are that relationship between skin dose and blood flow and relationship between skin blood flow and pixel values in hemoglobin image have been observed with their correlation coefficients being larger than 0.9. It was shown that skin toxicity can be represented by change of skin blood flow which is objective quantity. Because the present study quantitatively connects pixel values in hemoglobin image with skin dose, it would be promising to predict skin condition after irradiation in advance by making use of artificial synthesized image processing.

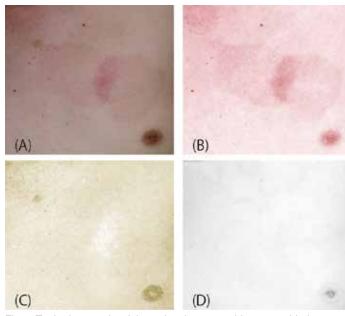

Fig. 1 Typical example of the color decomposition on a skin image which represents two-ports-irradiation erythema. An original image is (A). Color tones of hemoglobin, melanin, and others are (B), (C) and (D), respectively.

PS04.065 - Nasopharyngeal carcinoma tumor response to induction chemotherapy followed by concurrent chemo-radiotherapy: A volumetric magnetic resonance imaging study Author(s): <u>Nevin Mcvicar</u>¹, Joshua Giambattista², Benjamin Maas², Cheryl Ho³, Monty Martin⁴, Eric Berthelet²

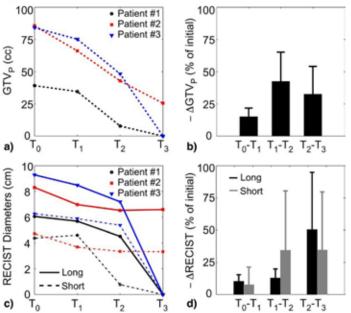

¹Medical Physics, BC Cancer Agency - Vancouver Cancer Centre, Vancouver/CANADA, ²Radiation Oncology, BC Cancer Agency -Vancouver Cancer Centre, Vancouver/CANADA, ³Medical Oncology, BC Cancer Agency, Vancouver/CANADA, ⁴Diagnostic Imaging, BC Cancer Agency - Vancouver Cancer Centre, Vancouver/CANADA

Purpose: Sequential induction chemotherapy followed by concurrent chemo-radiotherapy is currently under investigation for treatment of locally advanced nasopharyngeal carcinoma (NPC). Using magnetic resonance imaging (MRI), we have assessed tumor response at various stages of treatment for NPC patients prescribed with induction and concurrent chemo-radiotherapy. This study represents the first detailed volumetric analysis of primary gross tumor volumes (GTVP) in sequential treatment of NPC.

Methods: Fourteen locally advanced stage III-IV NPC patients who received treatment within the British Columbia Cancer Agency between 2011 and 2014 were used for this study. The induction phase included two cycles of gemcitabine combined with cisplatin. The concurrent phase included 5-7 cycles of cisplatin with radiation therapy delivered using volumetric modulated arc therapy (VMAT). All patients received a total dose of 70 Gy over 35 daily fractions given five days per week. All patients received three MRIs at specific stages of treatment (T0: before treatment, T1: after induction phase and T3: three months after concurrent phase). A subset of three patients also received an MRI approximately mid-way through concurrent phase (T2). GTVP and RECIST long (RL) and short (RS) diameters were calculated based on MRIs acquired at 1.5 Tesla using a gadolinium-enhanced fat-saturation T1 weighted spin-echo pulse sequence. GTVP were contoured in each MRI. Mean values are reported ± one standard deviation.

Results: In this preliminary analysis, we report on the subset of 3 patients who underwent 4 sequential MRIs. Before treatment, the mean GTVP was 69.6 ± 26.4 cc and the mean RL and RS diameters were 7.9 ± 1.7 cm and 5.1 ± 1.0 cm respectively. GTVP and RECIST diameters measured at each stage of treatment are shown for the in Figures 1a,c respectively. Figure 1b,d displays the average change in GTVPand RECIST diameters (as a percent of initial values calculated at T0) between each treatment phase with error bars equal to one standard deviation (N=3).

Discussion: Preliminary results indicate that two cycles of induction chemotherapy consistently reduced GTVP (15.1±6.7%) as well as RECIST diameters (long: 10.2±5.1%, short: 7.6±13.7%). NPC is very radiosensitive and tumor sizes reduced significantly throughout concurrent chemo-radiotherapy (~75%). RECIST diameters were more variable than GTVPmeasurements and were not accurate indicators of GTVP. NPC tumors are often irregular shapes making RECIST diameters not ideal markers of NPC tumor size. Analysis of the entire NPC patient dataset and quantification of tumor response during induction phase is ongoing.

PS04.066 - Volumetric Modulated Arc Therapy of Pancreatic Cancer: Dosimetric Advantages as Compared to 3D Conformal Radiation Treatment

Author(s): <u>Xiangyang Mei</u>¹, Tim Olding², Andrew Kerr³ ¹Medical Physics, Cancer Centre of Southeastern Ontario at Kingston General Hospital, Kingston/CANADA, ²Department Of Oncology, Queen's University, Kingston/ON/CANADA, ³Oncology, Queen's University, Kingston/ON/CANADA

Volumetric modulated arc therapy (VMAT) has been gaining wider adoption in radiation treatment of various cancer sites, and some recent studies have shown benefits of VMAT to the treatment of pancreatic cancer. This study is to show dosimetric advantages of VMAT with our planning strategies when compared to 3D conformal radiation therapy (3D-CRT) of pancreatic cancer.

The VMAT planning was performed retrospectively on 8 selected pancreatic cancer patients treated using a 3D-CRT technique. The 3D-CRT plans used mostly 4-fields (except one case of 5-fields) with 15 MV photon beams, and the beams arranged to maximally avoid left and/or right kidneys, while keeping sufficient dose coverage to PTV. Dynamic wedges were used for dose inhomogeneity compensation in cases of oblique beam arrangements. Both VMAT and 3D-CRT plans were planned using the Eclipse treatment planning system v.10 for delivery on a Varian Clinac iX/Trilogy linear accelerators (Varian Medical System, Palo Alto, CA, USA). The prescription dose was 4500 cGy in 25 fractions for all cases. The VMAT optimization objectives were designed to achieve maximal sparing to organs at risks, including left and right kidneys, liver and spinal canal with very strong weighting on both left and right kidneys, while ensuring sufficient dose coverage to CTV and PTV. Double arcs of two full rotations (one from 181° to 179°, and the other from 179° to 181°) with 6 MV photon beams were used for all VMAT plans. The PTV volume of these patients was 736 ± 213 cm³. The VMAT plans were normalized such that 99.5% PTV volume is covered by at least 95% of prescription dose (i.e. D99.5% =4275 cGy).

The plan evaluation comparisons between VMAT and 3D-CRT are shown in Table 1. From these results we show that, with our planning objectives, VMAT plans can achieve significantly better dose sparing to both kidneys and liver with lower V20 Gy and/or V30 Gy, lower max spinal canal dose, and better dose conformity to PTV than 3D-CRT plans.

Table 1 Plan evaluation comparisons between VMAT and 3D-CRT plans					
Volume	Dose parameter	3D-CRT	VMAT		
CTV	*D99.5%(cGy)	4379±38	4492±29		
	Mean dose(cGy)	4545±19	4595±21		
PTV	*D99.5%(cGy)	4212±22	4275±0		
	Mean dose(cGy)	4518±23	4568±19		
	**Conformity number	0.72±0.04	0.91±0.02		
Right-Kidney	***V20Gy	32.4%±20.6%	7.7%±7.8%		
	Mean dose(Gy)	15.1±7.1	10.9±3.1		
Left-Kidney	V20Gy	23.2%±9.4%	10.2%±5.5%		
	Mean dose(Gy)	12.3±3.4	11.6±2.6		
Liver	V30Gy	11.2%±10.2%	8.3%±7.5%		
	V20Gy	28.9%±14.6%	21.5%±13.5%		
	Mean dose(Gy)	12.2±5.0	11.5±4.2		
Spinal canal	Max dose(Gy)	33.1±6.3	27.7±7.4		
	Mean dose(Gy)	12.2±5.0	11.5±2.4		

* D99.5% means the minimum dose that covers 99.5% of the volume.

** Conformity number was calculated as the ratio between PTV and the 95% iso-dose volume.

*** V20 Gy means the fraction of the specified volume that receives at least 20 Gy of dose.

PS04.067 - Application of ExacTrack BrainLab system for Choroidal melanoma treatments using Stereotactic Radiotherapy and a not invasive immobilization system

Author(s): <u>Artur F. Menezes</u>¹, Delano V. Batista¹, Lucia H. Bardella¹, Aluisio J. Castro¹, Ademir X. Da Silva², Felipe E. Erlich¹ ¹Medical Physic, Centro de Oncologia Rede D´Or, Rio de Janeiro/ BRAZIL, ²Programa De Engenharia Nuclear, Universidade Federal do Rio de Janeiro, Rio de Janeiro/BRAZIL

Ocular melanoma is an aggressive skin cancer with metastatic behavior that can lead to death¹. External beam radiation therapy is an option to treat medium size lesions (2.5 - 10 mm) not eligible for brachytherapy (tumors close to the optical disk)².

The best results are only achieved if the position of the patient's eye during the computed tomography simulation (CT) can be reproduced during delivery of the radiation dose³. Jaywant et. al³ developed an elaborated system for treatment of ocular melanomas, comprising of an attachment systems, miniature camera, light emitting diode (LED) and image processing software. Although a high degree of sophistication, these systems are possibly associated with a high cost. In this regard, we describe an alternative methodology provide a low cost system that enables correct positioning and fixation of the eye.

Patients were immobilized with BrainLAB's frameless thermoplastic mask. Eye movement was monitored with a camera mounted on a free end of a plastic rod, and the other end was rigidly fixed in the mask. A cavity in the mask was performed at the level of the treated eye, so the images could be viewed from outside the treatment

and CT rooms. To fix the patient's eye, we used a LED, next to the camera, and the patient was instructed to keep their eyes fixed on the bright spot to keep the eyeball static during the CT scans and the treatment delivery. The planning was carried out using a dose prescription of 50 Gy over 5 fractions, usually with 9 radiation fields.

PS04.068 - Dosimetric evaluation of deliverable and navigated Pareto optimal plans generated with Multi-Criteria Optimization

Author(s): Archonteia Kyroudi¹, Sarah Ghandour², Marc Pachoud², Oscar Matzinger², Kristoffer Petersson¹, Mahmut Ozsahin³, Jean Bourhis³, François Bochud¹, <u>Raphaël Moeckli¹</u>

¹Institute Of Radiation Physics, CHUV, Lausanne/SWITZER-LAND, ²Radio-oncology Department, Riviera-Chablais Hospital, Vevey/SWITZERLAND, ³Radio-oncology Department, CHUV, Lausanne/SWITZERLAND

Multi-Criteria Optimization (MCO) is an optimization technique providing decision makers (radio-oncologist and medical physicist) with a wide range of clinical choices. It can help unfold the trade-offs involved in the treatment planning problem. MCO generates a set of fluence based Pareto optimal plans, for which no criterion can be improved without deteriorating another. This allows for continuous real time navigation among these optimal solutions. The solution selected by decision makers in the navigation step is converted to a deliverable dose distribution after a second optimization step, which includes direct machine parameter optimization and a final dose calculation. As a consequence, the final deliverable plan might not represent the clinical choices made during the navigation. The purpose of our study was to address this concern by exploring the dosimetric differences between navigated and deliverable plans.

Navigated and deliverable VMAT plans for five prostate and five lung cancer cases were created with RayStation TPS (RaySearch AB, Stockholm, Sweden). Two-dimensional Pareto fronts were created, representing the trade-off between PTV under-dosage vs. healthy tissue sparing. PTV under-dosage was evaluated through the volume of PTV receiving less than 95% of the prescribed dose, while healthy tissue sparing was evaluated through the $D_{50\%}$ parameter for rectum and V_{5Gy} for lung-PTV volume. In order to minimize the effect of the other parameters involved in the treatment planning problem we introduced optimization constraints on all other OARs, which ensured minimal dosimetric variations for these structures.

The Pareto front evaluation (see examples in Fig. 1) demonstrated a disagreement for the trade-off parameters between navigated and final deliverable plans for eight of our ten cases. For two prostate cases the deliverable Pareto fronts were improved compared to the navigated ones. For the other prostate cases the disagreement proved more random. In all lung cases, the deliverable plans deteriorated compared to the navigated ones, i.e. the PTV under-dosage increased (up to 17 %). Our results show that the final deliverable plan quality may be substantially different than that of the navigated plan selected by clinical decision makers, particularly for small

target volumes in lung.

Real time navigation on a wide range of treatment plans offer more and potentially better options during clinical decision making. However, dosimetric differences between navigated and deliverable plans due to the two-step approach may limit the practical use of MCO.

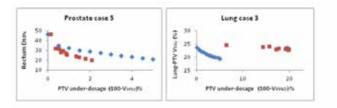

Figure 1: Example of navigated (points in blue) and deliverable (points in red) Pareto fronts for a prostate and a lung cancer case.

PS04.069 - 2D and 3D Approximate Entropy Algorithms for On-line Quantification of Threshold Structure Content in Large Radiotherapy Image Data

Author(s): <u>Christopher J. Moore</u>, Phillip Sharrock, Thomas Marchant

Christie Medical Physics & Engineering, The Christie NHS Foundation Trust, Manchester/UNITED KINGDOM

Expert interrogation (EI) remains the 'gold-standard' in many medical applications, excelling at identifying occult abnormality and disease, particularly under threshold conditions where noise dominates a region of interest Sophisticated regularity metrics have only been developed to help clinicians identify threshold structural changes in 1D data streams, e.g. approximate entropy (ApEn_{1D}) for physiological monitoring. This in the knowledge that the order in which the data appears, not just its variability, can indicate clinically significant perturbations [1].

Today, very large image data streams almost intractable to El are commonplace. 3D data volumes are fast becoming 4D with the proliferation of dynamic scanning in both diagnostic and therapeutic imaging settings c.f. X-ray fan-beam and cone-beam CT (FB/CBCT). Hitherto, the ApEn_{1D} algorithm has not been formally developed for routine use with higher dimensional data, though iterated deployment of 1D calculation [2] and promising pilot work towards an approach for differentiating cell and clinical images has been reported by the authors [3,4].

The purpose of this work is to show that it is feasible to rapidly compute a statistical measure of pattern regularity associated with all image points and their immediate surroundings, which is self calibrating to represent simplistic through to random structural content. This is a first step towards understanding El 'threshold working' in medical imaging in general, and manual radiotherapy structure delineation in particular, from an evidence based viewpoint with an associated single metric.

This paper formally presents approximate entropy algorithms in 2D and 3D forms (ApEn_{2D/3D}) for imaging. The concept of spatial divergence in the context of considering nearest neighbour pixel lattices is introduced as fundamental to the development of these algorithms. Observations of the mechanics of El during interactive image interrogation are also shown to be consistent with this approach.

Pilot software to calculate ApEn_{3D} for 3D image data was written using the scientific programming language IDL (ITT VIS, Boulder, CO). The time taken to compute ApEn_{3D} for each of the 512×512 voxels in a single CT slice image was approximately 3 minutes using a PC with 3GHz CPU (note that the calculation operates in 3D, hence a

block of adjacent slices is processed to compute ApEn values for the block's central slice). Optimised recoding in C reduces this to 10 seconds, making on-line use feasible. Still faster implementation using an Intel Xeon Phi card's MIC architecture is current work in progress.

For illustration the new ApEn_{2D/3D} algorithms are applied to FBCT and CBCT volume image data sets acquired for image-guided radiotherapy patients. Significant differences in the ApEn distribution between the two modalities are revealed, visually and quantitatively, reflecting the scatter-induced decreased uniformity and increased noise in CBCT.

PS04.070 - Dosimetric effects of seed positioning uncertainties in ophthalmic plaque brachytherapy

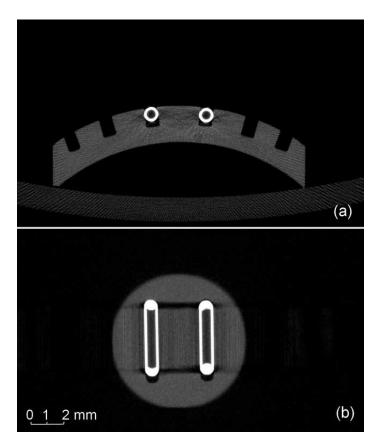

Author(s): <u>Hali Morrison</u>, Geetha Menon, Hans-Sonke Jans, Ron Sloboda

Medical Physics, Cross Cancer Institute, Edmonton/CANADA

Uveal melanoma affects approximately 3000 people each year in North America, many of whom are then treated with plaque brachytherapy, now a commonly used alternative to enucleation. One significant challenge in plaque brachytherapy dosimetry is the presence of very sharp dose gradients due to short treatment distances, making even small shifts in depth result in large changes in dose. Uncertainties associated with seed positioning were examined using two approaches: (i) by comparing EBT3 GafChromic film dose measurements and Plaque Simulator ophthalmic brachytherapy treatment planning software calculated doses; and (ii) by measuring seed positions in a COMS plaque insert using microCT scanning.

Film pieces were placed at depths of 6 mm and 12.3 mm within two 24.6 mm diameter spherical PMMA phantoms. The films within the phantoms were then irradiated with both 16 mm COMS and Eye Physics Super9 (model #930) brachytherapy plaques, each of which contained two centrally loaded IsoAid Advantage I-125 model IAI-125A seeds with an average activity of 8.0 mCi. The irradiations were performed in a water tank to provide full backscatter conditions, and a minimum dose of 6.5 Gy was delivered to the centre of each piece of film. The film dose measurements were compared to calculated doses using Plaque Simulator v5.7.3 software, with dosimetry parameters for the IsoAid I-125 seed in PMMA to account for the non-water material of the phantoms.

The CAX calculated doses at depths of 6 mm and 12.3 mm differed from the equivalent ones measured using film by 8-16%. The differences in dose could be accounted for by an average shift in depth of 0.5 mm for both the 16 mm COMS and Super9 plaques. For the COMS plaque, this change in depth is at least partially associated with seed placement in the Silastic insert as the seed slots have a depth 0.45 mm greater than the seed diameter. To measure precise positions of the seeds within the 16 mm COMS Silastic insert, high resolution CT images were obtained using a Siemans Inveon micro-PET/CT hybrid scanner with the insert loaded with IsoAid I-125 seed shells (no silver core was in the Ti shells to reduce metal artifacts in the CT images), as seen in Figure 1. These results highlight the impact of the steep dose gradients present in ophthalmic plaque brachytherapy as well as the importance of precise and careful assembly of the plaques for patient treatment.

PS04.071 - A Method for Evaluating Deformable Dose Accumulation in RayStation

Author(s): Joanne Moseley¹, Biu Chan², Jean-Pierre Bissonette² ¹Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/CANADA, ²Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/ON/CANADA

Purpose: To develop a method for evaluating the effect of various shrinkage rates on dose accumulation in the head and neck using a commercial treatment planning system (TPS).

Material/Methods: A biomechanical finite element based deformation software (MORFEUS) was used to register the planning CT and final fraction CT of a head and neck radiotherapy patient with large tumour shrinkage, thus generating a known deformation field. The deformation field was multiplied by fractions of the total deformation ranging from 10% to 100% to generate three series of target images (5 each) with varying amounts and rates of shrinkage. These images were imported into a commercial TPS (RayStation v4.4.100, Raysearch, Stockholm) and deformable image registration was performed using a hybrid algorithm (i.e., based on image intensity and contours). Dose was accumulated over 5 equidistant fractions in the following schemes: Shallow-Steep (10%-20%-30%-60%-100%), Linear (20%-40%-60%-80%-100%), and Steep-Shallow (10%-50%-80%-90%-100%). The dose statistics for the accumulated dose was compared with the planned dose using D99 for targets and D_{max} for organs at risk.

Results: The difference in dose statistics accumulated over 5 fractions for each of the three image sets is shown in Figure 2. For this particular disease presentation, the effect on dose difference is

greater the earlier the changes appear in treatment.

Conclusion: A set of images was generated with a known deformation field and linear changes between them. Images such as these can be used to evaluate the effect different magnitudes and rates of change have on accumulated dose.

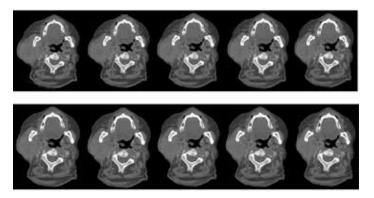

Fig. 1: Images deformed using MORFEUS, ranging from 10% of total deformation (upper left) to 100% of deformation (lower right).

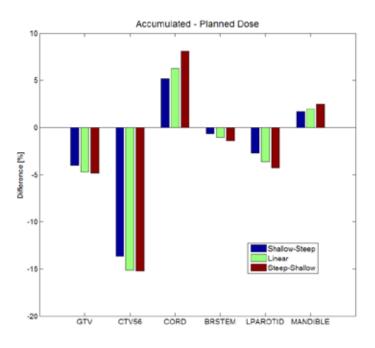

Fig. 2: The percentage difference between accumulated and planned dose over five fractions. D99 is compared for GTV and CTV, and D_{max} is compared for the organs at risk.

PS04.072 - Dosimetric comparison between 3D CRT, full Arc and Partial Arc Vmat techniques in the management of locally advanced lung Cancer using External Beam Radiation Therapy (EBRT).

Author(s): <u>Samir Mouatassim</u>¹, Omar El Alami¹, Latifa Mesbah² ¹Radiotherapy, Centre d'Oncologie Nakhil, Rabat/MOROCCO, ²Oncology, Moulay Youssef Hospital, Rabat/MOROCCO

BACKGROUND

The purpose of this study is to compare the planning target volume (PTV) coverage and sparing to organs at risk (OARs) achieved when using volumetric modulated arc therapy (VMAT) with Full Arc (FA),

Vmat with Partial Arc (PA) or static 3D Conformal Radiation Therapy treatment for locally advanced lung tumors.

MATERIALS AND METHOD

3D CRT and Vmat planning were done applying the 3A algorithm and the Vmat optimization module implemented on Eclipse workstations (v. 11 from Varian).

The treatment machine consists of a Varian high energy linac Silhouette with a 120 Multileaf collimator, on-board imaging (OBI) system including CBCT feature, IMRT and RapidArc capabilities.

Six patients with locally advanced NSCLC tumor were treated either by using 3D Conformal Radiation Therapy or Vmat (RapidArc) technique. Dose to Organs At Risk (OARs); such as the spinal cord, heart, esophagus, brachial plexus and lung were determined by performing and optimizing a 3D CRT plan and compared to those obtained with VMAT plans (FA Vmat and PA Vmat). All the Vmat plans were generated using the same dose constraints and planning objectives compiled from a systematic literature.

RESULTS

The VMAT plans delivered a significantly lower dose to the spinal cord, to brachial plexus, to lung and heart than do the 3D CRT plans. In addition, they show more optimal PTV coverage with better Conformity Index (CI) and more homogenous dose in the target. In contrast, the 3D CRT plans are obviously more efficient in dose delivery and the volumes of low dose are less important than those generated with Vmat plans.

The results demonstrate that using VMAT instead of static 3D CRT offers improvements in OARs sparing without detriment to PTV coverage. While both methods can result in conformal plans, the VMAT plans were found to conform more ideally to the target volume.

The PA Vmat plans show better OARs sparing and decrease of low dose to surrounding normal tissue compared to FA Vmat plans while both are leading to comparable PTV coverage, conformity and dose homogeneity.

PS04.073 - Dosimetric and clinical considerations for implementing CBCT based adaptive planning using RayStation Author(s): <u>Bongile Mzenda</u>, Rochelle Hiscock, Angela Wells Auckland Radiation Oncology, Auckland/NEW ZEALAND

Introduction

This study reports on the implementation of a CBCT (Elekta XVI) adaptive replanning technique for pelvis, chest and H&N treatments at our centre.

Method

Density tables for use in replanning were compared between the bulk density correction method for the RayStation TPS (Fig1a) and user-defined density tables derived from Catphan and Gammex 467 phantoms (Fig1b). These were applied to Rando phantom plans as well as patients having no contour changes to determine their dosimetric accuracy.

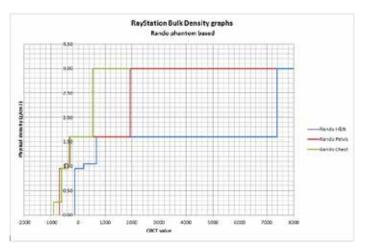

Figure 1a. Typical bulk density from RayStation TPS for Rando phantom sites

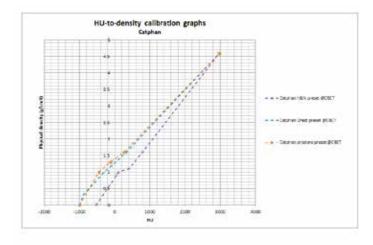

Figure 1b. Typical user derived densities for Rando phantom sites

For XVI adaptive planning additional presets were created for sufficient image quality and patient field of view.

In the clinical implementation for 10 patients who required replanning as a result of weight changes the CBCT method was compared to the repeat CT planning. Contouring was performed on both the repeat CTs and the CBCT images by the Radiation Oncologists and new plans generated. Contour comparisons of the CBCT generated volumes against the CT volumes were performed. Plan dosimetric metrics reviews and quantitative checks of gamma indices (3%/3mm and 2%/2mm) of the new plans were performed.

Results

For the pelvis region the bulk density method was found to be more consistent and accurate in real patients than the user-defined density table which gave higher discrepancy for the Rando phantom. For H&N and chest/thorax region the user defined density table consistently resulted in closer dosimetric agreement to the expected for phantom and real test patients. Good agreement was seen in the comparison between the plan metrics from repeat CT and computations on the CBCT datasets.

Conclusion

The implementation of CBCT plan adaptation for efficient clinical workflows requires critical assessment of the uncertainties due to imaging, density corrections and contour propagation on the resulting treatment plans.

PS04.074 - A Statistical Study based on comparison between two treatment planning systems while exporting RT structure set

Author(s): Richa Sharma¹, <u>Kamlesh R. Passi²</u>, Konthoujam M. Devi², Sandhya Sood²

¹Department Of Radiotherapy, Delhi State Cancer Institute, Delhi/ INDIA, ²Department Of Radiotherapy, Mohan Dai Oswal Hospital, Ludhiana/INDIA

Introduction: An RT structure set (RTSS) comprises of delineated target and OARs drawn on DICOM images by radiation oncologist. In a big radiation therapy department having many treatment planning systems (TPSs) and a huge patient load, it is a common practice to maximize the throughput by contouring on any available TPS irrespective of the TPS where actual planning is to be done. But when an RTSS is drawn on one TPS and is exported to other, volume of contoured structures gets modified. The objective of this study is to analyse such changes in volume on statistical basis in case of IMRT patients.

Material and Methods: In this study we have used two TPSs -CMS-Xio (v4.7) and Oncentra (v1.0). Thirty patients were selected from each TPS. RTSS volumes given by original TPS (on which RTSS was drawn) were recorded. After which all patient's DICOM images along with RTSS were sent to other TPS. Then, RTSS volumes given by new TPS were also noted down. These volumes were categorized organ wise. Thereafter, these original volumes and altered volumes were compared on the basis of percentage variation analyses. Moreover, range, measure of central tendency and absolute dispersion of percentage variation were determined for each category. Subsequently, scatter diagrams were plotted for each of the category, keeping originally drawn volumes on X-axis and altered volumes on Y-axis. Relationship between these volumes was estimated from respective approximating curve via least square fitting. With the help of such regression curve of Y on X, value of altered volume corresponding to a given original volume can be estimated. Measure of scatter about regression curve had also been found for each category. Total variation of altered volume, including explained variation and unexplained variation was also found for each categories and hence coefficient of determination and coefficient of correlation were determined. Further, this sample correlation coefficient r was used for estimating the value of theoretical population correlation coefficient p at 95% and 99% confidence level for each category on the basis of sampling theory of correlation.

Results and Discussion: High percentage variations had been estimated for small volume structures. Contours which had been drawn originally on Oncentra and CMS-Xio were found to have altered volumes greater than and less than originally drawn volumes respectively. But a few exceptions had also been noticed for both TPSs. In most of the cases nearly perfect linear correlation between volumes had been observed, except for a few cases like lens, indicating to the fact that the total variation of altered volumes in these cases comprise of a significant part of unexplained variation. Application of sampling theory of correlation further revealed that there is no linear correlation between original (drawn on CMS-Xio) and altered volumes for optic nerve.

In summary, it may be concluded that change in volume of RT structures on export between different TPSs may or may not be significant in other disease sites but is particularly important in case of brain and head and neck patients.

PS04.075 - The Characteristics and Implementation of XR-RV3 Gafchromic Film for Radiotherapy Dosimetry

Author(s): <u>Supriyanto Ardjo Pawiro</u>¹, Aditya Fergiawan¹, Pamungkas Hudigomo¹, Sugiyantari Soegijono², Andreas Nainggolan³, Djarwani Soeharso Soejoko¹

¹Department Of Physics, Faculty Of Mathematics And Natural Sciences, University of Indonesia, Depok/INDONESIA, ²Department Of Radiotherapy, Persahabatan Hospital, Jakarta/INDONESIA, ³Department Of Radiotherapy, MRCCC Siloam Hospitals, Jakarta/ INDONESIA

The purpose of this study is to compare the dosimetry characterization of XR-RV3 to EBT2 gafchromic film and also to implement both films in order to verify the dose of radiotherapy on IMRT and VMAT. The film response of each energies (foton 6 MV, 10 MV and Cobalt-60) was measured over the dose levels from 50 cGy to 10 Gy. Each film piece was scanned using EPSON Perfection V700 flatbed scanner, 48-bit color, 75 dpi spatial resolution. The data were analyzed using FilmQA Pro for each images with ROI size 3 x 3 cm². Furthermore, the evaluation of targeted dose is determined by putting films of Gafchromic XR-RV3 and EBT2 on Rando Alderson slab fantom to simulate prostate cancer. The experiment was performed with Varian Clinac Trilogy, Inc. Two cases of IMRT and VMAT plans were made using Eclipse TPS ver. 10. Exposed Gafchromic films was scanned using Epson Perfection V700 into (.TIF) format in 720dpi and RGB 48 bit was analyzed by using in-house algorithm and FilmQA pro. The comparison between EBT2 and XR-RV3 Gafchromic films were used to obtain average dose in the form of histogram curve. From this study, the result revealed that there was no significant difference in characteristics response between XR-RV3 and EBT2 film with standard deviation of ±3%. The energy dependence of XR-RV3 and EBT2 film was found to be relatively small within measurement uncertainties ±1%. The dependence of XR-RV3 film side orientation is negligibly small with the standard deviation of 0.2. On the other hand, the percentage of errors in the case of verification of prostate cancer toward the planned dose were -4.85% in EBT2 Gafchromic films and -1.94% in the XR-RV3 Gafchromic films on IMRT technique, whereas for VMAT were -4.48% on EBT2 Gafchromicfilms and -7.47% on XR-RV3 Gafchromic films.

PS04.076 - Weighted comprehensive score evaluation of CBCT image guided positioning accuracy in lung cancer radiation treatment

Author(s): <u>Yinglin Peng</u>, Songran Liu, Botian Huang, Dandan Zhang, Wenzhao Sun, Hui Liu, Xiaowu Deng

Radiation Oncology, Sun Yat-Sen University Cancer Center, Guang-zhou/CHINA

Background and Objective: Cone-beam computed tomography (CBCT) has been widely used in radiation treatment positioning as so called image guided radiation therapy (IGRT) technique. It is impossible to correct all local position error by doing global IGRT positioning since deformation always happens in the patient and the positioning shifts relies on the image registration technique used in the image guidance. This study evaluated and analyzed the regional accuracy of CBCT guided positioning used different image registration strategy with a comprehensive scoring method to provide a reasonable guidance for clinic application of cancer IGRT.

Materials and Methods: Planning CT and CBCT images acquired during the first radiation treatment positioning of 15 lung cancer cases were studied, registered with different image registration algorithms (bony and gray registration) and different registration area (target-only, ipsilateral structure and body).The CBCT target volume (GTV_{CBCT}) coverage by planning target volume (PTV_{CT}), the dice similarity coefficient (DSC) between the planning CT target volume (GTV_{CT}) and GTV_{CBCT} the volume of organ at risk on planning CT (OAR_{CT}) and on CBCT (OAR_{CBCT}), and the position deviation of

the GTV geometric center were compared. A weighted comprehensive scoring function was used to evaluate the positioning correction. The comprehensive registration factors (CRF) was defined as following, while the CRF values 100 meant all specific structures registered 100%.

$$CRF = F_{GTY} \times F_{OABi} \times F_{OABi} \times [DSC_{GTY} \times w_{GTY} + \sum_{i} (DSC_{OABi} \times w_{i})]$$

Results: For the tested lung cases, the bony registration had less accuracy in almost all evaluated specifications, especially when registered the target only. The coverage ratio of PTV_{CT} to GTV_{CBCT} of bony and gray registration in the three groups of registering target only, ipsilateral structure, body were $66\% \pm 35\%$ and $97\% \pm 8\%$ (P=0.005), 98 $\% \pm 5\%$ and 99 $\% \pm 2\%$ (P=0.034), 98 $\% \pm 4\%$ and 98 $\% \pm 4\%$ (P=0.478), res pectively. Using gray registration to register the ipsilateral structure had the best result, with the DSC of GTV and OARs of 0.86 \pm 0.10 (GTV), 0.71 \pm 0.10 (Esophagus), 0.76 \pm 0.10 (Spinal cord), 0.89 \pm 0.05 (Heart),and the deviation of GTV center of 2.5mm \pm 1.6mm, meanwhile the CRF was 55.28 \pm 40.59.

Conclusions: CBCT guided positioning is able to ensure that the GTV covered by PTV, which is the first goal of IGRT, when suitable image registration strategy is applied. Using gray registration and registering the ipsilateral structure is recommend for CBCT guided lung cancer radiation treatment positioning. The weighted comprehensive scoring is helpful for evaluating the image registration of IGRT.

PS04.077 - MCNP Simulation of Leksell Gamma Knife Using Disk Sources for Different Phantom Materials

Author(s): <u>Ma. Vanessa Francheska P. Perianes</u>, Doreen Alexis F. Villanueva, Jade D. Trono

Physics, De La Salle Unversity, Manila/PHILIPPINES

Leksell Gamma Knife (LGK) uses 201 Co-60 sources whose radiation intersects at the isocenter. The relative dose at the isocenter was verified using MCNP simulation. This study was divided into two simulations. Simulation A includes the simulation of 201-point sources to verify the location of the sources and the direction of the particles towards the center of a 160 mm water phantom. Simulation B includes the simulation of the 201-disk sources on the water phantom and water phantom with 1 cm thick shell made of Plastic Water. The diameter of the disk source used in the simulation corresponds to the diameter of the outer aperture of the full geometry collimator system for 4, 8, 14 and 18 mm. In order to produce a relative dose distribution, scoring bins were placed at the x-, y- and z-axes of the phantom. *F8 tally was used to convert the energy deposited into the scoring bins in MeV into dose in rad. Simple physics treatment was observed in the simulation. The relative dose distributions obtained in the simulation were compared. The results verified that the region of the highest dose was at the center of the phantom. The results of Water Phantom were compared with the results of Water Phantom with 1 cm thick Plastic Water shell (Figure 1 and Figure 2). There were no significant differences found between Simulation A and Simulation B. The lateral distribution of the dose along the z-axis increases as the diameter of the disk increases. In conclusion, the use of disk sources provides a simpler method in the simulation and obtaining a relative dose distribution instead of using the full geometry collimator system of the LGK.

PS04.078 - Dosimetric comparison between RAPIDARC and 3DCRT planning in extremity soft tissue sarcoma

Author(s): <u>Yannick Poirier</u>¹, David Sasaki¹, Darlene Courtney², Mohamed Akra³

¹Medical Physics, CancerCare Manitoba, Winnipeg/CANA-DA, ²Treatment Planning, CancerCare Manitoba, Winnipeg/CANA-DA, ³Radiation Oncology, CancerCare Manitoba, Winnipeg/CANADA

Introduction: Soft-tissue sarcomas presenting in extremities are usually treated with neo-adjuvant radiation therapy prior to limb-preserving surgery. These sites often present with large planning target volumes (PTVs) that are challenging to treat as they can envelop weight-bearing bone (e.g. femur). Limiting the dose to bone and skin reduces the risk of fracture and lymphedema or delayed post-surgery wound healing, respectively, but is difficult to achieve using traditional 3-D conformal radiation therapy (3D-CRT). As part of our institution's efforts to join the incoming SRC-6 clinical trial, we investigated the ability of RAPIDARC volumetric modulated arc therapy (VMAT) to improve coverage and spare organs at risk (OARs) compared to 3D-CRT plans, and investigated the sensitivity of VMAT plan quality to arc parameters.

Materials and Methods: VMAT plans were generated for five extremity sarcoma patients previously treated with 3D-CRT in our institution. The PTV average longitudinal length was 20.6 ± 6.8 cm with a range of 10.1-30.8 cm. The sites were planned using two partial arcs designed to avoid irradiation through the contralateral extremity or the rest of the body. Complimentary collimator angles (e.g. $30^{\circ}/330^{\circ}$) were used to maximize optimization flexibility. Patients with PTV longitudinal length >20 cm were planned using a four arc technique to avoid large segments of open fields. First, the

original two arcs were duplicated. Then, the size of each field was decreased to a maximum of 20 cm such that the PTV was partially covered by two arcs overlapping near the middle of the PTV for each collimator angle. We assessed the sensitivity of VMAT plan quality to collimator angles by generating alternate plans with varying collimator angles from $(0^{\circ}/0^{\circ})$ to $(90^{\circ}/270^{\circ})$ in increments of 15°. A standard prescription of 50 Gy in 25 fractions was used for every plan.

Plan quality was assessed using objectives from the SRC-6 protocol: namely, CTV V_{95%Rx} = 100%, PTV V_{95%Rx} > 95% V_{110%Rx} < 10%, infield-skin and longitudinal skin strip V_{20Gy} < 50%, and in-field bone V_{50Gy} < 50%.

Results: The generated VMAT plans satisfied all planning objectives for each patient. When renormalized to offer similar coverage, the VMAT plans outperformed the clinical 3D-CRT in dose homogeneity and OAR sparing. On average, PTV V_{110%Rx} was 5% ± 5% higher in 3DCRT plans compared to VMAT. While bone V_{50Gy} was only 3% ± 1% lower in VMAT plans compared to 3DCRT, VMAT offered much superior skin sparing by 10% ± 16% for total skin V_{20Gy} and 59% ± 11% for skin strip V_{20Gy} respectively.

VMAT plan quality was insensitive to collimator variation, as metrics showed variations of <1% for coverage and \pm 3% for OARs except for the extreme (0°/0° or 90°/270°) cases.

Conclusions: A VMAT planning method was devised and validated for the treatment of extremity soft-tissue sarcoma. Collimator angle had minimal impact on the quality of the plan. Long (>20 cm) PTV volumes were successfully planned using a four-arc single-isocentre technique. VMAT plans were able to spare more of the circumference of the skin compared to 3DCRT.

PS04.079 - Cerebral Functional Alterations Before and After Intensity-Modulated Radiation Therapy in Patients with Nasopharyngeal Carcinoma

Author(s): <u>Wenting Ren</u>¹, Kai Wang¹, Peng Huang¹, Junjie Miao¹, Yuan Tian¹, Pan Ma¹, Jiayun Chen¹, Feng Ye², Han Ouyang², Jianrong Dai¹

¹Department Of Radiation Oncology, Cancer Institute & Hospital, Chinese Academy of Medical Sciences, Beijing/CHINA, ²Department Of Radiology, Cancer Institute & Hospital, Chinese Academy of Medical Sciences, Beijing/CHINA

Purpose: Nasopharyngeal carcinoma (NPC) is sensitive to Radiation therapy (RT). However, NPC patients received RT always suffered from the cognitive impairment, which happens from the early time of RT without visible cerebral necrosis ^[1]. It is still unclear whether and where the brain function are affected in patients with NPC right after the RT. Thus, the study aims to explore the brain functional alterations before and one day after RT in patients with NPC by using resting-state functional MRI.

Methods: Sixteen NPC patients and sixteen age, sex, height, weight, handedness and years of education matched normal controls were recruited in this study. All the patients were treated with intensity-modulated RT with a prescribed dose of 70-74Gy. Resting-state functional MRI scanning (Discovery MR750, General Electric, Milwaukee, USA) and neurocognitive tests including Montreal cognitive assessment (MoCA), Auditory verbal learning test (AVLT), Self-rating depression scale (SDS), Self-rating anxiety scale (SAS), Social function activity survey scale (FAQ) were administered individually to each patient 1 day before initiation of RT and 1 day after completion of RT. The normal controls were also required the same MRI scanning and the neurocognitive tests after they were recruited. Amplitude of low-frequency (0.01-0.8 Hz) fluctuations (ALFF) during resting-state functional studies, which is thought to reflect spontaneous neural activity [2], were calculated by DPARSF software package (http://www.restfmri.net) to characterize regional

cerebral function. Paired T test was used to compare the cerebral functional alterations and neurocognitive tests scores before and after intensity-modulated radiation therapy in NPC patients while independent T test was used to compare the alterations between patients and controls before intensity-modulated radiation therapy. Significance was set at P=0.05, corrected by AlphaSim program.

Results: Compared with the patients before and after RT, decreased ALFF were observed in right cerebrum including temporal gyrus, limbic lobe, hippocampal gyrus, fusiform gyrus, inferior frontal gyrus and cerebellum while increased ALFF in left cerebrum including occipital gyrus, middle temporal gyrus, fusiform gyrus, both sides medial and superior frontal gyrus. However, these brain regions were not observed significant changes when compared with the normal controls before RT. There was no significant results of neurocognitive tests scores.

Conclusions: Our findings firstly demonstrated that the function of cerebellum, temporal gyrus, hippocampal gyrus, occipital gyrus and frontal gyrus were altered right after the RT, suggesting the function of cerebrum is sensitive to RT which could explain the cognitive deficits in NPC patients after RT. Thus, efforts should be made to protect the cerebral function by reduce the radiation dose and irradiated volume of functional regions without compromising the coverage of target volume. There were no significant results of cognitive tests may be due to the observe time was too short after RT, long-term follow-up would be needed. Our study also proposed that functional MRI could be used as a potential method to monitor the effect of RT on cerebral function.

PS04.080 - A Study of Accuracy from Varian Portal Dosimetry for VMAT Patient Specific QA using Monte Carlo

Author(s): Mohamad F. Rhani¹, Freddy Haryanto², I G. Dirgayussa², Sitti Yani², Idam Arif², Shaun P. Baggarley¹

¹Department Of Radiation Oncology, National University Cancer Institute Singapore, Singapore/SINGAPORE, ²Department Of Physics, Institut Teknologi Bandung, Bandung/INDONESIA

Purpose: A study of VMAT portal dose acquisition based on comparison of patient specific QA of clinical VMAT plan with Varian Portal Dosimetry and Monte Carlo simulation using BEAMnrc is performed.

Methods: In our study, 29 cases of VMAT plan for patient specific QA are verified by Varian Portal Dosimetry. For this verification, treatment planning system (Eclipse) calculates the portal dose predicted image for each case and to be compared with the image produced by portal imager. To evaluate the result of verifications for every VMAT plan, gamma analysis of 95%(3%/3mm) is used as passing rate criteria. For this study, measurements are done by extending the portal imager to Source to Detector Distance of 140 cm. Monte Carlo Simulation will be performed for two cases which one has the poorest gamma analysis and the other has the best gamma analysis. For simulation, the linac head model for Varian C-series equipped with MilleniumMLC120 is implemented.

Results: From 29 VMAT cases, 27 cases have passing rate criteria range between 97.1% and 100%. Of all these good passing rate criteria is independent of treatment site. Only two cases have passing rate criteria of 92.1% and 94.4%. Interestingly, these two cases belong to the same treatment site of brain. From the verifications result, one case with the passing rate criteria of 100% will be compared with the result from the Monte Carlo simulation. The comparison of measurement and simulation will be presented in the

meeting. As well as the comparison will be done for the case that has 92.1% of passing rate criteria.

Conclusion: This study shows that the verification process in general has good passing rate criteria regardless of the treatment site, except for brain. The Monte Carlo simulation can be used for justification of the verification which has the poorest passing rate criteria.

PS04.081 - A study on improvement method of dose distribution using bolus in boron neutron capture therapy for head and neck tumors

Author(s): Yoshinori Sakurai, Hiroki Tanaka, Takushi Takata, Nozomi Fujimoto, Natsuko Kondo, Yosuke Nakagawa, Tsubasa Watanabe, Masaru Narabayashi, Yuko Kinashi, Shinichiro Masunaga, Minoru Suzuki, Koji Ono, Akira Maruhashi

Kyoto University Research Reactor Institute, Osaka/JAPAN

Purpose: In boron neutron capture therapy (BNCT) for head and neck tumors, the irradiation is extremely difficult and the irradiation time becomes often long, when the target volume is in oropharynx and/or hypopharynx. The first reason is the positional reason that it is hard to fix the oropharynx and hypopharynx parts by the ideal posture for a collimator aperture. The second reason is the geometric reason that the thermal neutrons generated near the target volume is easy to leak out from the volume. Therefore, we are studying to develop the irradiation methods that the leak-out of thermal neutron is prevented and the dose rate distribution at the target volume and its surroundings is improved. The mount of bolus on neck is studied as one of the methods. This bolus works not only as neutron moderator, but also as neutron scatterer. The effectiveness of this method is introduced, based on the data for the BNCT studies for head and neck tumors, which are carried out at Heavy Water Neutron Irradiation Facility (HWNIF) installed in Kyoto University Reactor (KUR).

Methods: A dose estimation system for BNCT, named "Simulation Environment for Radiotherapy Applications (SERA)", was used in the simulation for dose distribution. The comparison was performed between the actual dose-estimation result for without bolus and the result for using the bolus, in the BNCT studies for oropharynx and hypopharynx. The estimation was performed not only for the merits in the improvement of thermal neutron distribution, tumor dose rate etc., but also for the demerits in the increase of the mucosal and skin dose rates, etc..

Results and Discussion: For one of the BNCT studies, it was confirmed that the dose rate was increased almost at 15% near the tumor part by mounting the bolus on the neck. In the while, the mucosal dose rate was increased almost at 15% and the skin dose rate was increased almost at 50%. The reason for the increase of the mucosal dose rate in the same level for the tumor dose rate is that the tumor and the mucosa are contiguous in this study. For the increase of the skin dose rate, the increase of 50% is acceptable because the mucosal peak dose is set to the tolerant dose for the criteria in this study. It is resulted that the irradiation time is shortened by 87%.

Conclusion: The effectiveness of this method using bolus was confirmed for some of the BNCT studies for head and neck tumors which are carried out at KUR-HWNIF. It is planned to confirm for the other BNCT studies, in order to find the proper condition that the effectiveness of this method can be effectively used.

PS04.082 - Peripheral neutron dose estimation: comparison between experimental measurements and TPS estimation Author(s): Leticia Irazola¹, Monica Ortiz-Seidel², Maria Trinitat Garcia-Hernandez³, José A. Terrón¹, <u>Beatriz Sanchez Nieto⁴</u>, Roberto Bedogni⁵, Francisco Sanchez-Doblado¹ ¹Fisiologia Medica Y Biofisica, Facultad Medicina, University of

Seville, Sevilla/SPAIN, ²Servicio De Radiofísica, Hospital Universitario Virgen Macarena, SEVILLA/SPAIN, ³Servicio De Radioterapia Eresa, Hospital General de Valencia, Valencia/SPAIN, ⁴Instituto De Física, Pontificia Universidad Católica de Chile, Santiago/CHILE, ⁵Istituto Nazionale Di Fisica Nucleare, Laboratori Nazionali di Frascati, Frascati RM/ITALY

Introduction

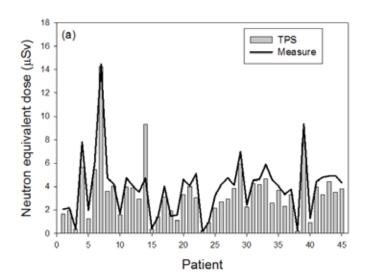

A newly TPS algorithm, implemented in Pinnacle³, has been developed for peripheral neutron dose estimation for radiotherapy patients. The script gives doses in several organs according to gender, treatment location and delivered high energy monitor units based on a previously facility characterization [1] following the procedure described in [2].

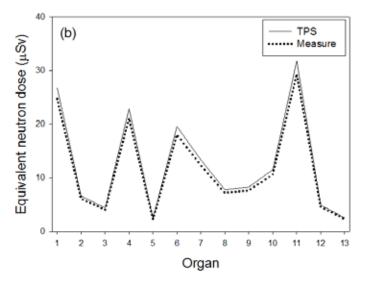

Matherial and Method

In order to validate these estimations, doses for a total of 119 patients were calculated with Pinnacle³ TPS script, and compared to the experimental measurements with the new Thermal Neutron Digital Detector (*TNRD*) [3]. The patients studied cover a wide range of pathologies for three different linacs (Siemens Primus, Siemens Oncor and Varian Truebeam) in 5 facilities from two institutions.

Results

As example, Fig.a shows peripheral neutron doses calculated by the TPS (grey bars) and measured (continuous line) for the thyroid in one of the Primus 15 MV linac, for a cohort of 45 patients. In addition, Fig.b shows organ neutron doses (1:thyroid, 2:oesophagus, 3:lung, 4:stomach, 5:liver, 6:colon, 7:bladder, 8:skin, 9:bone, 10:marrow,11:remainder ,12:breast, 13:ovary) for a rectum treatment in Varian TrueBeam linac. TPS estimations are represented by the continuous line while measurements are in dashed line.

Conclusions

The implementation of the peripheral neutron dose calculation script in Pinnacle³ TPS has shown as an appropriate tool for peripheral neutron dose calculations. It is able to estimate peripheral neutron doses by terms of patient parameters and thus give an idea of peripheral neutron doses when choosing patient treatment strategy.

PS04.083 - Dual Energy X-ray Stereoscopic Image Guidance for Spine SBRT

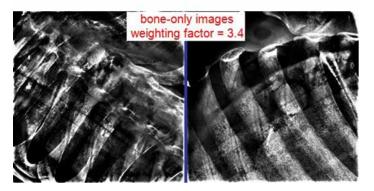

Author(s): Mike Sattarivand, Wesley Bowman, James Robar Department Of Medical Physics, Cancer Care Nova Scotia, Halifax/ CANADA

Image guidance is a key requirement for stereotactic body radiation therapy (SBRT) of spine to achieve a high accuracy in target positioning. Although cone beam computed tomography (CBCT) maybe used to acquire 3 dimensional volumetric imaging for target positioning, its acquisition is slow and it requires treatment interruption. Therefore, stereoscopic image guidance may be used which offers a faster image acquisition, finer resolution, and lower dose than CBCT. However, since stereoscopic imaging is based on projection imaging, soft tissue overlap on vertebral body may compromise its utility for spine SBRT, especially in large patients. The objective of this work is to investigate the feasibility of dual energy stereoscopic imaging to remove "anatomical noise" and create bone-only images for spine SBRT. An ExacTrac stereoscopic imaging system on a clinical linac was used to image an anthropomorphic Rando phantom with a 2.5 cm sphere (soft-tissue-equivalent) implanted in its lung (Figure 1). Tube voltage for low-energy and high-energy were chosen in the ranges of 40-80 kVp and 90-140 kVp respectively. A corresponding mAs was chosen in 6.3-63 range for each kVp to acquire high quality images without saturating the detectors. Weighting factors for log subtraction were chosen by trial and error. Imaging dose at isocenter from one X-ray tube was also measured for each available kVp using a calibrated dosimeter. Preliminary results showed that the best bone-only image could be obtained using a combination of 80 kVp and 140 kVp energies with a corresponding weighting factor of 3.4 (Figure 2). The corresponding dose for 80 and 140 kVp were 8.61 and 27.07 microGy/mAs respectively. Our results demonstrate the feasibility of dual energy stereoscopic imaging to create bone-only images that could be applied to spine SBRT. An optimal dose allowance between the low-energy and high-energy images needs to be established.

PS04.084 - Comparison between our EPID-IMRT-QA tool and commercial phantom based QA tools

Author(s): Otto Sauer, Simone Fink Department Of Radiation Oncology, University of Würzburg, Würzburg/GERMANY

Purpose: Different commercial solutions have been developed to take the increasing complexity of IMRT treatment plans into account and to provide a good relation between delivery errors of the calculated plans and the measured parameters. In our clinic we developed an IMRT quality assurance dosimetry tool based on the EPID attached to our LINACs. We compared the efficiency and accuracy of the patient specific plan QA between our EPID QA tool and two phantom-based commercial IMRT QA solutions.

Material and Methods: Elekta Synergy LINACs with 6 MV, 10 MV and 18 MV photons with an Agility MLC were used to perform the measurements. The EPID attached to these LINACs is the iView-GT[™] being the standard aSi-EPID with 1024 x 1024 pixels of size 0.4 x 0.4 mm². This corresponds to a pixel size of 0.25 x 0.25 mm² in the plane of the isocenter. For the calculation of the dose distribution we used Pinnacle 9.8. Processing of the EPID measurement signals was done with in-house developed software based on MATLAB (MathWorks Inc.). For the calibration of the EPID measurement grev scale values to dose, we use the quotient of the output in water in 5cm depth to the EPID signal, free in air, for quadratic homogeneous fields. For the Gamma Analysis we used Verisoft 6.0 and compared the calculated planar dose distributions to the EPID measurements. Reference values were achieved with the ionization chamber array OCTAVIUS Detector 729 by PTW, which has 27 x 27 ionization chambers with a size of (0.5 cm)³ and a distance center-to-center of 1.0 cm. To test our procedure we also measured exemplary fields with intentionally introduced errors.

The phantom based QA tools were the ArcCheck by SunNuclear and OCTAVIUS 4D by PTW. Phantom QA data were evaluated following our standard clinical protocol.

Results: The plan evaluation of our QA tool showed good agreement with the dose distribution calculated by the planning system and the one measured with the ionization chamber array. Due to the high resolution of the pixel array, the stricter 2%/2mm gamma criterion could be used for comparison of the EPID measurement data and the calculated planar dose distributions. The 2%/2mm gamma evaluation with the reference values achieved with the OCTAVIUS Detector 729 turned out to be not meaningful due to the low resolution of the chamber array.

The outcome of the ArcCheck QA showed good accordance with those of the EPID QA with both the 3%/3mm and the 2%/2mm gamma evaluation. The analysis of the OCTAVIUS 4D, restricted to the 3%/3mm criterion also showed comparable results. All systems were able to detect the intentionally introduced errors in dependence of the magnitude of the alterations.

Conclusion: We developed an EPID QA tool suitable for efficient step-and-shoot IMRT plan QA. The comparison with the commercial systems showed good agreement. As we can use the advantage of the high spatial resolution of the EPID, our QA tool provides a benefit particularly for the analysis of highly modulated IMRT plans.

PS04.085 - Dosimetric assessment of a novel metal artifact reduction tool (iMAR)

Author(s): Esther Bär¹, <u>Andrea Schwahofer²</u>, Stefan Kuchenbecker³, Peter Haering¹, Oliver Jäkel¹

¹Medical Physics In Radiation Oncology, German Cancer Research Center (DKFZ), Heidelberg/GERMANY, ²Vivantes Klinikum Neukölln, Berlin/GERMANY, ³Medical Physics In Radiology, German Cancer Research Center (DKFZ), Heidelberg/GERMANY

Purpose: Metal artifacts in CT images can cause relevant errors in

dose calculation. Algorithms developed to reduce these artifacts could improve these images but also introduce a bias in tissues surrounding metallic implants. The purpose of this study is to validate a pre-commercial metal artifact reduction tool for radiotherapy treatment planning.

Methods: The performance of the iterative Metal Artifact Reduction (iMAR) algorithm developed by Siemens Healthcare is evaluated on a test platform. A calibration phantom constituted of tissue-equivalent plastics is used to estimate the image bias from artifact correction. Patient CT data with metal implants (5 dental fillings, 1 bilateral hip) are reconstructed using the weighted filtered back projection (WFBP) and corrected using the iMAR algorithm. Radiotherapy treatment plans are calculated and compared on corrected and uncorrected images using the collapsed cone convolution (CCC) dose algorithm implemented in RayStation (RaySearch).

Results: Phantom scans show that iMAR reproduces HU for tissue equivalent substitutes in 3.6 cm² circular ROIs within \pm 25 HU. The effect of this HU difference on megavoltage photon dose calculation is shown to be within \pm 1 % dose error. Comparing patient plans from corrected and uncorrected images, dose differences of up to 5 % are discovered in PTV and OARs, depending on the treatment site.

Conclusion: The iMAR algorithm shows good performance in correcting metal artifacts in the context of radiotherapy. The technique reduces dose errors significantly while keeping calculated doses in the surrounding tissues within a clinically acceptable level in comparison to ground truth. Future work could aim at the improvement of benchmark methods for a clinical environment (e.g., the development of a specific test phantom).

PS04.086 - An Image quality and dose comparison between Varian OBI and Elekta XVI CBCT systems.

Author(s): <u>Amani Shaaer</u>, Konrad Leszczynski, Shuying Wan, Michael Oliver

Medical Physics, Northeast cancer centre, sudbury/CANADA

Purpose: As image-guided radiotherapy (IGRT) becomes common practice in radiation treatment, its overall quality and performance, such as image quality and amount of dose delivered, need to be assessed. In this study, we investigated the image quality and dose of cone-beam computed tomography (CBCT) of two imaging systems commonly used in radiotherapy: Varian On-Board Imager (OBI) and Elekta X-ray Volumetric Imager (XVI).

Materials and **Methods:** Our investigation involved two units of Varian OBI and two units of Elekta XVI. For CBCT imaging quality, several quality tests were performed, including high contrast resolution, Hounsfield Unit (HU) accuracy, low contrast sensitivity, and image uniformity. All imaging tests were carried out using a Catphan 500 phantom (model: CTP 504) and current clinical imaging protocols provided with both systems. The reconstructed images were analyzed using Osirix software v.5.8.2. The CBCT dose was estimated using standard CT dose index (CTDI). CTDI was measured by using a head and a body phantom, in which a 3 cm³ ion chamber was inserted. Measurements were taken under several imaging protocols.

Results: Regarding CBCT image quality, OBI revealed better high contrast resolution and HU accuracy when using head and pelvis protocols. CBCT dose measurements demonstrated that the XVI used lower doses for both head and body protocols than OBI did, which explained the observed differences in image quality. For the standard-dose head protocol, for example, OBI (#1) delivered 5.74 mGy, while XVI (#1) used 0.93 mGy dose for the same protocol. In addition, the head protocols in both systems delivered lower doses compared to body protocols to minimize the exposure of superficial organs located at the anterior part of the head to the radiation.

This is because both systems used a half-rotation scan for head and neck protocols (200°). In head and neck protocols of the OBI units, the anterior part of the head received only one-quarter of the maximum dose measured (posterior region), while for the XVI units, the ratio was one-third.

Conclusions: The Varian OBI and Elekta XVI were evaluated by performing image quality and dose measurements for four clinical protocols: head and neck, pelvis, prostate, and thorax. Based on the results, both systems are suitable for performing image-guided radiotherapy on a regular basis.

PS04.087 - An open-source treatment planning system for research in particle therapy: Implementation and dosimetric evaluation

Author(s): Maxime B.J. Desplanques¹, An Wang², Justin Phillips³, Gueorgui Gueorguiev³, Yang-Kyun Park³, Andras Lasso⁴, Csaba Pinter⁴, David Jaffray², Gabor Fichtinger⁴, <u>Gregory C. Sharp³</u>, Guido Baroni¹

¹Politecnico di Milano, Milano/ITALY, ²University of Western Ontario, Toronto/ON/CANADA, ³Massachusets General Hospital, Boston/ UNITED STATES OF AMERICA, ⁴Queen's University, Kingston/ON/ CANADA

The number of particle therapy centers substantially increased during recent years, yet it remains a very costly technique in terms of both facility and equipment. Commercial Treatment Planning Systems (TPS) are no exception and are often unaffordable for research groups. We introduce an open-source TPS aimed toward eliminating this economic barrier, and give global momentum to research in the radiotherapy community.

Our TPS is designed for passive scattering proton treatments, and is implemented based as part of the SlicerRt toolkit [1], which is an extension for the 3D Slicer medical image analysis and visualization tool [2]. It supports a large number of image types, including DICOM CT/MR/RT-images and the most widely supported image file formats. The interface was developed as a 3D Slicer Qt loadable module, and a pencil beam dose calculation engine was implemented in the open-source image computation software Plastimatch [3].

The dose calculation engine uses a differential approach for estimating Coulomb scattering along the beamlet pathway. Three different geometric approaches are used for pencil selection and summation. Computation results were compared with Monte Carlo simulations. The dose response of these algorithms show equivalent results to published literature in homogeneous conditions and better results for lateral scattering in heterogeneous media or air-gaps for the 10-250MeV energy range. These satisfying results allow a user to build accurate proton dosimetry of real, clinical cases like prostate or head & neck treatment plans. Regarding the calculation speed, our algorithms are approximately equivalent to commercial TPSs, and can calculate a dose volume for a multi-beams plan in few minutes.

The majority of the expected, user-friendly tools available in the commercial TPSs are also included in this open-source software: definition of a plan with multiple beams; automatic creation of a collimator fitting the beam aperture to the target shape; automatic construction of a range compensator in Lucite material; energy selection to create a spread out Bragg peak; selection of target proximal and distal limits; and margin calculations. The system also includes the possibility to visualize the Digital Reconstructed Radiograph, set a dose normalization point, or even customize the geometrical description of the beam line for a determined particle therapy center, including selection of the source and collimator positions and the source size.

We put forward our open-source TPS as a concrete solution for

research groups in the particle therapy field and confide that our efforts will contribute to the worldwide application of particle therapy. This software is continually in development and regularly improved with new tools.

PS04.088 - GMM guided automated Level Set algorithm for PET image segmentation

Author(s): <u>Chiara D. Soffientini</u>¹, Elisabetta De Bernardi², Giuseppe Baselli¹, Issam El Naqa³

¹Deib, Politecnico di Milano, Milan/ITALY, ²University of Milano-Bicocca, Monza/ITALY, ³McGill University, Montreal/CANADA

AIM. Positron Emission Tomography (PET) is nowadays one of the main imaging modalities used in oncology field. The accuracy in lesions borders identification has a key role since it may affects diagnosis, treatment planning and consequently patient outcome. Ideally, segmentation algorithm should be accurate and automatic as much as possible, avoiding to obtain user dependent contours. Many efforts have been spent facing the problem in many different ways. Level Set (LS) algorithms are a well established methods for object contouring where an initial function evolves until convergence of a predefined cost function. One of the drawback of this method is the necessity to properly set the values of parameters that weight and balance internal and external forces used to shrink or dilate the estimated boundaries until convergence. The basic idea of the present work is to develop a segmentation algorithm based on LS formulation where the best values for the weighting parameters are iteratively estimated using information from a clustering algorithm based on Gaussian Mixture Model (GMM).

MATERIALS AND METHODS. The proposed algorithm (LSGMM) starts with the initialization of the LS function using the segmentation performed after two iterations of the GMM based algorithm. Then the LS function is updated as indicated by the minimization of the Mumford-Shah functional. The LS parameters iteratively updated in the proposed algorithm are the ones weighting the internal and external object homogeneity and the one weighting their balance. Every 10 iterations of LS, weighting parameters are then updated on the basis of equations formulated as Gibbs functionals, using hard or fuzzy classification performed with GMM algorithm. Basically, updating equations use information derived by a clustering method to correctly tune the LS parameters. Finally, as LS method, LSGMM performs the object boundaries identification evaluating the sign of the converged LS function. The proposed method was tested on simulated data divided into three categories: homogeneous and heterogeneous lesions, and lesions with low background contrast and/ or near high uptake object that can be misinterpreted. Comparisons were performed among LSGMM, LS with manually tuned parameters, Black's and Schaefer's thresholding methods.

RESULTS. Applying LSGMM, segmentations of homogeneous and heterogeneous lesions were comparable to the ones obtained with manually tuned LS, with Dice indexes higher than 0.85 and errors in estimated volumes lower than 2% as mean value. LS parameters could increase or decrease independently in order to converge to the optimal ones. LSGMM was also able to overcome performances of Black's and Schaefer's algorithms.

CONCLUSIONS. A completely automated LS based algorithm was presented and promising results were shown. Further evaluations will be done in order to assess robustness of the method and its applicability to multimodal data.

PS04.089 - Impact of the magnitude of MLC radiation leakage in IMRT treatment planning

Author(s): <u>Jaziel Soto-Muñoz</u>, Jose M. Larraga-Gutierrez Medical Physics, Instituto Nacional de Neurología y Neurocirugía, Mexico City/MEXICO

Purpose: To assess the impact of the magnitude of the radiation leakage (RL) through the multileaf collimator (MLC) system on dose calculation for intensity modulated radiation therapy (IMRT) treatment planning. Previous works have demonstrated that the inclusion of RL on IMRT treatment planning is mandatory, in order to avoid dosimetric errors in treatment delivery up to 11% relative to the isocenter dose (Jin Sheng Li, Med. Phys. 2010). However, up to date there aren't studies about the impact on IMRT of different values of RL that may be originated by wrong measurements or MLC deterioration.

Material and Methods. Different values of RL (0.1, 0.5, 1.0, 1.5 and 2%) were used to simulate in the treatment planning system (TPS) wrong measurements and/or MLC deterioration of a m3-mMLC (BrainLab, Germany) with a 6 MV photon beam. The RL values were used to create TPS beam profiles, one for each RL value, in the TPS iPlan RT 4.1 (BrainLab, Germany) for dose calculation. A set of 5 IMRT patients were chosen randomly from our centre database, and a RL value of 1% was assumed to be the MLC true RL in order to set a reference beam profile. The 5 IMRT patients were re-optimized and the dose distributions were re-calculated and exported for posterior analysis by using each of the beam profiles (resulting in 4 re-optimizations per IMRT patient). After re-optimization, the monitor units (MU) were fixed and only the dose distribution was recalculated and exported for each re-optimization by using the reference beam profile (RL=1.0%). The resulting dose distributions were compared by calculating the differences between the calculated dose distribution of the re-optimized and the referenced plans. The differences were normalized to the prescription dose that was set to 2.0 Gy/fraction. On the other hand, the dose volume histograms for each re-optimization were exported and compared by using the following metrics: dose maximum, coverage, homogeneity index and conformity index.

Results. The comparison of the dose distribution showed differences up to 4% using the profile with RL=2%. This difference may reflect an overall absolute dose difference of 2.4 Gy for an standard 30 fraction treatment. The spatial location of this differences were found in the normal tissue. The DVH analysis showed differences from 7 to 20% in the maximum dose to organs at risk, differences up to 2% in coverage, 25% in conformity index, and 2% in homogeneity index.

Conclusions. The present results suggest that an accurate measurement and/or frequently verification of TL factor is needed, since small differences (up to +/- 1%) in the RL value produce a difference up to 4% for the TPS and the MLC system used in this work. The above result may compromise the allowed uncertainty in radiation therapy of 5%.

PS04.090 - Modelling multi-leaf collimator defocusing and focal spot partial shielding for TomoTherapy and Elekta accelerators using Monte Carlo methods

Author(s): Jason Belec, Ryan Studinski

Medical Physics, Ottawa Hospital Cancer Center, Ottawa/ON/ CANADA

Purpose: TomoTherapy and Elekta SynergyS/Agility accelerators include multi-leaf collimator (MLC) with defocused leaf sides with respect to the beam focal spot to minimize interleaf radiation leakage. We used Monte Carlo simulations and measurements to model MLC defocusing and quantify the impact on the dose distributions.

Materials and Methods: Monte Carlo simulations were performed with a modified version of the BEAMnrc/DOSXYZnrc codes. Measurements were done with films (EBT2), diodes (SFD) and ionization chambers (A1SL). The TomoTherapy MLC model was focused at a point located 2 mm above the target. The Elekta MLC model was rotated by 0.5 degrees around the crossplane axis and translated by 2.2 mm. Fine tuning of parameters were performed using different types of measurements such as transmission, tongue-groove and small off-axis fields.

Results: Figure 1 and Figure 2 show that tomotherapy simulations are modelling well (2%/1mm) small off-axis field and tongue-groove measurements. Figure 3 shows a simular example of tongue-groove measurements for the Elekta SynergyS accelerator.

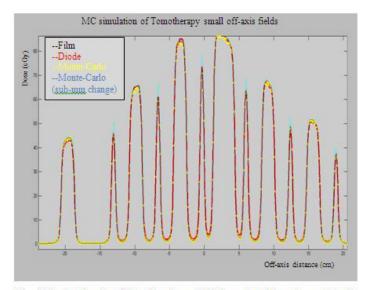

Figure 1 MC simulation of a modulated Tomotherapy field. The couch and the gantry are static and the field contains openings of different sizes (1 leaf, 2 leaves, 3 leaves) at various off-centered positions. Film measurements (normalized with ionization chamber reading in the largest open section of the field) are shown in black, SFD diode measurements are shown in red and Monte Carlo simulations are shown in yellow. The blue line is included to illustrate the impact on the Monte Carlo simulation of sub-num changes in the MLC geometry parameters.

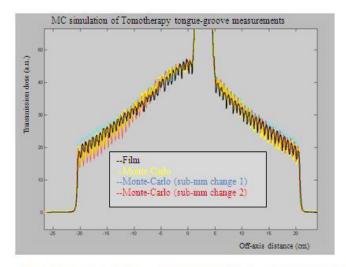

Figure 2 The Tomotherapy tongue & groove dose is obtained by summing the dose measured or calculated for two opposing fields having respectively odd and even leaves opened. Film measurements (normalized with ionization chamber reading in the small open section of the field) are shown in black and Monte Carlo simulations are shown in yellow. The blue line and the red line are included to illustrate the impact on the Monte Carlo simulation of sub-num changes in the MLC geometry parameters.

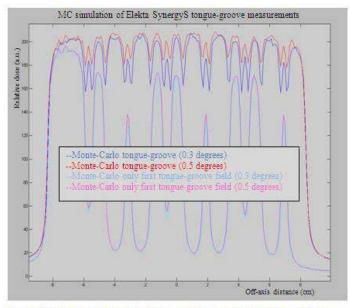

Figure 3 Monte Carlo simulation of tongue and groove dose for the Elekta Synergy5 treatment unit. The tongue & groove dose is obtained by summing the dose calculated for a given set of open leaves and the dose calculated with the opposite field (leaves that were closed are opened and vice versa). The blue line is for an MLC rotation of 0.5 degree and the red line is for an MLC rotation of 0.3 degrees. Only one of the added profiles is shown in light blue and pink (one for each MLC rotation).

Conclusion: Modeling accurately MLC defocusing is important because it can have a significant impact on interleaf leakage (> 1%), field size (>0.5 mm) and off-axis small field output factors (>5%) due to partial focal spot shielding.

PS04.091 - Can Image-Guided Intensity Modulated Brachytherapy delivery be better than IMRT and classical brachytherapy methods for cervical cancer: A Dosimetric analysis

Author(s): <u>Vellaiyan Subramani</u>, D.N. Sharma, Sharma Seema, G.K. Rath, Pathy Sushmita, Chander Subhash

Radiotherapy, All India Institute of Medical Sciences(AIIMS), New Delhi/INDIA

Objective: To evaluate the dosimetric superiority of intensity modulated brachytherapy(IMBT) based on inverse planning simulated annealing optimization method with external beam intensity modulated radiotherapy optimization and brachytherapy classical optimization methods in patients of cervical carcinoma.

Materials and Methods: Ten patient of cervical cancer who have already undergone interstitial HDR brachytherapy with MUPIT template, were selected for this study. The target volume was drawn and the target volume was in the range of 285.49 cm³ to 83.49 cm³. The planning was performed in PLATO-3D-planning system for HDR Ir-192 interstitial brachytherapy treatment. The actual treatment was carried out according to the catheter based plan using graphical optimization and considered as "conventional brachy plan" for comparison. The target based plans were made for dose point optimization(DPO), geometric optimization(GO), Inverse planning simulated annealing (IPSA) optimization techniques. The same target and OARs were transferred to Eclipse 3D planning system for external beam intensity modulated radiotherapy (IMRT) planning. The prescription dose was 10Gy to the target. All plans were evaluated using following dosimetric indices: volume receiving 90%(V_{on}), 95%(V₉₅), 100%(V₁₀₀), 150%(V₁₅₀) and 200%(V₂₀₀) of prescription dose and coverage index(CI), conformity index (COIN), dose non-uniformity ratio (DNR), homogeneity index (HI) and external volume index (EI) for target. For OARs, dose received by volume of 1cm³ (D_{1cc}), $2cm^3$ (D_{2cc}), 5cm³ (D_{5cc}) and also volume received by 50% and 75% of prescription dose (V₅₀) and (V₇₅) were evaluated for both bladder and rectum. The statistical analysis was done using paired t-test and a p-value <0.05 was considered significant.

Results: Percentage difference was calculated with respect to conventional brachy plan optimization. The maximum difference in V₉₅ was 16.8%, 18.1%, and 33.6% in DPO, GO, and IPSA respectively and it was statistically significant between conventional versus IPSA (p<0.001). Maximum difference in COIN was 58.1% for IPSA (p<0.0001) with conventional plan. The differences in DNR, EI, HI between classical optimizations and inverse optimizations were significant (p<0.0001).Maximum differences for IPSA in D₅₀₀ was 30.7% and 33.9% and in V_{75} the difference of 47.8% and 51.8% for both rectum and bladder respectively (p<0.001). In comparison between IMBT versus IMRT, the percentage difference was calculated with respect to brachy plan. The maximum difference in V95 between IMBT and IMRT plans was 20.1% and it was statistically significant (p<0.001) with IMBT. The similar difference in CION was 3.8% and it was not significant. In OAR dose comparison, the maximum differences between IMBT and IMRT in V_{50} and V_{75} were not statistically significant for both bladder and rectum

Conclusion: The IPSA resulted in improved dose conformity and homogeneity and reduced dose to OAR compared to classical brachytherapy optimization techniques. It has also been observed that the conventional brachy plan resulted in improved target coverage compared to IMRT technique. But, the target dose conformity was greatly improved with IMRT. As for OAR dose, IMRT technique resulted in reduced dose as compared to conventional brachy plan. The differences between IMBT and IMRT, in terms of target dose conformity and homogeneity and dose to OAR were not statically significant.

PS04.092 - Analysis on Volumetric and Dosimetric accuracy of Maximum-Intensity Projections based 4DCT for stereotactic body Radiotherapy

Author(s): <u>Vellaiyan Subramani</u>, Singh Megha, Sharma Seema, Chander Subhash

Radiotherapy, All India Institute of Medical Sciences(AIIMS), New Delhi/INDIA

Purpose: To compare and evaluate volumatric and dosimetric accuracy of 4DCT for stereotactic body radiotherapy between free breathing and maximum-intensity projection (MIP) imaging.

Method and Materials: Three lung cancer patients who had under-

gone the treatment of stereotactic body radiotherapy and QUASAR respiratory motion phantom were used in this study. The Philips 85cm Big-bore brilliance 16-slice CT scanner with bellow-belt system was used to generate the 4DCT data sets. The planning CT was done in free breathing (FB) conditions for treatment verification purpose. The patient 4DCT was obtained and its amplitude of motion parameters was used to acquire 4DCT data of moving phantom. Each patient had 13 different 4DCT sets. All these images were imported into the 3D-RTP system. Treatment planning was made using ADAC Pinnacle 8.0 system for Synergy-S linear accelerator for both phantom and patients for conformal stereotactic body radiotherapy. The treatment planning was made such as 0%-plan, 10%-plan, 20%-plan 30%-plan 40%-plan 50%-plan 60%-plan 70%-plan 80%-plan, and 90%-plan, AvgiP-plan, MIP-plan and FB-plan for both phantom and patients for comparison.

Results: In the phantom study, the percent of volume differences were found to be 55%, 35%, 74% between FB vs MIP for GTV, OAR-1 and OAR-2 respectively. In the patient study, the percent of volume differences were found to be 38% for GTV and 74%, for the spinal cord between FB vs MIP, respectively. All dosimetric variations between FB vs Avg-iP CT based plans were found to be 10-19.2% for target and OAR for both phantom and patients studies.

Conclusion: The volumetric and dosimetric variations between free-breathing and MIP images for both phantom and patient targets and organs-at-risk were significant. The free-breathing CT was underestimated the volumes compared to MIP images. The effect of motion becomes important for accurate dose planning in stereotac-tic body radiotherapy.

PS04.093 - 2D/3D registration for compensation of patient positioning error in Korea Heavy Ion Medical Accelerator Center Author(s): Min Joo Kim¹, Woong Cho², Won Gyun Jung³, <u>Tae-Suk</u> <u>Suh¹</u>

¹Dept. of Biomedical Engineering Research Institute of Biomedical Enegingeering The Catholic Univ. of Korea, Seoul/KOREA, ²Department Of Radiation Oncology, Seoul National University Hospital, Seoul/KOREA, ³Division Of Korea Heavy-ion Medical Accelerator, Korea Institute of Radiological and Medical Science, Seoul/KOREA

This research has proposed to develop the validation tool for compensation of patient positioning error using 2D/3D and 3D/3D image registration. For 2D/3D registration, digitally reconstructed radiography (DRR) and three-dimensional computed tomography (3D CT) image was applied. The ray casting algorithm is the most straightforward method to generate DRR. We adopted the traditional ray casting method which finds intersections of a ray with all objects, voxels of the 3D CT volume in the scene. Similarity between extracted DRR and orthogonal image was measured by using normalized mutual information method. Two orthogonal image was acquired from Cyber-knife system from anterior-posterior (AP) view and right lateral (RL) view. 3D CT and two orthogonal image of an anthropomorphic phantom and head and neck cancer patient were applied in this study. For 3D/3D registration, planning CT and in-room CT image was applied. After registration, translation and rotation factor was calculated to set 6 dimensionally movable couch. Registration accuracy with average errors of 2.12 mm ± 0.50 mm for transformation and 1.23° ± 0.40° for rotation using an anthropomorphic Alderson-Rando phantom has been acquired in 2D/3D registration. Also, registration accuracy with average errors of 0.90 mm \pm 0.30 mm for transformation and 1.00° ± 0.2° for rotation using CT image sets has been acquired. We demonstrated that this validation tool could compensate the patient positioning error. Also, this research could be fundamental research step to compensate patient positioning error in first Korea heavy ion medical accelerator treatment center.

PS04.094 - Cardiac movement in deep inspiration breath-hold for left-breast cancer radiotherapy

Author(s): Seu-Ran Lee¹, Min Joo Kim¹, Jae-Hong Jung², <u>Tae-Suk</u> Suh¹

¹Dept. of Biomedical Engineering Research Institute of Biomedical Enegingeering The Catholic Univ. of Korea, Seoul/KOREA, ²Department Of Radiation Oncology, Soonchunhyang University Hospital, Bucheon/KOREA

Most of breast cancer patient has suffered from unnecessary radiation exposure to heart, lung. Low radiation dose to the heart could lead to the worsening of pre-existing cardiovascular lesions caused by radiation. The objective of this study was to determine cardiac displacement by comparing the CT data and cardiac radiation exposure levels during Deep Inspiration Breath Hold (DIBH) and free breathing (FB). Treatment planning was performed on the computed tomography (CT) datasets of 10 patients who had received lumpectomy treatments. Heart, lung and both breasts were outlined. The prescribed dose was 50 Gy divided into 28 fractions. Displacement of heart was measured by calculating the distance between center of heart and left breast. Radiation dose to heart, minimum, maximum and mean dose to heart were calculated. Mann-Whitney U test was used for the statistical analysis of each evaluation index, and significance was set at an adjusted value of ≤0.05. The DIBH technique could help to reduce the risk of radiation dose-induced cardiac toxicity because the heart moved as far as 8.98 mm from the left breast with this technique; additionally, the cardiac motion in the LR direction varied between the DIBH CT and FB CT datasets (maximum, 7.9 mm), and the DIBH technique was found to reduce the delivered dose to the heart by a maximum of 3670 cGy, compared with FB. The DIBH technique could be used in an actual treatment room for a few minutes and could effectively reduce the cardiac dose.

PS04.095 - Dosimetric evaluation according to patient set-up errors using biophysical indices in whole breast irradiation Author(s): Seu-Ran Lee¹, Min Joo Kim¹, So-Hyun Park², Ji-Yeon Park³, Min-Young Lee¹, <u>Tae-Suk Suh¹</u>

¹Biomedical Engineering, The Catholic University of Korea, Seoul/ KOREA, ²Department Of Radiation Oncology, Uijeongbu St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Uijeongbu-si, Gyeonggi-do, Seoul/KOREA, ³Department Of Pediatrics And Molecular Imaging Program At Stanford, Stanford University, Stanford/UNITED STATES OF AMERICA

Purpose: The dose-related effects of patient setup errors on biophysical indices were evaluated for conventional wedge (CW) and field-in-field (FIF) whole breast irradiation techniques.

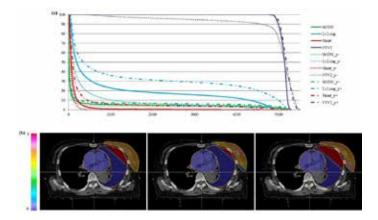

Methods: The treatment plans for 10 patients receiving whole left breast irradiation were retrospectively selected. Radiobiological and physical effects caused by dose variations were evaluated by shifting the isocenters and gantry angles of the treatment plans. Dose-volume histograms of the planning target volume (PTV), heart, and lungs were generated, and conformity index (CI), homogeneity index (HI), tumor control probability (TCP), and normal tissue complication probability (NTCP) were determined.

Results: For "isocenter shift plan" with posterior direction, the D_{95} of the PTV decreased by approximately 15% and the TCP of the PTV decreased by approximately 50% for the FIF technique and by 40% for the CW; however, the NTCPs of the lungs and heart increased by about 13% and 1%, respectively, for both techniques. Increasing the gantry angle decreased the TCPs of the PTV by 24.4% (CW) and by 34% (FIF). The NTCPs for the two techniques differed by only 3%. In case of CW, the CIs and HIs were much higher than that of the FIF in all cases. It had a significant difference between two techniques (p<0.01). According to our results, however, the FIF had more

sensitive response by set up errors rather than CW in bio-physical aspects.

Conclusions: The radiobiological-based analysis can detect significant dosimetric errors then, can provide a practical patient quality assurance method to guide the radiobiological and physical effects.

Figure 1. The physical and radiobiological results of isocenter shifts for a breast cancer patient (a) Dose volume histogram (DVH), (b) Tumor control probability (TCP) and normal tissue complication probability (NTCP) mapping of computed tomography (CT) images of the principal structures. The field-in-field technique was used. The origin, negative y direction, and positive y direction are shown in order.

PS04.096 - Comparison of proton boron fusion therapy with boron neutron capture therapy

Author(s): Joo-Young Jung, Do-Kun Yoon, Han-Back Shin, Moo-Sub Kim, Tae-Suk Suh

Biomedical Engineering, The catholic university of korea, Seoul/ KOREA

Proton boron fusion therapy (PBFT) is based on the treatment using characteristic of alpha particle. Because the PBFT is similar to the boron neutron capture therapy (BNCT) technique, the verification of feasibility of PBFT can be possible by the comparison of some performances of the BNCT. The verification and analysis were progressed by the Monte Carlo simulation code. Basically, the virtual water phantom including boron uptake region (tumor region) was simulated for the verification. The proton beam passed through the water phantom. The alpha particles were generated from reaction point between proton and boron particle. The variation of the alpha particle was observed from the percent depth dose (PDD) of proton beam. Also, the dramatic effectiveness of alpha particle by the PBFT was confirmed by the comparison. The utility of PBFT was verified using the simulation. It has sufficient worth of usage of radiation therapy.

PS04.097 - Verification for prompt gamma ray imaging during proton boron fusion therapy: A Monte Carlo study

Author(s): Han-Back Shin, Joo-Young Jung, <u>Tae-Suk Suh</u>, Do-Kun Yoon, Moo-Sub Kim

Biomedical Engineering Research Institute Of Biomedical Engineering, The Catholic University of Korea College of Medicine, korea/ KOREA

Purpose: The purpose of this study is to verify the three dimensional single photon emission computed tomography (SPECT) image using prompt gamma ray originated from proton boron fusion therapy (PBFT).

Methods: The imaging system during PBFT was simulated to acquire the reconstructed image of prompt gamma ray by using Monte Carlo simulation (MCNPX). We acquired the percentage depth dose (PDD) of the proton in the water phantom, energy spectrum of the prompt gamma ray and tomographic image. In order to verify the reconstructed image, the image profile and receiver operation characteristic (ROC) curve were analyzed.

Results: The PDD in the BUR shows higher efficiency than conventional proton therapy on the tumor region. The area under curve (AUC) of ROC values were acquired from results.

Conclusion: We confirmed that the prompt gamma ray image was successfully deducted, and results of quantitative image analysis show good agreement with the original pattern of the BUR.

PS04.098 - Feasibility study of flattening filter free beam for stereotactic ablative radiotherapy of localized prostate cancer patients

Author(s): Jin-Beom Chung¹, Jae-Sung Kim¹, Jeong-Woo Lee², Sang-Won Kang³, <u>Tae-Suk Suh³</u>

¹Radiation Oncology, Seoul National University Bundang Hospital, Seongnam/KOREA, ²Department Of Radiation Oncology, Konkuk University Medical Center, Seoul/KOREA, ³Biomedical Engineering, The Catholic University of Korea, Seoul/KOREA

The study was to evaluate the feasibility of flattening filter free (FFF) beam in stereotactic ablative body radiotherapy (SABR) planning for treatment of clinically localized prostate cancer using an endorectal balloon. Fifteen patients were enrolled for this study. Prostate SABR plans using volumetric modulated arc therapy (VMAT) with 2 full arcs were optimized in the Eclipse treatment planning system (TPS) using TrueBeam linear accelerator with high-definition multileaf collimator. All plans were prescribed with 42.7 Gy in 7 fractions of 6.1 Gy each. For each case, four SABR plans were computed with two FF beams and two FFF beams of 6 MV and 10 MV. All dose distributions were calculated with Acuros XB (AXB, version 11). For all plans, the cumulative dose-volume histograms (DVH) for the planning target volume (PTV) and organs at risk (OARs) were analyzed. Technical parameters, such as total Monitor units (MUs) and treatment delivery time, were also recorded and accessed. A pretreatment quality assurance (QA) using l'matrixx system and cubic phantom were performed to verify treatment delivery and the Gamma analysis was used to guantify the agreement between calculations and measurements. Differences in DVH for the PTV and OARs between plans with FFF and FF beams were statistically insignificant while remarkable reduced for treatment delivery time. All pretreatment plans were verified acceptable agreement. This study confirmed that prostate SABR with FFF beam provide the treatment efficiency relative to those with FF beam, and the strategy is associated with high dose conformity to prostate and decreased intra-fraction movements because of the shorter treatment delivery time. Future studies are necessary to assess clinical outcome and toxicity.

PS04.099 - The evaluation of radiobiological and physical impacts based on multi-modality images using in-house software Author(s): Seu-Ran Lee¹, Ji-Yeon Park², Min Joo Kim¹, <u>Tae-Suk Suh¹</u> ¹Biomedical Engineering, The Catholic University of Korea, Seoul/ KOREA, ²Department Of Pediatrics And Molecular Imaging Program At Stanford, Stanford University, Stanford/UNITED STATES OF AMERICA

Purpose: To develop an enhanced treatment plan evaluation tool based on multi modality imaging which incorporates physiological and radiobiological parameters

Methods: A software system was developed using MATLAB

v.7.10.0499 (The Mathworks, Inc., Natick, MA). The plan evaluation tool was enabled for users to provide physiological and radiobiological plan comparison and evaluation based on multi modality imaging. It incorporated to visualize 3D images after importing of various images such as computed tomography (CT), magnetic resonance image (MRI), and positron emitted tomography (PET). Dicom-RT files (dose, structure) exported from radiation treatment planning system also represented the input to the software. The differences of planning target volume (PTV) and organs at risk (OAR) contours and volumes depending on images were displayed with respect to the isocenter using the 3D coordinates of structure files. Further, the dose difference and gamma value (for reference Daniel Low's study) also were suggested in which cross section using this program. Finally, it can represent dose volume histogram (DVH) and calculate the normal tissue complication possibility (NTCP) and tumor control possibility (TCP) based on the equivalent uniform dose (EUD) referred to Niemierko's study. Three cases of treatment sites like head and neck, brain and lung were selected to verify the functions provided by this software.

Results: The results of plan evaluation can be compared more intuitionally and easily depending on plan based images for using this program. To test the program this study showed the results of three cases that there were the improvement of planning using multi modality images rather than only CT images.

Conclusions: The application of plan evaluation can help the user choose more biologically optimal treatment plans and potentially predict treatment outcome more accurately.

PS04.100 - Comparison of Conventional 3D Static Planning and 4D Planning using Dose Warping Technique for Liver SBRT Author(s): Seong-Hee Kang¹, Siyong Kim², Tae Ho Kim¹, Dong-Su Kim¹, Min-Seok Cho¹, Kyeong-Hyeon Kim¹, <u>Tae-Suk Suh¹</u> ¹Department Of Biomedical Engineering, Research Institute Of Biomedical Engineering, College Of Medicine, The Catholic Univ. of Korea, seoul/KOREA, ²Radiation Oncology, College Of Medicine, Virginia Commonwealth University, Richmond/UNITED STATES OF AMERICA

Currently, SBRT has been widely used to deliver highly conformal dose to target while sparing normal tissue. So, SBRT need accurate target delineation, dose calculation and motion management techniques such as breath-hold or abdominal compressor. In spite of the benefits about these techniques, there are still deformation and movement which could lead to reduce the probability for tumor control, imprecise prediction of normal tissue complication. This study aims to evaluate the dosimetric difference between four-dimensional planning using dose warping technique (4D dose) and conventional 3D static planning (3D dose) in liver stereotactic body radiotherapy (SBRT). Five patients who had previously treated liver SBRT were included in this study. The average prescription dose and the fraction size was 40 Gy and 8 Gy. Four-dimensional computed tomography (4DCT) images with 10 phases for all patients were acquired on multi-slice CT scanner (Siemens, Somatom definition). Treatment planning and delineation was done on 100% exhalation phase image. Target volume was generated according to the clinical protocol. The internal target volume (ITV) was defined as the sum of GTV at end exhalation and end inhalation phases, and a PTV was defined by adding 5mm margin to ITV. 3D dose calculation was performed using end-exhalation phase as a reference image. And then, the same planning information were copied to the other phases. 4D dose was accumulated using intensity-based deformable image registration (DIR) algorithm (Horn and Schunck optical flow) in DIRART. The target and normal organs dose were evaluated with the 4D dose and compared with those from 3D dose. The dose difference between 3D dose and 4D dose were analyzed from dose-volume histogram (DVH) and Index of achievement (IOA) which assesses how close the planned dose distribution is to be the planned one. The average difference of Dmean, Dmax, Dmin, EUD, and IOA was 0.6 %, 0.9 %, 1.6 %, 2.1 %, and 1.1 %. These results illustrate that there is no significant difference in PTV. The average difference of Dmean, Dmax, EUD, and BED was decrease by 3, 1, 5, and 4% in normal liver. however, in duodenum, it was decrease 16, 19, 16, and 21%, respectively. In case 2, we could find significant difference in duodenum which located close to PTV. Although the 3D dose calculation considered the moving target coverage, significant differences of various dosimetric parameters between 4D and 3D dose were observed in normal organs. In contrast, there was no significant difference for PTV. 4D dose which can consider dosimetric effect of respiratory motion has a possibility to predict the more accurate delivered dose to target and normal organs and improve treatment accuracy.

PS04.101 - Monte Carlo Design and Simulation of a Grid-type Multi-layer Pixel Collimator for Radiotherapy: Feasibility Study Author(s): Do-Kun Yoon, Joo-Young Jung, Han-Back Shin, Moo-Sub Kim, <u>Tae-Suk Suh</u>

College Of Medicine, Department Of Biomedical Engineering, The Catholic University of Korea, Seoul/KOREA

Purpose: In order to confirm the possibility of field application of a different type collimator with a multi-leaf collimator (MLC), we constructed a grid-type multi-layer pixel collimator (GTPC) by using a Monte Carlo n-particle simulation (MCNPX).

Methods: In this research, a number of factors related to the performance of the GPTC were evaluated using simulated output

data of a basic MLC model. A layer was comprised of a 1024-pixel collimator ($5.0 \times 5.0 \text{ mm}^2$) which could operate individually as a grid-type collimator (32×32). A 30-layer collimator was constructed for a specific portal form to pass radiation through the opening and closing of each pixel cover. The radiation attenuation level and the leakage were compared between the GTPC modality simulation and MLC modeling (tungsten, 17.50 g/cm³, $5.0 \times 70.0 \times 160.0 \text{ mm}^3$) currently used for a radiation field. Comparisons of the portal imaging, the lateral dose profile from a virtual water phantom, the dependence of the performance on the increase in the number of layers, the radiation intensity modulation verification, and the geometric error between the GTPC and the MLC were done using the MCNPX simulation data.

Results: From the simulation data, the intensity modulation of the GTPC showed a faster response than the MLC·s (29.6%). In addition, the agreement between the doses that should be delivered to the target region was measured as 97.0%, and the GTPC system had an error below 0.01%, which is identical to that of MLC.

Conclusions: A Monte Carlo simulation of the GTPC could be useful for verification of application possibilities. Because the line artifact is caused by the grid frame and the folded cover, a lineal dose transfer type is chosen for the operation of this system. However, the result of GTPC's performance showed that the methods of effective intensity modulation and the specific geometric beam shaping differed with the MLC modality.

PS04.102 - Feasibility study of patient alignment method using tactile array sensors

Author(s): Tae Ho Kim¹, Seong-Hee Kang¹, Dong-Su Kim¹, Min-Seok Cho¹, Kyeong-Hyeon Kim¹, Siyong Kim², <u>Tae-Suk Suh¹</u> ¹Biomedical Engineering, Research Institute Of Biomedical Engineering, The Catholic University of Korea College of Medicine, Seoul/KOREA, ²Radiation Oncology, College Of Medicine, Virginia Commonwealth University, Richmond/VA/UNITED STATES OF AMERICA

Ideal alignment method based on the external anatomical surface of the patient could consider an entire region of interest. However, optical camera-based systems cannot blindly monitor such areas, like the patient's back position, for example. Furthermore, it is impossible to collect enough information to correct the associated deformation error. The study aim is to propose a new patient alignment method using the tactile array sensors that can measure the distributed pressure profiles along the contacting surface. The TactArray system includes one sensor, a signal conditioning device (USB drive/interface electronics, power supply, and cables), and a pc. The tactile array sensor was placed between the patient's back and the treatment couch, and the deformation at different locations on the patient's back was evaluated. Three healthy male volunteers were enrolled in this study and pressure profile distributions (PPD) were obtained with and without immobilization. After the initial pretreatment setup using the laser alignment system, the PPD of the patient's back was acquired. The results were obtained at four different times and included a reference PPD dataset. The contact area and the center-of-pressure value were also acquired based on the PPD data for a more elaborate quantitative data analysis. To evaluate the clinical feasibility of the proposed alignment method for reducing the deformation error, we implemented a real-time self-correction procedure. Despite the initial alignment, we confirmed that PPD variation existed in both cases of the volunteer studies (with and without the use of the immobilization tool). Additionally, we confirmed that the contact area and center-of-pressure varied in both cases, and this variation was observed in all three volunteers. Based on the proposed alignment method and the real-time self-correction procedure, the deformation error was significantly reduced. Through the proposed alignment method, it is possible to account for the

limitation of the camera-based system and to improve the accuracy of the external surface-based patient setup.

PS04.103 - Analysis of motion-induced dose errors according to the tumor motion in helical tomotherapy

Author(s): Min-Seok Cho, Tae Ho Kim, Seong-Hee Kang, <u>Tae-Suk</u> <u>Suh</u>, Dong-Su Kim, Kyeong-Hyeon Kim

Department Of Biomedical Engineering, And Research Institute Of Biomedical Engineering, The Catholic University of Korea, Seoul/ KOREA

Motion-induced dose errors caused by tumor motion, couch motion, and gantry rotation can be observed in helical tomotherapy. The purpose of this work is to analyze motion-induced dose errors according to the change of the tumor motion amplitude, period, baseline drift and phase shift. Gafchromatic EBT2TM film (Ashland Inc., Covington KY) was used to acquire the static dose to make a total dose distribution. Slightly irregular tumor motion was simulated by 10% variations in the tumor motion parameters of amplitude, period, and baseline. Large irregular tumor motion was simulated by 40% variations. In addition, in order to account for the effects of phase shift on the total dose distribution, the initial phase of a tumor motion when the beam delivery started was divided into end-inspiration, mid-expiration, end-expiration, and mid-inspiration. The total dose distribution was determined by integrating the static dose on the different part of tumor due to tumor motion and couch motion. A position versus time curve was used to analyze the cause of motion-induced dose error. The larger variation of tumor motion parameters, the larger the motion-induced dose error that was generated. The larger variation of tumor motion parameters, the larger difference of total dose distributions according to the initial phase of a tumor motion was observed. Additionally, larger difference of total dose distribution was observed in the baseline drift case than tumor motion amplitude case and period case. These motion-induced dose errors can be reduced by using abdominal compression and respiratory training. This study could help to understand the impacts of tumor motion parameters and the initial phase of a tumor motion on the total dose distribution.

PS04.104 - Drift correction techniques in the tracking of lung tumor motion

Author(s): Peng T. Teo¹, Kaiming Guo¹, Nadia Alayoubi¹, Katherine Kehler¹, Stephen Pistorius²

¹Physics And Astronomy, University of Manitoba, Winnipeg/CANA-DA, ²Medical Physics, CancerCare Manitoba, Winnipeg/CANADA

This work compares three methods of tracking lung tumor motion using an optical flow algorithm to analyze portal images. An earlier approach used sequential image pairs (CU) to track the motion. Errors in the position of the tumor were found to accumulate when patient traces were used and two new approaches were introduced. The first method re-calibrates the position of the tumor at the endof-exhale (EoE) of each breathing cycle. This was done by computing the position directly between the new image and the previous reference image. The new image at the EoE is then assigned as the new reference frame, a process called reference shifting (RFSF). Between two EoE, sequential tracking was employed. The second approach derives the position of the tumor in each frame by applying the optical flow computation directly between each image and a reference image. However, since tracking is limited to a finite range (i.e. threshold), new reference images were required when the tumor exceeds a set distance from the reference position, a process called threshold shifting (THSF). Direct comparison of the position in subsequent images was made with respect to the new reference image. A 3D tumor prototype was fabricated using 3D printing techniques and seven patient traces were evaluated. Average position errors of

-0.01 \pm 0.65 mm, -0.10 \pm 0.42 mm and -0.14 \pm 0.25 were obtained for the CU, RFSF and THSF methods respectively.

PS04.105 - Application and Parametric Studies of a Sliding Window Neural Network for Respiratory Motion Predictions of Lung Cancer Patients

Author(s): <u>Peng T. Teo</u>¹, Neil Bruce², Stephen Pistorius¹ ¹Physics And Astronomy, University of Manitoba, Winnipeg/CAN-ADA, ²Computer Science, University of Manitoba, Winnipeg/MB/ CANADA

In real-time adaptive image-guided radiotherapy (IGRT), the beam delivery position is changed to follow the tumor motion. Most systems cannot respond instantaneously, and compensation for system lag is required. Typically, future tumor positions are predicted based on the respiratory motion tracked from an external surrogate. In the current work, a sliding window of time series data taken from the respiratory cycle is input into a neural network to predict a future position. The finite past history of the respiratory position is used to train the model. A nonlinear autoregressive neural network with exogenous inputs was used to simultaneously predict future positions. Patient data from the Respiratory Trace Generator (RTG) [1] was used for the training, validation and testing of the model.

Parametric studies involving the number of input nodes (length of sliding window), number of hidden nodes and prediction horizon were performed. Tradeoffs between under-learning, training rate and over-learning were identified. While training error decreases as the number of hidden nodes increases, the validation error increases beyond 20 nodes. Large errors occur during transitions between inhale and exhale as well as when the prediction horizon increases.

PS04.106 - VMAT delivery through couch tops: an illustration of loss of dose coverage for prostate plans

Author(s): Daria Comsa¹, <u>Monique Van Prooijen²</u>, Mohammad K. Islam², Robert K. Heaton³

¹Medical Physics, Stronach Regional Cancer Centre, Newmarket/ ON/CANADA, ²Radiation Physics, Princess Margaret Cancer Centre, Toronto/CANADA, ³Radiation Oncology, University of Toronto, Toronto/ON/CANADA

Introduction: Complex radiation therapy treatments are designed using computer algorithms which rely on specific dosimetric inputs. Optimization will be continued until all dosimetric criteria are met or otherwise accepted. Such optimization typically takes place on data sets that exclude the treatment couch top, yielding plans that do not reflect reality. We investigated what ignoring the couch top means dosimetrically for five full arc VMAT prostate plans.

Method: Four different couch tops were considered: iBeam evo, Sinmed Mastercouch, Varian flatpanel and Varian unipanel with t-bar support. Each of the Varian couch tops was considered with support bars in and out. Plans were selected based on range in target size and planning complexity. The starting point in each case was a previously accepted clinical case planned without a couch top. Couch tops were added in succession while maintaining the original beams. Parameters characterizing the dose distribution were assessed for each combination, including our standard clinical evaluation criteria. Prescription isodose line shifts were measured on 5 slices, at 3 posterior and 1 each lateral and anterior locations.

Results: For a prescribed dose of 78 Gy, the CTV V78Gy decreased from 0.2 - 40%, while the PTV V74.1Gy decreased from 0.6 - 9%. The greatest loss of dose occurred at the 105% dose level within the CTV.

Conclusion: CTV and PTV coverage reductions observed in this

study show that introducing couch information at the planning stage would produce a different plan than without couch information. These differences significantly exceed plan objectives and assessment criteria. This implies that either the current planning goals for these techniques are overly precise, resulting in little patient benefit gain from time invested in fine tuning a plan, or that planning which includes a model of the treatment couch is required to achieve the precision of dose delivery specified by the clinician.

PS04.107 - Edge Detection for Automated Biological Tumor Volume Definition Based on FDG-PET/CT-fused Imaging: An Agar Phantom study Author(s):

Purpose: Fused positron emission and computed tomography (PET/ CT) images have an important role in external beam radiotherapy (RT), especially for target volume delineation. For contouring on PET/CT images, the source-background algorithm is currently the used method, but its sensitivity to partial volume effects may produce inaccuracies when applied on small lesions. The goal of this research was to develop a computational algorithm based on the Canny's edge detection tool for processing PET/CT images. Materials and Methods: The software was implemented using the data analysis framework ROOT and the Grassroots DiCoM GDCM libraries (CERN, Geneva, Switzerland). First, a pre-processing Gaussian smoothing was applied to these images. Then directional derivatives and gradients were computed on the basis of multivariate calculation tools. Upon completion of this process, the boundaries of uptake regions having cylindrical shape within an Agar phantom were automatically sought by searching for the gradient magnitude and laplacian upper a pre-defined gradient threshold. Results: The mean diameters calculated by using the developed software have differences below 3% respect to the measured value (69 mm) for all the gradient thresholds between 15% and 55%. The diameters delimitated with the source-background algorithm are different to the measured value and only are similar when a source-background threshold of 35% is defined. Conclusion: Images from the gradient magnitude and Laplacian of counts for the Agar Phantom with 18F-FDG PET-CT, are associated with diffusion processes explained by the Fick laws. According to the obtained results, methods of delimitation of tumors with 18F-FDG PET-CT are still useful, even in the presence of diffusive phenomena.

PS04.108 - Comparison between HybridARC and sliding windows IMRT for Spine SBRT tumor

Author(s): Daniel Venencia, Nestor Vacca, Edgardo Garrigó, Lucas Caussa

Fisica Medica, Instituto de Radioterapia - Fundacion Marie Curie, Cordoba/ARGENTINA

Introduction

Spine SBRT treatments require high radiation dose to the PTV, located very close to organs at risk (OAR) like spinal cord, esophagus, kidneys and lung with very low tolerance doses compared to the prescribed tumor dose. The treatment requires high precision and treatment time should be as low as possible due to the patient condition. The objective of this work is to compare HybridARC (HA) with sliding windows IMRT (dMLC) treatment modality

Method and Materials

A 6MV photon beam with 1000MU/min dose rate (SRS beam) produced by a Novalis TX (Varian/BrainLAB) equipped with HD MLC was used. The treatment planning system used was iPlan v4.5.3 (BrainLAB). Treatment plans comparison was done for 5 patients. Dose prescription was 27Gy to in 3 fractions; all plans were equally normalized keeping OARs within dose tolerances. HybridARC plans were created using 1 arc plus 3 (HA3), 5 (HA5) and 8 (HA8) fixed IMRT fields. HybridARC plans used arc aperture optimization and IMRT inverse planning (OAR high modality). Between 60-40% of the prescribed dose was given by the arc. Treatment with dMLC used 15 fixed gantry angle beams. Treatment times, monitor units (MU), conformity index (CI), V50% and V20% was used for plans comparisons.

Results

Assuming dMLC IMRT treatment plans as reference, the treatment time was reduced by -14.6% with HA8, -8.6% with HA5 and -23% with HA3. Increasing arc dose proportion in HA (arc MU > 2000) requires 2 or more arcs which increments treatment time. Using 1000MU/min HA3 and HA5 exhibits beam hold off for fixed IMRT fields which in some cases need to be split in 2 segments. MU varied +4% with HA8, +3.7% with HA5 and -5% with HA3. CI increased +5% with HA8, +23% with HA5 and +37% with HA3. V50% increased +5% with HA8, +43% with HA5 and +62% with HA3. V20% increased +13.2% with HA8, +7.6% with HA5 and +1% with HA3. OARs doses were keep within tolerances in all plans. Patient specific QA for all modalities shows more than 90% of the pixel with g<1 with 3%/3mm pass criteria and high dose threshold of 30%.

Conclusion

HybridARC using an SRS beam for spine SBRT with 8 fix IMRT gantry angle shows a treatment time reduction, comparable MU and similar dose conformation to dMLC IMRT. HybridARC with 5 or 3 fix IMRT fields produce undesirable beam hold off, worse dose conformation and increments the total volume with 50% of the prescribed dose.

PS04.109 - real time dynamic prostate brachytherapy dose calculations using permanent i125 implants: technical description and preliminary experience

Author(s): Edgardo Garrigó, Maria J. Almada, Yaqueline Schworer, <u>Daniel Venencia</u>

Fisica Medica, Instituto deRadioterapia - Fundacion Marie Curie, Cordoba/ARGENTINA

INTRODUCTION: Low dose rate (LDR) prostate brachytherapy is an accepted treatment option for low risk prostate cancer patients. However, differences in prostate spatial location, volume and gland deformation between the images adquisition and later on during the implant procedure could carry to an incorrect dosimetry. The aim of this work is reporting on our treatment technique based on interactive real-time dynamic intra-operative dose calculation and to determine dosimetry differences

METHODS: Images from base to apex are obtained using a motorized stepper connected to the ultrasound and planning system. Physician draws the volumes Prostate, Uretra, Rectum, Bladder, and when is necessary a Boost volume. Then, we implant the periferical needles and capture them by the planning system in the true position. We finish the plan with central needles. Once definitive needle positions have been captured, dosimetry is performed intraoperatively and the physician approves the corresponding isodoses on real time. Each array of seeds are corrected in accordance with actual implanted seeds. This allows real-time intraoperative dosimetric analysis, allowing for correction of under-dosed zones during implantation in an interactive dynamic way. In this work we selected 10 plans and we compare the plans with real needles position (RNP) against the same plans without regard to needles position modifications (WRNP).

RESULTS: We began our LDR prostate brachytherapy program on

2012. We have treated 73 patients, all patients were treated with our real time dynamic intra-operative planning system. A median of 165.5Gy-165.5Gy for D90, of 53.6%-54.3% for V150, 97.2%-96.5% for V100 and 0.0% – 1.7% for Uretra V200 and 1.0cc – 1.1cc for Rectum V100. Was calculated for RNP plan and WRNP plan respectivly.

CONCLUSION: Real-time intra-operative planning was successfully implemented in our Institution. It avoids the possible implant quality and dose delivery disadvantages by improving the accuracy of seed placement on real time. The main advantage is the urethral protection which is translated in lower rates of acute and chronic GU morbidity

PS04.110 - Design of a simple device for end to end test of IGRT system using ExacTrac

Author(s): Daniel Venencia, Maria J. Almada, Yaqueline Schworer, Luis C. Medina, Edgardo Garrigó

Fisica Medica, Instituto de Radioterapia - Fundacion Marie Curie, Cordoba/ARGENTINA

Introduction

The ExacTrac system (BrainLAB) for image-guidance radiotherapy (IGRT) uses an infrared pre-positioning system and two RX oblique images for patient positioning based on bones or implanted fiducial. The accuracy of this system depends on the quality of the images, image transfer between TAC-TPS-ExacTrac, volume definition, isocenter calibration and mechanical precision of the treatment machine. Quality control of this complex network requires a phantom capable of verifying each of the stages.

The aim of this study is to design and test a simple phantom sufficient to verify end-to-end process of this IGRT using ExacTrac.

MATERIALS and METHODS

A rectangular acrylic phantom of 30 cm long, 30 cm wide and 6 cm high was designed. It has a cylindrical acrylic insert of 3 cm diameter with spherical endings in their borders, one constructed of plastic (PE) with different density and at the opposite border a lead sphere (PbE) of 2mm diameter in the center of the corresponding circumference. On the surface of the phantom baseplate with infrared markers are placed for CT. CT images of 2.5mm thickness are acquired with the cylindrical inserted in the PE side. CT images are sent to the TPS (iPlan v4.5.3) where the spherical volume of PE is drawn. Considering this volume as target an anterior field is located where the coordinate of the isocenter is the center of mass (CM) of the PE. Plan is exported to ExacTrac and isocenter coordinate matching is verified. ExacTrac system is calibrated using BrainLAB infrared and RX calibration phantoms. The phantom is placed on the treatment couch with the cylinder inserted in the PbE side with infrared markers used for treatment. Phantom prepositioning is performed guided by the spheres according to the movements indicated in ExacTrac screen. Then X-ray oblique images are obtained and the displacement of the radiological isocenter of ExacTrac to the center of the lead sphere is recorded. Using a 2x2cm² beam from the Linac portals images with ANT and LAT incidence are obtained. Images are analyzed and PbE displacements are determined relative to the center of the radiological field using RIT v5.3 software or ARIA off line review software. Primus linear accelerator (Siemens) and Novalis TX (BrainLAB / Varian) equipped with ExacTrac system were used to test the phantom.

Results

Density difference between acrylic insert and PE allowed adequate delineation. The coordinate of the treatment field, based on CM of PE, match with the center of the sphere. ExacTrac X-ray images showed an overlap of the radiological isocenter with the PbE projection image (error <1mm) in both treatment machines. The radiological displacement of the PBE with the center of the Linac field was less than 1mm for both machines. The duration of the end-to-end test with this device was less than 3 hours.

Conclusions

The designed phantom is economical and practical for End-to-End QA of ExacTrac IGRT system. Its construction is simple, easy positioning and its use allows a quantitative or qualitative correlation between displacement and errors obtained.

PS04.111 - Study on the use of an in-house device to consider the motion effects on absorbed dose determination and measurements using different calculation algorithms in lung SBRT cases

Author(s): <u>Victor A. Villamares-Vargas</u>¹, Mariana Hernández-Bojórquez², Héctor J. Uriarte-Rivera³, Jorge O. Hernández-Oviedo², Eugenio Torres-García¹

¹Facultad De Medicina Area De Posgrado, Universidad Autónoma del Estado de México, Toluca/MEXICO, ²Radioterapia Y Radiocirugía, Centro Médico ABC - Centro de Cáncer, México, D.F./ MEXICO, ³Departamento De Física, Instituto Politécnico Nacional -Escuela Superior de Física y Matemáticas, México, D.F./MEXICO

One of the challenges in radiation therapy consists in the administration of treatments for tumors that are susceptible to modify their position due to the respiratory cycle, as occurs in those located in the pulmonary or abdominal areas. There are different tomography simulation devices available which take into account the movements of the patient anatomy due to respiration cycles, known as *4DCT*. The *4DCT* scans are used to provide accurate representations of the motion effects, through datasets such as the maximum, minimum and mean projections. These can be useful for determining the contours of lung or liver tumors, which are modified by motion, as well as those of the surrounding organs at risk and healthy tissue. Therefore, the absorbed dose delivery considering these movements is possible. Also, a reduction of the target volume margins reduces the risk of complications due to the surrounding healthy tissue irradiation.

A movable platform was built to simulate one direction movement of an anthropomorphic thorax phantom in order to perform guality assurance (QA) processes for treatment planning using 4DCT. In this work the performance of this device is examined to run some QA tests for lung stereotactic body radiation therapy, taking into account the breathing movement of the patient. The verifications which compose the QA process are made in typical treatments of 50 Gy in 5 sessions using different planning systems such as: iPlan RT Dose and Eclipse, using three different algorithms for the calculation of the absorbed dose: Analytical Anisotropic Algorithm, Pencil Beam and Monte Carlo. To measure the absorbed dose a QUASARTM Multi-Purpose Body Phantom thorax is used with in-house manufactured cavities that allow the access of a SemiFlex, MicroLion and PinPoint ionization chambers. In addition, a separate set of inserts was designed to use radiochromic film sheets. The values of the absorbed dose calculated by the three algorithms are compared with the measurements obtained from the actually delivered absorbed dose on the radiation detectors. With the above, the precision of these algorithms can be quantified considering the implicit respiratory movement.

PS04.112 - In-vivo skin dose evaluation for Pd-103 permanent breast radiotherapy implants

Author(s): Ronald E. Beals¹, Elizabeth Watt², Tyler Meyer³, <u>Jose E.</u> <u>Villarreal-Barajas⁴</u>

¹Physics And Astronomy, University of Calgary, Calgary/CANA-DA, ²Tom Baker Cancer Centre, Calgary/CANADA, ³Oncology, University of Calgary, Calgary/CANADA, ⁴Oncology, University of Calgary, Calgary/AB/CANADA

Permanent breast seed implant (PBSI) using permanent seed LDR breast brachytherapy was pioneered in Toronto with the first procedure completed in 2004. In late 2013, our centre started a PBSI program using Pd-103 seeds. This study presents our preliminary results of the in-vivo skin dose evaluation on a cohort of six PBSI patients. All patients were forward planned using CT images where the physician defined a PTV as a 1 cm expansion of the CTV trimmed to the skin and chest wall. The implant plans were designed to cover at least 90% of the PTV by the prescribed dose of 90 Gy. The planned dose to the skin was limited to a maximum of 81 Gy. Given the limitations of the water based (TG-43) dose calculation algorithm used by the treatment palnning system and its potential underestimation of the dose to the skin, an in-vivo skin dose evaluation was performed using radiochromic dye film dosimetry (EBT3). The EBT3 films strips used for the skin dose evaluations were positioned in contact with the skin of the patients at the central axis of the implant. The patient films dose integration period varied from 3.25 hours to 47 hours (see Table 1). These films were scanned in order to obtain their associated net optical density (net O.D.). The net O.D. was used to estimate the skin dose using a 100 kV calibration (Figure 1). The validity of the calibration was verified using two Pd-103 point doses from a well controlled EBT3 irradiation experiment. The two highest skin doses measured correlated with observed skin reactions in the corresponding patients. More research is needed to assess the clinical significance of the measured skin doses and their role in the development of an effective metric for the relevant skin dose in PBSI.

ID.	net O.D.	Exp.time/h	Max. dose/Gy	Max. total dose / Gy
1	0.3490	47	4.710	61.3±4.3
2	0.0540	3.67	0.428	68.8±8.3
3	0.0423	5.0	0.324	38.3±7.3
4	0.0240	3.0	0.172	33.8±6.4
5	0.0293	3.75	0.215	33.8±7.1
6	0.0209	3.25	0.147	26.7±6.7

Table 1. Net optical density obtained by scanning the exposed films (red channel), patient film time exposure in hours, absorbed dose to water estimates for the corresponding exposure, and maximum total dose estimate obtained by integration based on the maximum dose in the patient film. The dose uncertainty in the maximum total dose column is derived from the variation (k=2) observed in the net 0.0. derivation of the 5 x 5 mm² area used to score the maximum dose in the patient films.

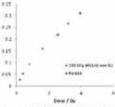

Figure 1. BETS film calibration using a 100 kV_p (HVL=3 mm Al) orthovoltage t ray clinical beam and two verification Pd-103 doses (2.55 and 3.95 Gy). The Pd-103 doses were estimated based on a measured activity and using the T6-43 formalism with a Monte Carlo based correction to obtain the dose to water in acrylic (PMMA). The Pd-103 dose estimates deviced from the measured net 0.0, are within SS of the expected doses derived using a 100 kV_p aray beam calibration.

PS04.113 - Dosimetric Variations in Permanent Breast Seed Implant (PBSI) Evaluated at Different Arm Positions using Deformable Image Registration

Author(s): <u>Elizabeth Watt</u>¹, Siraj Husain², Karen Long¹, Michael Sia², Derek Brown³, Tyler Meyer⁴

¹Tom Baker Cancer Centre, Calgary/CANADA, ²Oncology, University of Calgary, Calgary/CANADA, ³Radiation Medicine And Applied Sciences, University of California, San Diego, La Jolla/UNITED STATES OF AMERICA,⁴Physics & Astronomy, University of Calgary, Calgary/ CANADA

Purpose: Permanent Breast Seed Implant (PBSI) is a novel method of treating early-stage breast cancer. It is a one-day, outpatient procedure in which radioactive Pd-103 seeds are surgically implanted in and around the seroma following breast-conserving surgery. The planning for PBSI is done with the patient's ipsilateral arm raised; however, changes in implant geometry can be expected due to healing and anatomical motion as the patient resumes her daily activities. The purpose of this study is to quantify the effect of arm position on postplan dosimetry.

Methods: Thirteen patients treated at the Tom Baker Cancer Centre in Calgary, Alberta were included in this study. All of these patients underwent two post-implant CT scans on the day of implant. One scan was taken with the patient's ipsilateral arm raised above the head, recreating the position of the planning scan, while the other was taken with both arms down beside the body in a relaxed position. Postplans on both scans were completed using MIM Symphony[™] (MIM Software, Cleveland OH). The pre-implant planning scan was deformably registered to the post-implant scan to deform the seroma contour and other relevant contours to the post-implant scan. An evaluation PTV, with a 0.5 cm margin to the seroma, was generated after deformation. Statistical analysis was performed using a paired, two-tailed t-test, and an alpha value of 0.05 was used for statistical significance.

Results: A summary of the dosimetric parameters for the target volumes and nearby structures for both arm positions is shown in Table 1.

Table 1: Comparison of Dosimetric Parameters for Ipsilateral Arm Up and Down						
Parameter	p-value					
СТV [%]	90.7 (70.9–100.0)	93.9 (79.7–100.0)	0.08			
V100						
PTV [%]	83.7 (66.6–99.4)	86.0 (68.7–99.1)	0.17			
V90 V100	80.0 (60.8–97.9)	82.6 (65.3–98.0)	0.17			
V150	58.8 (29.9–79.3)	61.2 (35.9–84.5)	0.21			
V200	34.7 (15.9–54.5)	38.7 (18.9–61.5)	< 0.01			
Skin [cc]	1.6 (0.0–6.2)	1.7 (0.0–7.8)	0.59			
V80	1.2 (0.0–5.2)	1.3 (0.0–5.4)	0.52			
V90						
Lung [cc]	1.6 (0.0–5.2)	0.2 (0.0–1.4)	0.01			
V20Gy	,		0.01			
Heart* [cc]	0.04 (0.00–0.30)	0.00 (0.00–0.02)	0.30			
V20Gy	0.00	0.00				
V40Gy						

Notes: Values are mean (range).

*Only left-sided patients were analyzed for these parameters. Discussion and **Conclusions:** Results on thirteen patients thus far indicate that the implant becomes significantly hotter with the arm down (indicated by the increase in V200); however the increase exhibited when using a 1 cm PTV margin did not reach significance. Lung dose significantly improved in the arm down position. Change in seroma volume between the arm up and arm down scan (mean: -1.1%; range: -18.3% to 7.8%) is an influencing factor in dosimetric differences. Further investigation is necessary to also determine the effect of shape and seroma position. Seroma volume may change over time due to swelling and resolution (healing); future work will involve analysis of dosimetry on eight week post-implant CT scans to ensure that volume changes on the day 0 post-implant scan due to edema is not skewing the dosimetric results.

PS04.114 - Minimum Planning Target Volume Coverage Necessary for the Delivery of the Prescribed Dose in Lung Radiotherapy

Author(s): Madison Murdoch¹, Marcin Wierzbicki²

¹McMaster University, Niagara Falls, Ontario/CANADA, ²Juravinski Cancer Centre, Hamilton/ON/CANADA

Minimum Planning Target Volume Coverage Necessary for the Delivery of the Prescribed Dose in Lung Radiotherapy

Intensity Modulated Radiation Therapy (IMRT) has been used in lung cancer treatment to deliver dose distributions with steep gradients and exquisite target volume conformality. While many benefits of IMRT exist, significant challenges are involved when unpredictable intrafractional movement is combined with the highly optimized nature of IMRT. The National Cancer Institute (NCI) Guidelines for the Use of IMRT state that there is potential for significant dosimetric consequences if the target volume moves while treatment is being administered. Thus, lung IMRT is especially challenging due to breathing motion. Furthermore, tissue density differences at the lung-tumor interface contribute to disagreements between the administered and planned doses. It is believed that inhomogeneities allow for a relatively large amount of the planning target volume (PTV) to be left without coverage and the target will still receive the prescribed dose during treatment. For example, the Radiation Therapy Oncology Group (RTOG) 0617 study requires that 95% of the PTV is to be covered by 93% of the prescription dose during planning. The study assumed this planning goal was sufficient in ensuring coverage during treatment, although it is unclear if this was achieved due to target motion and the dosimetric effects of inhomogeneities.

This study aimed to establish an IMRT lung planning goal that ensures 99% of the internal target volume (ITV) is covered by 95% of the prescribed dose during treatment. Ten previously generated IMRT plans were compiled for analysis. Each plan was renormalized such that 95% of the PTV is covered by increasingly higher doses, ranging from 93 to 97% of the prescription. For each plan, multiple target movements were simulated by shifting the isocentre of the beams within a range previously measured for this patient population and recomputing the dose. Finally, the coverage of the ITV obtained during simulated treatment was established using dose-volume histograms for each planning goal. Advantage of certain planning goals versus others was established by comparing the number of simulated movements causing inadequate coverage of the ITV.

Kruskal-Wallis analysis showed that none of the studied planning goals was significantly different from another based on the number of times the ITV was not covered by 95% of the prescribed dose. In other words, the RTOG 0617 planning goal of 95% of the PTV covered by 93% of the prescription achieves the same result as the goal where 95% of the PTV is covered by 97% of the prescription. The complete data suggested that coverage failure may decrease with increasing coverage but the current study did not show the decrease was significant. We are currently applying the RTOG 0617 planning goal clinically and will repeat this analysis with additional patient data to ensure optimal delivery of lung IMRT at our institution.

PS04.115 - A modified methodology to accurately validate CT number constancy for proton therapy

Author(s): <u>Richard Y. Wu</u>¹, Amy Y. Liu², Kazumichi Suzuki², Michael Gillin², Ron Zhu²

¹Radiation Physics, M.D. Anderson Cancer Ctr, Houston/TX/UNITED STATES OF AMERICA, ²Radiation Physics, M.D. Anderson Cancer Ctr, Houston/UNITED STATES OF AMERICA

A modified methodology to accurately validate CT number constancy for proton therapy

Purpose

In proton therapy, the CT number is calibrated to convert proton stopping power ratio (SPR) and the calibration factor is entered into a treatment planning system. Since CT number vs. SPR is a nonlinear curve throughout the range of clinical interest, the current CT number quality assurance (QA) method is not adequate to test CT# accuracy/constancy for the entire human tissue range. We developed a method that will establish the criteria of the CT number variations which provide the desired percentage variation of the baseline values of SPR

Method

We began with a CT number vs SPR curve established in the Eclipse planning system for a designated proton CT scanner (Fig. 1). We separated the CT number vs. SPR curve into 3 sections representing lung, soft tissue, and bone tissue ranges and fit each section with a polynomial curve. When a given +/- 1% change occurs in the

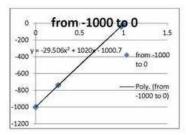

SPR, the corresponding CT number change can be calculated by applying the polynomial equation from each section.

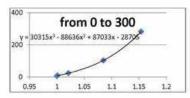

Result

Table 1 illustrates the calculated CT number change as a result of +/-1% changes of SPR for each entry point. These values are used in the annual CT number QA testing to validate that each entry value is consistent with the original calibration.

Conclusion

We have established a simple and quantitative method for CT number annual constancy testing through the scanner's entire clinical range.

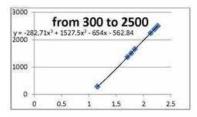

Fig.1

CT number vs. SPR curve are separated into 3 sections representing lung, soft tissue, and bone tissue ranges and each section is fit with a polynomial curve

PS04.116 - Development of a real-time portable applicator monitoring system for gynecologic intracavitary brachytherapy Author(s): Christian Bauer, Reinhard Beichel, Yusung Kim, Timothy Waldron, Wenqing Sun, Sudershan Bhatia, Junyi Xia Radiation Oncology, University of Iowa, Iowa City/UNITED STATES OF AMERICA

Purpose

To develop a real-time applicator position monitoring system (RAPS) for intracavitary brachytherapy.

Materials and Methods

Applicator displacement during brachytherapy can produce suboptimal dosimetric effects, especially in 3D image-guided brachytherapy, which requires high accuracy applicator localization. 2D X-ray imaging devices, such as C-arm, are routinely used for measuring applicator displacement, however, they deliver extra radiation dose to patients and lack the capability of continuous applicator monitoring. The RAPS was developed for continuous applicator position monitoring without any radiation dose. The RAPS consists of two custom-designed tracking targets with infrared reflective markers and a calibrated infrared stereo-camera setup. The RAPS can measure in real-time the applicator movement by computing the relative displacement between the two tracking targets, which are attached to the applicator and the patient. Both 3D printed tracking targets were custom designed for optimal tracking performance and to be easily attached to the Varian Tandem and Ovoid applicator. A phantom study was conducted to compare RAPS' measurements with known displacements from a high accuracy positioning stage (0.03mm accuracy) in the range of +/-25 mm.

Results

The RAPS achieved 120 frames per second using a laptop with Intel Core 2 dual CPU. At a camera-to-marker distance of 50 cm, the mean difference between RAPS' measurements and the positioning stage was 0.068 mm with a standard deviation (STD) of 0.044 mm in superior-inferior direction, 0.013 mm with a STD of 0.015 mm in lateral direction, and 0.061 mm with a STD of 0.024 mm in anterior-posterior direction.

Conclusions

This work demonstrates the feasibility of RAPS to detect applicator motion in real-time. An accuracy of 0.1mm was achieved in the phantom study.

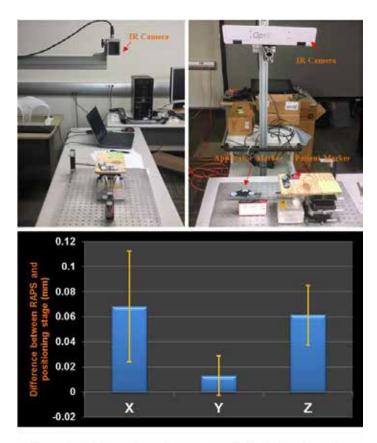

Figure 1. RAPS consists of two custom design infrared markers, an infrared camera, and a control laptop. The phantom study indicated that RAPS can achieve a mean accuracy of 0.07 mm in superior-inferior direction, 0.013 mm in lateral direction, and 0.06 mm in anterior-posterior direction.

PS04.117 - Quality Assurance of the Radiotherapy Workflow Integrating a Dedicated Wide-bore 3T MRI Simulator

Author(s): <u>Aitang Xing</u>, Gary Liney, Lois Holloway, Sankar Arumugam, Robba Rai, Ewa Juresic, Gary Goozee Cancer Therapy Centre, Liverpool Hospital, Sydney/NSW/AUSTRA-

LIA

Introduction: A MRI scanner dedicated for radiotherapy planning (also known as MRI simulator) was installed and integrated into our clinical workflow in June, 2013 [1]. There are international protocols regarding quality assurance of MRI for diagnostic performance [2], but there is lack of guidelines with regard to its integration in a radiotherapy workflow. The purpose of this study was to establish a QA program for quality control of an MRI-integrated radiotherapy workflow implemented in our centre.

Materials and methods: All scanning was performed on a dedicated wide bore 3.0 Tesla MRI scanner (Siemens Skyra) with radiotherapy accessories including a flat table top with integrated RF coil and external localization lasers for setting up patients at the same position as during treatment. The MRI simulator is integrated into our clinical workflow in following way: patient is first scanned on a Philip 4D CT simulator in the treatment position, and then scanned in this position on the MRI simulator which is in the next room The CT and MRI image are sent to the treatment planning system (Pinnacle version 9.8). The MRI is initially auto-coregistered with CT images using a mutual information algorithm and then manually adjusted by the radiotherapist (RT) and oncologist. Once the MRI images are registered with CT images, the oncologists delineate the target and organs at risk on MRI images and transfer the contours to CT images. In order to provide a quality assurance of the whole workflow, a cylindrical phantom routinely used for checking laser alignment was employed. The phantom has a base for levelling the phantom and external marks for phantom setup. The QA procedure using phantom is exactly same as the patient workflow. The phantom was scanned using CT head-neck protocol and then setup on MRI by aligning its external marks with localisation lasers and scanned using bore coils and a standard SE sequence (TE=30ms, TR=3410ms). Both CT and MRI images are sent to Pinnacle for co-registration as described previously and the translation and rotation parameters were recorded. This procedure was repeated for a period of eight days.

Results and discussion: The averaged translation parameters in all three directions were less than 1.2mm, whereas the rotation is less than 0.3 degrees. Especially along z direction, on average, there is no rotation and less than 1mm translation along x direction.. The standard deviation of translation and rotational parameters are less than 0.45, indicating that the MRI-integrated workflow is consistent and highly reproducible. It is recommended that the QA procedure be performed quarterly or in the event of MRI scanner maintenance and repair.

Conclusion: A phantom-based QA program for checking the consistency of MRI-integrated radiotherapy workflow was implemented in our centre. The QA procedure can be adopted by other centres.

PS04.118 - Evaluation of deformable accumulated parotid doses using different registration algorithms in adaptive head and neck radiotherapy

Author(s): <u>Shouping Xu</u>¹, Bo Liu², Haixia Liu³, Hanshun Gong³, Baolin Qu³, Lin Ma³, Fugen Zhou²

¹Key Laboratory Of Particle & Radiation Imaging, Tsinghua University, Ministry of Education, Beijing/CHINA, ²Beihang University, Beijing/CHINA, ³Radiation Oncology, PLA General Hospital, Beijing/CHINA

Purpose: Three deformable image registration (DIR) algorithms are utilized to perform deformable dose accumulation for head and neck tomotherapy treatment, and the differences of the accumulated doses are evaluated. Material and methods: Daily MVCT data for 10 patients with pathologically proven nasopharyngeal cancers were analyzed. The data were acquired using tomotherapy (TomoTherapy, Accuray) at the PLA General Hospital. The prescription dose to the primary target was 70Gy in 33 fractions. The contours of parotid glands on daily MVCTs were obtained by populating these contours from planning CTs to the daily CTs via rigid-body registration using the Adaptive plan software (Adaptive Plan, TomoTherapy) and were edited manually if necessary. The fractioned dose of parotids will be re-calculated. Three DIR methods (B-spline, Diffeomorphic Demons and MIMvista) were used to propagate parotid structures from planning CTs to the daily CTs and accumulate fractionated dose on the planning CTs. The mean accumulated doses of

parotids were quantitatively compared and the uncertainties of the propagated parotid contours were evaluated using Dice similarity index (DSI). Results: For 10 patient plans, the mean parotid volume (19.19±10.23cm³) at the last fraction was significantly smaller than those (29.44±13.32 cm³,p<0.0001) at the first fraction. The planned mean dose of the ipsilateral parotids (32.42±3.13Gy) was slightly higher than those of the contralateral parotids (31.38±3.19Gy). The difference between the accumulated mean doses of the ipsilateral parotids in the B-spline, Demons and MIMvista deformation algorithms (36.40±5.78Gy, 34.08±6.72Gy and 33.72±2.63Gy) were statistically significant (B-spline vs Demons, P<0.0001, B-spline vs MIMvista, p=0.002). And The difference between those of the contralateral parotids in the B-spline, Demons and MIMvista deformation algorithms (34.08±4.82Gy, 32.42±4.80Gy and 33.92±4.65Gy) were also significant (B-spline vs Demons, p = 0.009, B-spline vs MIMvista, p = 0.074). For the DSI analysis, the scores of B-spline, Demons and MIMvista DIRs were 0.90, 0.89 and 0.76. Conclusion: Shrinkage of parotid volumes results in the dose increase to the parotid glands in adaptive head and neck radiotherapy. The accumulated doses of parotids show significant difference using the different DIR algorithms between kVCT and MVCT. Therefore, the volume-based criterion (i.e. DSI) as a quantitative evaluation of registration accuracy is essential besides the visual assessment by the treating physician.

PS04.119 - Optimization of brain metastases radiotherapy with TomoHDA

Author(s): <u>Slav Yartsev</u> London Regional Cancer Program, London/CANADA

Introduction. Simultaneous in-field boost (SIB) approach has been shown advantageous for dose distribution in axial plain in radiation treatment with prescription of 60 Gy to brain metastases, aka gross tumor volume (GTV), and 30 Gy to the rest of the brain in 10 fractions [1]. However, in the case of tomotherapy system with static jaws, a penumbra of the order of fan beam width is present in superior-inferior (SI) direction both for the whole brain (WB) and GTV regions. Recently, the idea of movable jaws by Gladwish et al. [2] has been realized in the commercially available TomoHDA system. This innovation allowed for drastic reduction of the SI penumbra for the WB, but not for the SIB region. We explore a possibility to take full advantage of dynamic jaws on TomoHDA for brain metastases and whole brain radiotherapy.

Methods. A challenging case of the GTV close (9 mm) to the right optic nerve was planned using SIB approach with static and dynamic jaws. Also, two non-SIB treatment plans were generated: 1) WB planning target volume was prescribed to 30 Gy in 10 fractions with 5 cm fan beam/dynamic jaws and the GTV was planned to 20 Gy in 10 fractions; 2) another plan with 2.5 cm fan beam/dynamic with planned irradiation of only the GTV with 60 Gy minus the dose to the GTV from the first plan. Planned maximum doses to the optic nerve and chiasm obtained in SIB and two-phase approach were compared.

Results.

Table 1. Values of selected parameters for the whole brain (WB) planning target volume, GTV, and optic nerve (ON) planned with SIB method using static and dynamic jaws, compared to sequential radiotherapy option with different field sizes.

Plans	SIB	SIB	WB only	GTV only	GTV + WB
Fields	2.5 cm	2.5 cm	5 cm	2.5 cm	5 cm+2.5 cm
Jaws	static	dynamic	dynamic	dynamic	dynamic
WB, D _{mean}	32 Gy	32.5 Gy	29.4 Gy	3.8 Gy	33.2 Gy
GTV, D _{mean}	61.2 Gy	62 Gy	20.1 Gy	39.4 Gy	59.6 Gy
Chiasm, D _{max}	36.9 Gy	39 Gy	25 Gy	7.7 Gy	< 32.8 Gy
ON, D _{max}	41.1 Gy	40.7 Gy	23.6 Gy	9.9 Gy	< 33.5 Gy
Beam-on time	8.4 min	8.8 min	3.9 min	3.1 min	7 min

Conclusions. The proposed sequential radiotherapy of brain metastases and whole brain on TomoHDA allows for using dynamic jaws benefit in full. It saves beam-on time and provides improved dose distribution in superior-inferior direction compared to simultaneous in-field boost with static beam. This method can be applied for other disease sites.

PS04.120 - A Rapid Learning Approach for the Knowledge Modeling of Radiation Therapy Plan

Author(s): Lulin Yuan¹, Yaorong Ge², Fangfang Yin¹, Q Jackie Wu¹ ¹Department Of Radiation Oncology, Duke University Medical Center, Durham/NC/UNITED STATES OF AMERICA, ²Department Of Software And Information Systems, University of North Carolina at Charlotte, Charlotte/NC/UNITED STATES OF AMERICA

Purpose: The purpose of this study is to implement a rapid learning method to train the knowledge models to predict the organ-at-risk (OAR) dose sparing in radiation therapy (RT) based on an array of patient anatomical features. We also aim to establish the evaluation criteria and a solid validation to ensure an accurate and efficient learning process.

Method and Material: The knowledge models to predict OAR dose sparing have been shown to be useful tools to guide RT planning. A rapid learning approach is utilized to train the knowledge models in this study. A total of 100 clinical cancer cases in the pelvic region were retrospectively analyzed. Among them, 40 cases are low-to-intermediate risk prostate cases (Type I), 20 are high-risk prostate cases with lymph node irradiation (Type II), 40 are anorectal cancer cases (Type III). Starting from a base model for type I cases, increasing number of cases with more complex planning-targetvolume (PTV)-OAR anatomies (type II and type III) were continuously added into the training case pool. The studentized residual and the leverage values are calculated as evaluation criteria at each step. The studentized residual guantify how much the new case deviates from the previous model. The leverage measures the distance of the new case in the feature space to the distribution of the other cases and it is used to differentiate if a large residue is due to plan quality variation or because the new case is an isolated case in the feature space. Cases in the former category are excluded from model training.

The efficiency and accuracy of the learning method was quantified by the learning curve. It describes the longitudinal improvement of model accuracies with increasing number of training cases. In order to reduce the effect of cross-sectional data variation to the learning curve, the modeling accuracies were obtained by a repeated random splitting cross validation method. The gEUD in the bladder and rectum are compared between the model predictions and actual values for the validation cases. The Median of the Absolute value of their Differences (MAD) are calculated for the validation cases.

Results: The MAD of the predicted OAR gEUD in all three types of cases gradually decreases when increasing number of training cases are added in training. The MAD of the bladder and rectum gEUD in both type II and III validation cases reaches a stable value of 2.1% to 3.5% of prescription dose when 12 type II or type III are added in training in addition to the 30 type I cases, and they are comparable with the MAD value of 2.0% to 3.4% when all cases are used in training in a batch mode.

Conclusion: The rapid learning approach is able to learn knowledge models for multiple cancer types in the pelvic region with comparable accuracy to the batch training method and with improved efficiency. This approach will facilitate the implementation the knowledge based radiation therapy planning in clinics.

PS04.121 - Plan comparison and delivery verification for intracranial stereotactic treatments using Varian TrueBeam STx linac

Author(s): <u>Sergei Zavgorodni</u> Medical Physics, BC Cancer Agency, Victoria/CANADA

Modern stereotactic brain treatments are getting away from using rigid frame based head fixation systems and mostly rely on pre-treatment and intra-treatment imaging for patient setup and motion control. Circular cones are also getting obsolete and being commonly replaced by high definition multileaf collimators (HD MLCs) that allow using advanced treatment techniques producing more conformal dose distributions. With the aim to minimize potential intra-fraction motion treatment planning includes delivery time as one of considerations. Objective of this work was to evaluate different treatment techniques that utilize HD MLCs from the perspective of treatment plan quality, delivery time, and dosimetric accuracy achievable for different target sizes.

Treatment plans were produced using 7-field static conformal, conformal arc, 7-field IMRT, 2-arc VMAT, and 4-arc VMAT techniques with 6 MV and 10MV-FFF beams. In 4-arc VMAT plans two arcs were coplanar and another two were planned for 45 and 315 degree couch angles. The plans were produced and calculated using Eclipse AAA for the anthropomorphic head phantom that had an insert for micro-diamond detector for the dose measurements. The phantom also had a tungsten bead imbedded for beam position verification. The targets were outlined around the detector position as ellipsoids of 5, 8, 10, 15, 25 mm "effective diameter", and there where one to three targets per a plan. Plans were produced for treating all targets with a single isocentre. The plan quality was evaluated by using dose volume histograms for the target and surrounding artificial shells that allowed simple evaluation of the dose fall-off. Plans were delivered and the dose measured using micro-diamond detector. The setup was guided by CBCT and its accuracy was evaluated by comparing planned and treatment positions of the tungsten bead. If the plan had multiple targets, the dose in only one of them was measured.

VMAT produced the plans comparable to IMRT and superior to conformal techniques. Non-coplanar plans were more conformal, but the difference was deemed not significant. Plans that used 6MV beams were slightly more conformal than those produced by 10MV-FFF. However the latter, being four-fold faster to deliver are still attractive clinical option. had to be set accurately as it was not possible to compensate for this rotational misalignment through available couch movements. Remaining positional error could then be as much as 3 mm compared to 0.5mm when roll rotation was set correctly. 6DoF couch was able to accurately compensate translations and rotations of the phantom and position it within 0.5mm of the plan. For all techniques the dose agreement within 2% was found for the targets of 10mm diameter and larger. For smaller targets the measured dose exceeded the plan by as much as 11%. IMRT and VMAT plans had similar delivery times when delivered in "automated" mode. Conformal plans were about 50% faster to deliver due to nearly twice less monitor units.

PS04.122 - A method to convert cone-beam computed tomography (CBCT) image for dose calculation and the phantom evaluation

Author(s): <u>Guangshun Zhang</u>, Shaomin Huang, Dandan Zhang, Xiaowu Deng, Cui Chen

Radiation Oncology, Sun Yat-Sen University Cancer Center, Guangzhou/CHINA

Background and Objective: Cone-beam computed tomography (CBCT)image is widely used for image guided radiation therapy (IGRT) and has the potentiality to support adaptive radiation therapy (ART). However, uncorrected CBCT images can not be used for re-planning dose calculation due to the larger scatters and artifacts in the Hounsfield unit (HU). Co-relationship between Fan-beam computed tomography (FBC T) and CBCT images was established and used to convert the CBCT image for dose calculation in this study. The results was simulated and verified with an anthropomorphic phantom for IMRT treatment plan computation, compared with the original FBCT based plan.

Method and material: Using a self-compiled software based on a fitting function, by registering the FBCT and CBCT image sets of an anatomical head simulated phantom, the CBCT images wasconverted to get an approximately corrected data sets as CBCTcvt for dose calculation. The precision of $CBCT_{cvt}$ -based dose calculation was then tested and validated, by comparing the iso-dose distribution and dose volume histogram (DVH) of planning target volume (PTV) and organs at risk (OARs) with the FBCT-based computation using an IMRT plan. Gamma comparison in different criteria between CBCTcvt- and FBCT-based plans was provided as well.

Results: The gamma comparison between CBCTcvt- and FBCTbased dose computations showed that the pass-rates of (1%, 1mm) , (2%, 2mm) and (3%, 3mm) criteria were 71.28%, 97.55% and 99.72%. In the two results of the CBCTcvt- and FBCT based plan calculation, the differences in the mean dose, near minimum dose (D98%), near maximum dose (D2%) and V95% of the PGTV were 1.02%, 1.58%, 0.78% and 0.06%, separately; the near maximum dose (D2%) discrepancies of brain stem and spinal cord were 0.43% and 1.61%; deviation in the D50% of the left and right parotids were 0.89% and 0.88, separately. Fig 1 showed the DVH differences for the main structures.

When treated using regular (4DoF) couch the phantom "roll" rotation

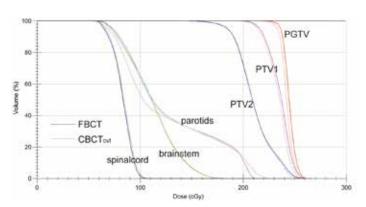

Fig. 1 DVH difference of the main concerned structures between the CBCTcvt- and FBCT-based plan calculation.

Conclusions: We established an relatively simple method to approximately correct and convert the CBCT image for feasible use of radiation treatment dose calculation, by fitting the HU values of FBCT. In the validation test using anthropomorphic phantom, the maximum discrepancy in DVH between the converted CBCT- and FBCT-based plan was less than 2%.

PS04.123 - Thermoluminescent dosimetry of the model BT-125-1 1251 interstitial brachytherapy seed

Author(s): Nan Zhao, Ruijie Yang, Junjie Wang

Radiation Oncology, Peking University Third Hospital, Beijing/CHINA

Purpose: To study the dosimetric parameters of dose rate constant, radial dose functions and anisotropy functions for the model BT-125-1¹²⁵I seed with thermoluminescent dosimeters.

Materials and Methods: The preliminary experiment is to study repeatability, linearity of dose response, dose rate effect and energy response of the thermoluminescent dosimeters (TLD). The seed was placed perpendicularly in the center of the PMMA phantom, and 12 TLDs were placed parallel to the source long axis at radial distance of 1 cm with 30° increments, to study the dose rate constant of the model BT-125-1 ¹²⁵I seed; the TLDs were placed at radial distances of 0.5, 0.7, 1.0 to 10.0 cm with a 0.5 cm increment and a 5° step, to study the radial dose functions of the model BT-125-1 ¹²⁵I seed. The seed was placed horizontally in the center of the PMMA phantom, and the TLDs were placed vertically to the longitudinal axis of the seed at radial distances of 0.5, 1, 1.5, 2, 3 to 7 cm with a 1 cm increment, and polar angles in 20° increments at the radial distance of 0.5 cm, while polar angles in 10° increments at the other radial distances, to study the anisotropy functions of the model BT-125-1 125 seed.

Results: For the model BT-125-1 ¹²⁵I seed, the maximum deviation of repeatability for TLDs was 4.0%. The TLDs had linear dose response without dose rate effect, but the dose response is energy dependent. The dose rate constant, radial dose functions and anisotropy functions were similar to the model 6711 ¹²⁵I presented in the TG43 U1 report.

Conclusions: The thermoluminescent dosimetry presented the dose rate constant, radial dose functions and anisotropy functions of the model BT-125-1 ¹²⁵I seed which were similar to those of model 6711 ¹²⁵I seed presented in the TG43U1 report.

PS04.124 - Phantom-based evaluations of two binning algorithms for four-dimensional CT reconstruction in lung cancer radiation therapy

Author(s): Fuli Zhang, Yd Wang

Radiation Oncology Department, The Military General Hospital of Beijing PLA, Beijing/CHINA

Objective: The purpose of this study was to evaluate the performance of the phase-binning algorithm and amplitude-binning algorithm. Methods: Quasar phantom data were used for evaluation. Methods: A phantom of known geometry was mounted on a four-dimensional (4D) motion platform programmed with twelve respiratory waves (twelve lung patients trajectories) and scanned with a Philips Brilliance Big bore 16-slice CT simulator. 4DCT images were reconstructed using both phase- and amplitude-binning algorithms. ITV (internal target volume, ITV) volumes of the phaseand amplitude-binned image sets was compared by evaluation of shape and volume distortions. Results: The phantom experiments illustrated that, as expected, maximum inhalation occurred at the 0% amplitude and maximum exhalation occurred at the 50% amplitude of the amplitude-binned 4DCT image sets. The amplitudebinned algorithm rendered smaller ITV than the phase-binning algorithm. Conclusions: the amplitude-binning algorithm for 4DCT reconstruction may have a potential advantage in reducing the margin and protecting normal lung tissue from unnecessary irradiation

PS05 - TRACK 05: DOSIMETRY AND RADIATION PROTECTION

PS05.005 - Dose analysis for paediatric patients under cardiac catheterization at Hamad General Hospital in Qatar. A.E.Aly, H.A. Al-Saloos, H.M. Al Naemi Hamad Medical Corporation, Qatar Author(s): <u>Antar Aly</u> Hamad Medical corporation, Doha/QATAR

Abstract

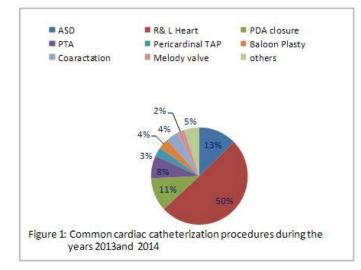

The risks associated with radiation exposure are higher in children compared adults. The use of fluoroscopy in common pediatric examinations such as left and right heart (L&R), patent ductus arteriosus (PDA), atrial septal defect (ASD), pericardial tap, patent truncus arteriosus (PTA) are the common procedures for paediatric undergoing cardiac catheterization requires accurate determination of the associated effective dose. In this study the results of an analysis of doses recorded for 198 paediatric patients for the last 2 years 2013 and 2014 carried out on pediatric patients.

Materials and Methods

One X-ray fluoroscopy machine from Hamad Medical Corporation (HMC) in Hamad General Hospital in the state of Qatar performing interventional Cardiology procedures used in this study. Database includes patient age, gender, procedure type and fluoroscopy time; Kerma Aria Product (KAP) and Cumulative dose data were recorded for 198 patients. The average peadiatric age, weight, and height were 3.03 year, 13.8 kg and 88.4 cm respectively. Peak voltage was 60.8 kVp - 80 kVp.

Results and discussion.

Figure 1 and table 1 illustrate the common cardiac catheterization procedures for paediatric patients. The average KAP \pm SD of cardiac catheterization was 956.7 \pm 1278.23 cGy \times cm². The average fluoroscopic time \pm SD was 11.83 \pm 9.7 minutes for children . The Cumulative Dose Interventional Reference point (CD_IRP) was 113.4 \pm 45.4 mGy. Body weight is an effective indicator of KAP for cardiac catheterization procedures in children as shown infigure 2. It's clear in figure 3 also good correlation between KAP/BW and KAP (R^2 = 0.7) for the paediatric patients less than or equal 6 years of age .

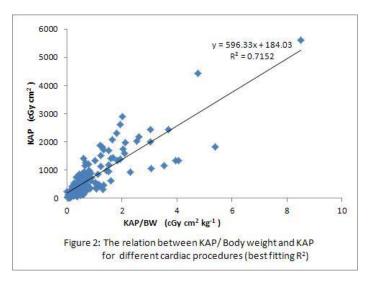

Table 1: Mean Kerma area product, Mean fluoroscopy time and Mean CD_{IRP} for different procedure .

Heart disease	No. of patients (n=198)	Mean fluoroscopy time (min.)	Mean KAP/W (cGyxcm² xkg⁻¹)	Mean CD mGy
ASD	25	18.5	864.2	88.8
R& L heart	100	17.86	925.17	118.1
PTA	15	11.2	815	113.6
Balloon	7	8.1	67	73
PDA	22	4.41	308.8	40.2

PS05.006 - In vivo dosimetry implementation with diodes at the National Radiotherapy Center of the Korle-Bu Teaching Hospital, Ghana

Author(s): <u>Vivian Della Atuwo-Ampoh</u>¹, Cyril Schandorf², Samuel N.A. Tagoe³, Eric K. Addison⁴

¹Medical Physics, School of Nuclear and Allied Health Sciences, University of Ghana Atomic Ghana, Accra/GHANA, ²School Of Nuclear And Allied Sciences, University of Ghana - Atomic Campus, Accra/GHANA, ³National Centre For Radiotherapy And Nuclear Medicine, Korle-Bu Teaching Hospital, Accra/GHANA, ⁴Oncology Directorate, Komfo Anokye Teaching Hospital, Kumasi/GHANA

Protocol for in vivo dosimetry using silicon diodes in radiotherapy department of the Korle-Bu Teaching Hospital is implemented. The diodes were calibrated using IAEA standards (TRS 389); correction factors were determined with solid water phantom and then implemented on patients.

The phantom studies conducted established that the mean deviation ($\Delta\pm\sigma$, %) between the measured and expected entrance doses was (0.34 ± 1.8%). Almost all were within ±5% as recommended by international standards .

The sites of measurement included; pelvis (n=60), head & neck (n=13), breast (n=48) and other cases (n=13) with corresponding mean deviations of $1.92\pm4.05\%$, $0.15\pm4.0\%$, $0.12\pm4.20\%$ and $1.66\pm3.23\%$ respectively.

Results obtained from patient measurements were comparable to works published in the literature. An overall mean deviation of $1.02\% \pm 4.1\%$ was observed (n=134). The percentage of measurement (N %) for which the deviation was within the 5% tolerance was 79.85%. About 3.73% of the total deviations were beyond 7%.

However, two actions levels were adopted for this study as 5% and 7% for simple and tangential fields respectively in line with similar studies using diodes in Poland.

The few major deviations that were however recorded can be attributed to sources of errors (wrong beam parameters) such as depth, wedges and the inability to precisely position the dosimeter in blocked and wedged fields.

There is more room for reduction of uncertainties associated with the measurement protocol by carefully limiting or avoiding all the errors

PS05.007 - Assessment of radiation dose due to radio frequency emitted from medical high voltage modules

Author(s): Mosa Moradi¹, Alireza Kamali Asl¹, <u>Mohammad Reza Ay</u>² ¹Radiation Medicine, Shahid Beheshti University, tehran/IRAN, ²Department Of Medical Physics & Biomedical Engineering, Tehran University of Medical Sciences, Tehran/IRAN

Public and occupational exposure of electromagnetic fields due to the growing trend of electronic devices may cause adverse effects on human health. The effects of radiofrequency (RF) radiation absorption on human health can be expressed as high temperature and thermal effects on body tissue. But it also lead to cancer in the body, especially the in head and nervous system. In this study, the dose resulting from the high voltage power supply (HVPS) that has built for the Single Photon Emission Computed Tomography (SPECT) system has been measured. Also, risks arising from the waves, according to a report by International Commission on Non Ionizing Radiation Protection (ICNIRP), to every organ of the body is defined by the beam and electromagnetic radiation from this electronic device on the human was investigated. In this study, the dose of high voltage module in switching mode at different frequencies using a scintillation detector was measured. Results showed that the maximum personal dose over 15 min working of mentioned HVPS don't exceed from 0.31 µSV/h (With aluminum shield). So, according to other sources of radiation, continuous working time of the system should not be more than 10 hours. Finally, a characteristic curve for secure working with modules at different frequencies been has reported. The RF input signal to the body for maximum penetration depth (δ) and specific electromagnetic energy absorption rate (SAR) of biological tissue can be obtained for each tissue.

PS05.008 - Software Assisted Skin Dose Calculation in Fluoroscopically Guided Interventional Procedures

Author(s): <u>Mohamed K. Badawy</u>¹, Daniel Carrion² ¹Medical Sciences, RMIT, Bundoora/AUSTRALIA, ²Independent, Melbourne/AUSTRALIA

Background

Patients undergoing fluoroscopically guided interventional procedures are subjected to ionising radiation which may lead to radiation injury. In order to predict the likelihood of radiation induced injury following a procedure a skin radiation dose estimation method must be employed. In order to achieve an accurate skin dose estimation from current monitoring methods, many factors must be taken into consideration and corrected for mathematically.

Objective

This presentation aims to instruct the audience how to calculate skin dose following a fluoroscopically guided procedure automatically by using the data provided in Digital Imaging and Communications in Medicine (DICOM) file headers and a simple Java program.

Methods

Using a Java program the audience is instructed in automating skin dose calculations for patients undergoing interventional procedures. This method relies heavily on manufacturer provided information found in the headers of DICOM files. The dcm4che project Java libraries are used in the Java program to interrogate this information from the DICOM files when calculating skin dose. This method is validated using direct measuring techniques to determine entrance skin dose which is then compared to values calculated by the program.

Results

The Java program is successfully used to calculate entrance skin dose following fluoroscopically guided procedures. However, there are many limitations that must be taken into considerations should this method be employed clinically. Validation of the program following corrections made for each unit provide accuracy to within 10%.

Conclusion

A Java program can be set up to automatically calculate the entrance skin dose from DICOM files following an interventional procedure. If limitations are taken into consideration this method proves accurate to within 10%.

PS05.009 - Current Statues of a-Si EPID Dosimtery: An Application for Dose Verification in Standard Radiotherapy Techniques Author(s): <u>Omemh Bawazeer</u>¹, Siva Sarasanandarajah¹, Sisira Herath², Tomas Kron², Pradip Deb¹

¹School Of Medical Radiation, RMIT University, Melbourne/AUS-TRALIA, ²Radiation Oncology, Peter MacCallum Cancer Centre, Melbourne/AUSTRALIA

As radiotherapy becomes more complicated, a required of dose verification is strongly recommended. Electronic portal imaging device (EPID) is a promising detector to use with the dose verification of radiotherapy technique. This is due to its advantages compared to other detectors, such as a high spatial resolution, large imaging area, and real-time acquisition and less setup time. Therefore, the implementation of EPID for dosimetry purpose in clinical practice has currently received a great attention with the increasing the need of dose verification [1, 2]. The purpose of this study is to firstly list the commercially available solutions for EPID dosimetry. Secondly offer the solutions that used to improve the performance accuracy of EPID dosimtry. Thirdly summarize clinical or proposed approaches based on EPID dosimtry for different radiotherapy techniques. The previous publications demonstrated a variety of reliable and accurate dose verification methods used based on EPID for intensity modulated radiotherapy (IMRT) while the dose verification with volumetric modulated arc therapy (VMAT) and stereotactic ablative body radiotherapy (SABR) is still under development [3-5], see Figure 1. However, further efforts are needed to optimize the time required for verification procedure based on EPID. Also, further research is required to study the possibility of replaced pre-treatment verification with in vivo verification. This may have the benefit of reduced workloads in clinical practice.

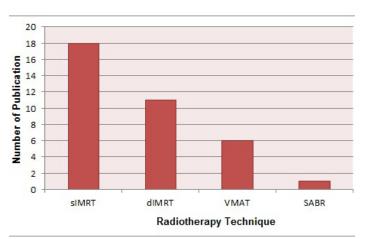

Figure 1: The current statues of a-Si EPID in dose verification

PS05.010 - Nanodosimetry of protons in the Bragg peak region based on ionisation cross sections of DNA constituents Author(s): Daniel Bennett, Benedikt Rudek, Mingjie Wang, Marion

Bug, Gerhard Hilgers, Hans Rabus

Fundamentals Of Dosimetry, Physikalisch-Technische Bundesanstalt (PTB), Braunschweig/GERMANY

The spatial distribution of energy deposited at the micro- and nanometre scale plays a crucial role in the radiobiological effectiveness of different radiation qualities [1]. Realistic numerical simulation of this distribution is fundamental to nanodosimetry and can be obtained using dedicated Monte Carlo track structure codes. Experimental nanodosimetry also benefits from these computer simulations, particularly for checking the detector response in a well characterised field and geometry. However, these track structure simulations rely heavily upon theoretical and measured interaction cross section data. Due to the absence of a complete set of ionisation cross sections for DNA in the literature, it is common practice in track structure simulations to use liquid water as a substitute for biological material.

Conducted within the framework of the European Metrology Research Program, the research project "BioQuaRT" [2] aims to develop a track structure simulation code based on a multi-scale approach and on interaction cross sections of DNA components. To achieve this aim, this work focuses on the measurement of double differential cross sections for the ionisation of pyrimidine, tetrahydrofuran and trimethylphosphate by protons with energies in the Bragg peak region. The first molecule represents two of the DNA bases, and the other two molecules represent the sugar and the phosphate residue of the DNA backbone. The experiments were carried out in our group's 150 keV ion accelerator. An electrostatic hemispherical electron spectrometer was used to detect the secondary electrons emitted at angles between 15° and 135° relative to the ion beam direction.

These ionisation interaction cross sections of DNA constituents are in the process of being evaluated and integrated into the multi-scale track structure code to obtain nanodosimetric quantities in biological matter and to benchmark the performance of nanodosimeters. Results will be presented at the conference.

PS05.011 - Micronuclei assessment of Selenium and Vitamin E radioprotective effects in human lymphocytes Author(s): <u>Vahid Changizi</u>, Aram Rostami

Technology Of Radiology And Radiotherapy, Tehran University of Medical Sciences, Tehran/IRAN

Intoduction

Critical macromolecules such as DNA are in exposure to damage of free radicals that induced from interaction of ionizing radiation with biological systems. selenium and vitamin E are natural campounds that have been shown to be a direct free radical scavenger. The aim of this study was to investigate the in vivo/in vitro radioprotective effect of selenium and vitamin E against genotoxicity induced by 6MV x-ray irradiation in human cultured blood lymphocytes.

Methods:

Five volunteers received selenium and vitamin E. Their peripheral blood samples were collected before and 1, 2 and 3 hours after taking selenium and vitamin E. The samples were exposed to 2Gy of 6Mv x-ray, and then were cultured with mutagenic stimulation to determine the chromosomal aberration with micronucleus assay on cytokinesis-blocked binucleated cells.

Result:

The lymphocytes in the blood samples collected at 1 hr after ingestion selenium and vitamin E, exposed in vitro to x-rays exhibited a significant decrease in the incidence of micronuclei, compared with control group at 0 hr. The maximum protection and decrease in the frequency of micronuclei(50%) was observed at 1 hr after administration of selenium and vitamin E.

Conclusion:

Selenium and vitamin E could be as radioprotector substances and may reduce genetic damage caused by x-ray irradiation.

PS05.012 - The Organ ans Skin Dose Distribution in Total Body Irradiation

Author(s): Jeongmin Yoon, Jungil Lee, Ho Lee, <u>Samju Cho</u>, Eungman Lee, Woonhoon Choi

Radiation Oncology, Yonsei University Health System, Seoul/KOREA

Purpose:

To achieve uniform dose distribution is the most important in total body irradiation. The aim of this work is to verify the organ dose distribution and skin dose distribution using OSLD within \pm 10% of the prescribed dose.

Materials and Methods:

An Adult male phantom (CIRS, Model 701, Φ 14mm hole placement for nanoDot) was irradiated bilateral total body technique. We placed optically stimulated luminescence detectors (OSLDs) inside the adult male phantom to measure the dose at brain, neck, lung, abdomen, pelvis and thigh. At the same time we placed OSLDs on adult male phantom to obtain skin dose during bilateral irradiation. The phantom was set at 410cm of source-axis distance (SAD) and irradiated with field size 164 ×164 cm² (40 x 40cm² at SAD 100cm) which covered the entire phantom with 10MV x-ray (Agility, Elekta Ltd, Crawley, UK). The prescription dose is 150cGy per fraction. We used aluminum compensators to adjust the thickness of tissue deficit easily.

Results:

From the OSLDs measurements, we obtained inside dose of phantom at the various anatomical regions. The differences from the prescription dose were shown: 0.8% (brain), 8.9% (neck), -2.64% (lung), +6% (abdomen), 0.78% (pelvis), -1.13% (thigh). We also checked the skin dose at the same organ plate positions: -8.5% (brain), -2.1% (neck), -0.9% (lung), 0.4% (abdomen), -4.3% (pelvis), 0% (thigh). All of the measured points showed within \pm 10% of the prescribed dose. As the results, we could achieve the homogeneous dose distribution of organ and skin during total body irradiation.

Conclusions:

The OLSDs results showed not only the organ homogeneous dose distribution but also skin uniform dose distribution during total body irradiation

Key words:

Total body irradiation, Organ and skin dosimetry, OSLD, Adult male phantom

PS05.013 - Comparison of 6MeV and 9MeV Electron Beams for Total Skin Irradiation

Author(s): <u>Ricardo Contreras</u>, Erick O. Montenegro, Erick E. Hernandez, Juan F. Lucero, Luis G. Garcia, Rafael E. Lengua, Luis A. Linares

 $\label{eq:metric} \begin{array}{l} \mbox{Medical Phisics, HOPE International Radiotherapy Center, Guatemala/GUATEMALA} \end{array}$

The total skin irradiation (TSI) is used to treat the Cutaneous T cell Lymphoma. The objective is to radiate superficially (3 to 5mm of depth) and evenly the entire patient's skin. The prescription dose is 36Gy in 1Gy daily fractions, 4 times a week. Protections for the eyes, gonads, nails and lips must be constructed.

The present work presents the comparison of two electrons beams (6 MeV and 9 MeV) generated by a Varian Clinac iX.

The Stanford technique was used. The distance calculated from the source to the patient was 3.90m.

Materials:

Varian Clinac iX linear accelerator, patient positioning platform, acrylic scattering screen (10mm thickness), IBA I'mRT phantom, PTW UNIDOS E electrometer, plane parallel ionization chamber PTW ROOS, PTW RW3 solid water phantom, GAFCHROMIC EBT3, EPSON PERFECTION V700.

Methods:

When using the Stanford technique, it's necessary to have a region of about 1.80m, depending on the patient's height, in which the field flatness is guaranteed to be below $\pm 10\%$ of variation. Because of the adaptors provided by the manufacturer, the field size was 36x36cm for the 9MeV and 34x34cm for the 6MeV beam. Since a single radiation field does not provide the desired flatness. It is indispensable to use two complementary fields that contribute 50% each and assure the desired flatness. The angle needed is calculated finding the 50% of a single irradiation field. The dose profile was measured using the gantry angles found, and it was below $\pm 10\%$ of variation for both energies.

Using the RW3 at treatment distance, the ionization chamber, the ionization-depth curve was found, from where the dose output was calculated.

Six different patient positions are used to complete a total irradiation, using three each day. These positions were simulated on the IBA phantom to obtain the dose distribution on a plane.

Results:

Measure	6 MeV	9 MeV
R100	3 mm	9 mm
R90	6 mm	14 mm
R80	8 mm	17 mm
R50	11 mm	22 mm
R10	15 mm	25 mm
Output	0.0635 cGy/MU	0.3911 cGy/MU
Gantry Angle	17.5°	15 ⁰
Treatment Time	3.5 min	48 min

Conclusion:

The best suited energy for the case is 6 MeV although the output is much smaller, translating to a longer treatment time.

PS05.014 - Analysis of Informal Commerce Sunglasses using Spectroscopy

Author(s): Juan Alberto L. Cruz, Tertuliano T. Neto, Ernando S. Ferreira

Department Of Physics, State University of Feira de Santana, FEIRA DE SANTANA/BRAZIL

Despite a growing of literature on the adverse biological effects of ultraviolet radiation on eyes and skin, a considerable number of persons follow buy sunglasses in informal commerce establishments, for photoprotection of the eye exposure at the ultraviolet radiation in sunlight. The main goal of this work was to perform experiments to verify if the sunglasses lenses with their filters types provide or not protection against ultraviolet radiation (280 - 380nm), in agreement with the specification of the European British Standard norm EN1836:2005, EN 1836. The experimental setup is basically composed by radiation sources (60 W white light and mercury lamps), which passes through the sunglasses lenses, and transmitted electromagnetic radiation is collected and guided by a optic fibre of 1 mm of diameter and 1 m of length connected to a spectrometer USB4000 from Ocean Optics. Then the spectrometer is coupled to a computer through which the measurements are controlled and analyzed using the Spectra Suite software. The spectrometer were configured to performed, transmission spectroscopy, to evaluate the lenses filtering power to ultraviolet radiation of 21 sunglasses pars (42 lenses) commercialized in informal establishments of Feira de Santa city, in Bahia, Brazil. The results from the transmittance experiments in the visible, all lenses of the sunglasses were classified in categories according to requirements of the Standard norm mentioned above. From the analyze of the results obtained in the transmittance experiments with the UV radiation, 04 sunglasses of 21 (19,04%) were considered no conforms because they allow the passage of ultraviolet radiation between 280 and 380 nm, and could produce adverse biological effects on eyes in accordance with the standards.

PS05.015 - Dosimetric Evaluation Of Lung Dose Using Indigenously Developed Respiratory motion phantom Author(s): <u>G Dheva Shantha Kumari</u>¹, Shanmugam Senthilkumar² ¹P.g. Dept. Of Physics, Fathima College, Madurai/INDIA, ²Radiotherapy, Govt. Rajaji Hospital & Madurai Medical College, Madurai/ INDIA

Introduction

Respiration induced organ motion is one of the major uncertainties in lung cancer radiotherapy,which may cause clinically significant targeting errors and greatly degrade the effectiveness of conformal radiotherapy.Motion of the tumor due to respiration during the radiation treatment process is difficult to manage.Without managing the respiratory motion, the critical organs may receive high radiation dose with decreasing target dose.Intrafraction motion is an issue that is becoming increasingly important in the era of IMRT.Intrafraction motion can be caused by the respiratory, skeletal, muscular, cardiac and gastrointestinal systems. The main aim of the present study was to evaluate the lung dose in the presence of respiratory movement and absence of movement in lung and also compare the dosimetric difference using indigenously developed Respiratory Gating Platform.

Material and Methods

Respiratory motion platform (RPM) was designed indigenously and constructed for testing the targeting accuracy of the lung tumor in respiratory condition. It consists of acrylic Chest Wall Platform, 2 DC motors, 4 IR sensors, speed controller circuit, 2 LEDS and 2 moving rods. The essential component of the device is a movable platform mounted to a base using precision linear bearings. The base and platform are made of clear, 15mm thick polycarbonate plastic. The

platform is driven along a linear trajectory using a motor controller that drives a stepper motor attached to the Bi-slide assembly. The targeting accuracy of the respiratory tracking system was evaluated with varied amplitude of skin motion, respiratory rate and tumor distance. The device was designed to be able to simulate the gross anatomical anterior posterior motion attributable to respirationinduced motion of the lung. Depending on the particular application, an appropriate phantom would be placed on the platform. Speed of motion is controlled by Control knob. This parameter controls the period, or how fast one breath cycle in seconds takes place. This value can be adjusted in 1/2 second intervals between 2 and 6 seconds.

Results:

The RMP was used to measure the 20 lung tumor patients with treatment planning system (TPS) calculated dose in both the respiratory and non respiratory condition. We have found 3% dose difference between the TPS calculated dose and measured value with the help of RMP in respiratory and non respiratory condition. So, for lung cancer radiotherapy treatment, respiratory motion has to be taken for better dose delivery to the lung tumor.

PS05.016 - Activation of Medical Linear Accelerators Author(s): Adam C. Dodd

Accelerators, Canadian Nuclear Safety Commission, Ottawa/CANADA

Purpose: Radioactivity is induced in medical linear accelerators (linacs) operating at high energies for extended periods of time through photoneutron reactions and subsequent neutron capture. The disposal of linacs is a potential health hazard especially for workers engaged in recycling the tungsten parts. New gamma spectroscopy data and recent experimental data on neutron production in combination with published Monte Carlo results have enabled a general analysis of the longer lived radioactivity induced in linacs.

Methods: A mechanically cooled high purity germanium detector placed at isocentre was used to identify the gamma emitting isotopes for a Truebeam STX. Self absorption correction factors are derived from the data by a differential absorption analysis. Neutron production data in combination with Monte Carlo results are used to determine the activities of pure beta and electron capture radioisotopes.

Results: The principal activities with half-lives longer than 1 day are W-181, W-185, Co-57, Co-60 & Mn-54. Results are presented for Elekta, Siemens and Varian models as a function of beam energy, workload and operating lifetime. The length of time activated components from a decommissioned linac should be kept before they can safely be disposed of is presented for Elekta, Siemens and Varian models.

PS05.017 - Assessment of Patient Dose in Selected Non-Cardiac Interventional Fluoroscopy Procedures Using OSL Dosimeters

Author(s): Isabel A. Elona

Center For Device Regulation, Radiation Health, And Research, Department of Health - FDA, Manila/PHILIPPINES

In recent years, interventional procedures have composed a major part in diagnostic radiology and increasingly replaced many surgical procedures. Despite its advantages, the utilization of ionizing radiation for diagnosis delivers radiation doses which present risk to the patient. The fundamental principles of radiation protection call for exposures to patients that are As Low as Reasonably Achievable (ALARA). The purpose of this study was to assess the level of radiation from selected non-cardiac interventional fluoroscopy procedures at the University of Santo Tomas Hospital, Cardiac Catheterization Laboratory. Radiation dose measurements, using Optically Stimulated Luminescence Dosimeters (OSLD) were performed on 4 patients on femoral angiogram and hepatic embolization. The results showed that interventional procedure such as embolization of the liver may exceed the threshold value for deterministic effects.

PS05.018 - Measurment of Photon and Neutron Dose Distribution in Cyclotron Bunker During F18 and N13 Production Author(s): Pardis Ghafarian¹, Seyedeh Masoumeh Khamesi¹, Mohammadrasa Golrokh Nodehi¹, Mohammad Reza Ay² ¹Chronic Respiratory Diseases Research Center, National Research Institute Of Tuberculosis And Lung Diseases (nritld), Shahid Beheshti University of Medical Sciences, tehran/IRAN, ²Department Of Medical Physics & Biomedical Engineering, Tehran University of Medical Sciences, Tehran/IRAN

Introduction: Self-shield hospital cyclotrons have been received a considerable attention due to have compact size and no necessity for concrete bunker. It is well known that during the bombardment of target in cyclotrons, neutron and gamma flux are produced. However, the activation caused by neutron interaction has considerable radiological hazard in cyclotron components. For safety purpose, measuring of neutron and photon dose rate in the area close to the shield are mandatory. In this investigation we measured the neutron and photon dose rate during 18F and 13N productions in different distance from radiation shield of GE PET Trace 700 the self shield cyclotron that recently installed in Masih Daneshvari hospital.

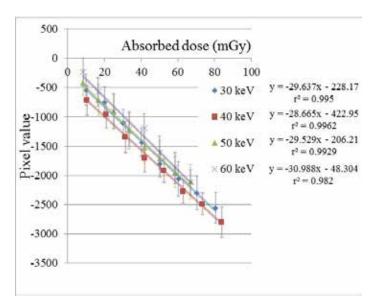

Material and methods: Dose rate measurement were done by neutron dosimeter (LB 6411) and Geiger Mueller dosimeter (BNS-92) during the operation of the cyclotron using different target current at various distance (from 0.5 to 2.5 meter) of self-shield cyclotron in step of 0.5 meter around the cyclotron. All measurements were done at the floor level and also the height of one meter (target position).

Results: With increasing target current from 30 to 35μ A at the distance of 0.5 meter at the gap between left and right doors, the gamma dose rate varies from 8.9 to 10.7μ Sv/h and decreasing neutron dose rate were obtained from 10 to 5.2μ Sv/h with increasing distance from 0.5 to 2.5 meter at the height of one meter, during the F-18 production. Whereas the gamma dose rate increases from 2.86 to 8.6 μ Sv/h at the distance of 0.5 meter from cyclotron during N-13 production with increasing of operation current from 30 to 35μ A. at 2.5 meter far from cyclotron at the interface of left and right doors this quantity reduced to 2 μ Sv/h at 35 μ A target current.

Conclusion: the low level of neutron and gamma dose rate outside the self-shield of cyclotron indicated that the polyethylene and concrete component used in GE PET Trace 700 cyclotron can produce nearly safe condition for entire the cyclotron bunker.

PS05.019 - Energy response of the GAFCHROMIC EBT3 in diagnosis range

Author(s): Tatsuhiro Gotanda¹, Toshizo Katsuda², <u>Rumi Gotanda³</u>, Tadao Kuwano⁴, Takuya Akagawa⁵, Nobuyoshi Tanki⁶, Akihiko Tabuchi⁷, Tetsunori Shimono¹, Yasuyuki Kawaji¹, Tadamitsu Ideguchi¹ ¹Department Of Radiological Science, Faculty Of Health Sciences, Junshin Gakuen University, Fukuoka/JAPAN, ²Department Of Human Relation, Tokai Gakuin University, Kakamigahara/JA-PAN, ³Department Of Radiological Sciences, Ibaraki Prefectural University of Health Sciences, Inashiki-gun, Ibaraki/JAPAN, ⁴Osaka Center for Cancer and Cardiovascular Diseases Prevention, Osaka/ JAPAN, ⁵Department Of Radiological Technology, Tokushima Red Cross Hospital, Tokushima/JAPAN, ⁶Center For Life Science Technologies, RIKEN, Kobe/JAPAN, ⁷Kawasaki Medical School Kawasaki Hospital, Okayama/JAPAN Although GAFCHROMIC EBT3 (EBT3) as a radiochromic film shows only slight energy dependency errors in comparison with other radiochromic films, the influence of energy dependence in the diagnosis energy range (less than 100 keV) is larger in the high energy range (over 100 keV). Based on this characteristic, adaptation of the EBT3 dosimetry in the diagnosis range was investigated. The energy response of the EBT3 in the diagnosis range at 30, 40, 50, 60 keV was measured using the density-absorbed dose calibration curve of the absorbed dose versus film density for the EBT3. Various data (degree of leaning, coefficient of determination) of each effective energy were compared. The density - absorbed dose calibration curves were linearly correlated in each of the effective energies. There was an energy dependent error of approximately 0.2 % from 30 to 60 keV (Fig. 1). As a result, it can be seen that the EBT3 is available in the diagnosis energy range. However, the influence of the non-uniformity error caused by the repeatability of the scan method must be considered because EBT3 distortion has a serious influence on measurement precision.

PS05.020 - Estimation of In Vivo Dosimetry Accuracy with Dose-Volume Histogram

Author(s): <u>Victor A. Gurvich</u>¹, John M. Pacyniak¹, Delnora Erickson² ¹Government Contractor In Radiology Clinic, Fort Belvoir Community Hospital, Fort Belvoir/UNITED STATES OF AMERICA, ²Radiation Oncology, Fort Belvoir Community Hospital, Fort Belvoir/UNITED STATES OF AMERICA

In vivo dosimetry is widely used for verification of the absolute dose received by patient during radiation treatment delivery. The difference between measured dose and calculated at the same point with treatment planning system (TPS) often exceed 5% and depends on patient's setup variation, organ movement and dose gradient in the point of measurement. The purpose of this study is the estimation of uncertainties and dose accuracy measured with small dosimeters like TLD, OSLD or MOSFET during radiation treatment delivery.

Our novel method for dosimetry measurements takes into consideration distance-to-agreement between measured and calculated points. However, instead of gamma index used as QA criteria in IMRT we apply a dose-volume histogram (DVH) for the area of assumed infra- and inter-fraction movement of measurement point. This area called a region of measurement (ROM) includes all most probable measurement points and can be contoured with TPS tools as organ at risk. Both cumulative and differential DVHs can be used for the analysis of in vivo dosimetry accuracy in the established acceptable dose interval. In our experiments we scanned an anthropometric phantom with Philips Brilliance Big Bore CT simulator and established measurement points in three regions: head & neck, chest, and pelvis. Then 3D conformal treatment plans for head and lung areas and IMRT plans for prostate were created. The prescribed dose for targets was 200 cGy per fraction.

The radiation dose was measured in given points using OSLD and MOSFET dosimeters. Analyzing the DVH we defined the acceptable dose interval from D80 to D20. These intervals (and measured doses) were 184.6 - 210.4 (measured 191.1) cGy for the head and neck plan, 83.7 - 92.7 (87.1) cGy for lung, 73.6 - 89.3 (74.3) cGy for prostate IMRT and 62.0 - 86.4 (64.0) cGy for prostate rapid arc plan. The length of dose intervals depended on the treatment site, location of measurement point, size of ROM, and type of treatment plan. In all studies the measured doses fell into the given acceptance interval, thereby validating the novel method as a way to perform real-time dosimetry.

The proposed method allows estimating the accuracy of delivered dose taking into account the displacement of the measurement point. It applies flexible and justified acceptance criteria. It is possible to define the limits of dose deviation during a treatment planning process. The influence of distance and direction of the measurement point displacement as well as ROM heterogeneity on dosimetric accuracy can be quantitatively analyzed.

PS05.021 - Evaluation of the dosimetric properties of water equivalent microDiamond detector in high energy photon beam.

Author(s): Hyun Do Huh¹, Chang Yeol Lee¹, Woo Chul Kim¹, Young Hoon Ji², Hun Jeong Kim¹, Sang Hoon Lee³, Chul Kee Min⁴, Kum Bae Kim², Gwang Hwan Jo⁵, Dong Oh Shin⁶, Seong Hoon Kim⁷ ¹Radiation Oncology, Inha University Hospital, Incheon/KOREA, ²Research Institute of Radiological and Medical Sciences, Korea Institute of Radiological and Medical, seoul/KOREA, ³Department of Radiation Oncology, College of Medicine, Kwandong University, Gangdeung, seoul/KOREA, ⁴Department of Radiation Oncology, College of Medicine, Soonchunhyang University, Cheonan/ KOREA, ⁵Department of Radiation Oncology, College of Medicine, Soonchunhyang University, boocheon/KOREA, ⁶Department of Radiation Oncology, College of Medicine, Kyunghee University, Seoul/ KOREA, ⁷Department of Radiation Oncology, College of Medicine, Hanyang University, Seoul/KOREA

The aim of this study was to evaluate the characteristic of a water equivalent synthetic diamond detector (PTW 60019 microDiamond, Germany) for the small field dosimetry in high energy photon beam. We have obtained data in cyberknife 6 MV photon beams of six different collimator size (from 5mm to 30 mm). Data were included dose linearity, dose rate dependence, output factors (OF), percent depth doses (PDD) and off center ratio (OCR). The results were compared to those of pinpoint ionization chamber, Old diamond detector, microLion liquid Ionization chamber and diode detector. The dose linearity results for the microDiamond detector showed good linearly proportional to dose. The microDiamond detector showed little dose rate dependency throughout the range of 100~600 MU/ min, while microLion liquid Ionization chamber showed a significant discrepancy of approximately 5.8%. The OF measured with micro-Diamond detector agreed within 3.8% with those measured with diode. PDD curves measured with silicon diode and diamond detector agreed well for all the field sizes. In particular, slightly sharper penumbras are obtained by the microdiamond detector, indicating a good spatial resolution. The results obtained confirm that the new PTW 60019 microDiamond detector is suitable candidate for application in small radiation field dosimetry. In future, we are evaluating using the Monte Carlo method in high energy photon beam.

PS05.022 - From simple to advanced dosimetry audits in radiotherapy: IAEA coordinated research

Author(s): Joanna Izewska, Pranabes Bera, Paulina Grochowska, Barbara Bencsik, Ahmed Meghzifene Nuclear Sciences And Applications, International Atomic Energy Agency, Vienna/AUSTRIA

A series of four coordinated research projects (CRPs) were conducted by the IAEA in 1995-2015 focusing on development of national quality audit programmes for radiotherapy dosimetry in low and middle income countries. The first CRP started with remote audits of beam output in reference conditions using thermoluminescent dosimetry (TLD). The audit programme was then extended through the second CRP to include dose audits in non-reference conditions for high energy photon and electron beams. The third CRP, concluded in 2012, has expanded the dosimetry audit tools to more complex techniques used for cancer treatment. New methodology has been developed and tested for dose audits of irregular fields shaped with mulileaf collimators (MLC), dose in the presence of heterogeneities and 2D profiles of small photon MLC shaped fields. This audit programme was based on TLDs and radiochromic films and used specially designed phantoms. The current CRP, initiated in 2013, focusses on dosimetry audits for more advanced technology in radiotherapy dose delivery. Auditing methodology has been developed for remote verification of calculation of small beam output factors by treatment planning systems (TPS), film audit of MLC positional performance for intensity modulated radiotherapy (IMRT), film audit of single clinical IMRT field dose delivery and 'end-to-end' dosimetry audit (imaging, planning, dose delivery) for multiple field IMRT techniques using TLDs and radiochromic films. This approach of gradually increasing the audit programme complexity was adopted to learn from experience of previous audit steps and to apply consistently the methods for development, testing and analysis of results for subsequent audit steps.

The IAEA Dosimetry Laboratory has participated in the experimental part of the CRPs, developed new phantoms and conducted multi-centre pilot studies to test the newly developed methodologies. Following such studies, the CRP participants adopt the methodology and organize trial audit runs with local radiotherapy centres in their countries. In addition, the IAEA contributes to strengthening QA of national audit networks by exchanging dosimeters with national dosimetry laboratories. Through the link with the IAEA Dosimetry Laboratory, the national networks closely cooperate at the consecutive stages of developing the dosimetry audit methodology locally and by carrying out cross-measurements. In this way the national audit systems are interlinked to ensure that international and national radiotherapy dosimetry audit networks are working to the consistent levels and standards.

Overall, the IAEA has supported the establishment of several national audit groups for radiotherapy dosimetry and assisted in the development of methodology for a range of dosimetry audit levels, from basic to advanced. The scope of the dosimetry parameters included in subsequent audits corresponds to the evolving complexity of radiotherapy as more advanced technologies are becoming increasingly used for cancer treatment across the world.

PS05.023 - Noise reduction of radiochromic film: median filter processing of subtraction image

Author(s): <u>Toshizo Katsuda</u>¹, Rumi Gotanda², Tatsuhiro Gotanda³, Takuya Akagawa⁴, Nobuyoshi Tanki⁵, Tadao Kuwano⁶, Kouichi Yabunaka⁷

¹Department Of Human Relation, Tokai Gakuin University, Kakamigahara/JAPAN, ²Department Of Radiological Sciences, Ibaraki Prefectural University of Health Sciences, Ibaraki/JAPAN, ³Department Of Radiological Science, Faculty Of Health Sciences, Junshin Gakuen University, Fukuoka/JAPAN, ⁴Department Of Radiological Technology, Tokushima Red Cross Hospital, Tokushima/JAPAN, ⁶Center For Life Science Technologies, RIKEN, Kobe/ JAPAN, ⁶Graduate School Of Health Sciences, Okayama University, Okayama/JAPAN, ⁷Graduate School Of Medicine, Tokyo University, Bunkyou-ku/JAPAN

Pre-ultraviolet rays exposure is a useful method to reduce non-uniformity error of radiochromic films. However, dust and scratch noises such as spike noise disturb precise measurement. To reduce these noises, median filter processing is applied for pre-subtraction and subtraction images.

To reduce non-uniformity error of the thickness unevenness of Gafchromic EBT film, ultraviolet rays were exposed to correct data. There were three kinds of images obtained: first ultraviolet exposure image, second ultraviolet exposure image and the subtraction image of both. Median filer processing was performed on all these images. Eleven kinds of median filter radius factors (0.0 to 5.0) were applied using image analysis software. Data and graphs were then estimated.

The maximum pixels value of dust was 229 on the second ultraviolet exposure image of film 3. After median filter pre-processing, the pixel value of the noises were similar to the minimum value. A 2.0-radius median filer is a useful factor for processing.

Noise reduction that affected data of estimated images may be applied to measure radiation doses on a variety of radiochromic films. Ultraviolet exposure and subtraction method with median filter processing enable precise measurement and high spatial resolution dose distribution.

PS05.024 - Proposed Guidelines for Image Quality in Chest PA X-Ray Examinations in Bangladesh Author(s): <u>Shahed Khan</u> UCL, Twickenham/UNITED KINGDOM

Abstract— The common practice for chest PA examinations in Bangladesh employ low kV imaging. This practice involves low-contrast images and requires much larger radiation doses than those associated with higher beam energy. Thus, we propose a model relating the change of Entrance Surface Dose (ESD) in response to changes in beam energy, in accordance with European standards for diagnostic radiographic chest imaging to find the optimal ESD corresponding to values of kVp used in Bangladeshi hospitals.

Results show that in order to maintain the standards of Quality for Diagnostic Radiographic Image every 10kVp increase in beam energy must be followed by a decrease of 8/6 in ESD that corresponds to a reduction of 15% in the equivalent dose. Hence, the range of optimal ESD accounting for the kVps practiced for chest PA examinations is 5.6-10 mGy, which represents a factor of 35 above the recommended ESD.

Finally we investigate the effect of Body Mass Index (BMI) on optimal ESD for overweighed Bangladeshi patients. We find that, for each additional 1kg, the ESD must increase 18% in order to maintain standards for chest PA x-ray image.

PS05.025 - Evaluation of inhomogeneity correction using monte carlo simulation in stereotactic body radiation therapy (SBRT)

Author(s): <u>Ji Na Kim</u>¹, Hun Joo Shin², Hong Seok Jang³, Young Nam Kang³

¹Department Of Biomedical Engineering, College of Medicine, The Catholic University of Korea, Seoul/KOREA, ²Department Of Radiation Oncology, Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Incheon/KOREA, ³Department Of Radiation Oncology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul/KOREA

Stereotactic Body Radiation Therapy (SBRT) requires high accuracy in order to protect surrouding normal tisse and destroy the tumor. The dosimetric behavior of the small beams used in SBRT in the presence of low-density inhomogeneities is critical for accurate dose optimization. In inhomogeneity materials for the lung, dose correction is not applied with the values calculated by applying the difference in calculation of the difference told that more than 30% are reported. Significant differences in dose calculation were made to compensate for heterogeneous material. However, the evaluation of dose calculation in molding the slope has not been accomplished. Integrated high-dose molding of slopes for dose calculation accuracy is critical. In this study, molding equipment for SBRT was acquired, including heterogeneinous material, to evaluate the accuracy of dose calculation. The accuracy of treatment planning and measurement data, which applied the inhomogeneity correction factor made comparison with result of monte carlo simulation. To measure and evaluation the effects of heterogeneous medium, a inhomogeneity correction phantom is required. Inhomogeneity Correction Phantom (ICP) is able to insert the inhomogeneity materials, which have 12 types in each different electron density. Also it is able to adapt the EBT film and 0.125 cc ion chamber for measurement of dose distribution and point dose. In comparison with monte carlo simulation, the average difference applied the inhomogeneity correction factor was 1.63% and 10.05% in each plan and film measurement data, respectively. In addition, the average difference in dose distribution was 10.09% for each measurement film. The average difference of point dose was 0.43% and 2.09% in each plan and measurement data, respectively. In conclusion, if the inhomogeneity correction factor was not applied in small field, a greater difference in measurement data was observed. In SBRT using small field, it needs to precisely identify the correct inhomogeneity correction factor.

PS05.026 - Dosimetric effect of low dose 4D CT by a commercial iterative reconstruction on dose calculation in radiation treatment planning: A phantom study

Author(s): <u>Hee Jung Kim</u>, Ah Ram Chang, Sung Yong Park Soonchunhyang University Hospital, Seoul/KOREA

We investigated the HU and dose difference due to the use of CT images acquired with the reduced imaging dose by using a commercial iterative reconstruction technique (iDose, Philips). The phantom with various density materials from 0.2 g/cc to 1.53 g/ cc was scanned by the Philips Big Bore CT, using two energies (90 and 120 kV) and four currents (50, 100, 200 and 400 mAs). The CT images were reconstructed with and without iDose with level 5. As the density is higher, the use of iDose increased the mean HU that the maximum change of mean HU was 109 HU in 1.53 g/cc bone core material at 90 kV. At the same energy, the HU with reducing mAs showed a difference less than 27 HU. The 4D CT of lung phantom (CIRS) was scanned with two different exposures of 598 mAs without iDose and 163 mAs with iDose. We performed 2D and VMAT spine planning and 3D CRT and VMAT lung planning based on the 50% phase of CT with and without iDose reconstruction. The difference of mean dose was within 1% in all plans. Therefore, this dose reduction technique in big bore CT is applicable to the radiotherapy

treatment planning. If the high density material is included, it should be used with a caution for the dose calculation in the treatment planning because the HU difference due to the iDose is greater as the density is higher.

PS05.027 - An Evaluation of the Use Factor for CyberKnife using Clinical Data

Author(s): Yu Ra Cho¹, <u>Dong Han Lee¹</u>, Yong Min Lee¹, Mun Kyu Park¹, Han Yeong Lee², Ung Kyu Chang¹

¹Korean Institute of Radiological & Medical Sciences, Seoul/KO-REA, ²HanBeamTec, Seongnam-si/KOREA

In order to reduce the regulation limit of integral dose of CyberKnife to below 10%, presently the international guideline standard of the CyberKnife use factor is 0.05(%), which is very small compared to 5~40(%) of conventional radiation therapy, and this shows that the shielding standard of CyberKnife is very strict. In this study, based on the clinical data of patients who had received CyberKnife treatment, tried to examine the adequacy of the existing shielding guideline. 60 patients among approx. 220 who had received CyberKnife (ver. 9.5, Accuray, Sunnyvale, USA) treatment from February 2013 to May 2014 were selected and for intracranial and body, two groups of 30 patients were classified into skull tracking and spine tracking mode. After extracting the specific trajectory of the robot on the beam data of each patient, the direction of the beam towards the shielding wall by using the origin (ver. 9.1, OriginLab, USA) program was reproduced in three dimensions. And many beams examined in each direction were set as one zone, and then MU of formed beams was analyzed. And in order to estimate shielding workload and IMRT factor, prescription dose and total MU were analyzed at the same time. Intracranial patients received an average of 1.9 fractions with 12 Gy per fraction prescribed at the 80.2% isodose line, using 147.2 beams and 1,8163 MU. Body patients received an average of 3.63 fractions with 9.5 Gy per fraction prescribed at the 77.6% isodose line, using 166.6 beams and 4,7942 MU. The most used collimator size was 7.5~35 mm, and fixed and Iris collimators of 1~4 types of size were used. In intracranial and body treatments, 82% of the total beams were distributed being directed towards the floor, and there were few beams directed towards the ceiling. And 18% of the beams were directed towards the surrounding walls and for body no beams were directed to the right side wall from the position of couch. It could be confirmed that more beams were spread on the walls in intracranial than body, and as a result of analyzing MU of each beam, it could be observed that more 'hot zone' were produced in intracranial than body. Because use factor and IMRT factor recommended by the CyberKnife shielding guideline are small and large respectively, more barriers are required for shielding of CyberKnife treatment rooms, which leads to spatial in-efficiency and cost increase in hospitals. Thus, if the use factor analyzed in this study based on the clinical data is considered in designing treatment rooms, more reasonable treatment room designing may be possible.

PS05.028 - Lung Dose Estimation for a Total Body Computed Tomography Protocol

Author(s): Juliana C. Martins, Denise Y. Nersissian, Paulo R. Costa Radiation Dosimetry And Medical Physics Group, Physics Institute, University of São Paulo, São Paulo/BRAZIL

Introduction: Computed Tomography (CT) procedures are important diagnostic tools. It is estimated that CT accounts for over 13% of all diagnostic examinations, contributing for approximately 30% of the collective dose in the United States. In Germany, CT represents 7% of total X-Ray examinations, with contribution of 60% for collective effective dose. This work studies a methodology to estimate lung doses on an adult anthropomorphic phantom (The Phantom Laboratory, Salem, USA), undergoing total body CT using Lithium-Fluorite (LiF) thermoluminescent dosimeters (TLD).

Methods: LiF TLDs were introduced inside the holes of the phantom, in nine slices, correspondent to lung position (Figure 1). Fourteen groups of five dosimeters were allocated in dosimeterholders designed for this purpose. The phantom was irradiated in a PET/CT scanner (Discovery PET/CT 690, GE Healthcare). After performing double scan projection radiographs (SPR) (anteroposterior and lateral), the phantom was irradiated using a total-body protocol. TLD data were read by TL/OSL reader Risø (DTU Nutech, Inc.,Roskilde, Denmark) and these results converted to "counts" by a routine implemented with the Software Origin 8.5.1 (OriginLab Co., MA, USA). These counts were corrected to a calibration curve, for radiation quality RQT 9. Mean absorbed dose, D, for the lung were calculated using equation (1)

$D = \sum_{i} f_{i} \cdot D_{i} (1)$

where f_i is the fraction of the total lung mass in phantom slice D_i and is the average dose to the organ in slice.

Figure 1– Adult anthropomorphic phantom positioned inside the gantry (above); positions of the dosimeter-holders (in green) inside slice 15 (below).

Results and Discussion: The lung dose value obtained was (44.4 \pm 1.5) mGy, with 0.148 mGy.mAs⁻¹ This value is considered reasonable when compared to similar studies. The doses due to both SPR are accounted in this estimation, which could explain this larger absorbed dose values.

Conclusions: This work shows a methodology to estimate lung doses to adult anthropomorphic phantom due to CT exams. The methodology will be extended to other organs of interest and other protocols in the course of time, and also adapted to a pediatric anthropomorphic phantoms.

SP05.029 - Verification of axial dose distributions with radiochromic films for a translational Total Body Irradiation technique

Author(s): Bozidar Casar, Ignasi Mendez, David Cugura Institute of Oncology Ljubljana, Ljubljana/SLOVENIA

Purpose:

Radiochromic films were used to validate dosimetrically a translational Total Body Irradiation (TBI) technique. The main objective was to analyze the homogeneity of the dose distribution in the axial plane for the thoracic and pelvic regions. Additionally, the surface dose was studied for two different positions of the PMMA beam spoiler.

Methods and materials:

Two phantoms were used: CIRS Thorax (Model 0002LFC, Computerized Imaging Reference Systems Inc. Norfolk, VA) and CIRS Pelvis (Model 002PRA). They were irradiated according to a translational TBI technique [1] in supine and prone positions, and with a 1 cm PMMA spoiler situated 15 cm and 125 cm above the phantom surface. For each irradiation, two 8 in. x 10 in. EBT3 Gafchromic films (Ashland Inc., Wayne, NJ) were used to measure the dose distribution in the phantom. Doses were calculated using Radiochromic. com v1.7 (http://radiochromic.com) [2].

Results:

The homogeneity index (HI), calculated as D5/D95, was 1.16 and 1.23 for the pelvis and thorax phantom, respectively. This was mainly due to the shape of the phantoms, which become thinner in the lateral direction, producing doses up to 20% higher in the laterals than in the midline. Considering only a segment of the dose plane of 6cm around the midline (3cm on each side), the HI was 1.03 and 1.07 for the pelvis and thorax phantom, respectively, exhibiting higher dose homogeneity in the anteroposterior axis. When the spoiler was situated 15 cm above the phantom surface, the skin dose in the midline was 94% of Dmax. When it was 125 cm above the phantom, the same isodose was achieved at a depth of 6 mm.

Conclusions:

It was concluded that a 1 cm thick PMMA beam spoiler, situated 15 cm above the phantom, raises the surface dose to an acceptable level. Near the midline, this TBI technique delivers a dose homogeneity in the anteroposterior axis well within the common limits of +/- 10% relative to the prescription dose. For thinner regions, higher doses up to 25% relative to the prescription dose were considered admissible with the present technique.

PS05.030 - Experimental assessment of out-of-field dose components in high-energy electron beams used in external-beamradiotherapy

Author(s): <u>Mohamad Mohamad Alabdoaburas</u>¹, Jean Pierre Mège², Jean Chavaudra², Atilla Veres³, Florent De Vathaire², Dimitri Lefkopoulos², Ibrahima Diallo²

¹University of Paris-Sud(11), Orsay/FRANCE, ²Madical Physics, Gustave Roussy, Villejuif Cedex/FRANCE, ³Equal-Estro laboratory, Villejuif Cedex/FRANCE

Purpose/objective:

The higher survival rate of radiotherapy patients entails a growing concern on late effects associated to peripheral doses. The purpose of this work is to evaluate experimentally the peripheral dose outside applicators at the patient level, in different high-energy electron beams used in external-beam-radiotherapy.

Methods and materials:

Commissioning was performed for 6,9,12 and 18 MeV electron beams on three different linear accelerators equipped with three different types of applicators. For each beam energy, measurements were performed, in a water phantom, at different depths, with applicator sizes varying from $6 \times 6 \text{ cm}^2$ to $20 \times 20 \text{ cm}^2$, for off-axis distances from 5cm to 65cm outward. Thermoluminescent dosimeters (TLD-700) powder measurements were compared to EBT3 films measurements and plane-parallel ionization chamber NACP measurements. Measurements at 10 cm without applicator were made and were compared to the same measurements with applicator.

Results:

Whatever the field size and energy beam, a peak dose spot appeared about at 12.5 cm from the field edge for the Siemens applicators. For Siemens Primus with an applicator size of 10 x 10 cm², this peak reaches 2.3%, 1%, 0.9% and 1.3% of the maximum central axis dose (Dmax) for 6,9,12 and 18MeV electron beams, respectively, doubled for 6 x 6 cm², field size. For Siemens Oncor, with the above applicator size, this peak dose reaches 0.8%, 1%, 1.4% and 1.5% of Dmax for 6,9,12 and 14 MeV, respectively, increased when applicator size increased. In contrast for Varian 2300C/D, the doses at 12.5 cm from field edge are 0.3%, 0.5%, 0.6% and 1.1% of Dmax for 6, 9, 12 and 18MeV, respectively, increased with increasing of applicator size. No peak dose spot is evidenced for Varian applicator. Measurements made at 10cm depth show that, depending on beam energy, applicator size, collimator size, and out-of-field distance, the peripheral dose represents 0.01% to 1% of Dmax. Peripheral dose, for the measurements made at 10cm depth without applicator, was of 55% less than peripheral dose for the same measurements with applicator.

Conclusion:

In certain circumstances the peripheral doses from electron beams may be comparable to values reported for photon beams. Our results should be considered in the optimization of treatment planning and also in studies exploring RT long term effects.

PS05.031 - Dosimetric study for a set iodine-125 seeds using radiochromic films in solid water plates

Author(s): <u>Arnaldo P. Mourao Filho</u>¹, Lucas C. Tomaz², Suely E. Grynberg³

¹Nehos, CEFET-MG, Belo Horizonte/BRAZIL, ²Centro de desenvolvimento da Tecnologia Nuclear, Belo Horizonte/BRAZIL, ³Centro de Desenvolvimento da Tecnologia Nuclear, Belo Horizonte/BRAZIL

Brachytherapy seeds are frequently used in cancer treatment. A set of four iodine-125 seeds, model 6711 produced by Amersham Health, were used in this work. These seeds are ranked among the top choices when it comes to the treatment of prostate cancer. These sources emit X and gamma photons with an average energy of 28 keV and a half-life of 59.4 days. The dosimetric characteristics for a seed were obtained taking into account the recommendations of TG-43 protocol, developed by the AAPM (American Association of Physicists in Medicine). To realize the experiment three plates of Standard Grade Solid Water, model 457 Gammex were used. One solid water plate was machined for accommodate the seed set and radiochromic films were used on the machined plate and under

another solid water plate to recorder the radiation dose. The set of seeds was placed in a configuration trying to simulate an arrangement which may occur in vivo during treatment. The machined plate were placed between the other two for better reliability in measurements. The films were irradiated by an equivalente X-ray beam using the reference radiation RQR 3 IEC (International Electrotechnical Commission) with different doses (0.5 to 1.0 Gy) to obtain the calibration curve in the dose region measured. After validation of the methodology, the study of the interaction between the radiation fields of the set of seeds became possible and the survey of isodose curves of these setting was conducted.

PS05.032 - Evaluation of bismuth shielding use in cervical spine CT scans

Author(s): <u>Arnaldo P. Mourao Filho</u>, Carolina Aleme Nehos, Centro Federal de Educação Tecnológica de Minas Gerais, Belo Horizonte/BRAZIL

Computed tomography (CT) is one of the imaging techniques most commonly used for invasive assessments of internal structures of the human body. However, the radiation exposure of patients can cause damages to their health. This study aims to evaluate changes in image quality in scans of the cervical spine CT, when using bismuth shield to reduce the radiation dose deposited in the thyroid. In a multislice GE Bright Speed CT scanner with 32 channels were done two scans of the neck region, in order to generate diagnostic images of the cervical spine of an Alderson Rando male phantom. The scans were performed with the standard hospital protocol for cervical spine evaluation. The first scan using the thyroid bismuth shielding on the front neck region, and the second without it. Punctual radiation doses in organs (thyroid, breasts, lenses and spinal cord) was recorded using thermoluminescent dosimeters and the image quality control parameters were observed using the image J software. The use of sismuth shielding resulted in a reduction of 26% in the thyroid dose, while generated a small degradation in the axial images obtained, mainly in the frontal structures, closer to the surface where was the bismuth shielding. Thus, the use of bismuth shielding improved the diagnostic process allowing for dose reduction without compromising the diagnostic quality imaging of the skeletal structures of the neck.

PS05.033 - Scanning irradiation of microbeam x-rays in ionization chambers as micro-scale dose analysis tool Author(s): <u>Nobuteru Nariyama¹</u>, Keiji Umetani²

¹Light Source And Optics Division, Japan Synchrotron Radiation Research Institute, Hyogo/JAPAN, ²Research And Utilization Division, Japan Synchrotron Radiation Research Institute, Hyogo/JAPAN

Microbeam x-rays have been used extensively in various applications, with further applications in the medical field being highly anticipated. For the realization of clinical applications, high spatial-resolution dosimetry is necessary. GafChromic films HD-810 have long been used for microbeam dose distribution; if another dosimeter is available, the use of these films for this purpose will be fully examined.

Ionization chambers are widely used as absolute dosimeters. The sensitive volume is surrounded by resin, so that the step-by-step scanning microbeam irradiation near the sensitive volume/resin interface was expected to enable the measurement of micro-scale dose distribution in the resin. Figure 1(a) shows the energy deposition in the sensitive volume of the Advanced Markus chamber calculated using a Monte Carlo (MC) code as a function of the incident microbeam position on the side of the chamber along the direction of electric force. Around the edge of the PMMA electrode, the right hand shoulder curves were almost in agreement with the dose distribution in the PMMA phantom calculated using the MC code [1].

An experiment was carried out at the BL28B2 beamline of SPring-8. A 25-mm-wide microbeam of x-rays was scanned at 6-mm intervals in the chamber. Figure 1(b) shows the resulting energy deposition curves compared with results at a 1-mm depth in the PMMA phantom measured using a GafChromic film [1] at a probably slightly different alignment condition.

[1] N. Nariyama, et al. Appl. Radiat. Isot. 67, 155 (2009).

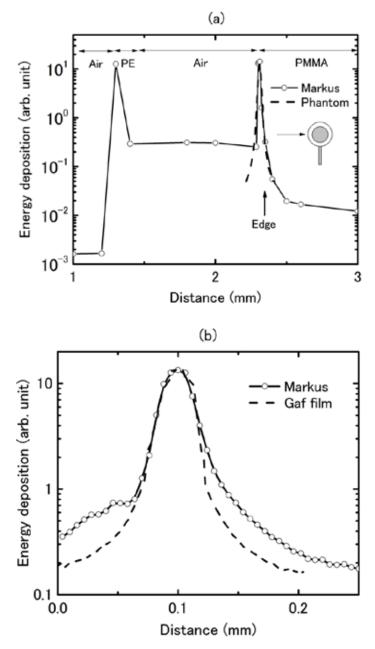

Fig. 1 a) calculated and b) measured energy depositions in the sensitive volume of the Advanced Markus chamber compared with phantom doses calculated using the MC code and measured using GafChromic films, which are fitted to the peaks for the Advanced Markus chamber, respectively.

PS05.034 - Dosimetric verification of the scatter integration algorithm of MIRS

treatment planning system for photon dose calculations Author(s): Mansoureh Sadat Nabavi¹, <u>Hassan Ali Nedaie</u>¹, Rasa Golrokh², Mansour Naderi¹, Bahram Andalib³, Saeedeh Sakhaee³ ¹Radiotherapy Oncology Department, Cancer Research Centre, Cancer Institute, Tehran University of Medical Sciences, Tehran/ IRAN, ²Dr.Masih Daneshvari Hospital, Tehran/IRAN, ³Karaj Radiotherapy Centre, Karaj/IRAN

Background and purpose: Dosimetric quality control methods by IAEA for treatment planning systems, were tested for scatter integration algorithm. The purpose of this study was to find out the extent of the deviation between planned and delivered dose in different fields and photon energies in homogeneous and heterogeneous media.

Materials and methods: The methodology was based on a semianthropomorphic 002LFC CIRS Thorax phantom. The computed tomography (CT) images of mentioned phantom with 2mm slice thickness were transferred to the examed TPS(MIRS treatment planning system) and seven different plans according to IAEA task report (TEC-DOC 1583) were designed. Experimental measurements by a farmer type chamber 0.6cc (PTW 30010 ion chamber) at 13 points carried out at 6, 10 and 18 nominal photon energies.

Results: A total of 21 clinical test case datasets for different energies were produced. In most of cases in homogeneous media, the results were in agreement with predefined criteria. The amount of variations in heterogeneous area increases with the beam energy and decreases with the depth increasing.

Conclusion: Large deviations exist in wedge fields and heterogeneities especially in lung. In homogeneous media and using open fields the scatter integration algorithm results are reliable.

PS05.035 - Characterisation of EPSONV700 flatbed scanner for EBT3 Gafchromic film dosimetry.

Author(s): Vinod K. Nelson

Medical Physics, Liverpool & MacArthur Cancer Therapy Centres, Campbelltown/AUSTRALIA

Purpose: When a flatbed type scanner, not specifically made for radiotherapy dosimetry, is used to acquire Gafchromic film dosimetry data, error can occur in the measured pixel value. These errors result from the position dependent response of the scanner, the variation in thickness of the active layer in Gaf film which occurs during the manufacturing process, rotation of the film dosimeters and the scattered photons entering the film dosimeter scanning area. The purpose of this work is to determine the magnitude of these errors and propose methods to correct for these errors.

Methods and Materials: To determine the positional dependent response of the flatbed scanner two types of tests were carried out. In the first test one whole unirradiated film was scanned. Average pixel value measured with the region of interest (ROI) covering whole film. Orthogonal profiles at five locations, covering the whole film were performed and average pixel value for each location was calculated. In the second test, the scanning area was divided into 12 equally spaced regions. A 2 cm² piece of unirradiated film was placed in each position and scans were performed for each location. To determine the effect of film rotation, one 2 cm² piece of film was irradiated to 1Gy dose. Scans were performed with the film at 0°, 22.5°, 45°, 67.5° and 90° rotations and change in the average pixel value and standard deviation was compared. The scanner was operated with SilverFast (LaserSoft Imaging) software, in transparency mode, with colour correction disabled. To reduce noise due to random fluctuations of the light signal, 3 scans were performed as a 48 bit non compressed TIF images. The central 1 cm² region of each square

was averaged to obtain the response (pixel value) corresponding to the delivered dose, using ImageJ software.

Results: The average pixel value for the whole film was $42093 \pm 263 (0.6\%)$ and for the 12 equally spaced areas of the scanned film, average pixel value was $42092 \pm 275 (0.7\%)$. For the 12 positions on the scanning area, the variation in the pixel value was $0.7\% (41642 \pm 297)$. The variation in pixel value for the five orthogonal profile measured different locations was close to $\pm 0.5\%$ except for the left vertical region of the film. The variation in pixel value with film rotation ranged from -1% at 22.5° to -5% at 90° rotation, with respect to 0° rotation.

Conclusion: The ESPON V700 is a suitable scanner for EBT3 Gafchromic film dosimetry. The variation in pixel value of EBT3 film scanned using EPSONV700 scanner is negligible except in the extreme left and top of the scanned area. Placing the film dosimeters in the central part of the scanning area and using a template with cut outs for placing film dosimeters orthogonally will further reduce the errors due to film detector non-uniformity, scanner response, rotation of film dosimeter and the scattered light photons.

PS05.036 - Nanodosimetric parameters obtained using the Monte Carlo codes PARTRAC, PTra and Geant4-DNA: a comparison study

Author(s): Ana Belchior¹, Carmen Villagrasa², <u>Heidi Nettelbeck³</u>, Marion Bug³, Reinhard W. Schulte⁴, Werner Friedland⁵, Hans Rabus³ ¹Associação do Instituto Superior Técnico para a Investigação e Desenvolvimento, Lisboa/PORTUGAL, ²Institut de Radioprotection et de Sûreté Nucléaire (IRSN), Fontenay-aux-Roses/FRANCE, ³Fundamentals Of Dosimetry, Physikalisch-Technische Bundesanstalt (PTB), Braunschweig/GERMANY, ⁴Radiation Research Laboratories, Loma Linda University, Loma Linda/UNITED STATES OF AMERI-CA, ⁵German Research Center For Environmental Health, Helmholtz Zentrum München, Neuherberg/GERMANY

The nanoscopic pattern of ionising radiation, called track structure, is a crucial tool for estimating nanodosimetric quantities that are not directly measurable in biological tissues. This work compares nanodosimetric parameters of track structure (NPTS) obtained with the Monte Carlo track structure codes PARTRAC [1], PTra [2] and Geant4-DNA [3].

In order to calculate the NPTS, two simplified target geometries were used: a liquid-water cylinder of 2.3 nm diameter and 3.4 nm length, representing a 10-base-pair DNA segment; and a liquid water cylinder of 6 nm diameter and 10 nm length, representing a nucleosome. For the comparison study of the three codes the following particle type and energies were used: electrons with energies ranging from 20 eV to 1000 eV, protons with energies between 3 MeV and 10 MeV; and alpha particles with incident energies of 8 MeV, 10 MeV and 20 MeV. The radiation field was simulated as a monoenergetic pencil beam incident on the surface of the liquid water cylinders at half their height. The ion beam energies were matched to those used for cell irradiations performed at the PTB ion microbeam facility as part of the BioQuaRT project [4].

In nanodosimetry, the physical features of charged particles passing or penetrating a given target volume at a given distance are described by the probability distribution of the number of ionisations occurring within the volume. This probability distribution, which characterises the radiation quality Q associated with the particle track, also depends on the geometry and orientation of the target volume. This work compares the probability distributions and their statistical moments, such as the mean ionisation cluster size $M_1(Q)$, obtained for all three codes. In general, the results show a good agreement between the codes for all particle types and energies, except for electrons below 150 eV, where results obtained with PTra deviate from those obtained with PARTRAC and Geant4-DNA. This work has been funded by the EMRP Researcher Excellence Grant SIB06-REG3. The EMRP is jointly funded by the EMRP participating countries within EURAMET and the European Union.

PS05.037 - A method to reduce the patient's eye lens dose during cerebral angiography procedures

Author(s): Mohammad Javad Safari, <u>Kwan Hoong Ng</u>, Jeannie Hsiu Ding Wong, Khairul Azmi Bin Abd Kadir

Biomedical Imaging, University of Malaya, Kuala Lumpur/MALAYSIA

Purpose: To propose a radiation protector layer to reduce the radiation dose to the patient's eye lens during cerebral angiography procedures.

Materials and methods: The radiation protector layer was fabricated using VytaFlex 40 polyurethane rubber, with thickness and CT number of 1.8 cm and 89.0 HU, respectively.

The radiation dose received at the left eye and left eyelid for an aneurysm procedure were measured using an adult female anthropomorphic phantom and Gafchromic XR-RV3 film [Fig. 1]. The procedure was repeated with and without using the protector layer and effects of this layer on the fluoroscopic image and Automatic Brightness Control (ABC) exposure parameters were studied.

Result: The protective layer reduced the dose to the left eyelid by 31% and to the left eye lens by 16.7%. The protector layer is radio-lucent under DSA, but it can be seen in fluoroscopy images [Figure 1(b& c)]. However, the protector does not affect the ABC exposure parameters and does not perturb and interfere with the treatment procedure.

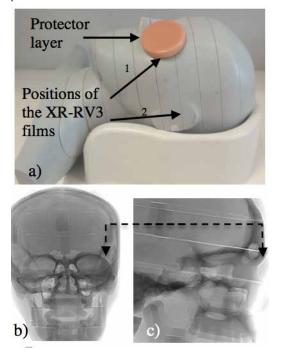

Figure 1a) The positions of the protector layer and radiochromic film, 1: underneath the protector layer and 2: sandwiched between the phantom's slabs. Effect of protector layer on fluoroscopic image from (b) frontal and (c) lateral tube

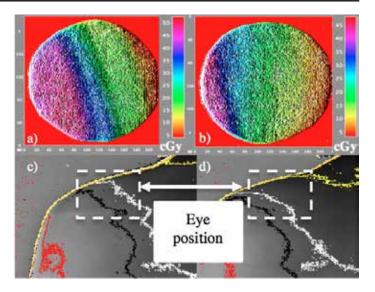

Figure 2shows the effect of the radiation protector layer on dose level at left eyelid position, (a) without and (b) with protector, and dose distribution over the patient's head, (c) without and (d) with protector, during an randomly selected aneurysm procedure.

Conclusion: The eye lens protector layer reduces the patient's eye lens dose during cerebral angiography procedure by attenuating the primary x-ray beam from the lateral tube.

PS05.038 - Bremsstrahlung generating and shielding by the source of the beta ray.

Author(s): <u>Hiroki Ohtani</u>, Takeshi Shima Tokyo Metropolitan University, Tokyo/JAPAN

⁹⁰Sr which generates a beta ray is contained in the radioactive material contained in the contaminated water generated according to the accident of the nuclear power plant. A beta ray generates bremsstrahlung by an interaction with a shield wall. In this case, there is radiation exposure to the worker of the contaminated water tank circumference. The purpose of this research shields the beta ray from ⁹⁰Sr with a lead or iron, and detects generating of bremsstrahlung. It presumes that the bremsstrahlung is of beta ray origin, and the validity of a shield with an acrylics board is verified.

The beta ray generated from seal ⁹⁰Sr was measured using the GM survey meter. The acrylics board was put in between the source of a beta ray, and the survey meter, and the beta ray shield ratio of the acrylics board was measured. To the beta ray generated from Sr-90, it shielded with Pb board of 1.0 mm, and Fe board of 1.6 mm, and bremsstrahlung generated from there was measured. The effect of the acrylics board was verified.

As a beta ray shield of an acrylics board, the beta ray shield ratio of thickness 2.0 mm was 98.1 %. The increases in the discrete value of bremsstrahlung origin were 1.5 % of a 1.0 mm Pb board, and 3.6 % of the 1.6 mm Fe board. Furthermore, the discrete value decreased in the case where an acrylics board is added. The shield of a beta ray with an acrylics board is effective, and it was suggested that generating of bremsstrahlung of beta ray origin can be suppressed by using an acrylics board.

PS05.039 - Angular dependence of absorption spectrum of Gafchromic EBT2 film

Author(s): <u>Soah Park</u>¹, Sei-Kwon Kang¹, Kwang-Ho Cheong¹, Taejin Hwang¹, Jai-Woong Yoon¹, Taejin Han¹, Haeyoung Kim¹, Me-Yeon Lee¹, Kyoungju Kim¹, Hoonsik Bae¹, Seung Jae Oh², Yong-Min Huh², Jin-Suck Suh²

¹Radiation Oncology, Hallym University College of Medicine, Seoul/ KOREA, ²College Of Medicine, Yonsei University, Seoul/KOREA

It is important to study absorption spectrum in film dosimetry because the spectral absorbance of the film relates to the film's total absorption dose. We investigated the absorption spectra of Gafchromic EBT2 film with various rotational angles in a visible wavelength band. The film was irradiated with 6 MV photon beams and a total dose of 300 cGy. Absorption spectra were taken under different rotational angles after 24 h irradiation and we fitted the spectra using Lorentzian functions. There were two dominant absorption peaks at approximately 586 nm (green) and 634 nm (red). The measured spectrum was decomposed 542 nm, 558 nm, 578 nm, 586 nm, 626 nm, 634 nm, and 641 nm. The maximum total area of the red band absorption spectrum was at 45° (225°) and the minimum at 90° (270°). As the angle of rotation changed, the intensity and integrated area of the blue and green peaks also changed with 180° period, with minima at 90° and 270°, and maxima at 0° and 180°, although the overall absorbance is very low. The spectral peak wavelengths remained constant within ±1.2 nm for all angles. There was no hysteresis of absorption spectrum of the film; spectra taken at 0° and 360° were substantially the same and showed similar behavior for all rotational angles. The change of absorbance with rotational angle of the film affected the dosimetric properties, resulting in rotational variations of film dosimetry in each red-greenblue channel.

PS05.040 - Patient dose audit in mammography

Author(s): Ana R. Roda¹, Maria Carmo Lopes², Maria Carmen Sousa², <u>Grisel M. Paula³</u>

¹Medical Physics, IPOCFG,EPE, coimbra/PORTUGAL, ²Medical Physics, IPOCFG,EPE, Coimbra/PORTUGAL, ³Fcul, Institute of Biophysics and Biomedical Engineering, Lisbon/PORTUGAL

This study presents the results of a patient dose audit performed in the period Dec 2013 to Feb 2014 on a full field digital mammography unit GE Senographe DS, to: evaluate conformance with the European diagnostic reference levels (DRL's); provide the physician with an estimate of the effective doses involved in bilateral mammography examinations; and, evaluate if displayed dose indicators (Entrance skin exposure (ESE) and average glandular dose (AGD)) can give direct information, relevante for patient dose assessment. According with the Portuguese legislation for medical radiological exposures [Decree-law nº 180/2002] we applied the diagnostic reference level concept in mammography examinations, estimating the average entrance surface dose (ESD) for a sample of 10 standard breasts. and compared it with the European DRL - ESD of the 3rd quartil of a broad dose survey distribution. To assess the patient radiation doses involved we estimated the average dose to the glandular tissue within breast (AGD) since it is the glandular tissue that is believed to be the most sensitive to radiation induced carcinogenesis, and opcionally converted it into effective dose for comparison with other diagnostic radiology exams. Half-value layer (HVL) and radiation output data obtained from quality control (according with EFOMP Mamo Protocol 2014) were used for the entrance surface dose (ESD) and average gandular dose (AGD) assessments using the apropriate conversion factors [IAEA (2007), Dance (2000), Dance (2009)]. AGD and effective doses for bilateral mammography were obtained for a range of breast thickness intervals using Dance tables and ICRP 103 breast tissue weighting factor 0.12. The percentage of glandularity was determined using the qualitative method described by Byng (1994). The results were: ESD = 5.8 mGy for cranio caudal

(CC) and ESD = 6.1 mGyfor medio lateral oblique (MLO) projections. These results are considerably below the European DRL's (10 mGy). Average effective doses for a bilateral mamography for each compressed breast thickness interval results were: E = 0.28 mSv for small breasts (34.5±4.5mm); For medium breasts we considered 3 compressed thickness intervals E = 0.35 mSv (44.5±4.5mm); E = 0.33 mSv (54.5±4.5mm); E = 0.45 mSv (64.5±4.5mm); E = 0.61 mSv for large breasts (74.5±4.5mm) and E= 0.69 mSv for very large breasts (84.5±4.5mm). In general, larger compressed breast thickness is associated with a higher AGD and patient effective dose. No correlation was found between AGD shown on the GE Senographe DS display and calculated AGD, but high correlation was found between the displayed entrance skin exposure (ESE) and entrance skin air kerma(ESAK) measurements the average conversion coeficient with 2σ confidence level being (1.01 ±0.05). This results suggests we can use displayed ESE for dose assessments. The annual system conversion factor (CF) measurement (factor used by the system to convert brightness to dose for all AOP-related calculations) and HVL measurement (measures HVL and Output) are essential for dose optimization and patient dose calculations with Senographe DS.

PS05.041 - Experience in implementing a dosimetric registry in an oncological facility of a developing country

Author(s): <u>Sandra L. Rocha Nava</u>¹, Yolanda Villaseñor Navarro², Erick Benitez¹, Hector Galvan², Erika Ramirez Lopez¹ ¹Biomedical Engineering, Instituto Nacional de Cancerologia, Mexico DF/MEXICO, ²Radiology Department, Instituto Nacional de Cancerologia, Mexico DF/MEXICO

Diagnostic Radiology and Nuclear Medicine studies are an effective tool especially in an oncology facilities where are needed for the diagnostic and also to known the treatment response.

Radiation and radiation dose reduction are at the top of the list of controversial topics in medical imaging today. The risks associated with the use of ionizing radiation in diagnostic imaging include cancer, burns and other injuries.

Is known that the main contribution to cumulative dose is for CT scans (49%), but represents a minus percentage (16%) by type of procedures. However in an Oncology Hospital of Mexico the CT's scans and PET-CT represent more than 30% of the total studies. In this country currently there aren't a national policy of registry or collection of dosimetric data.

We have identified several patients with more than 20 CT scans in 24 months or patients with several PET-CT in a small time. That is why in 2014 began the implementation of a registry dose for dosimetric data collection. Unfortunately even when all the radiological equipment are digital direct, some of them had not installed the ionization chamber. When was required data information to the service providers, they didn't know the topic.

A CT scanner was installed in 2011 and was not acquired the license DICOM RDSR. But a second CT was acquired in 2014 and the provider didn't know the license required. Also the PACS system has not the ability to receive DICOM RDSR and there are no plans to integrate or upgrade for registry dose data.

To choose the system to collect the dose data we did some market research and found that one of the commercial systems offered great logging capabilities of different modalities. However, this system is not available for the reference country.

That was why we decided to implement the Radiance system, which allowed us to start the dosimetry data collection of 4 CTs, finding information that allowed us to start internal political request for radiological studies. PS05.042 - Effects of irradiation with low and high doses using in vivo rats: analysis of trace elements in blood using SR-TXRF Author(s): Carla L. Mota¹, Arissa Pickler¹, Andrea Mantuano², <u>Camila Salata³</u>, Delson Braz¹, Liebert P. Nogueira², Samara Machado², Regina C. Barroso², Carlos Eduardo De Almeida² ¹Nuclear Engineering Program, UFRJ, RIO DE JANEIRO/BRA-ZIL, ²UERJ, Rio de Janeiro/BRAZIL, ³CNEN, Rio de Janeiro/BRAZIL

Both natural and man-made sources of ionizing radiation contribute to human exposure and consequently pose a possible risk to human health. While natural background radiation is unavoidable, the increased medical use of radiation, e.g. X-ray and CT scans for diagnosis, inevitably increases the public's health risk concerns over exposure of low doses of ionizing radiation. The effect of low-dose radiation on cells and tissues is a public health concern, because the human population is exposed to low-dose ionizing radiation coming from a variety of sources, such as cosmic rays, soil radioactivity, environmental contaminations, and various medical procedures. And the effect of high dose radiation can cause more severe damage, by radiotherapy treatment or nuclear accidents such as Chernobyl in 1986 and the Fukushima Daiichi Nuclear Power Plant in 2011. Exposure to ionizing radiation may cause various types of cell damage, and the type of damage is different from low to high doses of radiation. Although the damaging health effects of exposure to high doses of radiation are well documented, more work needs to be done to establish a biologic signature for exposure to low dose. Previous studies have shown that exposure to low radiation dose reduces cell killing compared with a single dose of high radiation dose. There is great interest in the identification of biological markers for exposure to ionizing radiation for the detection of people exposed to high or low radiation dose, which could be in risk to develop late side effects of this exposition. To our knowledge, until now there is no such a convenient biomarker. Our purpose is to use an animal model, with Wistar rats, to analyze the peripheral blood after low and high doses of ionizing radiation. In this work were used male Wistar rats (n = 15), three months old, weighing approximately 260g, will be kept in appropriate cages with 4 animals each, on a 12-h light/dark cycle with food and water provided ad libitum. The animals will be divided into three groups, five animals each: control (were not irradiated), LD (received 0.1Gy total body irradiation) and HD (received 2Gy total body irradiation). The study protocol was approved by the local ethical council (No. CEUA/010/2012). The aim is to quantify the trace elements contained in the blood, and compare the results between three groups (control, LD and HD). The obtained results will help to identify the differences in the elements concentrations among the analyzed groups, and it can be associated with the received radiation doses. These results are be important to better identify individuals with potentially lethal exposures and providing appropriate therapy (eg, supportive care, growth factors, transfusions, antibiotics). The obtained results help to identify the differences in the elements concentrations among the analyzed groups, and it can be associated with the received radiation doses.

PS05.043 - Effects of cable extension and photon irradiation on TNRD neutron detector in radiotherapy

Author(s): Leticia Irazola¹, José A. Terrón², <u>Beatriz Sanchez Nieto³</u>, Roberto Bedogni⁴, Faustino Gómez⁵, Francisco Sanchez-Doblado¹ ¹Fisiologia Medica Y Biofisica, Facultad Medicina, University of Seville, Sevilla/SPAIN, ²Servicio De Radiofísica, Hospital Universitario Virgen Macarena, SEVILLA/SPAIN, ³Instituto De Física, Pontificia Universidad Católica de Chile, Santiago/CHILE, ⁴Istituto Nazionale Di Fisica Nucleare, Laboratori Nazionali di Frascati, Frascati RM/ ITALY, ⁵Fisica De Particulas, Facultad de Fisica, Universidad de Santiago, Santiago de Compostela/SPAIN

Introduction

A new thermal neutron detector (TNRD), developed for nuclear

research, has shown to be effective for clinical use in peripheral neutron dose estimation, either in patient and 'in-phantom' measurements [1]. This work shows some difficulties when adapting *TNRD* to radiotherapy environments, mainly due to the fact that it has shown structural limitations. Two problems have been studied: (1) the influence of cable lengthening, necessary to be operative in a radiotherapy environment and (2) cable irradiation during the measurements. As we are measuring very small signals, we have to take into account not only these two facts but also the quality of the materials and connectors used.

Material and Method

Original cable length of *TNRD* detectors was 0.8 m but an extension to a 2.4 m (5.4 m for the reference detector [1]) cable was found to be necessary to reach all the anthropomorphic phantom measuring points from the electronic box. Cable lengthening influence (having special care in the implementation and quality of the components) and its linearity response, were evaluated under a 10x10 cm² squared field in 15 MV (SSD=100 cm). The influence of the unavoidable cable irradiation [2], was evaluated by series of 300 MU measurements in 4 consecutive fields, with and without cable irradiation (ranging from 10 to 65.6 cm of cable irradiated).

All the measurements were performed in a 15 MV Siemens Primus linac, with detectors inserted in the middle of 8 cm of polyethylene.

Results

Mean loss of signal of (-0.09 \pm 0.08) % per meter of cable, has been obtained for the six detectors when measuring with extension cables with respect to the original setup. A good linearity response with the new configuration, was observed (R²=1) for all detectors in the range 100-4000 MU.

Table shows *TNRD* signal in 15 MV, difference in readings between irradiation and no-irradiation of the cable, and the percentage that represents this difference with respect to total values.

Field size (cm ²)	Total signal (V∙s)	Irradiation- No Irradiation (V·s)	Relative Deviation (%)
10x10	74.17	-0.60	-0.63
20x10	81.49	-0.76	-0.70
30x10	87.30	-1.22	-1.19
40x10	87.68	-1.20	-1.09

Conclusions

Our experiences showed both, the substantial necessity of using extended cables and the impossibility of measuring in anthropomorphic phantom points without cable irradiation. Measurements are now possible with the proposed improved setup here detailed, taking special care on cables and connections quality. Cable extension has a negligible contribution. Cable irradiation could reach a variation up to 1.2%. Thus, the irradiation of the cables should be considered in order to minimize its influence during the measurements.

PS05.044 - Thermoluminescence dosimetry (TLD) for in vivo dosimetry in radiation therapy with high single doses Author(s): <u>Andrea Schwahofer</u>¹, Christin Glowa², Wolfgang Schlegel²

¹Radiation Therapy, Vivantes Clinic Neukoelln, Berlin/GER-MANY, ²Medical Physics In Radiation Therapy, German Cancer Research Center, Heidelberg/GERMANY

Purpose: The aim of this work was to find an extrapolation model to describe the non-linearity of thermoluminescence (TL) dosimeters and to measure single high absolute doses *in vivo* in rat tissue as accurately as possible.

Materials and Methods: For dose-to-water calibrated TL phosphors (rod shaped LiF detectors), the supralinearity of high doses up to 70 Gy was determined using a self-developed calibration phantom. Dose values between 0.1 and 70 Gy were measured incrementally and the measurements were repeated three times. Supralinear behavior of TL phosphors generally follows the correlation D_{TI} = f(D_{irr}), whereas D_{TI} is the measured TL output and D_{irr} is the irradiated dose. The mathematical model is then used to perform a first trial of in vivo dosimetry in animals with TL-Detectors. For this trial, male rats were transplanted with a syngeneic prostate tumor (Dunning R3327-HI) at the right hind limb. The TL-Detectors were embedded in a commercially available shrink-on tube to avoid surface contamination of the detectors with substances of any kind e.g. dust, blood. Four detectors were placed via 3 mm long incisions subcutaneously around the tumor volume (Fig. 1b) of six male rats. Dose levels of 30, 50 and 70 Gy were chosen referring to former dose-response experiments with this tumor model.

Results: The resulting progression of supralinearity needed to be split in three regions regarding to the TL output. Following sections were specified: 1) linear relation for $D_{TL} = 0...2$ Gy, 2) square root fit for $D_{TL} = 2...55$ Gy and 3) cubic polynomial fit function for $D_{TL} = 55...70$ Gy (Fig. 1a). The resulting models fit the measured data points with an average error of ± 2.6 %. Measured values in the rats for irradiations with 30 (50 and 70 Gy) were determined between 29.5 and 32.5 Gy (50.1 and 53.1 Gy / 69.8 and 73.5 Gy, respectively). It was even possible to define dose gradients at the field edge due to the position of the TL detector according to the position of the tumor volume.

Conclusion: The trial was a novel method of *in vivo* dose measurement and produced convincing results with very high accuracy. Thus the experiments of this study are an important step for *in vivo* dosimetry. As a future project, the phosphors might be implanted already at an early stage of tumor growth in order to achieve more representative dose values in the center of the tumor volume.

I: a) determined supralinearity of the TL photphors at the linear accelerator with 6MV photons; b) TL detector placed into a pocket around the tumor and c) experimental setup of the tumor irradiation at the linear accelerator

PS05.045 - Study of the response of ionization chambers in photon beams

for off-axis point dose

Author(s): <u>Tetsunori Shimono</u>¹, Yasuyuki Kawaji¹, Kousuke Matsubara², Tatsuhiro Gotanda¹, Hiroshi Okuda³, Rumi Gotanda⁴ ¹Department Of Radiological Science, Faculty Of Health Sciences, Junshin Gakuen University, Fukuoka/JAPAN, ²Department Of Quantum Medical Technology, Faculty Of Health Sciences Department Of Radiology, Faculty Of Medicine, Kanazawa University, Ishikawa/ JAPAN, ³Department Of Radiology, Hoshigaoka Medical Center, Osaka/JAPAN, ⁴Department Of Radiological Sciences, Ibaraki Prefectural University of Health Sciences, Inashiki-gun, Ibaraki/JAPAN

Numerous challenges associated with small-field dosimetry compared with standard dosimetry, primarily because of the different irradiation conditions than that of the standard case. These challenges include concerns regarding reliability in the fields of small-field stereotactic radiotherapy and radiosurgery with respect to radiation detection. Furthermore, the use of intensity modulated radiotherapy (IMRT) has increased for the treatment of difficultly situated carcinomas. Therefore, while employing IMRT, measurements should include small fields as well as off-axis measurements. In this study, we investigated the response of small-volume ionization chambers and Farmer-type chambers for dose profile measurements at different measurement depths. We found that the response of the ionization chamber decreased at maximum dose depth when moving from the central axis to the 15 cm off-axis position. Until now, only a 0.1 cm³-volume iionization chamber has been investigated. The Farmer-type ionization chamber investigated herein behaved similarly to the small-volume ionization chamber. The response of for Farmer-type ionization chamber decreased by 3.1% and 3.5% for the 4 and 14 MV beams, respectively. Furthermore, the response both Farmer-type ionization chamber and small-volume ionization chamber increased with decreasing nominal photon energy. This under response could be the result of the variation of the wall correction factor.

PS05.046 - Analysis of gamma evaluation according to low-dose threshold on VMAT QA

Author(s): Ji-Hye Song¹, Min Joo Kim¹, So-Hyun Park², Seu-Ran Lee¹, Min-Young Lee¹, Dong-Su Lee², <u>Tae-Suk Suh¹</u> ¹Department Of Biomedical Engineering, And Research Institute Of Biomedical Engineering, The Catholic University of Korea, College of Medicine, Seoul/KOREA, ²Department Of Radiation Oncology, Uijeongbu St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Uijeongbu-si, Gyeonggi-do, Seoul/KOREA

The American Association of Physicists in Medicine task group-119 (TG-119) recommends applying 10% of the low-dose threshold for gamma evaluation to restrict low-dose region. However, TG-119 didn't present clinical data to quantitatively demonstrate the impact of the low-dose threshold on the gamma index. Therefore, we performed a gamma evaluation with various low-dose thresholds in the range of 0% to 15% according to both global and local normalization and different acceptance criteria (3%/3 mm, 2%/2 mm, and 1%/1 mm). A total of 30 treatment plans-10 head and neck (H&N), 10 brain, and 10 prostate cancer cases-were selected from the Varian Eclipse treatment planning system (TPS) retrospectively. For the gamma evaluation, a calculated portal image was acquired through a verification plan process in the Eclipse TPS, and a measured portal image was obtained using an electronic portal imaging device. Then, the gamma evaluation was performed using Portal Dosimetry software. As a result, for the global normalization, the gamma passing rate (%GP) decreased as the low-dose threshold increased, and all cases of low-dose thresholds exhibited an acceptable %GP above 95% for both the 3%/3 mm and 2%/2 mm criteria. On the other hand, for local normalization, the %GP with 10% of low dose threshold increased by 18.64% and 17.45% compared with

the 0% of low dose threshold in brain case for 1%/1 mm and 2%/2 mm criteria, respectively. Even in 3%/3 mm acceptance criteria, the %GP increased by up to 9.22%. In conclusion, we suggest applying the 2%/2 mm criteria, which are more stringent criteria than those of 3%/3 mm, for the global gamma evaluation because it exhibits a tolerable passing rate for all low-dose thresholds. In contrast, local gamma analysis should be used for a lower dose threshold level below 10% to acquire more precise test results, despite the TG-119 recommendation, because it may provide an overestimated %GP by excessively excluding the dose discrepancy of the low-dose region.

PS05.047 - Dosimetric accuracy of Acuros XB dose calculation algorithm on an air cavity for EBT3 Gafchromic film

Author(s): Sang-Won Kang¹, Jin-Beom Chung², Jeong-Woo Lee³, Ji-Yeon Park⁴, <u>Tae-Suk Suh</u>¹

¹Biomedical Enginerring, The Catholic Uinv. of Korea, Seoul/KO-REA, ²Radiation Oncology, Seoul National University Bundang Hospital, Seongnam/KOREA, ³Department Of Radiation Oncology, Konkuk University Medical Center, Seoul/KOREA, ⁴Department Of Pediatrics And Molecular Imaging Program At Stanford, Stanford University, Stanford/UNITED STATES OF AMERICA

Purpose: This study was to verify the dosimetric accuracy of Acuros XB (AXB) dose calculation algorithm on an air cavity for a single radiation field using EBT3 Gafchromic film.

Methods: A rectangular slab phantom containing an air cavity was made especially for this study. The phantom with and without the Gafchromic EBT3 films was scanned using Philips Big-bore CT scanner. The digital imaging and communications in medicine CT datasets of scanned the phantom were then transferred to the Eclipse treatment planning system. The central axis doses were calculated by anisotropic analytical algorithm (AAA) and AXB using a single filed of 6 MV flattening filter-free beam from TrueBeam linear accelerator. In phantom, we used various field sizes from $2 \times 2 \text{ cm}^2$ to $5 \times 5 \text{ cm}^2$. The dose profiles were generated at the depth of 4.5, 5.5, 6.5 and 7.5 cm, including the presence of an air cavity. All measurements for film dosimetry were performed under the same condition of the calculation with film.

Results: With film in the slab phantom, CADs for AXB and AAA overestimated -5.55% and 131.60%, compared to those of measurements. However, differences of CADs without film were -27.72% and 144.20%. The CAD differences between AXB and AAA reduced with increasing field size and increased relative to the depth increment. The AXB dose calculation in an air cavity showed more agreement than AAA. Also the root means square error (RMSE) value of dose profiles for AXB were within 10%, while those of AAA were more difference than 30%.

Conclusions: In this study, we confirmed that inclusion of film within an air cavity has affected on dose calculation with both algorithms. Our experimental phantom study demonstrated that the AXB is significantly more accurate for dose calculation in the region of an air cavity when compared with AAA. Therefore, we recommend the use of AXB instead of AAA for avoiding inaccurate dose calculation, especially on the clinical cases including air cavity.

PS05.048 - Evaluation of Dosimetric Effects on Metal Artifact: Comparison of Dose

Distributions Affected by Patient Teeth and Implants

Author(s): Min-Young Lee¹, Jeong-Woo Lee², Ji-Yeon Park³, Hye-Jin Park⁴, Sang-Won Kang¹, <u>Tae-Suk Suh</u>¹

¹department Of Biomedical Engineering, Research Institute of Biomedical Engineering, Seoul/KOREA, ²Department Of Radiation Oncology, Konkuk University Medical Center, Seoul/KOREA, ³Department Of Pediatrics And Molecular Imaging Program At Stanford, Stanford University, Stanford/UNITED STATES OF AMERICA, ⁴Department Of Radiation Oncology, Ajou University School of Medicine, Suwon/KOREA

Purpose: Implant-supported dentures seem particularly appropriate for the predicament of becoming edentulous and cancer patients are no exceptions. Metal artifacts generated by dental implants cause dose discrepancy in head-and-neck cancer cases due to the inaccurate predicted doses. To verify the theoretical analysis of the metal artifact, streak artifact and dark artifact, and also critical analysis of dosimetric effect which cause by dental implants in CT images of head and neck cancer patients with the patient teeth and implants inserted humanoid phantom. Methods: The phantom comprises cylinder which is shaped to simulate the anatomical structures of a human head and neck. Through applying various clinical cases, made phantom which is closely allied to human. Developed phantom can verify two classes: (i) dose measurement when patient closed mouth (ii) dose measurement when patient opened mouth. RapidArc plans of 4 cases were created in the Eclipse planning system. Total dose of 2000cGy in 10 fractions is prescribed to the whole planning target volume (PTV) using 6MV photon beams. Acuros XB (AXB) advanced dose calculation algorithm, Analytical Anisotropic Algorithm (AAA) and progressive resolution optimizer were used in dose optimization and calculation. Results: In closed and opened mouth phantom, because dark artifacts formed extensively around the metal implants, dose variation was relatively higher than that of streak artifacts. As the PTV was delineated on the dark regions or large streak artifact regions, maximum 7% dose error and average 3% difference was observed. The averaged minimum dose to the PTV predicted by AAA was about 5% higher and OARs doses are also 5% higher compared to AXB. Conclusion: AXB was found to have better dose predictions than AAA and at the tissue interfaces where backscatter occurs. Therefore, AXB is more appropriate to use for dose predictions, especially when low-density heterogeneities are involved.

PS05.049 - Advancement of Dedicated Phantom to demonstrate Dosimetric Effect

of Metal Artifact in Head and Neck Cancer

Author(s): Min-Young Lee¹, Jeong-Woo Lee², <u>Tae-Suk Suh</u>¹, Ji-Yeon Park³, Hye-Jin Park⁴

¹department Of Biomedical Engineering, Research Institute of Biomedical Engineering, Seoul/KOREA, ²Department Of Radiation Oncology, Konkuk University Medical Center, Seoul/KOREA, ³Department Of Pediatrics And Molecular Imaging Program At Stanford, Stanford University, Stanford/UNITED STATES OF AMERICA, ⁴Department Of Radiation Oncology, Ajou University School of Medicine, Suwon/KOREA

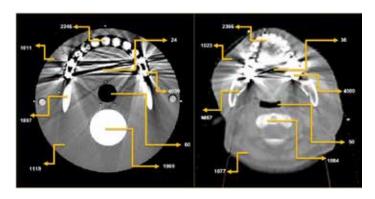

Purpose: Implant-supported dentures seem particularly appropriate for the predicament of becoming edentulous and cancer patients are no exceptions. The purpose of this study is to verify the clinical dosimetric effects of metal artifact in clinical cases by developing a realistic head and neck phantom.

Materials and Methods: The phantom comprises cylinder which is shaped to simulate the anatomical structures of a human head and neck. Through applying various clinical cases, Fig.1, phantom is closely allied to human. Developed phantom can verify two classes: (i) closed mouth (ii) opened mouth. Also, the inserted patient tooth can trade places. The phantom was made to enable film to be set-up between two slabs to compare the dosimetric impact and variation of dose distributions. Furthermore, mid-slabs of phantom contain few cylindroid holes for Radio-Photoluminescence Glass Dosimeter (RPLGD), same spots in opened and closed phantoms, where cause the streak and dark artifacts for the dose verification.

Results: The accuracy of dose calculations is essential to the quality of the radiotherapy treatment planning and tumor response. As after scanning the phantom, in closed and opened mouth phantom, because dark artifacts formed extensively around the metal implants, dose variation was relatively higher than that of streak artifacts. The phantom was capable of producing realistic head and neck metal artifact imaging data from which imaging devices and techniques can be evaluated.

Conclusions: The phantom provides a unique and useful tool in head and neck dosimetry research. It can be used in the development of new imaging instrumentation, image acquisition strategies, and image processing and reconstruction methods.

PS05.050 - Accuracy of radionuclide generation simulation using Antisymmetrized Molecular Dynamics (AMD)

Author(s): <u>Masaaki Takashina</u>¹, Yusuke Sakurai¹, Kouta Fukunaga², Masao Matsumoto¹, Masahiko Koizumi¹, Akira Ono³ ¹Graduate School Of Medicine, Osaka University, Suita, Osaka/ JAPAN, ²Division Of Health Sciences, Osaka University, Osaka/ JAPAN, ³Graduate School Of Science, Tohoku University, Sendai/ JAPAN

1. Introduction

During particle therapy, radionuclides are produced in patient bodies and equipment. In the view point of utilizing them for the beam on-line PET, radiation protection, etc., it is important to understand the phenomena induced by therapeutic particle beams, and simulation is essential as well as measurements. Although Quantum Molecular Dynamics (QMD) is frequently adopted in simulation as the model for nuclear reactions, they do not entirely reproduce experimental data. In this study, we focus on Antisymmetrized Molecular Dynamics (AMD), which is thought to have more theoretical validity than QMD, and investigate its accuracy comparing with QMD.

2. Materials and Methods

We use the AMD code developed by Ono1). The QMD calculation is performed with PHITS2). AMD and QMD describe the dynamical processes of nuclear reactions. The resultant fragments may be in excited states, and decay with the statistical process, which is described by a generalized evaporation model (GEM)3). The GEM calculation after QMD is done as a sequence of the PHITS calculation. For GEM after AMD, we use the same code as in PHITS. We investigate 12C induced nuclear reactions at E/A=20 MeV - 400 MeV. As the target nuclei, we consider 12C, 16O and 40Ca. The calculated results are compared with experimental data.

3. Results and Discussion

Fig.1 is an example of the results, which shows the mass distribution of the fragments produced in the 12C+12C reaction at E/A=400 MeV. The open diamonds (triangles) represent the results of AMD (QMD) followed by GEM. AMD is found to give comparable results with QMD. In particular, they both give the cross sections of 7Be and 11C close to the experimental data4) (solid circles). On the other hand, for the neutron cross section, AMD is better than QMD.

4. Conclusion

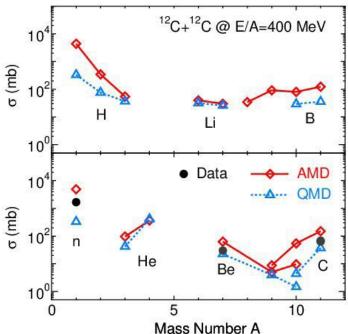

Since AMD and QMD show the similar results of cross sections, we cannot determine which model is better for 12C+12C reaction. For the 40Ca target case, the difference is noticeable, but there exist too few appropriate data. In order to make simulation more accurate, more data are strongly desired.

PS05.051 - Accurate small field dosimetry requires systematic consistent approaches to measurement, modelling and data reporting.

Author(s): Gavin Cranmer-Sargison¹, Paul Charles², Jamie Trapp³, <u>David Thwaites</u>⁴

¹Medical Physics, Saskatchewan Cancer Agency, Saskatoon/CAN-ADA, ²Radiation Oncology, Princess Alexandra Hospital, Brisbane/ AUSTRALIA, ³Science And Engineering Faculty, Queensland University of Technology, Brisbane/AUSTRALIA, ⁴Institute Of Medical Physics, School Of Physics, University of Sydney, Camperdown, Sydney/AUSTRALIA

Small field dosimetry is clearly recognized as difficult, increasingly

so as the size reduces, yet consistent data is necessary for accuracy in clinical use, for applications of small fields themselves and also as components of more complex beams. However, the overall reported data in the literature contains relatively large inconsistencies. To consider how to resolve these differences and how to improve the practical approaches and associated uncertainties requires careful standardised measurements, validated Monte-Carlo (MC)-based correction factors and possible new thinking on detectors. In addition it requires clear understanding of what the parameters reported truly describe and clear reporting of data, where values should be correlated to actual delivered dosimetric field size, and not to nominal or set field size, to enable careful comparison between linacs. For very small field sizes, greater attention is required to the experimental measurement and reporting methods, requiring clear guidelines for what is a 'very small field size' and for when such more detailed methods are needed.

A range of measurements and MC modelling studies have been reported by our joint collaborative groups. Based on these methods and results, data and recommendations have been published on:

- commissioning/fine-tuning MC models for small field sizes; and the interplay between modelling and measurements to achieve this; - modelling-based correction factors for a range of shielded and unshielded diodes for 6MV beams; - what constitutes a 'very small field size' (essentially fields smaller than 1.5 cm in size for 6 MV), based on the different effects as field size gets smaller and their consequences for uncertainties; - measurement methods necessary to control uncertainties at these smaller field sizes (essentially measuring beam profiles at the same time as output factor, to ensure good alignment, but also to measure the actual dosimetric field sizes; - reporting of output factors for consistent comparison and applications; ie reporting against an effective field size taking into account measured dosimetric field sizes; and not just against nominal field size, in order to reduce the variations in reported data and allow interpolation between reported tabulated data eg on correction factors; - observations on detector design and modelling for possible 'correction-free' small detectors (eg scintillators, but also modified standard detectors such as diodes).

The approaches to each of these areas and the practical use of the data must be systematic and consistent. The above sets of work and recommendations provide coherent approaches, which are inter-linked. As national (eg AAPM) and international (eg IAEA) bodies develop protocols for small field dosimetry, it is critical that clear inter-dependent measurement and modelling based methods and data are recommended to improve the consistency and uncertainties involved and to provide the best accuracy possible in these increasingly clinically-used conditions.

PS05.052 - Determination of Radon/Thoron Concentrations in Some Iraqi Building Materials By Using CR –39 Author(s): <u>Abdulredha S. Younis</u>¹, Nada Tawfiq²

¹Physiology Department, Hawler Medical University, Erbil/ IRAQ, ²Al-Nahrain University, Baghdad/IRAQ

Common building materials used for construction of houses, which are considered as major source of radon / thoron gases in indoor environment such as cement, gypsum, sand, and bricks. Samples of these materials had been collected from different factories distributed at different Iraqi areas in Baghdad, south, and in the west. The determinations of ra-don/thoron concentrations have been studied by using sealed can technique and CR-39 track detectors were irradiation for 30 days in a closed can. Standardization of irradiation effects for the same period on CR-39 detectors has been done on samples of known alpha particles emitters' concentration, which are adopted by the International Atomic Energy Agency (IAEA). Radon/Thoron concentrations have been found to be varying from minimum value of 119.7 \pm 2.6 Bq/m3 for Lime sample to a maximum value of 309 \pm 8.6 Bq/m3 for Ordinary black cement. These results show that Iraqi building materials constituents contains low concentrations of background Radon / thoron natural sources of radiation.

PS05.053 - Evaluation of Scattered Dose Reduction in Interventional Radiology Using Lead-Free Protection Sheets

Author(s): Khamizah Taharim¹, <u>Chai Hong Yeong</u>¹, Kwan Hong Ng¹, Basri Johan Jeet Abdullah², Chu En Ting¹

¹Department Of Biomedical Imaging, Faculty Of Medicine, University of Malaya, Kuala Lumpur/MALAYSIA, ²University Of Malaya, University of Malaya Research Imaging Center, Kuala Lumpur/MALAYSIA

Introduction

Occupational radiation dose in interventional radiology (IR) has become a concern due to increasing complexity of the procedures and fluoroscopic time. A lead-free (primarily Bi-83 and Sb-51) protection drape has been introduced to absorb scattered radiation by 50 to 95% at 90 kVp during IR procedures. To ensure the safety of medical personnel working with radiation, it is imperative that the efficacy of protection equipment meets the required standards.

Aims and Objectives

This research aimed to establish the physical characteristics and assess the efficacy of the protection drape (RadPad, Worldwide Innovations & Technologies, USA) in reducing scattered dose to the personnel, in comparison to a typical lead shield.

Methods

The physical characteristics of RadPad (Orange with a claimed 90% attenuation and Yellow with 75%) were assessed by establishing its attenuating and backscattering properties and its dose reduction profile. The percentage attenuation was measured using two calibrated semiconductor detectors, each placed before and after the protection drape, which was placed on a phantom and exposed at varying X-ray energies. Backscatter properties of RadPad were studied by measuring the entrance surface air kerma on a phantom, with and without the RadPad drape in place. An increase in reading when RadPad is in use would indicate backscattered radiation. Rad-Pad's dose reduction profile was established by analysing exposed radiochromic films partially covered by the protective drape. Additionally, the films were sandwiched between sheets of 2cm thick Perspex phantom to simulate dose distribution at different depths within the patient body. RadPad's efficacy in dose reduction was further assessed through scattered radiation dose mapping during a simulated fluoroscopy-guided procedure, in which phantoms were used to simulate a radiologist and a patient. RadPad was placed over the patient phantom and exposure was made using routine fluoroscopy settings. Dose readings were obtained at varying heights on the radiologist phantom (brain, thyroid chest level) and at different positioning of the phantom in the fluoroscopy suite.

Results and Conclusion

RadPad significantly reduces scattered radiation dose to staff during prolonged fluoroscopy-guided procedure. RadPad Orange (90% attenuation) shows similar attenuation to 0.25 mm lead-equivalent shield at 90 kVp. However, empirical results show deviation from manufacturer specifications (85.8% and 71.6% for Orange and Yellow instead of 90% and 75% at 90 kVp respectively). Backscattered radiation was detected when RadPad was placed over the phantom, indicating possible increase in patient skin dose. 0.25 mm lead-equivalent produces higher backscatter radiation compared to RadPad, suggesting that RadPad is advantageous in reducing patient skin dose. RadPad has potential as additional radiation shielding, however its lower linear attenuation coefficient compared to lead suggests that it would not be an ideal replacement for lead as the primary personal radiation protection for medical staff.

PS05.054 - Dosimetric validation of Volumetric Modulated Arc Therapy (VMAT) in an upgraded Clinac 2100CD using AAPM TG-119 bench mark plans for Flattening Filter Free(FFF) photon beam

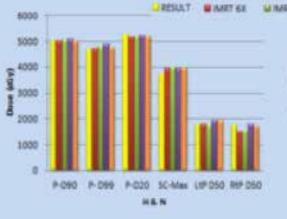

Author(s): S. Ashokkumar^{1, 2}, K.M. Ganesh^{1, 3}, K. Ramalingam^{1, 2}, K. Karthikeyan^{1, 2}, N. Jagadeeshkumar², V.S. Subramanian^{1, 2}; ¹Bharathiar University, Research and Development Center, Coimbatore/ INDIA, ²Department of Radiation Oncology, Yashoda Hospital, Secunderabad/INDIA, 3Department of Radiation Physics, Kidwai Memorial Institute of Oncology, Bangalore/INDIA

Introduction: Recently in our center we have upgraded our Varian Clinac 2100CD linear accelerator machine with 6MV Flattening Filter Free (FFF) beam. Even though the dosimetric characteristics of FFF beam have been reported both in experimental and Monte Carlo studies, the application of FFF beams in planning and delivery is complicated.

Aim of this study is to validate the commissioning of upgraded 6MV FFF beam dosimetrically using AAPM-TG-119 bench-mark plans for VMAT and to compare with IMRT plan data for both FF and FFF beams.

Material and Methods: AAPM TG-119 proposes a set of test clinical cases for testing the accuracy IMRT planning and delivery system. For these test cases, we generated two treatment plans. The first plan was done using 7-9 IMRT fields and a second plan utilizing one- or two-arc VMAT. Dose optimization and calculations were performed using 6MV FF & FFF photons in EclipseTPS. Dose prescription and planning objectives were set according to the TG-119 goals and plans were scored based on planning objectives. Treatment plans were compared using dose coverage, con-formity index (CI) for reference dose and homogeneity index (HI D5–D95). Point doses were measured at points recommended using ion chamber CC13. Planner Dosimetry was done using Imatrix with Multicube and

6000 5668 į 2000 1000 5

gamma evaluation was done using omnipro IMRT software with the criteria of 3% DD and 3 mm DTA.

Results and Discussion: VMAT dose distributions were comparable to IMRT plans. Our planning results were matched TG-119 planning results as shown in figure 1. conformity indices were ranged from 1.02-1.18. The point dose results were within 2% of planned dose values. All gamma evaluation results show gamma less than one for more than 95% data points.

There was a average reduction in treatment time using FFF beam as compare to FF beams for sliding window IMRT.In case of VMAT the reduction in treatment time was not significant as the dose per fraction was low and the gantry speed cannot be increased beyond 4.8% sec.

Conclusion: The result from the study shows that FFF beam upgraded in Clinac 2100CD satisfies AAPM-TG-119 for the given bench mark plans. They are also helpful to gain confidence in new modalities like FFF based VMAT and to test its capabilities at preclinical implementation stage. Interestingly the study deduced that sliding window IMRT using 6MV FFF beam shows 40% reduction in the treatment time as compared to conventional 6MV FF.

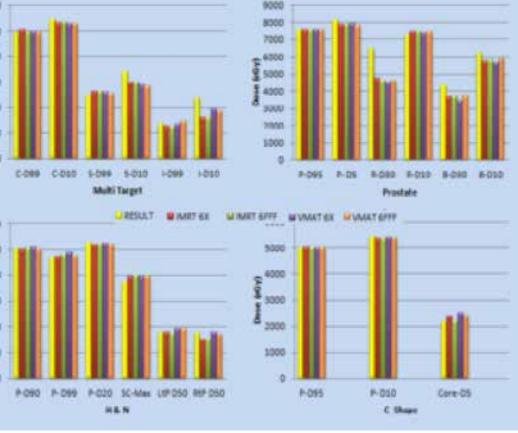

Figure.1-Results achieved for-TG-119cases.

PS05.055 - Study on Ion-recombination effect of 6MV Flattening Filter Free beam at isocenter and tray-level configuration using various detectors

Author(s): K. Ramalingam^{1, 2}, S. Senthil Kumar^{1, 3}, S. Ashokkumar^{1, 2}, K. Karthikeyan^{1, 2}, N. Jagadeeshkumar^{2, 4}, <u>S. Subramaniam^{1, 2}</u>; ¹Bharathiar University, Research and Development Center, Coimbatore/INDIA, ²Department of Radiation Oncology, Yashoda Hospital, Secunderabad/INDIA, ³Radiation Oncology, Madurai Medical College and Rajaji Govt Hospital, Madurai/INDIA, ⁴School of Advanced Science, Vellore Institute of Technology, Vellore/INDIA

Introduction: In high energy linac, removal of flattening filter from the path of the beam produces unflat-beam, with increased dose-rate (1400 MU/min for 6MV FFF beam and 2400 MU/min for 10MV FFF beam). The recombination of ions formed by separate ionizing particle tracks is dependent on the density of ionizing particles i.e., Dose-rate. This effect depends on the chamber geometry and applied polarizing voltage (IAEA-TRS398).

VMAT employs dose-rate modulation with Gantry angle, but during Patient specific QA, point dose and 2D-Planar dosimetry calibration is done with a fixed constant dose-rate.

Recently vendors are coming up with 3D-online verification methods using (Transmission) detectors placed near tray-level of the gantry. For 6MV-FFF, the dose-rate at tray-level (SDD=62cm) is 3750MU/min.

The aim of this work, is to study the ion-recombination factor(ks) of 6MV-FFF beam at central-axis and off-axis of the beam using different volume chambers, with available dose-rates and also to study ion recombination effect near tray-level configuration.

Material and Methods: Measurements were performed on VarianTM Clinac 2100CD capable of delivering VMAT. Recently, we have upgraded the Clinac to deliver 6MV FFF beam with a maximum dose-rate of 1400MU/min. Different volume ion chambers FC65G, CC13, PPC05 and A14 with different electrode separation were used for measurement.

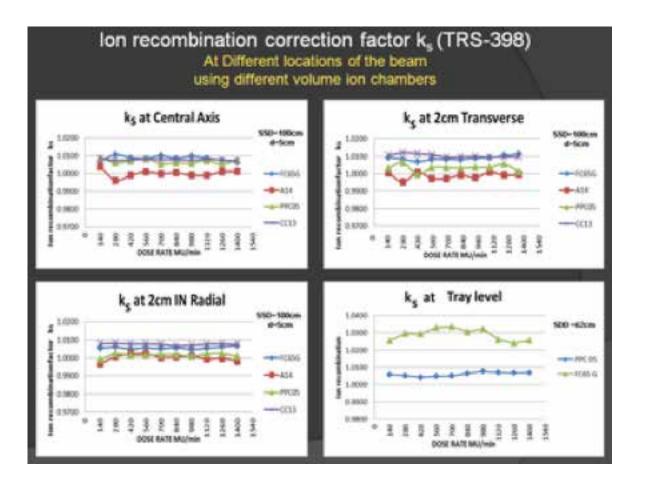

For a field size of 10x10cm2, SSD=100cm and depth 5cm, ks was measured at central-axis and 2cm off-axis for different available dose-rates. To simulate tray-level configuration ks was measured using PPC05 and FC65G chambers with a build up of 2 cm. ks was calculated using two-voltage method for +300V&+150V and analysed.

Results and Discussion: Ion recombination(ks) was increasing with increase in chamber volume. But for a particular chamber, it was less significant for variations in nominal dose-rate, Figure 1.

At Central-axis the average ks for FC65G (rcav=3.1mm,0.65cc) was 1.0086±0.0014 (1SD) and for CC13 (rcav=3.0mm,0.13cc) was 1.0091±0.0014 (1SD), which was closely comparable. It shows that ks depends not only on chamber volume but also on electrode separation (rcav).

At Tray-level configuration, the average ks was $1.029\pm0.0034(1SD)$ for FC65G (rcav=3.1mm) and $1.0060\pm0.0011(1SD)$ for PPC05 (2mm electrode spacing). However the ks was less significant for variations with nominal dose-rate.

Conclusion: For 6MV-FFF VMAT-QA, small volume chambers can be used for verification without correcting for ks in both CAX and off-axis. For Tray-level measurements, small volume chambers with electrode separation <2mm can be used without correcting for ks. However, at tray-level, lon-recombination effect should be accounted for when electrode separation is >2mm.

PS06 - TRACK 06: NEW TECHNOLOGIES IN CANCER RESEARCH AND TREATMENT

SP06.001 - GEANT4 versus MCNP5: Monte-Carlo ophthalmic brachytherapy dosimetry in the presence of gold nanoparticles for 125I and 103Pd

Author(s): Shervin Vahidian, Mohammad Vahidian, <u>Somayeh Asadi</u>, Mehdi Vaez-Zadeh

Physics, K.N.Toosi University of Technology, tehran/IRAN

The emphasis of the present work is to compare the effect of gold nanoparticles (AuNps) on healthy human ocular tissues in ophthalmic brachytherapy dosimetry, between water and eve phantoms by utilization of the two most noteworthy Monte-Carlo codes of GEANT4 and MCNP5. The intended study was based upon a simulated model of the human eye consisting different parts such as Lens, Cornea, retina, Choroid, Sclera, skull bone, Anterior Chamber and a melanoma tumor which was latticed to house AuNps required for the dosimetry comparisons of two uniquely defined radionuclides of ¹²⁵I and ¹⁰³Pd. The effects of the presence of AuNps on the absorbed dose by the tumor have been taken into account using both Monte-Carlo codes mentioned above; furthermore, the aberrations in dose calculations of the simple eye phantom and the realistic eye model were also an element of consideration. The importance of such evaluations on various compositions that are most common in Monte Carlo studies could prove to be rewarding, especially in presence of external anomalies such as AuNPs. With respect to the numerous distinctions between codes themselves, it is always fruitful to compare multiple of these programs with one another; hence, a rigorous inspection of the results has been executed, and dissimilarities have been highlighted for better understanding of the advantages and deficiencies of both codes. All in all, it is best stated that interdisciplinary methods of combining diverse therapeutic applications have gained much ground in our current era, and serve to significantly increase efficiency of cures worldwide.

SP06.002 - Clinical Implementation of an Elekta HexaPOD evo RT Couchtop with kV Cone beam Image Guided Radiation Therapy

Author(s): Lourdes M. Garcia, Cathy Neath

Medical Physics, Durham Regional Cancer Centre, Lakeridge Health, Oshawa/ON/CANADA

Image guidance is indispensable in modern radiation therapy, allowing fast and precise correction of misalignments thereby improving the efficiency and accuracy of the patient setup and treatment. The HexaPOD evo RT couchtop is a robotic couch with 6° of freedom, which allows automatic and remote correction of discrepancies between the pre-treatment and reference images. This work details the commissioning and post clinical implementation daily QA results of the HexaPOD installed on two linacs within our centre.

Commissioning of the HexaPOD and iGUIDE 2.0 tracking systems was performed by applying known translations and rotations of the Pentaguide phantom, acquiring and registering a CBCT (XVI 4.5), applying the shifts and evaluating residual error. The rotational accuracy of the 3D-CBCT is a limiting factor in the accuracy of the patient position. This was assessed using the EMMA phantom (SIE-MENS) which has 12 localization beads at the 3, 6, 9, and 12 o'clock position in 3 planes, -9.5cm, 0 and +9.5cm. The daily QA assurance program established incorporates the Pentaguide mounted on the Tilt Plate (Modus Medical Devices Inc.) with known rotations (1.25°, 0.7° and 1.0°) and translations. A localization scan is performed, registered, shifts applied, and a verification scan is acquired to assess the residual rotation.

Results of the daily QA (Dec 2014-Jan 2015) residual rotation and

translation for both HexaPOD systems are illustrated in Table 1 and Figure 1. The average residual rotation is $0.05^{\circ}\pm0.19^{\circ}$, and translation 0.00 ± 0.01 cm, over all directions and both systems. The residual rotation is limited by the accuracy of the CBCT reconstruction found to be up to 0.4° as assessed with the Emma phantom.

The Elekta HexaPOD robotic couchtop is operating within the manufacturer specifications. However, when used in combination with our current XVI imaging system, larger uncertainties are present.

PS06.003 - Ex-vivo experimental study with a new cluster-type microwave ablation antenna

Author(s): Qun Nan, Xiaohui Nie

College of Life Science and Bio-engineering, Beijing University of Technology, Beijing/CHINA

Microwave ablation which has the advantages of minimally invasive and high-efficiency was more and more used into a number of areas such as cancer treatment. when the tumor diameter is less than 3cm the ablation effect is ideal, but for larger tumors it must be a higher ablation time and a higher power which can result in the reduction of the antenna performance, so the uncertainty of curative effect enhanced. Therefore the study uses in ex-vivo bovine liver to explore the performance of a new cluster-type microwave antenna which has three microwave ablation needles. The temperature distribution and 60°C isotherm which can decide the scope of the effective ablation were explored. The study carries out with net power of 40W, 60W; ablation time was 5min, 10min, 15min, respectively. For the power of 40W, the maximum temperature, area, volume, diameter and longitudinal diameter was 88.812°C, 9.0511cm², 7.917 cm³, 2.902cm, 3.830cm, respectively with the ablation time 5min while 99.184°C, 19.043 cm2, 50.936 cm3, 3.794 cm, 5.835 cm, respectively with the ablation time 10min and 106.094°C, 25.627 cm², 81.655cm³, 4.612 cm, 6.719cm, respectively with the ablation time 15min. For the power of 60W, the maximum temperature, area, volume, diameter and longitudinal diameter was 100.047°C, 25.372 cm². 80.345 cm³, 5.343 cm, 6.908 cm, respectively with the ablation time 5min while 108.863°C, 42.216 cm², 185.716 cm³, 6.319 cm, 8.102 cm, respectively with the ablation time 10min and 110.219°C, 49.803 cm², 244.965 cm³, 7.228 cm, 8.720 cm, respectively with the ablation time 15min. The 60°C isotherm was ellipsoid-like. Under the same power, the 60°C isotherm increase with ablation time and at the same time. the 60°C isotherm increase with power, too. This study may make an important support for the development and clinical application of the antenna.

PS06.004 - Bio Magnetic Nano Particles (BMNPs) used for cancer treatment via Hyperthermia method

Author(s): <u>Amirsadegh Rezazadeh Nochehdehi</u>, Minoo Sadri, Ali Moahmmadzadeh

Biomaterials Engineering, Materials and Biomaterials Research center (MBMRC), Tehran/IRAN

Magnetic nano particles for various applications in the medical field such as Separation, Immunoassay, Drug delivery, Magnetic Resonance Imaging and Hyperthermia has been developed by many researchers. Therefore, the use of magnetic nano particles for the treatment of various cancers by using heat therapy is a rapidly growing and growing. In contrast, one of the main challenges facing researchers, optimization of properties and mechanism of biological effects induced Hyperthermia to control and minimize it. The purpose of this paper is to investigate, develop and identify different types of bio magnetic nano particles (BMNPs) in the diagnosis and treatment of cancer that has a new approach to the introduction of heat therapy (Hyperthermia) in the treatment of cancer as an alternative to radiotherapy and chemotherapy. Because of the use these nano particles directly in humans and animals, is very

important to evaluation of physical and bio-compatibility properties according to International Standard (ISO 10993) that in this article we have tried to be fully addressed. After studies done on previous research, it was found that the use of basic iron and cobalt nano particles with a bio-compatible coatings of polymer and ceramic compounds are the best option for medical applications. Furthermore, the need for fundamental and applied research in this area was further emphasized.

PS06.005 - GATE Monte Carlo Simulation for Dual Head LINAC Modeling

Author(s): <u>Seungwoo Park</u>, Han Kyeol Song, Su Chul Han, Haijo Jung, Kum Bae Kim, Young Hoon Ji

Korea Institute of Radiological and Medical Sciences, SEOUL/KO-REA

Introduction

In this study, we purposed a new LINAC system which had dual head to reduce irradiation time for tumor treatment. In order to design the dual head LINAC, 6 MV photon beam was simulated and evaluated quantitatively with GATE Monte Carlo code as a preliminary study.

Materials & Methods

The LINAC head was designed with VARIAN manufacturer's information. 6 MV photons were generated from the head and the photons irradiated to a water phantom for beam evaluation. GATE simulation was segmented by two stages, the one was to generate X-ray spectrum and the other one was for irradiation X-ray to the water phantom.

Results

The dual head irradiation was compared to single head irradiation in terms of the deposited energy which corresponded to treatment time. At single head simulation, the head was fixed along longitudinal axis direction. Whereas in dual head simulation the one head was placed at same position with the single head case but the other head was rotated along transversal axis direction. Fig 1-2 showed the deposited dose at box and sphere phantom, respectively. The efficiency was calculated that deposited dose from dual heads was divided by the dose from single head. At all conditions, dual heads showed higher treatment efficiency. Efficiency was increased about 40 to 60%.

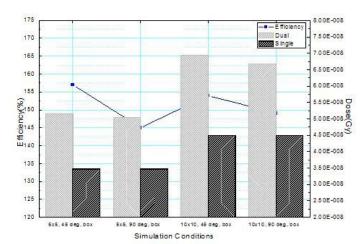

Figure 1. Comparison of the deposited dose and its efficiency at box phantom

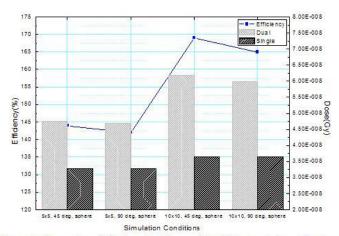

Figure 2. Comparison of the deposited dose and its efficiency at sphere phantom Conclusions

From the result, the dual head system had a higher dose deposition than a single head system. The dual head system will contribute to the real radiotherapy. However, the treatment planning system for dual head LINAC and dosimetry method are not established yet. The result was that measured deposited dose within the whole phantom size. Therefore, the planning method has to be defined and estimated. The real dual head LINAC system is being built and the specific research will be conducted on with the dual head system.

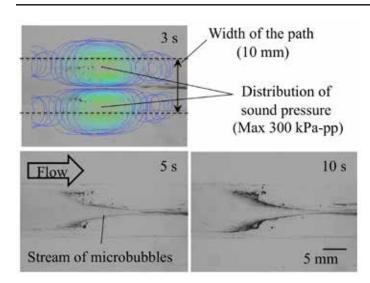

PS06.006 - Active control of microbubbles in flow using position and phase variations in three-dimensional acoustic field Author(s): <u>Kohji Masuda</u>, Shinya Miyazawa, Toi Sawaguchi, Naoto Hosaka, Takashi Mochizuki

Tokyo Univ. of Agriculture and Technology, Koganei/JAPAN

Though many experiments using effective combination of ultrasound and microbubbles for medical tratment, e.g., thermal therapy and drug delivery, have been reported, because injected microbubbles disperse in the human body, there are the following two major problems; low concentration of microbubbles in the target area, and risk of side effects due to unwanted microbubbles. To enhance local concentration of microbubbles, we have reported our attempts for active control of microbubbles by acoustic radiation forces, which were active path selectioin, aggregation formation, and trapping in flow. Since 2013 we have produced three-dimensional acoustic field of continuous wave to produce three-dimensional acoustic force using a matrix array transducer. In this presentation, we introduce our attempts for active control of microbubbles in flow using position and phase variations in three-dimensional acoustic field.

The flat array transducer has 64 elements on the aparture of 23.9 x 23.9 mm² with the resonance frequency of 1 MHz. A flow path was fixedly floated from the bottom of a water tank filled with water. Also we prepared the suspension of microbubbles with an average diameter of 0.5 μ m, which were produced from poly(ethylene glycol)-modified liposomes and perfluoropropane gas.

We have produced time-shared acoustic fields including the pairs of two focal points. Figure shows the successive images of the observation area after injection of microbubbles suspension (concentration of 0.05 mg lipid/ml) with flow velocity of 30 mm/s, where the maximum sound pressure was 300 kPa-pp and the positions of two peaks were moved periodically along the direction of flow. The inner shape of the path was with the thickness of 2 mm and the width of 10 mm. In the first frame, contour lines were superimposed to indicate the magnitude of sound pressure. Streamline of microbubbles was clearly confirmed in the middle of the two focal points, which indicates that most microbubbles were induced between them.

Here we have to mention that the phase difference between the two focal points in the fugure was opposite phase. On the other hand, in case of in-phase between the two points, most microbubbles were trapped in the middle of the path because two points were merged to form greater acoustic field. From this result acoustic force can be produced from the sound source to not only a propelling direction but also an attractive direction by position and phase variations in three-dimensional acoustic field.

PS06.007 - Adaptive radiation therapy of pancreatic cancer patients treated using Tomotherapy: Validation of dose accumulation algorithms using deformable image registration in SlicerRT

Author(s): <u>Eric Vorauer</u>¹, Peggy Le¹, Mithunan Modchalingam¹, Daniel Glick¹, Hans Chung¹, Lee Chin²

¹Sunnybrook Health Sciences Centre, Toronto/CANADA, ²University of Toronto, Department of Radiation Oncology, Toronto/CANADA

Introduction

Pancreatic cancer is one of the leading causes of cancer death in Canada. Radiation therapy treatments for pancreatic cancer at the Odette Cancer Centre typically consists of 54 Gy administered over 30 fractions. Due to the long treatment course, the patient's anatomy can shift away from what was used to create the original treatment plan. This interfractional variation can occur due to organ motion, weight loss or a change in the tumour volume. Using the Planned Adaptive ™ module from Tomotherapy, planning contours can be rigidly fused to a daily IGRT MVCT image to determine the actual daily dose to the target and surrounding organs at risk and assess the potential dosimetric risk due to such anatomical changes. However, the Planned Adaptive module currently lacks the ability to account for non-rigid changes in organ motion. Deformable image registration has the potential to account for daily deformations by performing a voxel by voxel mapping of the planning contours to the daily IGRT image. Previously, we optimized and validated a DIR algorithm to perform non-rigid deformable image registration of contours between planning KVCT and daily MVCT images using the radiation therapy research toolkit, SlicerRT. In the current work, we verify the accuracy of the developed DIR algorithm for daily dose accumulation and dose volume histogram assessment for targets and organs at risk.

Methods

Deformable image registration was performed on the first and last daily MVCT images acquired from the Tomotherapy unit of a patient undergoing treatment for pancreatic cancer. Two methods were performed to validate the potential of the DIR algorithm for dose accumulation.

In the "forwards" registration approach, planning contours are deformed onto the daily image containing on a "daily" dose calculated using the original treatment plan. In the "inverse" registration, the dose from the daily image is deformed onto the planning image containing the contours. Both registration directions use the same registration parameters, and in both cases, dose volume histograms are created after deformation. Dose volume histograms of the forwards and inverse methods will be compared using a DVH acceptance agreement criterion. In addition, V20 of the kidneys, V30 of the liver and max cord dose will be analyzed.

Preliminary Results

Initial results of the average DVH acceptance agreement from 5 patients are shown in Table 1.

Table 1. DVH acceptance agreement average for first and last fractions from 5 patients. Criterion is 1% dose and 1% volume.

First Fraction Organ	DVH Acceptance (%)	Last Fraction Organ	DVH Acceptance (%)
GTV	98.3	GTV	97.9

PS07 - TRACK 07: SURGERY, COMPUTER AIDED SURGERY, MINIMAL INVASIVE INTERVENTIONS, ENDOSCOPY AND IMAGE-GUIDED THERAPY, MODELLING AND SIMULATION

PS07.001 - Predictive Fluoroscopy: Minimizing Radiation Dose in Planning Endovascular Therapy for Intracranial Aneurysms Author(s): John S.H. Baxter¹, Peter Johnson², Elvis C.S. Chen¹, Terry M. Peters¹

¹Imaging, Robarts Research Institute, London/CANADA, ²University Hospital, London/CANADA

Introduction: Intracranial aneurysms are vascular abnormalities thought to be the effect of localized weakness in the arterial wall. [1] These often appear as vascular outpouching which have significant risk of rupture causing subarachnoid haemorrhage with mortality rates ranging from 50% to 80% [2]. Endovascular procedures are often used, requiring some form of guidance. The standard-of-care is to employ pre-operative CT and CTA for detecting the aneurysm, followed by peri-operative rotational angiography to determine C-arm fluoroscopic working angles for use during the intervention. Determining the working angle is complex, requiring the interventionalist to reason about the orientation and geometry of the aneurysm and surrounding vasculature with many confounding factors making automatic working angle selection problematic. The imaging involved in this workflow also involves significant radiation dose to the patient, which is of major concern.

Objective: Our objective is to develop a peri-interventional system for the selection of fluoroscopic angles for endovascular procedures without the use of peri-operative rotational angiography, resulting in a lower radiation dose to the patient.

Methods: We first co-register the CT and CTA, treating their coordinate systems as synonymous. The CT is then registered into a physical co-ordinate space using two peri-operative fluoroscopic views. Our interface uses a custom direct volume rendering [3] class to render the CTA. This view is replicated by operdictive fluoroscopy derived from the CT with the closest feasible C-arm angles. Once an adequate visualization is chosen, these angles can be programmed into the C-arm prior to the intervention. In total, this system eliminates the necessity of rotational angiography, thus simplifying workflow and mitigating radiation dose.

Future Work: Phantom experiments and retrospective studies using human data will be performed. These studies will determine if the registration accuracy is sufficient and that selected working angles

on CTA are not significantly different from those selected using rotational angiography. Additional work in human factors will be used to characterize how users interact with this system, guiding further improvements.

PS07.002 - Automatically Better Segmentation Author(s): John S.H. Baxter, Terry M. Peters Imaging, Robarts Research Institute, London/CANADA

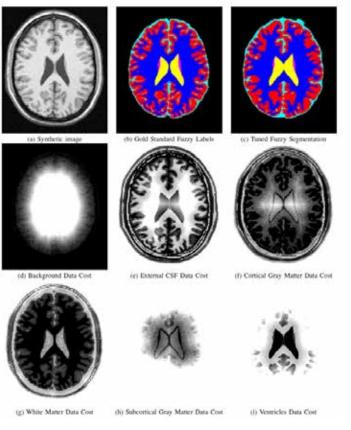

Introduction: Image segmentation is a fundamental procedure in many medical image analysis and modelling applications. Recently, advanced in convex optimization such as discrete graph-cuts and continuous max-flow algorithms have allowed for complex image segmentation procedures to be expressed in terms of a series of weighted convex functions, the sum of which can be readily and globally optimized. However, such an optimization-based segmentation framework suffers from one major drawback: the increasing number and inter-relatedness of weighting parameters[1]. Parameter selection algorithms exist for segmentation problems with a low number of degrees-of-freedom[1] or for discrete (non-probabilistic) segmentation[2], but there has yet to be proposed a framework for parameter selection in segmentation problems founded in variation optimization, such as continuous max-flow.

Methods: This approach is supervised meaning that a gold standard segmentation is provided to the algorithm which then finds the weighting parameters that imply the global optimality of the gold standard in terms of unweighted functionals also provided. The algorithm maintains an estimate of the set of these weights and iteratively generates competing max-flow-optimal segmentations. To ensure the gold standard has a lower energy than these competing segmentations, linear inequalities are created which further refine the estimate.

Compute $E_D(u^G)$, $E_S(u^G)$, and $E_D(u^*(\infty))$ Set $P_{-1} \leftarrow \emptyset$, $P_0 = \{\alpha | \alpha \ge 0, \alpha \in C(u^*(\infty))\}, t \leftarrow 0$ while $P_t/P_{t-1} \neq \emptyset$ do $Q \leftarrow$ the vertices of P_t $M \leftarrow \text{mean}(Q)$ if M is $\geq \epsilon$ away from any prior evaluated α then $u' \leftarrow$ output of solver with parameters M Update $P_{t+1} \leftarrow P_{t+1} \cap C(u')$ else Remove any of P_{t-1} 's vertices from QSet $P_{t+1} \leftarrow P_t$ for $\forall \alpha' \in Q$ do $u' \leftarrow$ output of solver with parameters α' Update $P_{t+1} \leftarrow P_{t+1} \cap C(u')$ end for end if Set $t \leftarrow t+1$ end while Return P_t

Results: The algorithm shown was proven to be mathematically correct. For empirical validation, the BrainWeb[3] MRI simulator was used with realistic functionals.[4] After four iterations, the algorithm

found the closest possible max-flow-optimal segmentation to the gold standard with only 2% of voxels mislabelled compared to 5% from thresholding. This algorithm is a low-cost, automatic method for improving segmentation, readily encorporated into any variational optimization-based segmentation framework used in modelling or simulation.

PS07.003 - Utilizing stream feature in GPU Monte Carlo Code to simulate photon Radiotherapy

Author(s): Yakub A. Bayhaqi¹, Supriyanto Ardjo Pawiro¹, Heru Suhartanto²

¹Department Of Physics, Faculty Of Mathematics And Natural Science, University of Indonesia, Depok/INDONESIA, ²Faculty Of Computer Science, University of Indonesia, depok/INDONESIA

Introduction: The development of Monte Carlo algorithm is still being conducted, including the use of computational methods in parallel on a GPU that in some computer applications can provide increased efficiency significantly. As one of the latest development in the use of computing in the Monte Carlo method has been carried out in a package called gDPM been done by Xun Jia with basic DPM algorithms previously developed in 2011. This gDPM package has been known to accelerate computing DPM package prior to 69.1 ~ 87.2 times with the accuracy of more than 97% were observed at an NVIDIA Tesla C2050 GPU against a CPU 2.27GHz Intel Xeon processors. Meanwhile, the current GPU devices can do more advanced utilization in parallelization such as streaming and dynamic parallelism. Thus, further development of gDPM still needs to be done to decrease time of Monte Carlo Simulation.

Method and Materials: The package uses ionizing particle in-

teraction simulation scheme that divides the process into several separate kernel to simulate the interaction between electrons and photons. Each thread of the GPU is responsible for the simulation of a particle, either primary or secondary. This simulation separation of electrons and photons can increase the computation time because of transition when the GPU must change kernel electrons to photons and vice versa, respectively and repeatedly. The streaming feature on the GPU allows two different kernel runs in a single program, so the merger between the simulated photons and electrons can be done. Therefore, the purposed streaming method were tested by using the NVIDIA GTX TITAN BLACK GPU which supports streaming. The gDPM code were also modified to be run in the final CUDA version.

Result and Discussion: Theoretically, the use of stream to solve two or more kernels in the GPU program can reduce computing time with a speedup of up to 1.33x. The sequence between photon and electron were then turn into a concurrent process which gives a more flexible transition. The result of streamed code is almost significant to the original code in accuracy. A maximum of 8.67% estimated dose discrepancy compared to ion chamber measurement were achieved in simulating a 6 MV photon beam in homogenous water phantom with 1 billion of particle history. While, the original gDPM code has a maximum discrepancy of 6.34% estimated dose. The simulation were done within 2.37x faster than the original code. In addition, a simulation of an IMRT Head and Neck cancer patient example from the original gDPM code, were also been done to take account of the code optimization and accuracy in heterogeneous material. A maximum of 1.92% discrepancy in estimated dose compared to the original code were achieved with 1.83x of speedup. Conclusion: This study shows that it is still possible to accelerate again in the computation time Monte Carlo along with the development of computing technology. The GPU stream feature slightly increase the efficiency of gDPM code. Although, there should be more investigation due to the accuracy because of the randomness in Monte Carlo method.

PS07.004 - The influence of two different drug infusion profiles on the pharmacodynamics model performance

Author(s): <u>Ana L. Ferreira</u>¹, Catarina S. Nunes², Joaquim Gabriel³, Pedro Amorim⁴

¹Faculdade de Engenharia da Universidade do Porto, Porto/PORTU-GAL, ²Universidade Aberta, Departamento de Ciências e Tecnologia, Delegação do Porto, Porto/PORTUGAL, ³Inegi, Faculdade de Engenharia da Universidade do Porto, Porto/PORTUGAL, ⁴Centro De Investigação Clínica Em Anestesiologia, Serviço de Anestesiologia, Centro Hospitalar do Porto, Porto/PORTUGAL

To model the effect of anesthetic drugs on the Bispectral Index (BIS) of the EEG is of great importance for a reliable predictive response model during surgery. In this study, the impact of using two different drug infusion profiles in a pharmacodynamics interaction model was studied and the methods were compared with respect to their performance. Clinical data of 22 patients were considered. The interaction model was optimized per patient using nonlinear least squares during the induction of anesthesia, and tested for prediction abilities of test patients. In the optimization phase, all models could follow the BIS trend with errors not significantly different from zero. In the test data the choice of drug infusion profile proved to have a significant impact, showing that the performance is greatly influenced by the interaction. Results also show a time delay between the BIS signal and the Modeled BIS in both groups. This delay corresponds to a delay in the dynamics of the patient and could be related to the delay in BIS processing time. This work is an important step to predict the effect of anesthetic drugs.

PS07.005 - Force Modeling of MRI-Compatible Robot for Pediatric Bone Biopsy

Author(s): Peyman Shokrollahi¹, Elnaz Shokrollahi², James Drake³, Andrew Goldenberg²

¹Biomaterial And Biomedical Engineering, University of Toronto, Toronto/CANADA, ²Mechanical And Industrial Engineering, University of Toronto, Toronto/ON/CANADA, ³Division Of Neurosurgery, Hospital for Sick Children, Toronto/CANADA

Purpose

Prediction of forces is pivotal to the success of skull/bone drilling in stereotactic neurological operations and orthopedic surgery [1]. A general mechanical model of this process that would help developing methods of avoiding bone trauma does not exist [2]. Uncontrolled forces can cause bone tissue trauma due to drill-bit breakage, drill breakthrough, and excessive heat generation [3]. Furthermore, controlling the applied force is more complicated inside a magnetic resonance imaging (MRI) system due to the existence of large static and gradient magnetic fields. A model considering the nonlinearities of drilling mechanics as well as the MRI effects is required to determine the optimal design and parameters.

Methods

To perform innocuous pediatric bone biopsy in the MRI, our goal is to model the applied force generated by an ultrasonic actuator and transferred by the biopsy hollow-drill to the bone, while observing MRI effects on the force. Therefore, the initial force was measured outside the MRI to evaluate the range and bandwidth (BW) of the force by implementing the system (Figure 1). The drilling force was applied on the epiphysis, metaphysis, and diaphysis of hen and swine femurs utilizing a bone biopsy drill and a cordless power drill.

Results and Discussion

The penetration force was in the range of 60-80 N for the hen and 80-100 N for the swine, producing a sinusoidal shape with the biopsy drill. However, a step-shape signal was achieved with a force lowered by 20 N when the power drill was used (Figure 2). The BWs of the signals were calculated using the Fourier transform; a maximum BW of 15 Hz was achieved for manual drilling of the swine bone and a minimum BW of 5 Hz for the power drilling of the hen bone. In conclusion, the model is valuable for controlling MRI-compatible bone-drilling tools.

PS07.006 - Comparing the Effects of Three MRI RF Sequences on Ultrasonic Motors

Author(s): Peyman Shokrollahi¹, James M. Drake², Andrew A. Goldenberg³

¹Biomaterial And Biomedical Engineering, University of Toronto, Toronto/CANADA, ²Division Of Neurosurgery, Hospital for Sick Children, Toronto/CANADA, ³Mechanical And Industrial Engineering, University of Toronto, Toronto/ON/CANADA

Obtaining accurate force and kinesthetic information produced by actuators is necessary for the success of robot-assistive surgical operations. Access to such information is not readily possible in MR environments due to the effects of giant static and gradient magnetic fields. The goal of this study is to quantify the effects of MRI on the behavior of ultrasonic motors (USMs), while performing bone biopsies on pediatric surgery. In this study, the effects of three sequences (FFE, balanced FFE, and ultra-fast spin echo, SSH-TSE) were considered on the torque generated by a USM, transferred as an axial force by our implemented robot and measured by our developed force feedback system. Different sequences show different effects on the generated axial force while the motor rotates in different directions

PS07.007 - Robotic positioning system of ultrasound transducer for ultrasonic therapy

Author(s): <u>Shinya Onogi</u>¹, Kaoru Natsume², Takashi Mochizuki², Makoto Hashizume³, Kohji Masuda²

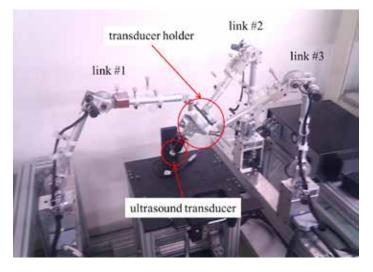

¹Center For Advanced Medical Innovation, Kyushu University, Fukuoka/JAPAN, ²Graduate School Of Bio-applications And Systems Engineering, Tokyo University of Agriculture and Technology, Tokyo/ JAPAN, ³Faculty Of Medical Science, Kyushu University, Fukuoka/ JAPAN

Microbubbles are widely used as contrast agents for ultrasound diagnosis. Moreover, microbubbles can also be used for therapeutic purpose; e.g. the heat amplification of high-intensity focused ultrasound ablation or carriers of acoustic targeted drug/gene delivery. However, injected microbubbles in a blood vessel are diffused throughout the whole body; therefore, the efficiency is limited. To address the issue, we have proposed microbubble delivery technique by using acoustic forces of ultrasound, and confirmed microbubbles can be controled in an artificial blood vessel. To apply the technique in vivo, navigation and robotic system are required to position ultrasound filed passing through target bifurcations of blood vessel network. In this study, we propose a robotic system for a microbubble delivery technique. The system feasibility was validated.

The system consists of a parallel link robot (Fig. 1) for positioning of a ultrasound transducer, an optical tracking device, in-house navigation software, and an ultrasound imaging device with a phased array 3D probe. To validate the system feasibility, we performed positioning accuracy validation by emitting ultrasound to a hydrophone in an agar phantom, and microbubble induction tests by using artificial blood vessel. Regarding the first experiment, the hydrophone was potted in the agar phantom and the position was measured by the tracking device. Under the guidance of the navigation, ultrasound was emitted to the hydrophone by the robot. The measured sound pressure was compared with the emitted ultrasound. Regarding the second experiment, a Y-shape artificial vessel (1 in and 2 out) was prepared and its Doppler volume was acquired by the 3D ultrasound. As pre-processing, bifurcations of the blood vessel network were extracted by the navigation software. To induce microbubbles into an intended path, the transducer position was controlled by the robot using the bifurcation position. Next, concentration of microbubbles was injected in the vessel, then ultrasound was emitted for induction of microbubbles. In the experiment, microbubbles behavior was observed by a microscope.

In the positioning accuracy validation, the system can position the transducer by 1 mm errors. Also, measured ultrasound pressure was 62.6 % of input pressure. The result includes attenuation. In the microbubble induction test, induced microbubbles were observed.

In this study, we developed and validated the robotic system with the ultrasound navigation for ultrasonic microbubble delivery technique in order to achieve less invasive therapy. We confirmed that ultrasound is surely emitted to a target position and microbubbles are induced by the system.

PS08.002 - Novel Optical Method to Determine Glass Transition Temperature of Polymers

Author(s): Yao-Xiong Huang, Jiang He

Department Of Biomedical Engineering, Ji Nan University, Guang Zhou/CHINA

A novel optical method is proposed for the determination of polymer glass transition temperature (T_g) by monitoring the refractive index variation of polymer microspheres with temperature using our method of microsphere imaging. It was demonstrated that the present method can eliminate most thermal lag and has sensitivity about six fold higher than the conventional method in T_g determination. So the determined T_g is more accurate and less change with heating rate than that obtained with conventional methods. The most attractive character of our method is that it can simultaneously determine the T_g of several polymers in an experiment, thus greatly saving time and heating energy. The method is not only applicable for polymer microspheres, but also for the materials with arbitrary shapes, therefore, it is expected to be broadly applied to different fundamental researches and practical applications of polymers.

PS08.003 - The Comparison of Temporal Change between Typically Developing Children and Children with ADHD in Rotational Motion Speed of Arms

Author(s): Miki Kaneko

Graduate School Of Systems Life Sciences, Kyushu University, Fukuoka/JAPAN

When medical doctors diagnose participants with ADHD, they evaluate soft neurological signs (SNS) from their motion by a visual observation. Rotational motion of arms (Pronation and supination) is one of SNS. The participant bends elbow to 90 degrees, and rotates the palm and the back of hands. These methods are hoped to be quantitatively established. In previous our study, we developed quantitative and simple evaluation system of pronation and supination using small wireless hybrid sensors. Our system was consisted of acceleration and angular velocity sensors and a notebook computer. We could obtain different features between typically developing children and children with ADHD by our system. In this paper, we compared temporal change of rotational motion speed between typically developing children (TDC) and children with ADHD in order to find features of pronates and supinates at full speed. Firstly, we separated 4 phases in measurement time and calculate FFT peak frequency in each phase. Measurement time is 10 seconds. Sampling frequency is 100 Hz. Subjects are 203 typically developing children and 40 children with ADHD aged from 7 to 12. From this result, we could obtain the different features between 2 groups (TDC and children with ADHD). The rotational motion speed of TDC decreased with time. In rotational speed of children with ADHD, variations were observed in each phase. From these result, rotational motion speed of children with ADHD is not stable compared to TDC. In TDC, the speed of rotational increased as they grew older.

PS09 - TRACK 09: BIOSIGNAL PROCESSING

PS09.001 - Sensitivity of heart rate variability indices for artificially simulated data

Author(s): Aleksandr A. Fedotov, <u>Anna S. Alulova</u> Lasers And Bioengineering Systems, Samara State Aerospace University, Samara/RUSSIAN FEDERATION

In modern cardiac practice methods for the analysis of heart-rate variability (HRV) are implemented to forecast the detection of different pathologies of the cardiovascular system. The heart rate is an important physiological index, which reflects processes of autonomic, neurohumoral, and central regulation in the cardiovascular system and throughout the entire human organism. In order to form diagnostic HRV indices mathematical analysis for the variability of durations of beat-to-beat intervals, defined as the time interval between two consecutive fiducial points of the biosignals like ECG signal or pulse wave are applied.

The application of modern mathematical methods of processing non-stationary and quasi-periodic data, such as Rescaled range analysis, Detrended fluctuation analysis, Rectified phase signal averaging, for analysis of heart rate variability (HRV) was considered. The mathematical models for simulating artificial cardiac beat-to-beat intervals that take into account the presence of various noise processes were created. The state model of the cardiovascular system based on analysis of self-similarity of heart rate was developed. The theoretical sensitivity of HRV indices to the change of the state of the cardiovascular system for the artificially simulated data was estimated.

The following HRV indices will be described and analyzed in details:

1) Statistical Index *RMSSD*: the square root of the mean of the squares of the successive differences between adjacent beat-to-beat intervals.

2) Spectral ratio LF/HF – the ratio of the spectral power density of beat-to-beat intervals at low frequency range (LF) (from 0.04 Hz to 0.15 Hz) to the spectral power at high frequency range HF (from 0.15 Hz to 0.4 Hz).

3) Hurst exponent H, calculated by the normalized range method (R/S analysis), characterize the ratio of the strength of the trend to the level of the noise.

4) The coefficient of fluctuations α , determined by Detrended Fluctuation Analysis (DFA). The DFA method enables to study the structure of different processes, including non-stationary processes, from the point of view of statistical self-similarity.

5) Acceleration capacity (AC) and deceleration capacity (DC) of heart rate. These coefficients are non-linear and determine the intensity of the quasi-periodic trends in heart rate and calculated by phase-rectified signal averaging method.

PS09.002 - The Smoothness of a signal as a new feature in Signal Averaged Electrocardiogram that can be used in cardiac electrophysiology diagnosis.

Author(s): Peyman Sheikhzadeh¹, Negisa Seyyedi² ¹Medical Physics And Engineering Department, Tehran University of medical science, tehran/IRAN, ²Medical Informatics Department, Shahid Beheshti university of medical science, Tehran/IRAN

Introduction:

Sudden cardiac death is the most common cause of death in the world. Myocardial infarction (MI) and ventricular arrhythmias caused

by MIs are among the main factors of sudden cardiac deaths. Accurate recognition, discrimination and prognosis of myocardial infarction and ventricular arrhythmias will be able to reduce the mortality. Several ECG-based methods such as Signal Averaged Electrocardiogram (SAECG) have been proposed , however signal analysis and extraction of new features is being investigated.

Methods and materials:

The signals of orthogonal leads from 120 cases containing healthy subjects and myocardial infarction with and without the history of ventricular tachycardia (VT) and fibrillation (VF) were filtered, denoised and averaged following their selection from PTB diagnostic database. After the calculation of vector magnitude, final signal smoothness was obtained which is the smoothness magnitude of the curve in SAECG. In order to measure the smoothness of function y (t) over an interval [0, n], the sum over square of second derivative of y (t) was used, where t is the number of samples (time) and y (t) is the signal amplitude (voltage). To obtain comparable criteria, the acquired values were normalized to the maximum peak in all cases. Finally, the new feature has been evaluated using T-test and Mann-Whitney U statistical analysis for the two groups of MI patients and healthy controls and MI Patients with and without ventricular arrhythmias (VT&VF), respectively.

Results:

Statistical comparisons of 50 MI patients and 50 healthy controls using T-Test analysis indicated that the signal smoothness in MI patients valued more than healthy people (0.2 ± 0.12 vs. 0.12 ± 0.03 , P-value < 0.001). Also, the area under the ROC curve for this feature was obtained 0.725. In addition, statistical comparisons of 50 MI Patients and 20 MI+VT/VF using Mann-Whitney U analysis showed that the value of signal smoothness in MI+VT/VF was much more than MI patients without any ventricular arrhythmias (0.3 ± 0.22 vs. 0.19 ± 0.11 , P-value =0.208(P< 0.05)).

Conclusion:

In this study, we proposed a new feature and index called curve smoothness in SAECG to differentiate MI patients from healthy controls. The feature represented good results to distinguish MI patients with and without ventricular arrhythmias so it can be very effective in prognosis of these arrhythmias. Evaluation of other cardiac signals using this new feature may hopefully leads to the valuable results in cardiac electrophysiology studies.

PS09.003 - Comparison of the Three Filter Algorithms for Detection of Electrically-Evoked Short-Latency Responses in Retinal Ganglion Cells.

Author(s): <u>Myounghwan Choi</u>¹, Jungyeol Ahn², Sungjin Oh³, Kilhwa Pi³, Youngjoon Chee¹, Hyoungho Ko⁴, Dongil Cho³, Yongsook Goo², Kyo-In Koo¹

¹Department Of Biomedical Engineering, University of Ulsan, Ulsan/ KOREA, ²Department Of Physiology, Chungbuk National University School of Medicine, Cheongju/KOREA, ³School Of Electrical Engineering And Computer Science, Seoul National University, Seoul/KOREA, ⁴Department Of Electronics Engineering, Chungnam National University, Daejeon/KOREA

When retinal ganglion cells are stimulated *ex vivo* by electrical current, short latency responses (within 30 ms) and long latency responses (over 30 ms) are evoked. The short-la-tency response is suspected to be originated from the direct elec-trical stimulation. For optimal stimulation protocol of retinal prosthesis, this short-latency response is getting important more and more. In this paper, we compared and evaluated perfor-mance of the three algorithms for the short-latency spike detec-tion; suppression of artifacts by local polynomial approximation (SALPA), moving average filter

(MAF), and forward-reverse filter (FR filter). The SALPA and the FR filter showed better detection performance comparing with the MAF algorithm.

PS09.004 - Photoacoustic Speckle and Spectral analysis of Vasculature Trees

Author(s): <u>Muhannad N. Fadhel</u>, Michael C. Kolios Physics, Ryerson University, Toronto/CANADA

This paper discusses the use of ultrasound tissue characterization methods to photoacoustic (PA) data to differentiate between tissues with different vasculature structures. The dominant source responsible for ultrasound scattering in soft tissues (including tumors) is not well known in pulse echo ultrasound. PA imaging is based on the detection of ultrasound waves generated by optical absorption. Since the hemoglobin in blood dominates the absorption of light in soft tissues (at particular laser wavelengths), the PA signal is dominated by the contribution of the vasculature. Organized and chaotic vasculature trees were simulated using a fractal model to represent normal and tumor vasculature, respectively. The generated PA signals from these vascular were simulated through the solution of the photoacoustic wave equation using the Green's function approach. Ultrasound resolution PA signals generated were detected by simulating a 256 element transducer with a 10-50 MHz bandwidth. Reconstructed images were acquired using a delay and sum method. Image analysis was performed by fitting the image probability density functions (PDF) of Rayleigh, Nakagami (NG), and Generalized Gamma (GG) distributions to the histogram of the reconstructed images. The speckle sizes of the reconstructed PA images were calculated using autocovariance. Spectrum analysis of the ultrasound frequency components of the photoacoustic signals was performed by linear regression analysis of the power spectrums of the radiofrequency (RF) data, as done in conventional ultrasound tissue characterisation. The results suggest that the Rayleigh, NG distributions, and the power spectrum regression analysis can be used to differentiate between the simulated normal and tumor vasculatures. The changes in these parameters correlate to a higher density of tumor vasculatures than normal vasculatures.

PS09.005 - The algorithm for the diagnosis of ventricular tachycardias from electrocardiogram

Author(s): Martin Holub, Martina Šrutová, Vaclav Kremen, Lenka Lhotska

Department Of Cybernetics, Czech Technical University in Prague, Prague/CZECH REPUBLIC

Ventricular tachycardias (VT), fibrillations (VF) and flutters (FL) are heart rate disturbances ranked among life threatening arrhythmias. We designed and tested an algorithm for automated detection of VT, VF, and FL events from Holter ECG data. The algorithm is based on the detection in a frequency domain, which is supported by the detection in a time domain. The algorithm was tested using ECG signals including VT, VF, and FL taken from AHA and MIT-BIH databases. Overall performance of the algorithm was sensitivity 80.9% and positive predictivity 66.8% (whole data set). The results show a discrimination of VT, VF, and FL from the normal sinus rhythm and its discrimination from the noise. The importance to reach high sensitivity is reflected in the detection. The algorithm achieved a very high resistance to the power line interference and random noise. It provided very good results, in particular with well-balanced ratio between sensitivity and positive predictivity.

PS09.006 - Modelling of Platelet and White Blood Cell in Dengue Patients using Bioelectrical Impedance Analysis technique Author(s): <u>Fatimah Ibrahim</u>¹, Nurhidayah Mohd Paiz¹, Saadah Sulaiman², Sharifah Faridah Syed Omar³

¹Biomedical Engineering, University Malaya, Kuala Lumpur/MALAY-

SIA, ²KPJ Damansara Specialist Hospital, Petaling Jaya/MALAY-SIA, ³Medicine, University Malaya, Kuala Lumpur/MALAYSIA

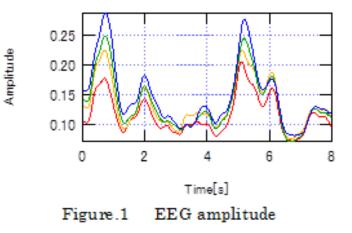

Abstract This paper presents a modelling for predicting white blood cell (WBC) and platelet (PLT) in dengue patients by using bioimpedance analysis (BIA) technique. Analysis was done using multiple regression analysis to find predictive equations for WBC and PLT. All BIA parameters, patient's symptoms and demographic data were investigated to find best predictors. In this analysis, best predictors are phase angle (PA), extracellular mass (ECM), total body water (TBW), dizziness, myalgia and petechial rash to predict WBC. For PLT, best predictors are resistance (RES), ratio of extracellular water to intracellular water (ERI), vomiting and epigastric pain. However, PLT and WBC modelling are able to predict 18.4% and 24.9%, respectively. METHODS Dengue database was obtained from Ibrahim, F. 2005. 210 adult patients aged 12 years and above, admitted in Hospital Universiti Kebangsaan Malaysia (HUKM) with confirmed dengue infection were prospectively studied. Before BIA measurement, patients were asked to refrain from eating and drinking at least 4 hours. Data collected were in the form of patient's clinical and epidemiological data, including fever onset, symptoms, signs, physical examination, blood results and BIA measurements. For BIA measurement, patient was asked to lie supine and two sets of electrodes were placed on hand and foot at right-hand side. As patients admitted at different stages of illness, data collected was based on day of defervescence, where the fever subsided below 37.5°C. Day 0 was used to represent defervescence day. Thus, PLT and WBC modelling was evaluated on fever day 0 as most patients' condition worsen and deteriorate suddenly. The statistical data analysis was done using simple linear regression and multiple linear regression tests to predict significant predictors for both models, using SPSS software. RESULTS From analysis done, resistance (RES) and ratio of extracellular water to intracellular water (ERI) were found as significant predictors for WBC. The adjusted R2 was around 1.8%. Gastric and vomit were also the significant predictors as well and when added to the model, the adjusted R2 improved to 18.4%. Hence the model can be written as follow: PLT = 47.468 + 7.806(RES) + 11.145(ERI) - 25.588(vomit) - 18.574(gastric) Multiple regression analysis was used to find the best predictors for modelling WBC. As dizziness, myalgia and petechial rash were also found as significant predictors, they explained 15.9% of the WBC's variation. When PA, ECM and TBW were added into the model, adjusted R2 was around 24.9%. Hence the model can be written as follow: WBC = 6.774 - 0.115(PA) - 0.090(ECM) + 0.115(TBW) + 1.227(dizziness) + 0.612(myalgia) - 1.771(petechial rash) CONCLUSION Future work is to improve the PLT and WBC modelling using BIA technique by increasing the number of samples and using an advanced artificial intelligence method. REFERENCE Ibrahim, F. Prognosis of Dengue Fever and Dengue Haemorrhagic Fever using Bioelectrical Impedance, PhD Thesis, Faculty of Electrical Engineering, July 2005, 1-398 ACKNOWLEDGMENTS We would like to thank University of Malaya High Impact Research Grant UM-MOHE UM.C/625/1/HIR/ MOHE/05 from Ministry of Higher Education Malaysia and University of Malaya Research Grant (UMRG: RP009A-13AET) for supporting our research.

PS09.007 - Combination of Multiple Signal Processing Techniques for Multi-class Motor Imagery Detection using Mu Rhythm

Author(s): <u>Rina Kojima</u>, Masaki Kyoso, Yuichi Shimatani The Graduate School Of Engineering, Tokyo City University, Tokyo/ JAPAN

BCI (Brain-Computer Interface) can be classified into two types, that is, input type to send information to the brain and output type using reversal direction of information. We focused on the output type because it is a technology capable of controlling the external equipment at will and processes the measured brain signals in the

computer. Especially, noninvasive motor imagery based braincomputer interface (BCI) is an appropriate solution for upper limb stroke rehabilitation. However, in multi-class brain activity detection with scalp EEG. robustness against background EEG are required for practical use. We proposed the combined application of signal processing techniques such like independent component analysis (ICA), coherent analysis and so on to solve the problems. These are the techniques to separate and enhance each signal source with multi-channel mixed source signal. In this study, multi-channel scalp EEG signals recorded during hand and leg movements were used for the evaluations and the analysis. Figure1 is an example of the measured mu rhythms from four electrodes with hand movement in 2-5 seconds. In mu rhythm, he amplitude is reduced while movement including pre-movements and recovery after movements however it must be processed with some techniques for applications because this phenomenon is unstable. This study also tried to apply the signal processing techniques to improve it. Multi-channel scalp EEG signal measurement was performed with four electrodes placed on the primary motor area along central sulcus. Slides for instructions were used to notify the timing of movements the subject. EEG signals measured from primary motor area were analyzed by ICA. Then the signals in which event-related desynchronizations were found were compared with the original signals. The results by using ICA show that the components with and without desynchronizations were separated. The results on the rate of amplitude degradation from event-related desynchronization show that ICA could enhance event-related desynchoronization by separating background scalp EEG component. For further improvement, additional signal analysis is in progress. Techniques which can enhance the phenomena induced by the different motions such like coherent analysis have been applied to the ICA output.

PS09.008 - The comparison of severity assessment methods of kinetic tremor in Parkinson's disease using wearable sensors Author(s): <u>Hong Ji Lee</u>¹, Han Byul Kim¹, Hyo Seon Jeon¹, Sang Kyong Kim¹, Woong Woo Lee², Hye Young Park², Chae Won Shin², Beom Seok Jeon², Kwang Suk Park¹

¹Seoul National University, Seoul/KOREA, ²Seoul National University Hospital, Seoul/KOREA

Tremor is involuntary and rhythmical shaking movement of a body part and one of symptoms in Parkinson's disease (PD). Gold standard method for PD' tremor assessment is the Unified Parkinson's Disease Rating Scale (UPDRS). Because UPDRS is based on visual observation, tremor severities are subjectively rated depending on clinical expertise. Several studies have reported objective tremor assessment methods using accelerometers, EMG, and actigraphy. They focus on rest and postural tremors that are rated relatively accurate because of steady state. However, although kinetic tremor, especially finger-to-nose test, includes several tremor factors such as intention tremor (goal-directed movement), action tremor (voluntary movement), and postural tremor (stretch forward and stay at target), there have rarely been researches about finger-to-nose test. Especially, kinetic tremor is difficult to assess by visual observation because of movement of a body part.

This study was approved by the Institutional Review Board of Seoul National University Hospital (IRB No. D-1407-011-590). 31 patients with PD participated in the kinetic tremor examination. All patients provided written informed consent prior to study participation. The number of patients was 9, 10, 7, and 5 according to mean UPDRS 0, 1, 2, and 3, separately.

Our device integrated tri-accelerometers and tri-gyroscopes (\pm 8 g and \pm 2000 dps) was attached on the patient's index finger. Patients moved slowly their finger from their nose to the target repetitively. The sampling rate was 125 Hz. Measured accelerometer and gyroscope signals were scaled and integrated. Then, root mean square and peak power were calculated as features. The average UPDRS of two clinicians was used as standard.

Two filtering methods for removing voluntary movement during finger-to-nose were compared. The movement velocity considerably depends on patients. First, fixed frequency filter, 1 Hz or 2 Hz high-pass-filter that did not affect tremor frequency band (3-12 Hz), was used. Second, adaptive filter, Multivariate Empirical Mode Decomposition (MEMD), was utilized. The signals were expressed by the sum of the intrinsic mode functions in tremor frequency band. Moreover, two classifiers, linear Support Vector Machine (SVM) and Hidden Markov Model (HMM), were compared, because kinetic tremor is time dependent signal. Features were extracted from 3 s moving window with 1.5 s overlapping for HMM. Leave-one-out Cross-validation was used for performance evaluation.

Tremor severities were estimated as 0, 1, 2, or 3 by combination results of accelerometers and gyroscopes. When using fixed frequency filter to remove voluntary movement, the accuracy of tremor severity estimation showed 64.5% on SVM. However, the performances from MEMD filter increased to 83.9% on SVM. Moreover, the results from HMM had 93.5% accuracy that was higher than 83.9% accuracy from SVM.

Therefore, adaptive filter was suitable for removing background noise and voluntary movement during kinetic tremor and HMM classifier fits for time dependent tremor signals. Tremor severities are objectively and accurately assessed through this methods on rest and postural tremors as well as kinetic tremor.

ACKNOWLEDGMENT: This study was supported by a grant of the Korean Health Technology R&D Project, Ministry of Health & Welfare, Republic of Korea (No. HI13C0455).

PS09.009 - Unobstructive blinking detection wearable device utilizing transparent conductive ITO film for smartphone users to prevent of computer vision syndrome Author(s): Jeong Su Lee, Kwang Suk Park Seoul National University, Seoul/KOREA

About 90% of the people who spend three hours or more a day at a visual display unit device such as a computer screen or a television were affected computer vision syndrome (CVS), according to the National Institute of Occupational Safety and Health. CVS is resulting from focusing the eyes on visual display terminal for protracted periods of time. It includes some symptoms such as headaches, blurred vision, and dry eye. Recently, the risk of the syndrome has been boosted by the prevalence of smartphone. Decreasing of

frequency of blinking might cause dry eye. Conventional method of blinking is electrooculography (EOG) which requires direct electrical contact between the skin and Ag/AgCl electrodes via conductive gel. However, using of such electrodes is not adequate since it would cause skin irritation. Alternative methods which are image processing approaches available for use with a video camera. However, these require the user's face to be within the angle of the video camera at a fixed distance. To resolve the lingering shortcomings of these alternative approaches, we propose a blink detection system based on a non-direct electrical contact electrodes which are capacitively coupled electrodes. We developed unobstructive blink rate detection wearable device which is glasses utilizing transparent conductive films. The films were attached to the lens of conventional glasses and able to measure eye blink while not blocking field of vision. When a user blinks the eye, significant positive peak was detected through the pair of films and acquired signal was transmitted to a computer. 4 Healthy subjects who were no symptom of dry eye were participated in this study to validate proposed system. Blinking rate was measured at rest state, during playing a smartphone game and searching the internet with smartphone for 5 minutes respectively. We counted the number of blinking at different task. According to the result, we found that the device didn't miss any blinking signals in comparison to reference EOG signal. We also found that blinking rate is decreased by up to 50% when the subjects using their smartphone in comparison with resting state. We expect that the proposed device with visual or auditory feedback when the rate of blinking is below certain threshold is able to prevent dry eye when smartphone users are using their smartphone.

PS09.010 - A Simple, CO2-Based Method to Reconstruct the Molar Mass of the Dried Respiratory Gas within a New Double-Tracer Single Breath Washout

Author(s): <u>Johannes Port</u>, Christoph Joppek, Joachim H. Nagel Institute of Biomedical Engineering, Stuttgart/GERMANY

A new single breath washout (SBW) using sulfur hexafluoride and helium as tracers has been proposed, which offers a considerable potential for the early detection of obstructive airway diseases like cystic fibroses (CF), chronic obstructive pulmonary diseases (COPD) and asthma (AS). After normal breathing of medical air, just one single breath of the double-tracer gas (DTG) that has the same molar mass (MM) as medical air, is necessary, a major advantage especially for elderly and very young patients since the measuring time is very short and only normal tidal breaths are required.

For the diagnosis, the expiration phase just after inspiration of the DTG is of interest. The respiratory flow and the carbon dioxide concentration (CO₂) of the undried gas, as well as the MM of the gas dried in a nafion tube, are measured. Specific parameters could be determined from the difference between the MM-signals with and without DTG. However, during this phase the MM without DTG is unknown and first needs to be reconstructed from the values of the MM- and the CO₂-signals measured without DTG. From these data, the first 25% but not more than 5s and the last 500ms are deleted. This precludes artifacts resulting from insufficient sealing of the mouth piece at the beginning of the measurement, and the rise time of a spike, which occurs at the inspiration of the DTG. Additionally, we use a 2nd order Bessel low pass filter with a cutoff frequency of 3Hz for the CO₂-signal to adapt its shape to that of the MM-signal, which due to dispersion effects within the nation tube is low pass filtered.

With the results, the ordinary least squares regression method is applied to determine the slope and intercept values needed for the prediction of the MM-signal from the CO_2 -signal. To compensate for the time delay between the MM- and the CO_2 -signals, which are measured at different sites, we apply the regression method for different time shifts between both signals. The time shift, at which the

predicted and measured MM values yield the lowest mean square error, is taken to synchronize the signals.

This reconstruction method has been applied to the independent datasets of 92 adult subjects and 60 school-aged children. The adult group included 35 healthy (HA), 19 COPD, 13 CF, and 25 AS subjects, among the school-aged children, there have been 18 HA, 21 CF, and 21 AS children. The reconstruction proved independent from the health status, and the mean coefficients of determination calculated over all adult and school-aged subjects, and over the datasets separated by their health status yield values very close to 1 with standard deviations close to zero. Thus, the proposed reconstruction method fulfills all requirements to become the standard method of choice within the DTG-SBW, since it is simple and has a high reliability and reproducibility. Using a standard reconstruction method avoids variability within the datasets coming from different methods, and it makes the datasets comparable among each other.

PS09.011 - Mirror Movements in Writer's Cramp—A Study with Multi-Channel EMG

Author(s): Venkateshwarla R. Raju

Biomedical Eng & Neurology & Neurosurgery And, Nizam's Inst of Medical Sciences (NIMS) University & Hospital, HYDERABAD/INDIA

The purpose of present investigation is to design and fabricate multichannel EMG to differentiate between those with concordant(C) and discordant(D) mirror movements(MMs) in Writer's cramp (WC), in order to establish that there is a quantifiable difference between these two groups.

This study was conducted at Nizam's Institute of Medical Sciences (NIMS) a tertiary-care-centre in Hyderabad(India). A suitable multi-channel EMG was designed-fabricated (with an input impedance of 200MegaΩ to record digitized EMG signals simultaneously with a set of five, innocuous microelectrodes 50µ). The basic signal data consisted of EMG-signals gathered from5muscles of RH, when subject (patient) first wrote with RH and then, with LH i.e., righthand-writing-signal(RHWS) and left-hand-writing-signal(LHWS). Duration of signal-recording was10seconds, with3kHz-Sampling-frequency, giving30,000 readings for each-muscle. The study showed significant quantifiable EMG differences in the signals seen while writing with R and L hands between those WC-subjects with concordant MMs(C-group) versus those with discordant MMs(D-group). This was mainly seen in the measures-of-dispersion of signal(standard-dispersion), variances and their-ratio(F-ratio). These were statistically significantly different between two groups(C-and-D), and pattern-of-differences were consistent with the hypothesis that the D-group had a compensatory-force which overcame the dystonic-force resulting in the final abnormal-posture. This was seen in the form of larger-variances and standard-differences in the RHWS in D-group as compared to C-group, as the dystonic and compensatory-forces both contribute to the instability. These differences were robust and seen in every measure-of-dispersion, such as in the patterns of significance of f-values for ratios of variances. Cluster and more sophisticated-analyses using advanced-multivariate-techniques leading to effective data summarization and measures of dissimilarity between subjects as reflected in the signals recorded and consequent possible clustering among them, however, did not lead to any meaningful clinical conclusions. These analyses could possibly be applied to longitudinal follow-ups and correlations with a normal control population in future to better comprehend WC phenomena.

PS10 - TRACK 10: REHABILITATION MEDICINE, SPORTS MEDICINE, REHABILITATION ENGINEERING AND PROSTHETICS

PS10.001 - Human Knee Simulation Using CMAC ANN Author(s): Roberto A. Lima, <u>Lourdes M. Brasil</u>, Vera R.F.D.S. Marães, João P. Martins Fga, UnB, Brasília/BRAZIL

This paper aims to show the use of a CMAC (Cerebellar Model Articulation Control), a kind of ANN (Artificial Neural Network). The CMAC is based on cerebellum of mammals, but despite this characteristic, actually, what promotes its use, is its very fast operation, which makes it suitable for adaptive control in real time. This type of control is needed, for example, to control an active transfemoral prosthesis. Simulation of knee angular velocities, based on collected data from the contralateral knee, is presented. The simulation is available as open source software.

PS10.002 - Development of New Method to Create In-school Tactile Maps for Visually Impaired Children

Author(s): <u>Kouki Doi</u>¹, Takahiro Nishimura¹, Masaru Kawano¹, Yumi Umesawa², Harumi Matsumori², Hiroshi Fujimoto³, Mayumi Sawada¹, Yoshihiro Tanaka¹, Takeshi Kaneko¹, Katsuhiro Kanamori¹, Masumi Takei⁴

¹National Institute of Special Needs Education, Yokosuka/JA-PAN, ²Graduate School Of Human Sciences, Waseda University, Tokorozawa-shi, Saitama/JAPAN, ³Waseda University, Tokorozawa/ JAPAN, ⁴Gunma Prefectural School for the Blind, Maebashi/JAPAN

Adequate information support for visually impaired children and adults is necessary. In particular, there is a demand for information support tools that ensure students with visual impairment have access to necessary information in public facilities (e.g., schools). Teachers and visually impaired students at schools for the blind require tactile maps that allow the students to grasp the arrangement of school facilities and classrooms. On the other hand, because much time is needed to read and comprehend tactile maps, audio information support is also required. In this study, we established a method for creating in-school tactile maps (trial version) that can allow visually impaired students at schools for the blind to grasp the arrangement of school facilities and classrooms. In particular, we developed a device to create Braille and tactile maps using ultraviolet curable resin ink (Figures 1), and created tactile maps (trial version) with high tactility. We also improved the usability of a voice-reading interface (pen type) that allows visually impaired students to obtain audio information from tactile maps (Figures 2). Moreover, instead of using a stand-alone model for the pen-shaped interface, we placed voice-reading data on a network server, which allowed voice outputs of registered data from terminal units such as tablets. Therefore, it became easy to update the voice data. In addition, we conducted interviews with teachers in the field of education for the blind and visually impaired students to research the usability of in-school tactile maps. Their comments showed that almost all of the teachers and students who participated in this research found our proposed in-school tactile maps highly usable. This study led to the proposal of a method for creating in-school tactile maps that allow visually impaired students to grasp the arrangement of school facilities and classrooms.

PS10.003 - Experimental Study on Usability Evaluation of a Hydraulic Jack Lever

Author(s): Atsushi Sugama¹, Takahiro Nishimura², <u>Kouki Doi</u>², Shigenobu Shimada³, Manabu Chikai⁴, Kiyohiko Nunokawa⁵, Shuichi Ino⁴ ¹National Institute of Occupational Safety and Health, Japan, Kiyose/ JAPAN, ²National Institute of Special Needs Education, Yokosuka/ JAPAN, ³Tokyo Metropolitan Industrial Technology Research Institute, Sumida/JAPAN,⁴National Institute of Advanced Industrial Science and Technology, Tsukuba/JAPAN, ⁵Tokyo International University, Kawagoe/JAPAN

Hydraulic jacks can be used to rescue drivers trapped inside vehicles during car accidents or victims trapped under debris during earthquakes. However, firefighters using hydraulic jacks have indicated that they apply excessive workloads on the body. Therefore, the workload on the body should be reduced and their usability should be improved. The purpose of this study is to evaluate the physical load during lever operation of existing jacks and to determine the appropriate posture for lever operation, as an initial research step.

As an experimental task, subjects squatted to the side of a jack and operated the lever up and down with one hand. We used Blackhawk Automotive Porto-Power hydraulic cylinders for the hydraulic jacks. There were three experimental conditions consisting of squatting positions relative to the jack lever. The three conditions are as follows: a near condition (side1), a far condition (side2), and a front condition (front), as shown in Figure 1.The operating speeds were one second each for lifting and lowering the lever, and each trial was performed in 30 s. A Motion Capture System and floor reaction force sensor were used to measure operating postures and floor reaction force, as shown in Figure 2. In order to evaluate muscle loads, surface EMG sensors were used. For subjective evaluation, interview surveys during operation were investigated in 50 stages from 1 (extremely light) to 50 (maximal exertion).

From the results of the experiment, we found that the near condition experienced fewer loads than the far and front conditions. The results of the EMG showed muscles such as deltoid, biceps, and triceps are active. In addition, erector spinae muscles are believed to be also active in maintaining a squatting posture. Since the lever requires repeated operation, it is necessary to reduce the muscle loads.

PS10.004 - Neuromuscular Reconnection Methodology By Cap Sense Absorption And Diffusion Signal

Author(s): <u>Ricardo Jaramillo Diaz</u>¹, Luis J. Martinez¹, Hermann Dávila Torres²

¹Coordinacion De Biomedica, Universidad ECCI, Bogotá/COLOM-BIA, ²Bogotá D.c, Universidad ECCI, Bogotá D.C/COLOMBIA

According to statistics from the World Health Organization (WHO), approximately 250,000 to 500,000 people suffer from different types of spinal cord injury every year, therefore making the need for neuromuscular rehabilitation a global goal which seeks to continually improve the ability to return as much quality of life as possible to these patients. Spinal cord injuries type Asia A and type Asia B are potentially risky due to the possible development of secondary pathologies, therefore treatments should aim to regain communication from the sensorimotor cortex to isolated areas as promptly possible. Early treatment of spinal cord injuries by reconnecting the injured, isolated areas to the sensorimotor cortex prevents the development of secondary conditions that diminish quality of life for the patients. Systems such as brain computer interface (BCI) recover the motor signal generated from the brain but under current applications the signal is used to generate motion of a robotic prosthetic, without use of the muscles thus leading to muscle atrophy in the muscular system. World news about cell transplantation of olfactory mucosa to completely regenerate the human spinal cord provides an optimistic treatment option but the time between neurological reconnection, mobility and sensitivity is too long causing the process to be more aggravating for the patient. Pathway afferent and efferent signals can be reconnected to the generated signal by the respective cortex when the original signal is captured by CapSense and processed as resistance, inductance and analyzed as a nerve branch which is induced by hydrogel and characterized electromagnetically with ion doping. Potential somatosensory stimulus on the skin is captured by CapSense which manipulates a matrix of amplified mobile phone which activates various functions via cutaneous stimuli. Current technology changed for medical purposes provides emulation for some organic functions for medical treatments that are effective to complete rehabilitation.

PS10.005 - The Development of an Isokinetic Adapter for Prosthesis Users

Author(s): Usha Kuruganti¹, Victoria Chester², Sarah Hamza³ ¹Faculty Of Kinesiology, University of New Brunswick, Fredericton/ CANADA, ²Kinesiology, University of New Brunswick, Fredericton/ NB/CANADA, ³Mechanical Engineering, University of New Brunswick, Fredericton/CANADA

Upper limb amputations can have a significant impact on daily function and affect the quality of life of an individual. There have been significant advances in the materials used to build prosthetic devices resulting in lighter and stronger artificial limbs; however, users have indicated that improved function and control strategies are desirable to become more in line with able-bodied limb function. Quantitative clinical assessment has been challenging due to the complexity of the muscle physiology of those with amputations. In addition, most clinical research has focused on studying isometric (stationary) limb movements. In order to develop more robust systems, it is critical to study muscle mechanics of those with amputations under dynamic (moving) movements. One method of safely examining dynamic movements is the use of isokinetic dynamometers. These machines allow measurement of upper and lower extremity isokinetic movements at controlled angular velocities while ensuring no stress is placed on the individual (even if the participant is unable to move the lever arm). For able-bodied participants, this does not present a problem. However, there is currently no commercially available isokinetic dynamometer adapter for prosthesis users. The purpose of this project was to develop an adapter that can be used by those with amputations to safely and effectively operate the

dynamometer.

There were three stages to the development of this new tool: prototype development, refinement and testing. During the prototype development stage an isokinetic dynamometer (Cybex) was examined to determine the method of attachment. From this a preliminary design was created. Refinements to the first prototype were then completed including attaching a mechanism to allow the user to change the elbow angle to improve the robustness of the device. Modifications were also required to allow the device to mould to the shape of the residual limb of a prosthesis user. The device was also lined to ensure safety and comfort of the user. Finally, the prototype adapter was tested for comfort on a willing below elbow amputee. The subject was asked to fit the adapter on his existing prosthetic with the end attachment removed, as well as to wear it without the prosthetic. The test subject showed no discomfort with either protocol. The tool that was developed connects to the arm of the dynamometer and is adjustable for different prosthesis users.

There are few devices available to evaluate functional ability of upper limb amputees. While there are measures such as hand held dynamometry and myometry as well as ambulatory accelerometry techniques, all other methods of measuring strength are questionnaire based and require observation of the patient (DASH, ADL). The ability to use an assistive device attached to the Cybex opens up many possibilities to measure strength from those with amputations. It may also help to develop strength training programs using this type of equipment. Future work will involve a clinical trial of the device with prosthetic users to determine the device's viability as well as comparing strength between prosthetic and non-prosthetic users.

PS10.006 - High Density Electromyography (EMG) for Improved Prosthesis Control

Author(s): Usha Kuruganti¹, Victoria Chester¹, Yves Losier², Craig Prime³

¹Faculty Of Kinesiology, University of New Brunswick, Fredericton/ CANADA, ²Mechanical Engineering, University of New Brunswick, Fredericton/CANADA, ³Faculty Of Kinesiology, University of New Brunswick, Fredericton/NB/CANADA

Pattern recognition-based controllers have the potential to significantly improve myoelectric control systems for prosthesis control by increasing the number of controllable movements. These systems use pattern classifiers to analyze electromyography (EMG) signals and classify the movement produced based on predetermined settings. The effectiveness of the classifier is measured by its classification accuracy. Recently, high-density EMG (HDEMG) systems have allowed for non-invasive collection of myoelectric signals from many closely spaced electrodes. The data obtained can be examined through the use of 'colour maps,' which provide a visual indication of the distribution and intensity of muscle activation. The relationship between pattern classification accuracy and HDEMG based colour maps is unknown, however understanding this relationship may help to better understand muscle activation patterns with applications in prosthesis development as well as imaging muscle activity in rehabilitation (e.g. in stroke or sport injury). Thus, the purpose of this work was to examine four different hand movements to determine repeatability as well as the relationship between between classification accuracy and colour map patterns.

A HDEMG system was used to evaluate four different hand movements (hand open, hand closed, pronation, and supination) at a self-selected medium contraction level. Twenty able-bodied individuals (mean age = 31.6 ± 12.0 years, 9 females and 11 males) participated in this study. Sixty-four channels of EMG were collected from electrodes placed in an 8 by 8 grid formation over the forearm region. The areas on the forearm that experienced muscle activity during given movements were illustrated in topographical (colour) maps for each trial. Pattern recognition was performed to determine how well each contraction could be distinguished using a Linear Discriminate Analysis (LDA) classifier. The colour maps were visually inspected to determine any changes in intensity (amplitude) and pattern repeatability between trials. Pattern classification accuracies were computed for all movements (Table 1). Visual examination of each colour map suggests that both pattern and intensity changes differ in relation to classification accuracy with those with higher classification accuracy having more consistent colour maps. However, a mathematical relationship between classification accuracy and colour map changes is yet to be established.

These results suggest that classification accuracy differ according to both pattern and intensity changes, however the exact relationship remains elusive. Understanding this connection may help to provide better understanding of muscle activity for improved prosthetic control as well as develop new imaging techniques for those with reduced muscle activation due to injury or disability.

Table 1: Classification accuracies for hand open (HO), hand closed (HC), pronation (PR) and supination (SP). All values are %.						
	НО	HC	PR	SP		
Mean Pattern Classifi- cation Accuracy	87.9 ± 14.5	95.7 ± 11.1	86.4 ± 17.1	92.2 ± 13.6		

PS10.007 - Influence of Spaces between Tactile Dot Patterns and Raised Boundary Line on Tactile Guide Map Line Perceptibility

Author(s): <u>Harumi Matsumori</u>¹, Kouki Doi², Hiroshi Fujimoto³ ¹Graduate School Of Human Sciences, Waseda University, Tokorozawa-shi, Saitama/JAPAN, ²National Institute of Special Needs Education, Yokosuka/JAPAN, ³Waseda University, Tokorozawa/JAPAN

Tactile guide maps are well-known information support tools for visually impaired persons. In particular, tactile guide maps have long been used in schools for the blind. In a tactile guide map, area information is expressed using tactile dot patterns and raised boundary lines. Maps designers must place spaces between these tactile dot patterns and raised boundary lines so that users can easily discriminate the lines (Figure 1). However, there is a lack of quantitative data on the perceptibility of tactile guide map lines.

In this study, we investigated the influence of the spaces between the tactile dot patterns and raised boundary lines on the perceptibility of the lines. We developed test pieces with seven different dot distances for dot patterns and five different space distances. The participants included 20 younger sighted persons and 20 older sighted persons as tactile guide map beginners. The participants were asked to determine the direction of a line, which could be horizontal, vertical, diagonally left, or diagonally right (Figure 2). Based on the results, we found that lines were highly discriminable when the distance between the dot patterns and lines was greater than 5 mm (Figure 3). This knowledge will be helpful for maps designers.

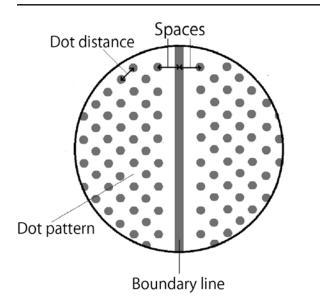

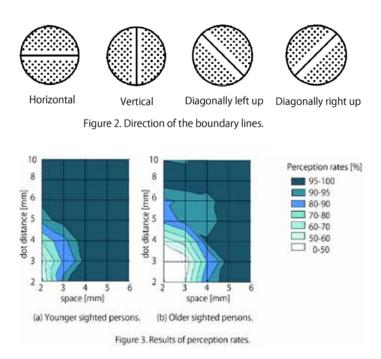

Figure 1. Test piece used in this experiment.

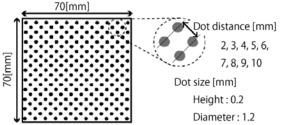

PS10.008 - Influence of Dot Distances on Discrimination of Dot Patterns in Tactile Guide Maps

Author(s): <u>Harumi Matsumori</u>¹, Kouki Doi², Hiroshi Fujimoto³ ¹Graduate School Of Human Sciences, Waseda University, Tokorozawa-shi, Saitama/JAPAN, ²National Institute of Special Needs Education, Yokosuka/JAPAN, ³Waseda University, Tokorozawa/JAPAN

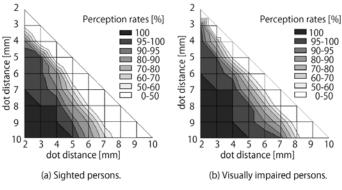

Recently, many tactile guide maps have been installed at various public facilities. Designers have used raised dot patterns to display drawings on a tactile guide map. However, there is a lack of quantitative data on the discrimination of raised dot patterns for the design of easily understandable tactile maps. In this study, we investigated the influence of dot distances on the discrimination of the dot patterns used in tactile guide maps by conducting an experiment to find highly discriminable dot pattern combinations by comparing pairs of dot patterns (Figures 1 and 2). A total of 10 visually impaired persons (expert users) and 14 sighted persons (beginner users) participated in this experiment. The results showed that combinations of dot patterns with larger differences in the distances between dots had higher discriminability (Figure 3). When the differences were the same, the combinations with larger dot distances had lower discriminability. Dot patterns with differences between dot distances greater than 5 mm were highly discriminable for sighted persons, whereas those with differences greater than 4 mm were highly discriminable for visually impaired persons. This knowledge will be helpful in discussions among map makers on how to design tactile guide maps.

PS10.009 - Statistical Evaluation of Objectivisation of Rehabilitation Process

Author(s): <u>Iva Novotná</u>¹, Michaela Tomanová², Lenka Lhotská¹ ¹Cybernetics, Czech Technical University, Prague/CZECH REPUB-LIC, ²Czech Technical University, Prague/CZECH REPUBLIC

Aim of the research described in this paper is to find the most objective and least stressful measurement and successive evaluation of the rehabilitation process based on the comparison of effectiveness of the treatment before and after application of a special rehabilitation INFINITY Method. As basic requirements we defined non-invasiveness, lower time demand, patient comfort, possibility of

comparison of temporal development and ease of examination for the medical professionals. We focused on well-known basic plantographic and posturographic parameters. Furthermore, we focused on patient's subjective pain recorded by visual analogue scale (VAS) before and after treatment. Data were collected from patients hospitalized in the Rehabilitation Centre Brandýs nad Orlicí. Three studies containing 33, 100 and 331 patients were used. Student's T-test and Wilcoxon signed-rank test were applied for statistical analysis. Majority of measured patients (60.6 %) showed an improvement in all relevant parameters, in the first study. According to VAS, relieve of pain came in 91 % of patients. The difference in the efficacy of therapy with INIFINITY Method and without is almost 20 % (p < 0.001) according to VAS. We evaluated statistically significant differences between the parameters measured in four standing positions in the third study. The overall results imply that in all four standing positions two parameters were statistically significant (p <0.05). Therefore, experiments proved suitability of the proposed methodology. We succeeded in identification of the most informative parameters relevant to the course of the rehabilitation process. In this paper we will focus on statistical evaluation of the measured parameters and will discuss the reached results.

PS10.010 - Satisfactory Vibrating Conditions of Latissimus Dorsi Tendon to Induce Illusory Horizontal Shoulder Flexion Author(s): <u>Yumi Umesawa</u>¹, Kouki Doi², Hiroshi Fujimoto¹ ¹Human Science, Waseda University, Tokorozawa/JAPAN, ²National Institute of Special Needs Education, Yokosuka/JAPAN

Motor images of the human body can easily deteriorate - for example, due to quadriplegia or the fracture of a bone. In this study, we focused on the illusion of kinesthesia to develop practical applications that can be used for training or to enhance motor images. However, basic knowledge regarding the presence of illusions and vibrating conditions is lacking. In this study, we investigated satisfactory vibrating conditions for inducing illusory horizontal shoulder flexion and conducted an experiment to examine the satisfactory vibrating conditions. The participants in this study were 20 young people. The experimental factors were the vibration frequencies of 30, 50, 70, 90, 110, and 130 Hz. We subjectively assessed the presence or absence of an illusion and its vividness on a five-point scale. At the same time, we measured the perceptual time it took for an illusion to appear and the maximum illusory angle. The results showed that when the vibration frequency conditions were within 70-110 Hz, the occurrence rate of the illusion was 98% (Figure 1). In particular, when the vibration frequency condition was 110 Hz, the vividness of the illusion and the maximum illusory angle reached maximum (Figure 2). It took approximately 7 s for an illusion to appear, regardless of the vibration frequency conditions. Under these stimulation conditions, we found that horizontal shoulder flexion can be easily produced. Based on this knowledge, we plan to develop an interface device that will only provide kinesthetic sensations without the actual motion. This device could potentially be used in the rehabilitation and education fields for training on motor images.

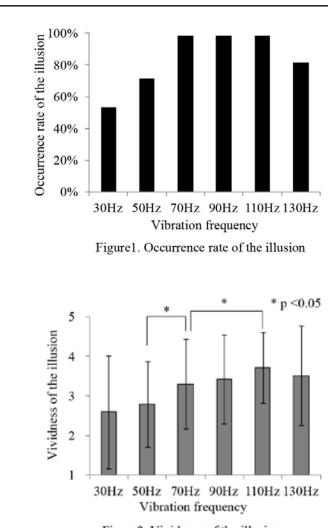

Figure2. Vividness of the illusion

PS10.011 - Satisfactory Vibrating Conditions of Extensor Digitorum Tendon to Induce Illusory Finger Flexion Author(s): <u>Yumi Umesawa</u>¹, Kouki Doi², Hiroshi Fujimoto¹ ¹Human Science, Waseda University, Tokorozawa/JAPAN, ²National Institute of Special Needs Education, Yokosuka/JAPAN

Motor images of the human body can easily deteriorate - for example, due to quadriplegia or the fracture of a bone. In particular, because a high level of dexterity is needed for finger movement, this movement is the most difficult to recover during rehabilitation.We focused on the finger movement illusion of kinesthesia to develop practical applications that can be used for training or to enhance motor images of high-dexterity behaviour with finger movement. However, basic knowledge regarding the presence of finger movement illusions and vibrating conditions is lacking. We investigated the satisfactory vibrating conditions for inducing illusory finger flexion. In this study, we conducted an experiment to examine these conditions for the metacarpophalangeal joint of the index finger. The participants in this study were five young people. The experimental factors were the vibration frequencies of 50, 70, 90, 110, 130, 150, 170, and 190 Hz. We subjectively assessed the presence or absence of an illusion and its vividness on a five-point scale. At the same time, we measured the perceptual time it took for an illusion to appear and the maximum angle of the Illusory finger flexion. The results showed that when the vibration frequency conditions were within 50-130 Hz, the occurrence rate of the illusion was 100% (Figure 1). In particular, when the vibration frequency condition was 90 Hz, the maximum angle of the Illusory finger flexion reached

maximum (Figure 2). It took approximately 4.8 s for an illusion to appear at 90 Hz. Under these stimulation conditions, we found that finger flexion can be easily produced. Based on this knowledge, we plan to induce a kinesthetic illusion of high-dexterity behaviour – for example, a grip or a pinch. This could potentially be used in the rehabilitation and education fields for training on the motor images of finger movement.

PS10.012 - Prefrontal Brain Activity of Goal Keeper when Penalty Kick

Author(s): Taishi Kurioka¹, Miho Asano², Masayuki Nambu³, <u>Masaki</u> Yoshida¹

¹Department Of Physical Therapy, Osaka Electro-Communication University, Shijonawate/JAPAN, ²Open University of Japan, Chiba/ JAPAN, ³Healthcare(System Institute, Seika/JAPAN

Penalty kick is the special play which influences a result of the game in the football. A goalkeeper should react to the ball instantaneously at the penalty kick, we estimated that the state of the reaction is different in a trained football player and an inexperienced person. Therefore, we got a hypothesis from which a cerebral reaction may be different by the trained football player and an inexperienced person. To inspect this hypothesis, we measured prefrontal activity of the trained and inexperienced subjects when they watch the video of penalty kick, using NIRS. Subjects were 12 years old to 25 years old. Four of them were trained football player and others were inexperienced people.

In this study, we measured the cerebral blood flows of voluntary subjects when they watch the scene of the penalty kick, using a Near Infra-Red Spectroscopy (NIRS), because we focused on the prefrontal activity. We ordered subjects to sit down on the chair placed in front of the LCD monitor and watch the video. We also ordered subjects to concentrate to the scene of the video. Fig.1 shows the results of blood flow of the prefrontal area of inexperienced people when the kicker kicked the ball. Fig.2 shows that of trained football player. As the result of the experiment, we found that specific region of prefrontal area reacts strongly in a trained football player. Therefore, we suggest that prefrontal activity will be an index for state of training in the football.

PS10.013 - Effect of the moderate high pressure circumstances to metabolism

Author(s): Masaki Yoshida¹, Miho Asano²

¹Department Of Physical Therapy, Osaka Electro-Communication University, Shijonawate/JAPAN, ²Open University of Japan, Chiba/ JAPAN

The high pressure air capsule was developed for the purpose of medical treatment. Recently, this capsule is attracted the attention of an effect of health, and is used for the conditioning or for the anti-aging. However, some peoples have a pain in an ear for high pressure. We can hope that many people are easily available by lowering the air pressure. Therefore we considered whether the same effect could expect moderate high pressure in this research. We made a moderate high pressure chamber (MHPC). The air pressure in MHPC is set 120 hPa higher than outside air pressure. In addition, the carbon dioxide density in the chamber increases in the carbon dioxide included in the expiration of the person, but is regulated not to exceed 5,000ppm. 13 subjects (20 - 40 years old, 3 females and 10 males) participated in this study. The subject stayed in the chamber for 60 minutes. We measured blood partial pressure of oxygen and carbon dioxide of the subject. Furthermore, we measured the basal metabolism before and after MHPC treatment. Fig. 1 shows the change of blood partial pressure of oxygen and carbon dioxide of the subject in the chamber. Blood partial pressures of oxygen increase rapidly just after a start, but gradually decrease afterwards. The blood carbon dioxide partial pressure rises from 30 minutes later. The basal metabolism at the end significantly increased in comparison with that at the start (see Fig.2). Other items did not have the meaningful change. It became clear to affect the human being in the moderate high pressure circumstances. For a physiological index, the basal metabolism was most greatly affected. It is suggested that this is caused by change of the blood carbon dioxide partial pressure.

PS11 - TRACK 11: NEUROENGINEERING, NEURAL SYSTEMS

PS11.001 - Objective Evaluation of Likes and Dislikes by Prefrontal Blood Flows

Author(s): <u>Miho Asano</u>¹, Masayuki Nambu², Masaki Yoshida³, Yasuhiro Kawahara¹

¹Open University of Japan, Chiba/JAPAN, ²Healthcare System Institute, Seika/JAPAN, ³Department Of Physical Therapy, Osaka Electro-Communication University, Shijonawate/JAPAN

It is difficult to know the emotion of likes and dislikes. Questionnaire is the only method to know likes and dislikes, and has low reliability because it is not objective evaluation method. In this paper, we reported about a technique to distinguish the likes and dislikes objectively by measuring prefrontal blood flows, because emotions were based on prefrontal activity. We show images of selected solid colors which were red, blue, orange, indigo, yellow, purple, green, black, and white, and we measured the blood flows of the subject, using near infra-red spectroscopy (NIRS). In addition, we asked subjects about likes and dislikes with the color by the order after the experiment. The result of an experiment shown in fig.1. By the way, artifacts based on the body motion or change of the blood pressure are included the signal of the NIRS which is shown in fig. 1. Therefore, we obtained the approximation of the artifact using polynomial approximation algorithm. Then we subtract the approximation from the original signal. As the result of the subtraction, we confirmed the artifact was reduced as shown in fig.2. As the result of the experiment, the level of the oxyhemoglobin when the subject answered "I don't like" was relatively high, compared with the level of the oxyhemoglobin when the subject answered "I like". We consider that undesirable stimulus is more impressed than desirable stimulus. Furthermore, we consider that we will distinguish that likes and dislikes by measuring the cerebral blood flows in the future.

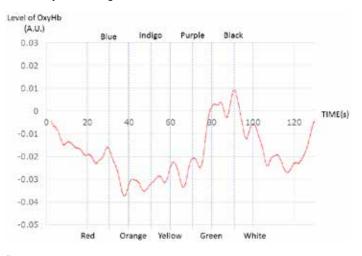

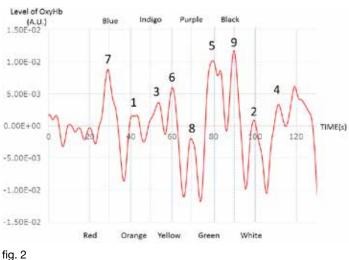

fig. 1

(Numbers of the graph show the order of likes and dislikes)

PS11.002 - Robotic Wheelchair Commanded by People with **Disabilities Using Low/High-Frequency SSVEP-based BCI** Author(s): Teodiano Bastos-Filho

Electrical Engineering, Federal University of Espirito Santo, Vitoria/ BRAZIL

Brain-Computer Interfaces (BCIs) are systems developed to improve the daily life of people with disabilities. Nevertheless, this assistive technology is yet far away from the patients' home and the BCI should adapt to the requirements of the user. This paper presents a practical BCI based on Steady-State Visual Evoked Potentials (SS-VEP) currently being used by people with disabilities. The BCI was applied to navigate a wheelchair at two ranges of SSVEP frequency, increasing the possibilities of its application. Two stimulation systems were used: checkerboards flickering at low-frequency range and LED flickering at high-frequency range. Five volunteers with disabilities tested the SSVEP-based BCI. They attempted to command the wheelchair in order to accomplish four different navigation tasks. Then, the volunteers answered a questionnaire about their comfort and performance. Average accuracy detections of 54% and 51% were achieved at low- and high-frequency stimulation, respectively. Volunteers reported lesser visual tiredness when high-frequency LED stimuli were used. The flexible BCI system here developed showed that people with disabilities could operate a robotic wheelchair using visual stimuli in two ranges of frequency. Moreover, preliminary results indicated that visual stimuli flickering at high frequency were more comfortable than low frequency stimuli.

PS11.003 - Quantifying and overcoming the effect of distractions on cognitive load and brain-computer interface (BCI) performance: Implications for real-world BCI use and cognitive neuroscience

Author(s): Zahra Emami

Holland-Bloorview Kids Rehabilitation Hospital, Toronto/CANADA

Brain-computer interfaces (BCIs) are a revolutionary technology enlisting the neural activity, or cognitive capacity, of its user in order to operate a certain device or application. Since BCIs do not require any motor input, the technology has significant applications for individuals with severely impaired motor control, such as those with amyotrophic lateral sclerosis or locked-in syndrome. BCIs have been largely examined in the lab setting and under controlled conditions, however, the ultimate target for its use lies in real-world situations such as homes and clinics, which are often rife with distractions. Distractions can cause an enhanced burden on the cognitive

processes of BCI users through an increased expenditure of cognitive resources, which are already largely occupied by the BCI task at hand. Distractions can therefore potentially limit the resources available for BCI control, and in turn jeopardize BCI performance. The purpose of this proposed study is twofold. This study will look to determine the effect and extent of distractions on cognitive load and to compare this to the effect on BCI task performance. The study will also look to examine whether or not performance can be enhanced in the presence of distractions through techniques that reduce cognitive load. These techniques include emphasizing the BCI task visual interface or repeating the BCI task signaling stimuli in order to redirect attention from the distraction back to the BCI task. Following BCI neurofeedback training, 10 able-bodied participants will be enlisted to undergo a motor-imagery based EEG-BCI protocol in conditions of no distraction, visual distraction, and cognitive-load reducing techniques in the presence of distraction. Cognitive load will be determined via objective measures such as the Youden Index and EEG alpha band pattern, and subjective measures such as the NASA-TLX, and will be compared to measures of BCI performance for each condition. It is expected that optimal BCI performance will be attained in the no-distraction condition where cognitive load is relatively low, while the presence of task-irrelevant visual distractions will increase cognitive load and cause a decreased BCI performance. Redirection of attention to the BCI task stimuli, through emphasis or repetition, is expected to attenuate cognitive load and rescue BCI performance. The findings of the proposed study is expected to demonstrate the impact of task-irrelevant information on cognitive resources, its consequent influence on BCI performance, and will emphasize the potential importance of considering the effect of cognitive load on BCI systems, especially in real-world environments. With accounting for uncontrolled environmental factors, BCI systems can be robustified such that its translation from the lab to the home, or where the end-users are likely to use the technology, will be more effective.

PS11.004 - How Mental Strategy Affects Beta/Theta Neurofeedback Training

Author(s): Xiaoting Qu¹, Limin Yang¹, Qi Tang¹, Wenya Nan¹, Janir Nuno Da Cruz¹, Feng Wan¹, Pedro Antonio Mou¹, Pui-In Mak¹, Peng Un Mak¹, Mang I Vai¹, Yong Hu², Agostinho Rosa³ ¹University of Macau, Macau/MACAU, ²University of HongKong, HongKong/HONG KONG, ³University of Lisbon, Lisbon/PORTUGAL

Neurofeedback training (NFT) has been proven to have positive effects for human cognitive performance enhancement and to be a potential non-pharmacological supportive treatment for many neurological and psychiatric disorders. The mental strategies the participants use during the NFT are a determinant feature in a successful NFT. However, most existing studies focus on either the training protocols or the training effects. Therefore, this study investigates the mental strategy effects during beta/theta ratio based NFT and attempts to find an efficient method to analyze the mental strategies that can be used to improve the success rate in NFT researches. Objective beta/theta ratio value scores and gualitative mental strategy classification were used for analysis. The results showed that no specific mental strategy is more significantly useful for NFT under this protocol but the strategies that required more attention performed better, which is consistent with the findings in previous NFT studies.

PS11.005 - Stimulations to Basal Ganglia and the Efficiency of Microminiaturized Electrode Recording (MER) to Quantify STN Neurons with Deep Brain Stimulator (DBS)— the Lead Point in Parkinson Diseased Conditions

Author(s): Venkateshwarla R. Raju

Biomedical Eng & Neurology & Neurosurgery And, Nizam's Inst of Medical Sciences (NIMS) University & Hospital, HYDERABAD/INDIA

Deep brain stimulation (DBS) of bilateral subthalamic nuclei (STN) is an efficient method of rehabilitation in subjects with advanced idiopathic Parkinson disease (PD). Accurate targeting of STN neurons and placement of microelectrodes are paramount importance for optimal results after STN-DBS. Stereo tactic assessment, intra-operative microelectrode recording and intra-operative stimulation effects have all been used in targeting, albeit the individual role of each modality is still not known. Microelectrode recordings of STN were detected in a mean of 3.5 ±1.1 channels on right hemisphere and 3.6 ±1.04 on left hemisphere.. Final channel selected were most commonly central seen in 42.3% followed by anterior in 33.7%. Concordance of final tract with the channel having the highest recording was 58.7%, with the channel showing maximum depth of recording was 48% and with either was 64%. Absence of any recording in the final tract chosen was seen in 6.52%, in these subjects the tract was chosen based on stimulation results. The depths of microelectrodes were detected by microelectrode recording in 75.6%. Microelectrode recording is useful to identify and confirm the tract in which DBS electrodes are placed and is most useful in determining the depth of electrodes placement but has to be taken in consideration with effects seen on macro-stimulation.

PS11.006 - SCHIZOPHRENIA: Interaction between factors

Author(s): <u>Bernadete M. Voichcoski</u>¹, Vicente Machado Neto² ¹Electronic Engineering, Technological Federal University of Parana, Curitiba-PR/BRAZIL, ²Electronica, Technological Federal University of Parana, Curitiba PR/BRAZIL

Background

Schizophrenia is an endogenous and multifactorial disease that causes for the person that suffers, disconnections with reality, difficulties at real facts processing, difficulties of cognition and memorization, disorders on social, affective and personal life. The disease is classified in six types and the causes are related with each brain area that is damaged. Like the disease is multifactor, is difficult to the doctor to view patient history as a whole. The panoramic view about the disease for each patient and the relations with and between them, the aim of this work, allows to the doctor perceives the patient by globalized and correlated form and no segmented, since the disease happens with the interaction the various factors together.

Methods

The research about possible causes and hypotheses for disease was raised through articles published on the fifteen years last and positioned at Block Diagram, according with main factors of the disease and relations between them.

Results

It was found six main factors of the disease: Genetic, Physical, Metabolism, Nutrition, Psychic and Environment. All the points studied can be positioned into this six main factors and it was possible to realize the relations between them.

Conclusions

The main purpose is to allow to the doctor perceive the patient by globalized form and facilitate the treatment preventing the conse-

quences by interventions realized by medicines and its side effects or adverse, nutrition or therapy. The secondary purpose is to perceive where can be made interventions for to mitigate the causes of the disease for the next generations.

PS12 - TRACK 12: MEDICAL DEVICES

PS12.001 - Challenges and opportunities in home-based monitoring of cardiac dynamics

Author(s): Yashodhan Athavale, Sridhar Krishnan

Electrical & Computer Engineering, Ryerson University, Toronto/ON/ CANADA

Advances in sensor and data acquisition technologies, Big Data, rising health care costs, public awareness of improving the quality of life, has spurred a boom in wearable "health-tech" in the smart device market. Tele-monitoring of cardiac dynamics (or ECG analysis) using smart devices is becoming a popular choice as it helps the consumer in maintaining daily fitness, food intake, and also helps cardiac patients in proper treatment such as medicine intake times, relaxation or activity break times, or even calling the nearest health care facility in case of emergency. Although these devices give the user a nice graphical output about the cardiac state, their signal analysis is still challengeable with regards to device capability and the significance of clinical data [1, 2, 6].

Our survey indicates that clinical ECG exceeds the smart-device ECG, in terms of signal quality, low artifacts and information content [1-6]. Despite their reliability, hospital-based cardiac monitoring tools are cumbersome and don't support transfer to a home-based ECG monitoring environment [2]. Although some currently available devices (such as smart watches, wrist bands etc.) are capable of monitoring cardiac health, their analysis is quite limited and may not be helpful from a clinical perspective [6]. Meaning, the signals acquired through these devices may depict only a portion of the entire heart's dynamics, and cannot be interpreted into meaningful information by the consumer. Hence their usage is still questionable without the ground truth from clinicians [6]. Such type of unsupervised data acquisition and pattern recognition systems could also question the type of ECG data collected, its format, the storing methods, privacy and confidentiality of consumers. These wearable devices may be a lifestyle improvement choice for the underserved healthy population, but they may not be useful for subjects who have a tendency for severe cardiac disorders. Analysis of biosignals such as ECG requires an algorithm which can extensively perform artifact removal, feature extraction, pattern recognition and highly optimized for processing hardware in terms of power and area requirements. Recommendations of a reliable and practical home-based ECG monitoring include the following specifications: [i] user friendly [1,2], [ii] compact and wireless hardware design, [iii] non-invasive and comfortable to use sensors, [iv] standardized data acquisition and security, [v] user understandable informed decision and output, [vi] provision for data synchronization with local healthcare provider, [vii] reliable signal quality, [viii] low power and memory consumption, [ix] low data processing time, and [x] cost effectiveness.

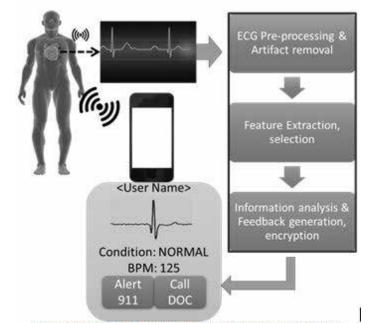

Figure 1, Design of a practical ECG Tele-monitoring System

PS12.002 - Application of Support Vector Machines in Intelligent Monitoring of Cardiovascular Health on a Mobile Device Author(s): <u>Omar Boursalie</u>¹, Thomas E. Doyle², Reza Samavi³ ¹School Of Biomedical Engineering, McMaster University, Hamilton/ CANADA, ²School Of Biomedical Engineering, Electrical And Computer Engineering, McMaster University, Hamilton/CANADA, ³Computing And Software, McMaster University, Hamilton/CANADA

Cardiovascular Disease (CVD) is the leading cause of death in the developed world. There are many risk factors and early treatment through pharmacotherapy and lifestyle changes can reduce the severity of CVD. Due to this, patients at risk for CVD are closely monitored. Current monitoring techniques include periodic visits to the doctor, which causes stress on the healthcare system. Increasingly, mobile devices with unobtrusive sensors are providing patients with information regarding their own health. However they provide an abundance of data that patients and health care professionals do not use. In the case of wearable devices this has contributed to the low long-term usage of such devices.

Recent work has focused on the use of a support vector machines (SVM) for analyzing medical data. SVM is a flexible algorithm that can learn from data rather than following an explicit program. In a previous study, a SVM was developed for continuous monitoring of a patient's electrocardiogram (ECG) in real time. However this SVM was used for the comparison of a single variable and did not consider the wide variety of factors that contribute to CVD. Another study developed a multi-variable SVM algorithm that was used to monitor the effectiveness of drugs in diabetes patients in a smart-phone device. It depended on user input and analyzed multiple factors however it did not make use of the data collected automatically by smartphone devices. A similar CVD device has also not been developed to analyze multiple factors on a mobile platform.

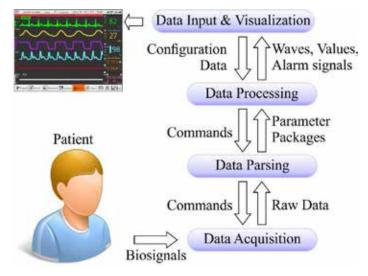

The focus of this project would be a SVM-based program that will be used on smartphones to monitor the vitals of a patient with CVD. The device will obtain input data for a SVM algorithm through sensors and electronic health records (EHR). Sensors will be used to monitor the patient's real-time vitals. EHR provide information regarding the patient's basic information (gender, age, sex etc), medical history and demographics. Together, these sources of data will provide the SVM a comprehensive overview of the patient's health. A SVM is a supervised, classification algorithm which is trained using known data provided from clinical databases. The algorithm is ideal for studying CVD because it can create solutions to complex problems where it is impractical or impossible to program a solution directly. The algorithm will be trained to monitor an individual patient's condition. The SVM will be able to identify and present only the relevant data to health care professionals and patients.

The SVMs will be evaluated by determining its accuracy in analyzing new data. It will improve on current monitoring systems because the SVM will allow for the integration of a wide range of factors and can be adapted for individual patients. The patient would be an active contributor in the management of their own disease. This will reduce stress on the healthcare system by informing health care professionals about serious cases and can be used in preventative medicine. The factors can then be further analyzed to determine if pharmacotherapy or lifestyle changes are necessary.

PS12.003 - Design and Implementation of the Software for Multi-parameter Patient's Monitor

Author(s): <u>Maite Cañizares</u>, Alberto R. Rodríguez, Gemma Rodríguez, Daniel Jiménez, Hector Torres, Daniel A. Romero, Miguel Portieles, Miguel Gómez, René González-Fernández Digital Medical Technologies, Havana/CUBA

Features of design and implementation of the preliminary version of the main software for a multiparameter patient's monitor are presented. Alarm Control Subsystem is highlighted. The design fulfills requirements of standards for monitoring systems. The software was designed with multi-layer architecture conformed by four layers.

Functions for acquiring, processing and visualization of signals and values are connected but, at the same time, are independent. Software was implemented using Qt environment tools like multithread, object oriented programming and signals-slots. It provide to the doctors and nurse with different configuration options like setting variable limits and customize the performing of visual and sound alarm notifications. The software was implemented to be used on a monitoring device with a main board based on ARM-9 microprocessor. Using multi-layer architecture it is possible to verify each subsystem inde-pendently and to make more easy update and maintenance tasks. Monitoring and operational performance of the monitor reached expected results.

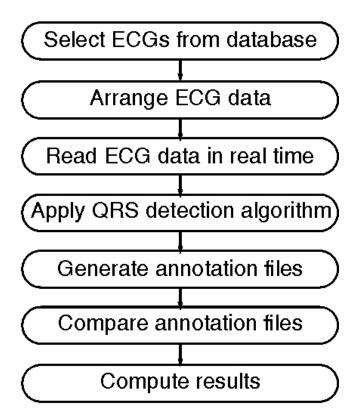

PS12.004 - Strategy and Tools for Validation of QRS Detection Algorithms in Real Time ECG Monitors

Author(s): Maite Cañizares, Alberto R. Rodríguez, René González-Fernández

Digital Medical Technologies, Havana/CUBA

Tools designed to help during the validation of algorithms for QRS detection included in real time patient monitors is presented. Validation of these algorithms is a requisite established in the international standards.

Steps of the strategy followed during validation process were described. First of all, an appropriated set of ECG signals must be selected from ECG databases recommended in the standards. The second step consists of arrange the ECG signals in the appropriated format (sample rate, data structure), according to the system where the detection algorithms must be validated. Patient monitor program must be able of reading ECG signals from files. Next step is to apply the QRS detection algorithm to all data read from the files and generate the annotations files with database annotation files format. Finally both annotations files must be compared for calculating sensibility and specificity of the algorithm.

Steps for validation of QRS detection algorithms in real time.

The proposed strategy was tested using a patient monitor based on ARM-9 and Linux architecture which acquires until three ECG channels with a sample rate of 250 Hz. For validation were re-sampled 50 ECG signals from the MIT-BIH Arrhythmia Database. Running a "Test Mode" option the program acquired signals in real time from re-sampled files. The functions of QRS detection algorithm were included in an external library that later could be included in another similar application. Annotation files were created for each re-sampled signal. A Qt application was developed with visual interface for review signals and comparison of annotation files. This program implements functions for creation of re-sample ECG signals files and for generation and comparison of annotations files. The strategy defines the steps for validation of algorithms for ECG analysis in real time systems.

The created application has a friendly interface for viewing and analyzing validation results generated for algorithms used in real time system or those used offline.

PS12.005 - Basic Study on Variability of Measured Data from Touch Test Using Semmes-Weinstein Monofilaments

Author(s): <u>Manabu Chikai</u>¹, Emi Ozawa², Noriyo Takahashi³, Shuichi Ino¹

¹National Institute Advanced Industrial Science and Technology, Tsukuba/JAPAN, ²Showa Inan General Hospital, Komagane/JA-PAN, ³Tokuyukai Rehabilitation Clinic, Toyonaka/JAPAN

The aim of our research was to develop new equipment for easily and noninvasively diagnosing diabetic peripheral neuropathy (DPN). The International Diabetes Federation (IDF) reported that 387 million people have diabetes. Diabetes is associated with life-threatening health risks. One of these risks is DPN, which causes hypoesthesia in a patient's toes. The early and easy detection of DPN in a clinic is the hope of diabetic patients and medical staff. Several methods are used for DPN screening tests. One of these is a touch test using a device with nylon Semmes-Weinstein monofilaments (SWMs) embedded in a plastic handle. A low pushing force is applied at the handle to bow the filaments. A member of the medical staff presses the filaments at nearly a 90° angle against the patient's hand or foot until they bow. A previous study reported that the SWMs did not generate the same values on repeated tasks. However, it was uncertain whether the variability of the measured data was caused by the mechanical property of the nylon fiber or the operator's hand motion. In this study, we elucidated the variability of the SWM test data.

We carried out two experiments on (1) the effect of the number of compressions on the buckling force of the SWMs and (2) the effect of the human operator variability using the SWMs. This study used 5.07/10g SWMs. In experiment 1, the SWMs were pressed using an X-axis positioning stage. We measured the buckling force of the SWMs using a force sensor. The stage moving speed was 10 mm/s. In experiment 2, the SWMs were operated by individual participants. Ten participants (6 men and 4 women) ranging in age from 20 to 60 years (mean age 42 years) were recruited. We measured their hand motion using an optical motion capture system, and measured the buckling force of the SWMs using a force of the SWMs using a force sensor.

Based on the experimental results, the average buckling force of the first compression was 8.2 g, and it was 7.5 g after ten successive trials. The average force of all the compressions was 7.7 ± 0.3 g. The average hand motion velocity for all the participants and the average buckling force were 0.23 ± 0.1 m/s and 7.5 ± 0.6 g, respectively. Thus, the hand motion during the SWM tests varied by participant. Therefore, the SWM test results varied from both the effect of repeated tests and the effect of the operator's hand motion. In other words, an SWM test needs to consider the number of test cycles, and manual training needs to be developed for the medical staff.

We elucidated the variability problem of sensory testing using SMWs. The buckling force of the SWMs was decreased through numerous test trials, and the hand motion varied by participant. In future work, we will find a solution to the variability of the SWM test results and develop a new testing system for tactile sensibility for DPN screening.

PS12.006 - Design and construction of temperature and humidity control channel for a bacteriological incubator Author(s): <u>Carlos R. Duharte</u>¹, Ibrain Ceballo², Carmen Busoch¹,

Angel Regueiro¹ ¹Centro De Bioingenieria (cebio), (CUJAE) Instituto Superior Politéc-

Centro De Bioingeniería (Cebio), (CUJAE) instituto Superior Politecnico Jose Antonio Echeverría, La Habana/CUBA, 2Centro Nacional de Electromedicina, La Habana/CUBA

During the study and research of microbial growth in biological samples, it is essential to have an incubation station. This incubator permits to control the temperature and humidity for an adequate characterization of the different stages of growth of microorganisms, especially pathogens. This paper supports the development of new methods for rapid detection of these microorganisms, not only applicable to industrial biological samples (food, raw materials, etc.) but also to clinical samples (urine, blood, etc.).

The paper discusses the design and characterization of a lab incubator prototype to support studies of Microbiology, particularly for research phase of bacterial growth in biological samples through integrating optical methods (photo stimulation and turbidimetry) and bioimpedance measurements. The basic stages of electrical design and operation are described as well as the control program (software) developed based on these of microcontroller AT89C51. Furthermore, the results of simulation and experimentation of the proposed design are shown for measurement channels of the variables of interest (temperature and humidity), in which high linearity and adequate strength from the selection of system components was obtained.

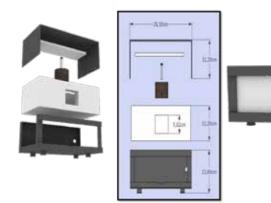

Figure 1. Mechanic design of incubator

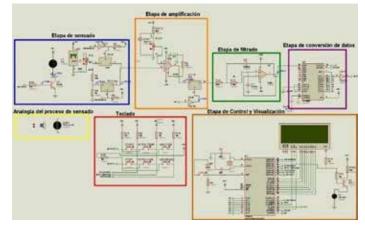

Figura 2. Diagram of the design of channel of temperature sensing and regulation.

PS12.007 - High-Reliability Nerve Stimulator For Aiding Regional Anesthesia Procedures

Author(s): <u>Carlos A. Ferri</u>, Antônio A.F. Quevedo Biomedical Engineering, UNICAMP, Campinas/BRAZIL

In the last decades, the use of nerve stimulators in nerve blockade anesthesia procedures has shown benefits to patients, since it allows a better location of the nerve plexus, leading to correct positioning of the needle through which the anesthetic is applied. However, many of the nerve stimulators available in the market for this purpose do not comply with minimum recommended features and specifications for a good stimulator. This can lead to risks to the patient. This study aims to develop an equipment that meets all the characteristics for a successful blockade. We developed a highquality and high-precision device using embedded digital and analog electronics for accurate control for all stimulation parameters. The system consists of modules for generation and overall control of the current pulse, the patient interface, and communication interface with a personal computer. The results show that the proposed system fits into suggested specifications for a good neurostimulator to be used for nerve location during regional anesthesia procedures.

PS12.008 - A study of pressure-volume characteristics of the cuff for hemodymamic parameters measurement

Author(s): Jan Dvořák, Martin Tuček, Jan Havlík

Faculty Of Electrical Engineering, Czech Technical University in Prague, Prague/CZECH REPUBLIC

This contribution deals with the pressure-volume characteristics of the cuffs used for blood pressure measurement. The linearity of characteristics is a very important factor for the accurate conversion from volume change to pressure change. Several cuffs were tested during the study, including new cuffs, old cuffs, cuffs with different sizes, volumes and clamping systems. Results of the measurement in the range between minimal diastolic to maximal systolic pressure have been statistically evaluated.

PS12.009 - Format for National Inventory of the Genomic Technology

Author(s): <u>Beatriz Hernandez</u> Medical Infrastructure, Vitalmex, Distrito Federal/MEXICO

Introduction: The scientific research in health is an important activity for development of the countries. In Mexico there are many Universities, private and public Institutions and companies that work in different research project. However this institutions needs money for buy laboratory equipment, solutions, materials and payroll.

In the last decade medicine genomic has had a big impact in medicine around the world, many countries have been spending many money for obtain infrastructure and laboratory devices for the different projects, but is necessary to make more efficient the existing technology. Mexico is a country that need improve the health. Mexico has priority in resolve the principal health problems that affect at the population, so research in medicine genomic is necessary for this goal.

For this is important have a national inventory where the scientific can obtain information about the kind of technology, conditions, specifications and location. The reserved information is very common in research it is a factor that not has permitted know about the different resources that each Institution have.

Objetive: identify the information necessary that allow do one national inventory and know where is the laboratory devices, their specifications and which are their operational conditions. Looking for an more generation of collaborative agreements to decrease

spending on technology.

Material and methods: The first step was to identify the different Institutions and universities private and public as well as companies that do research or service in medicine genomic, also the different lines that medicine genomic has been developing, the kind of technology that use each Institution and their general technical specifications. Other action was to identify for each research line the kind of technology necessary and their importance in the different research.

An important point was know technical information, cost, sales level with the manufactures of genomic technology.

After we create a database and their contacts, we analyzed the information and we create a format for identify exactly that kind of technology have each Institutions. For this was necessary create indicators for determine that level of impact of each technology and focus the information only to technology with high impact.

At the same time we analyzed the variables of census that did SNIICyT (National system of information of science infrastructure and technology in Mexico), this information is only for government institutions.

Finally we used tools of market research for identify the variables for integrated in the inventory format.

Result: we create a format in paper and digital which can be used in the national inventory of genomic technology, applicable to private and public organizations as well as different kind of Institutions academic and not academic.

Conclusions: Is necessary have a reliable inventory that help to scientists and managers of genomics technology to generate collaborative project that make more efficient the resources, increasing the number of research that will impact in the public health.

PS12.010 - Development of the bedridden person support system using Kinect.

Author(s): Kouhei Ichimura, Kazushige Magatani Tokai University, hiratsukashi kanagawa/JAPAN

The purpose of this study is to support the bedridden and physically handicapped persons who live independently. It is not so easy for them to control home environments, home appliances and to communicate with family or nursing care staffs. Therefore, some supports are necessary for them. Our objective is to solve these problems. We developed a home environments and home appliance control system using Kinect. And then this system was tested and the results of experiment were assessed.

Fig.1 shows the system overview. The system consists of the control interface, a personal computer and control objects. In our system, the control interface consists of sensors which are used for hand motion recognition and the display which indicate the application menu for operation. A control interface senses hand and finger motion and recognize these motions (raising a hand, grasp and release). Recognized results are used to operate the system. And this interface is also used to show the control applications on the display. Our system is constructed as the interactive system, and simple operations for the bedridden and physically handicapped user are realized.

We used Kinect which is a kind of infrared ray sensing system to detect hand motions. OpenNI2 and NiTE2 were also used as software developing libraries in our system. The skeleton detection that is supported by these libraries cannot use for the user who lays on the bed. So, the gesture applications which is provided by NiTE2 were used in order to track hand motions. In our system, electric devices which support a user are controlled by a personal computer using a programmable infrared ray remote control interface. In other words pre-programmed infrared ray code according as objective is sent to the target device. In this paper, target devices are lighting equipment, a television and an air conditioner.

Our developed system was tested with some normal subject and results of the experiment were evaluated. In this experiment, all subjects laid on the bed and tried to control our system. As results, most of subjects were able to control our developed system perfectly. However, motion tracking of some subject's hand was reset forcibly. It was difficult for these subjects to make the system recognize his opened hand. From these results, we think if this problem will be improved our support system will be useful for the bedridden and physically handicapped persons.

PS12.011 - Quantitative sensory testing using lateral skin stretch at the foot for simple screening of diabetic neuropathy Author(s): <u>Shuichi Ino</u>¹, Manabu Chikai¹, Noriyo Takahashi², Tadasuke Ohnishi³, Kouki Doi⁴, Kiyohiko Nunokawa⁵

¹National Institute of Advanced Industrial Science and Technology, Tsukuba/JAPAN, ²Tokuyukai Rehabilitation Clinic, Toyonaka/ JAPAN, ³Showa Inan General Hospital, Komagane/JAPAN, ⁴National Institute of Special Needs Education, Yokosuka/JAPAN, ⁵Tokyo International University, Kawagoe/JAPAN

Objective: Changes in food behavior and lifestyle have resulted in a considerable increase in the incidence of diabetes. Many people with diabetes have reduced quality of life because of diabetes-associated complications, which include neuropathy, retinopathy, and nephropathy. About half of the people with diabetes in the world, however, are unaware of their condition. One of the healthcare challenges is how to best implement screening, educational, and treatment programs for the prevention of diabetes. Conventional noninvasive diagnostic techniques for diabetic neuropathy have several problems, including the accuracy of a quantitative estimation, durability, and the time of testing. Therefore, the aim of this study was to develop simple point-of-care equipment to quantify plantar tactile sensibility for early diagnosis and tracking of peripheral neuropathy caused by diabetes.

peripheral regions such as the foot and hand, which is a common symptom in patients with diabetic neuropathy and appears at a relatively early stage of disease. The tactile stimulation of our testing method is adopted for lateral skin stretches, which is more sensitive than perpendicular skin indentations. A new system of quantitative sensory testing for screening of diabetic neuropathy consists of a plantar tactile stimulation platform with a small moving contactor to stretch the skin tangentially, a response switch for each tactile stimulus, a motor control box, and a personal computer for psychophysical data processing. Seven healthy adults (3 women and 4 men; mean \pm SD age, 39.6 \pm 8.6 years) and one patient (woman, aged 77 years) in the early stage of diabetes were examined to measure the absolute detection thresholds of the lateral skin stretch on the plantar surface using the system of quantitative sensory testing. The stretch stimulations were applied to five different sites (the first toe, fifth toe, first metatarsal head, fifth metatarsal head, and heel) of the right foot. The skin hardness of the plantar sites was measured using a durometer.

Results: The absolute detection thresholds of the lateral skin stretch at the foot ranged from approximately 10 to 30 µm for healthy subjects. The thresholds at the fifth toe and first metatarsal head were higher than those at the other plantar sites (p < 0.01). The tactile sensitivity of each site mainly improved as the stretch speed increased. Significant difference in threshold value was observed between the healthy adults and the patients with early-stage diabetes (p < 0.001). Meanwhile, relatively weak correlations were found between the detection threshold and skin hardness at the foot sole.

Conclusion: The present study demonstrates that the detection threshold (μ m-order resolution) of the lateral skin stretch was highly sensitive in comparison with a two-point discrimination threshold (mm-order resolution) that was well known in sensory testing. The experimental results also suggest that our testing method based on the plantar sensation elicited by a lateral skin stretch may be a simple, noninvasive method for the quantitative screening of diabetic neuropathy.

PS12.012 - A development of the robot hand for the disability which include sensory feedback.

Author(s): Tomohiro Iwaki, Kazushige Magatani Tokai University, kanagawa-ken/JAPAN

SEMG is an electrical signal associated with the activation of the muscle. Various artificial hands and robot hands which act according to SEMG patterns have been experimentally developed. Most of them can grasp and release an object according to the instruction from generated SEMG. However, most of them cannot feedback grasping power to the operator. Therefore, it is difficult to grasp an object using correct power in most systems. If an operator can feel grasping condition, more accurate operation will be enabled.

So, our objective of this study development of the feedback system which can defects grasping power of the artificial hand or robot hand and feedback this power to the operator as air pressure to the finger. Our developed system consists of two parts. One is the robot hand (the artificial hand) which acts some hand motions according to generated forearm SEMG pattern. The other is the grasping power feedback system which defect grasping power and feedback this condition to the operator.

In the robot hand system, 48 channel forearm SEMG are measured and analyzed. Motion of the robot hand was controlled according to analyzed result. And we also suppose that muscle power is proportional to the amplitude of SEMG. If analyzed result of hand motion is grasping, grasping power is calculated using SEMG amplitude, and grasping power of the robot hand is also controlled using this result.

Methods: We focused on reducing the tactile sensation at the

In our robot hand, pressure sensors are set on the hand surface and

we can measure real grasping power. The grasping power feedback system consists of these pressure sensor, a micro-processor, a syringe and an air pressure display. The piston of a syringe is driven by a stepping motor which is controlled by a micro-processor. A rubber balloon which is connected with output of the syringe displays grasping power to operator's finger by change of air pressure. A block diagram of this system is shown in Fig.1.

The developed grasping feedback system was tested with some normal subjects and characteristics of this system were evaluated. In the experiment, all subject could feel the grasping condition of a robot hand. However, it became clear that there is some time delay in the response of the feedback system. From the experimental results, we think that if these problems are improved, our system will be useful system for the amputee.

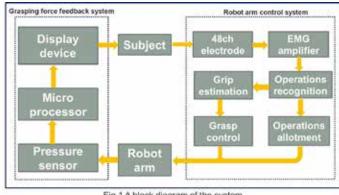

Fig.1 A block diagram of the system

PS12.013 - Motor cortical excitability enhanced by paired-pulse transcranial magnetic stimulation with biphasic pulse-form Author(s): Petro Julkunen¹, Gustaf Järnefelt², Petri Savolainen², Jarmo Laine², Jari Karhu²

¹Department Of Clinical Neurophysiology, Kuopio University Hospital, Kuopio/FINLAND, ²Nexstim Plc, Helsinki/FINLAND

Introduction: Motor threshold is a commonly used measure of corticospinal excitability in transcranial magnetic stimulation (TMS) determined by stimulating the primary motor cortex. Conventionally, the immediate excitability of the motor cortex has been modulated by the use of paired-pulse TMS using monophasic pulses with and inter-stimulus interval (ISI) of 1.5-200ms. Monophasic pulses are more easily produced by the stimulator as compared to biphasic pulses, which instead are more energy-efficient. The problem with the biphasic pulse-form to produce biphasic pulses has been the low recovery-rate of the stimulator. However, provided that this problem can be overcome, it would be possible to produce same excitability modulation with biphasic pulses as with monophasic pulses, but with better energy-efficiency and with lower stimulus intensities, meaning that maximum stimulator output could be greater. This would make the biphasic paired-pulse paradigms better applicable in patients with reduced cortical excitability.

Materials and Methods: Nexstim Plc produced a prototype stimulator for biphasic paired-pulses, effect of which was studied in 8 healthy volunteers. Resting motor thresholds (rMTs) were determined from the subjects using single-pulse paradigm from the right and left hand abductor pollicis brevis muscles, and the right tibialis anterior muscle by targeting neuronavigated TMS to the corresponding targets on the motor cortex, mapped prior to rMT measurement. Then, 20 single-pulse motor evoked potentials (MEPs) were gathered at an intensity of 110% of rMT. Subsequently, rMTs and MEPs were measured using 3 paired-pulse setups (ISI = 3ms, 7ms or 15ms) from all muscles in randomized order. In the paired-pulses, the stimulus intensity of the second pulse was 80% of the first pulse intensity.

Results and Discussion: We found that the ISI had a significant effect on the rMTs, meaning that rMTs were lower than the corresponding single-pulse rMTs and MEPs with biphasic paired-pulses were also higher than with single-pulses (Figure). The effect was emphasized at 3ms ISI.

Our findings suggest that the application of biphasic paired-pulses is possible and the potential applications are not limited similarly to monophasic pulses. For instance, paired-pulse stimulation with biphasic pulse-form could potentially be applied in repetitive TMS, in order to enhance therapy effects.

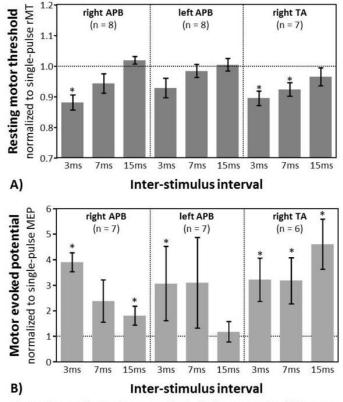

Figure: A) Normalized resting motor thresholds (mean ± SEM) at different ISIs. B) Normalized motor evoked potentials (mean ± SEM) at different ISIs. *p<0.05 compared to single-pulse TMS (non-parametric test).

PS12.014 - Quality management systems for medical devices in the production of hospital beds

Author(s): Ivana Jurickova, Vit Prindis

Department Of Biomedical Technology, Czech Technical University in Prague, Faculty of Biomedical Engineering, Kladno/CZECH REPUBLIC

Quality management systems becomes in recent years an integral part of the corporate structure. Allmost every successful company at the world has established some kind of quality management system. This study describe the situation in the field of quality management systems used in serial production, especially in health care and in the company Linet spol. s r.o., one of the biggest manufacturers of medical equipment, specializes with manufacturing of hospital beds. Bacis of this study are based on the analysis of the current situation in the world, domestic field and in the company itself. Based at the results was found recommendations for the next development of a quality system that ensures the growth of production with high-quality products at Linet spol. s r.o.

PS12.015 - Value of information analysis for use in health technology assessment

Author(s): Ivana Jurickova, Jiri Havlik

Department Of Biomedical Technology, Czech Technical University in Prague, Faculty of Biomedical Engineering, Kladno/CZECH REPUBLIC

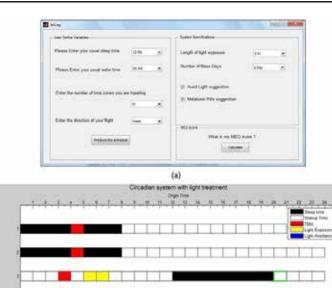

Nowadays every decision is, less or more, associated with uncertainty. In everyday life we are intuitively trying to reduce this uncertainty by collecting new information, e.g. reading newspapers or watching TV. In health technology assessment, where we should consider besides health effects also safety, technical parameters, economic impacts etc., we can do it in more sophisticated and specific ways - through the specialized literature, consultation with experts certain decision problems or collection of new evidence in additional research. Theoretically, we can do this over and over until we have enough evidence to confirm our decision. Practically, facing limited resources, mostly financial, we have to find balance between information gathering and our resources and here we can use value of information analysis.

PS12.016 - Development of a Software Tool for Quick Re-entrainment of the Circadian Pacemaker

Author(s): Omid Ranjbar Pouya¹, Ehsan Shams², Zahra Kazem-Moussavi¹

¹Biomedical Engineering, University of Manitoba, Winnipeg/MB/ CANADA, ²John Buhler Research Centre, Winnipeg/MB/CANADA

According to the Stat Canada, over a million people per month take trans-oceanic flights from Canada to overseas countries and vice versa .In all of travels exceeding five time zones , the misalignment of circadian phase, known as "jet lag", can cause health problems for the travelers . Other than frequent travelers , as of 2006 there were approximately 1.5 million Canadians, excluding US residents, living abroad who suffer from jet lag whenever they travel to their motherland. The adverse effects of jet lag impair the judgment of business people and politicians, compromise the performance of athletes, and pose a threat to public safety as it degrades performance and operational readiness of deployed military personnel. However, despite several studies suggesting protocols for designing interventions that facilitate re-entrainment to a shifted sleep-wake schedule, there is vet no standard scheduled light therapy protocol. Furthermore, although light seems to be the main stimulus to the circadian system, but the combined effect of it with other stimulants, such as melatonin pills, has not received enough attention. In this paper, we have distilled a common denominator in the literature for the response of the circadian system to light and melatonin pills and have developed a software tool that can recommend optimal timing for light exposure/avoidance as well as taking melatonin pills to compensate for the loss of alertness. The produced schedule is based on returning the time of minimum body temperature, known as Tmin, into its correct location in the sleep cycle. Contrary to the most of available solutions, our software took into account Individual circadian-phase differences by using Horne-Ostberg Morningness/Eveningness Questionnaire (MEQ) to quantify the differences and use them in calculating Tmin. This questionnaire consists of nineteen four-choice questions that can be optionally answered by user. Moreover, in the proposed software the average duration of the light exposure in each day can be estimated by user which affects the amplitude of phase shift. The produce schedule for reentrainment is developed in both form of graphic output and simple text instructions(not shown here). The figure of the software and its produced schedule is provided below for better illustration:

6)

Figure 1: (a).User interface of the software. (b).Sample schedule for a passenger who travels 12 time zones to East . The green boxes show suggested times for taking melatonin pills.

PS12.017 - Which one is better in detecting the speed and quantity of intravenous infusion in the hospital, transmissive or reflective optical method?

Author(s): <u>Hyun-Woo Lee</u>¹, Jaeyeong Park², Jinhan Lee², Hyun Hee Bang², Chul-Woo Park¹, Sanghyun Joung¹, Kwangja Hur³, Kyoung Yong Park⁴, Ilhyung Park⁵

¹Medical Device and Robot Institute of Park, Daegu/KOREA, ²Division Of Biomedical Science, Kyungpook National University, Daegu/ KOREA, ³Kyungpook National University Hospital, Daegu/KO-REA, ⁴Korea Institute of Industrial Technology, Ansan/KOREA, ⁵Department Of Orthopedic Surgery, Kyungpook National University, Daegu/KOREA

We developed an infusion monitoring system using a reflective optical sensor which can detect the infusion speed and quantity. The system detect infusion drips and calculate the amount of intravenous fluid left. We use both reflective and transmissive optical sensor to detect the infusion drips, and compare the results.

Intravenous (IV) therapy is one of common treatment in the hospital for medication delivery, blood transfusion and chemotherapy. IV therapy primarily employ a drip chamber to prevent air embolism. Based on the individual prescription, the speed of IV infusion should be adjusted by medical staffs. Medical staffs observe the number of drips in the drip chamber and manually adjust the speed using a regulator. Furthermore, regular monitoring is required during IV therapy to prevent malfunction such as embolism, back flow and fluid overload. Thus, medical staffs need to frequently check the IV therapy and the patient's status. To overcome these inconveniences, a new system that automatically detects the infusion speed and quantity is required. Several researches to automatically monitor the IV therapy have been conducted using weight measurement, capacitance, or optical methods. The optical method is using a sensor attached to the drip chamber to detect infusion drips and calculate the infusion speed. The optical method can detect abnormal status such as blockage and fluid overflow. Regardless types of solution bags, the optical method is compatible because sensors are attached to the drip chamber. Figure1 (a) shows conventional transmissive method to detect drips in the chamber. Since the detection range of transmissive method varies depending on the angle of the drip chamber and the deviation of the output sensitivity, we suggest reflective method (figure1 (b)).

Two experiments were performed using the infusion set. We compare the performance between the transmissive and the reflective optical sensor. First, the drip detection rate was compared depending on each position angles using both transmissive and reflective methods. Second, the error rate of drip detection of the transmissive and reflective methods was respectively measured under the same condition.

In both experiments, the drip detection rate was significantly improved when using the reflective method. The reflective sensor showed a low error rate of less than 11%, in comparison up to 65% error rate of the transmissive sensor.

In this study, the reflective optical sensor was much more reliable than the conventional transmissive optical sensor.

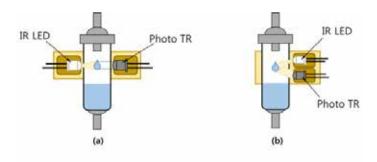

Figure1 Concepts of optical sensors; (a) conventional transmissive method, (b) suggested reflective method

PS12.018 - The effect of stented valve oversizing on hemodynamic flow in the diseased right atrium

Author(s): Munirah Ismail¹, Foad Kabinejadian², <u>Hwa Liang Leo³</u>, Karthik Kannan¹

¹Biomedical Engineering, National University of Singapore, Singapore/SINGAPORE, ²Department Of Surgery, National University of Singapore, Singapore/SINGAPORE, ³Department Of Biomedical Engineering, National University of Singapore, Singapore/SINGAPORE

Tricuspid regurgitation (TR) occurs in many individuals and is usually considered mild but severe TR is life-threatening. Even so, many patients with severe TR are denied of the replacement valve surgery because their old age or co-morbidities put them at high risk for conventional open heart surgery. With the advent of transcatheter technology, it is now possible to deliver the valve to the desired location without the need for open heart surgery. However, so far, there has been no commercially available transcatheter tricuspid valve. This may because of the complex tricuspid valve anatomy and lack of an anchorage zone. Thus, the next best anchorage zone is the vena cava. Placing the valves in the superior and inferior vena cava will prevent the back flow of blood into the venous structures and possibly reverse peripheral edema and ascites which are caused by the elevated venous pressure. The hemodynamic characteristics of these valves are tested in a mock circulatory system

(MCS) which emulates the physiological pressure and flow conditions in the cardiovascular system. The sizes of the valves implanted onto the vena cava also affect the flow. In this study, we analysed how valves of different sizes affected the flow patterns as well as the magnitude of the velocity. Particle image velocimetry is used to study the flow characteristics in the MCS.

PS12.019 - Device trial to improve blood flow rate with controlled pressure for blood flow at venous side in single needle dialysis

Author(s): <u>Yasuyuki Miwa</u>, Kawabe Manabu, Takashi Kano, Yoshihisa Yamashita

School Of Biomedical Engineering, Faculty Of Health And Medical Care, Saitama Medical University, hidaka,saitama/JAPAN

Single needle dialysis can be performed using only one needle. However, because blood is both removed and returned with only one needle, the dialysis effect is less than when two needles are used. If the blood return time can be reduced when using controlled pressure for blood flow at venous side in the single needle method, improved blood flow rate and dialysis rate can be expected over time. In conventional single needle dialysis, air is compressed in a vein air capture chamber. Therefore, it isn't possible to actively control the return time. In the present study, we used air pistons run by solenoid in an attempt to reduce return time and to safely improve the efficiency of single needle dialysis. To design and test a device to improve blood flow rate in single needle dialysis and to compare the device with previous methods. The conventional method uses the force of compressed air within the air capture chamber to return blood. This method reduces pressure in the second half of blood return, which further reduces the amount of blood returned. The present device prevents the reduction in pressure using the solenoid. The blood in the vein air capture chamber is constantly pressured by the solenoid. This makes it possible to prevent a reduction in the sent blood flow rate. Results, the present device, when compared with conventional methods, significantly increases blood flow rate. The present device, although simple, can reduce blood return time and increase blood flow rate. Indicate that this device can be anticipated to improve dialysis efficiency.

PS12.020 - An Embedded Software Solution for Rest ECG Devices

Author(s): <u>Gisela Montes De Oca</u>, Maite Cañizares, René González-Fernández

ICID-Digital Medical Technologies, Havana/CUBA

This paper discusses the design and implementation of a software solution to be used in the development of digital electrocardiographs. These electrocardiographs acquire simultaneously the standard 12-lead electrocardiogram, display the waveforms (ECG) on a high-resolution graphic display and print the ECG with several formats. The software also performs measurements and diagnostic interpretation. ECGs and their associated information are stored on a database. The information can be transmitted to any informatics systems like HIS and expert consulting opinion systems which help physician on actions to take with the patient being treated. Software solutions were developed by using the Integrated Development Environment (IDE) Qt Creator and the cross-platform Qt library. The design and programming process employed object programming techniques developing classes to encapsulate all the functions used by the system. The hardware solution used the processing board CID 300-9, based on the S3C2440 microprocessor with ARM9 architecture and Linux operating system.. The technical parameters of the equipment and software were assessed according to the requirements of the IEC 60601-2-25 standard, with satisfactory results.

PS12.021 - Development of innovative gas phase sterilization technology for nucleolytic degradation

Author(s): <u>Toshihiko Okazaki</u>¹, Yasushi Suzuki²

¹Aro Advanced Medical Center, Kyushu University Hospital, Fukuoka city/JAPAN, ²Sealive, Niihama-city/JAPAN

With the worldwide major trends of next generation medical technology development, such as regenerative medicine and gene therapy, it is getting urgent need to establish and improve advanced aseptic (germ and virus-free) manufacturing environments of fabrication plant for quality assurance of the products. But there still remain critical problems with conventional sterilization method due to its limited spectrum, environmental pollution, health impairment and such, especially at present, there is no available decisive decomposition method for nucleic acid.

Recently we have developed innovative technology as the catalytic reaction type mixed gas generating system using methanol as a raw material, (Biovector, pat.no.5463378), and its remarkable efficacy of sterilization effect, as well as nucleic acid decomposition will be reported.

The Biovector system consists of a mixed biogas generator, a small experimental chamber and a scrub exhaust device for detoxification equipped with catalyst detoxification apparatus. The system enables to make continuous monitoring of inside temperature and humidity as well as the hydrogen concentration and other biogas elements.

We investigated sterilization effect of Biovector by biological indicators (BI) of both *Bacillus. atrophaeus* and *Geobacillus. stearothermophilus* (RAVEN Co.), and determination was evaluated according to Food and Drug Administration Guidance for Industry and Japanese Pharmacopoeia sterility testing. For evaluation of nucleolytic degradation efficacy of Biovector, DNA samples were purified from HeLa cell lines, and fragmented DNA was analyzed by real time PCR method and Bioanalyzer (Agilent Technologies) system for sizing and quantitation.

By the Biovector gas exposure for 5 minutes at 50 °C, the complete eradication effect was observed in all of BI applied in the amount from 106 to 108, which resulted in achievement of sterile assurance level (SAL) of 10-6. Also in the evaluation of nucleolytic degradation ability, the complete degradation effect of DNA into 10 or less base pairs was elucidated by the time of exposure for 15 minutes at 37° C of Biovector gas under the condition of both moist and dry of up to 10ug of DNA. It also revealed the ability of Biovector are temperature dependent (50>45>37°C).

Taken together, in this study, newly developed Biovector gaseous sterilization system revealed its remarkable sterility and nucleolytic degradation ability, which could not be attained in the conventional method so far. Biovector will be highly useful for improving aseptic environment and public health preventing pandemic risk for pathogenic organisms, moreover the future clinical applications such as endoscopic sterilization equipment and automated cell processing system.

PS12.022 - Ultrasound Modular Platform: a general purpose open architecture system for medical imaging research

Author(s): <u>Haroldo J. Onisto</u>¹, Santiago Rodriguez¹, Glauber E. Sapia¹, Rodrigo G. Borges¹, Iliezer Tamagno¹, Eduardo T. Costa², José E. Bertuzzo¹

¹Eldorado Research Institute, Campinas/BRAZIL, ²Biomedical Engineering Department, University of Campinas, Campinas/BRAZIL

Introduction: A demand signaled by the Brazilian Ministry of Health has led to the development of an Ultrasound Modular Platform which aims to medical imaging research. It was conducted in a partnership between top Brazilian universities, led by the University of Campinas jointly with Eldorado Research Institute, a top Brazilian center in IT and innovation engineering. In this paper we present the achievements and experiences gained in this recent development. *Methodology:* Our platform is a real-time processing machine, designed with robust, versatile and flexible hardware architecture of 64 physically independent channels, expandable to 128. It is based on analog front-end circuits for the excitation of transducers in transmission mode and initial signal conditioning of received echoes. The core signal processing is left to reprogrammable integrated circuits, Digital Signal Processor (DSP) and Field-Programmable Gate Arrays (FPGAs), composing the digital back-end system.

The architecture consists of two identical 32-channel analog transmission boards and one 64-channel analog reception board along with four digital boards based on Virtex-6 FPGA. The digital boards are arranged so that one of them controls the two beamforming transmission boards and the reception board. An extra board is used to connect the DSP. The backplane integrates connectors for two probes and delivers signals from the power supply to the entire complex. A Personal Computer (PC) accounts for user interface, medical applications and image display.

The firmware architecture was designed to work as a mechanism of a data-flow machine. Thus, to develop algorithms for beamforming in addition to image and signal processing, we adopted the Model-driven Engineering approach using MATLAB to initially model their blocks and then to automatically generate Verilog/VHDL and C/C++ codes. This allowed rapid proofs of concept and reduced project costs.

The equipment works by setting a protocol (*e.g.* cardiac exam) using proper PC-based user interface, initializing medical application software. The protocol generates a service request to the hardware control, a role played by DSP. The DSP acts as a manager, first receiving settings from the PC and determining the beamforming parameters that is sent to the FPGAs. After receiving the pre-processed signals from FPGAs, the DSP performs image processing and delivers them back to the PC to be displayed on the screen.

At this stage, the developed system is able to generate B-mode and M-mode ultrasound imaging, with a module for Doppler imaging (Color and Power Doppler). The system accepts ECG signals for proper coupling to cardiac applications. Although being able to work in faster modes, it was decided to run the platform achieving at least 30 frames per second. The several university groups working on the platform are developing special modules as add on applications such as elastography, coded excitation, breast cancer detection and others.

Conclusion: Preliminary results have shown that the developed platform can be employed as a useful and low cost medical ultrasound system with great potential to test and innovate on medical (and non-medical) ultrasound imaging techniques.

PS12.023 - Design and Preliminary Validation of a Dual Mechanical-Anthropomorphic Breast Phantom with Inclusions Author(s): James Antaki, Molly Blank, <u>Shigeto Ono</u> Biomedical Engineering, Carnegie Mellon University, Pittsburgh/ UNITED STATES OF AMERICA

Tissue phantoms can be categorized into two broad categories: anthropomorphic phantoms used for imaging calibration of structures, and mechanical or optical phantoms for validating tissue characteristics such as stiffness or acoustic attenuation. Both structural and mechanical features of lesions are useful in a complete clinical diagnosis of breast cancer, yet no phantom exists that can accurately depict anatomy and elasticity. Recent developments in ultrasound elastography have increased the need for more mechanically realistic phantom models since the pathology of a breast mass often correlates with mechanical stiffness. This work describes design and preliminary validation of representative benign and malignant masses in a dual structural and mechanical breast phantom. Polyvinyl alcohol (PVA) cryogels are widely accepted as an accurate mechanical tissue analog and will be used to simulate both the bulk fatty, fibroglandular tissues of the breast and pathological inclusions. PVA cryogels exhibit wide ranges of elasticity and are tunable based on different preparation methods; predominantly varying the number of freeze-thaw cycles and concentration of PVA in the cryogel solution. Dynamic mechanical compression testing is conducted to validate the protocol to achieve elastic modulus values from literature comparable to that of fibroadenoma and invasive lobular carcinoma. The representative benign fibroadenoma is characterized by well-defined boundaries, and the malignant invasive lobular carcinoma has a speculated shape integrated into the surrounding tissues. The key contribution of this design is the shape of both the benign and malignant pathologies; derived from physician-annotated patient MRI images. A 3D mesh of the inclusions are exported into Solidworks and 3D printed into a thermoplastic polyester mold. Unlike existing phantoms, the breast phantom described combines anthropromophic and mechanically validated inclusions to facilitate the development of diagnostic imaging devices and techniques.

PS12.024 - Evaluation and Analysis of the Results of a prototype Medical Device Vigilance System (MEDEVIPAS)

Author(s): Kallirroi Stavrianou¹, Zhivko Bliznakov¹, Athanasios Anastasiou², <u>Nicolas Pallikarakis¹</u>

¹Biomedical Engineering Unit, University of Patras, Rio-Patras/ GREECE, ²School Of Electrical & Computer Eng., National Technical University of Athens, ATHENS/GREECE

Biomedical Technology has contributed decisively to the impressive progress of modern healthcare over the last half century and at the same time medical devices play a vital role in the delivery of high quality healthcare. Although recent technological advancements have led to much more reliable and safer Medical Devices (MDs) unfortunately the potential risk of failure on medical devices and the associated adverse incidents cannot be neglected. In fact, adverse incidents, due to MDs, have recently increased in absolute terms, because of the exponential increase in the number of devices used nowadays. Therefore, MD recalls by manufacturers contribute to the safe function of the devices, in order to avoid incidents that could lead to injuries and deaths.

In terms of technology, in order to create a safer environment, providing rapid and accurate information on adverse events, is necessary to avoid their repetition. The traditional approach of MD Vigilance based only on official user reports of adverse incidents has been proven inadequate today. A modern approach to the problem is based on the introduction of additional means, such as data mining, extraction, standardization and codification of the information, from different direct and indirect sources worldwide, and its systematic classification and archiving in dedicated databases. The aim is to timely extract the information on potentially hazardous MDs and make it available where appropriate.

Process evaluation involves collecting and analyzing information about a program's activities, characteristics, and outcomes and consequently yields the information needed to make adjustments to strategy implementation in order to strengthen effectiveness. Particularly, the system evaluation process performed included both data verification/validation and software evaluation. In some cases, the results were cross-checked using specific multiple approaches, assets and different dedicated techniques. The procedure for data processing included the determination, transformation, modelling and codification of the data in order to highlight relevant information, as well as to support decision making and conclusions.

To demonstrate and objectively assess the quality and usability of the design, questionnaire of the vigilance system has been created and filled-in by users and reviewers. Moreover an analysis of the databases has been conducted aiming to provide a comprehensive interpretation of the results of this investigation. Additionally, various methods and techniques have been used to identify specific characteristics of the MDs failures and, based on that, forecast trends in areas requiring special attention were investigated. In conclusion, it has been demonstrated that MEDEVIPAS System could be a very effective tool for world-wide use advancing MD vigilance.

PS12.025 - Medical Device Development - Risk Management Author(s): Mayur Patel, Mark Humphries Cambridge Technology Centre, PA Consulting Group, Melbourn/ UNITED KINGDOM

Risk Management is critical, and challenging to implement pragmatically during early phase development.

Pragmatic, compliant Risk Management currently challenges many medical device manufacturers in hospitals and start-up companies. The harmonized risk management of medical devices standard, ISO 14971:2012, gives presumption to conformity to some aspects of the Medical Devices Directive (MDD) along with other harmonized standards. ISO 14971:2012 is a process standard that establishes the requirements for risk management to determine the safety of a medical device. The challenge for developers is to determine how best to implement the standards during the 'proof-of-concept' as at this point of development it is not clear if the device is feasible in terms of technology and market-need.

A further challenge is to consider how to maximize investments in prototypes when the appropriate risk management approach has not been followed from the start.

I have come across many sophisticated prototype medical devices requiring regulatory approvals in hospitals and industry. Challenges arise when a prototype device is further developed and is to be approved in the absence of Risk Management documents relevant to the initial stages. Whilst undesirable, if the safety and efficacy of the device can be assured then a carefully structured and planned retrospective risk management file may be accepted for ISO 14971:2012 submission. The approach will still involve following all processes described in the standard but in a different perspective. It will require a carefully prepared risk management plan to address the risks that were not addressed in the prototype development stage.

Putting in place the right risk management processes and tools, is important for your development, and knowing how to use them correctly is critical.

The gap analysis above may be based around FTA, FMEA or FMECA depending on the status of prototype development. The scoring in the analysis plays an important role in identifying risks within the system. Many manufacturers are uncertain as to how best to construct their risk matrix tables – what is an acceptable risk? Whether to use qualitative or quantitative scoring for probability scores? Whether to use 'detectability' or 'P1-and-P2' scoring? [Here, the probability score P1 is a likelihood of failure occurring and P2 is likelihood of this failure resulting in harm] Such decisions are important as they have significant impacts on safety and compliance with the standard. To clarify the differences, consider a motoring analogy - if a car braking system fails and the car is designed to detect the failure, then the 'detectability' score is high which would reduce the overall risk score significantly (but would not necessarily reduce the potential for harm). If P2 score is used for the failure then the score will not reduce until the car system is designed to not only detect but also prevent harm.

Even after deciding the scoring mechanism, the next challenge is how to score the severity of the failure. Where should we set the score in the analysis – is it correct to use the worst case or the most likely?

PS12.026 - Analysis of the terminology to name medical devices used in Intensive Care Units - ICUs

Author(s): <u>Pamela T. Ribeiro</u>¹, José A. Ferreira Filho², Mariangela Araujo¹

¹Human Factors Laboratory Federal University of Itajuba, Itajuba/ BRAZIL, ²Institute Of Systems Engineering And Information Technology, Federal University of Itajubá, Itajubá/BRAZIL

The purpose of the proposed study is to analyze the terminology of medical products used in Intensive Care Units - ICUs in Brazil, focusing on their morphological and semantic aspects. The research aims to understand the terminology used on this particular branch of medicine, with emphasis on the following specific objectives:

a. Raising the names of medical products used in ICUs with the help of experts in the field;

b. Searching variants of the selected terms;

c. Observing the existence of synonyms and the coordination relations between terms;

d. Describing the morphological and semantic behavior of the terms found.

For this research, it was first studied the theories regarding terminology, lexicography and word formation. After this step, we started collecting the terms relating to medical products used in ICUs in documents issued by the governmental regulator agency - ANVISA. Through documents called "Resolutions of the Board of Directors – RDC", ANVISA adopts procedures and determines behaviors for all groups and institutions involved with the issue at hand. In the case of this study, we used as a reference specifically the Resolution of the Board of Directors RDC number 7, of 24 February 2010, which details the minimum requirements for Intensive Care Units operation. In a meeting with specialists, we concluded that we would use as corpora for this research the manuals of equipment manufacturers, since it is through them that the first contact between medical technologies and users is established.

The analysis of the manuals was made through Terminus, a software developed by the IULATERM Group, Institut Universitari of Applied Linguistics at Universitat Pompeu Fabra – Barcelona – ES. After validation of the terms that referred to medical devices by the specialists, were selected five of the 34 terms that name the medical products for a preliminary study.

From the analysis of selected terms and all its variants, we proposed conceptual relationships based on examples from the manual and, we notice complex relationships between the terms and an expressive number of syntagmatic formations.

PS12.027 - Determination of Breath Acetone in 298 Type 2 Diabetic Patients using a Ringdown Breath Acetone Analyzer Author(s): <u>Meixiu Sun</u>, Zhuying Chen, Xiaomeng Zhao, Zhennan Wang, Yuan Yuan, Chenyu Jiang, Yingxin Li, Chuji Wang Institute Of Biomedical Engineering, Chinese Academy of Medical Sciences, Tianjin/CHINA

Breath analysis is a promising new technique for nonintrusive disease diagnosis and metabolic status monitoring by testing exhaled breath components. The detection of exhaled nitric oxide has been used as a tool in support of asthma diagnosis for some years. Breath acetone has long been known as a biomarker for diabetes. However the results from published data by far have been inconclusive regarding whether breath acetone is a reliable index of diabetic control. Huge variations exist among the results of different studies because there has been no "best-practice method" for breath-acetone measurements as a result of technical problems of sampling and analysis. Over 90 % of diabetic patients have Type 2 diabetes (T2D). In this work, a near-real-time on-line breath-acetone analyzer based on cavity ringdown spectroscopy was developed and used for breath-acetone measurement of 298 T2D subjects and 42 healthy subjects, one of the largest numbers of T2D subjects ever used in a single study. Four breath samples were taken from each subject under each of four different conditions: fasting, 2 h post-breakfast, 2 h post-lunch, and 2 h post-dinner. Simultaneous blood glucose (BG) levels were also measured using a standard diabetic-management blood-glucose meter. For the 298 T2D subjects, their exhaled breath acetone concentrations ranged from 0.1 to 19.8 ppm; four different ranges of breath acetone concentration, 0.1-19.8, 0.1-7.1, 0.1-10.9, and 0.1-10.6 ppm, were obtained for the subjects under the four different conditions, respectively. For the 42 healthy subjects, their breath acetone concentration ranged from 0.1 to 2.6 ppm; four different ranges of breath acetone concentration, 0.3-2.6, 0.1-2.6, 0.1-1.7, and 0.3-1.6 ppm, were obtained for the four different conditions. The mean breath acetone concentration of the 298 T2D subjects was determined to be 1.5±1.3 ppm, which was 1.5 times that of 1.0±0.6 ppm for the 42 healthy subjects. No correlation was found between the breath acetone concentration and the blood glucose level of the T2D subjects and the healthy volunteers. This study using a relatively large number of subjects provides new data regarding breath acetone in diabetes (Type 1 diabetes and T2D) and suggests that an elevated mean breath acetone concentration exists in T2D. However it arguably still too early to draw a general conclusion on the use of breath acetone as a reliable substitute of BG for diabetes diagnostics and screening on the basis of the currently limited data. The relationships between breath acetone level and BG level and other bioinformatic variables need to be further investigated with a large number of subjects (e.g. thousands) by use of a high-data-throughput real-time online analytical technique.

PS12.028 - A study of the differences between uncompressed sound source and compressed sound source gives EEG of human

Author(s): <u>Takashi Suzuki</u>¹, Kazushige Magatani² ¹Tokai University, Yokohama/JAPAN, ²Tokai University, kanagawa-ken/JAPAN

In recent years, the way of sell music has changed CD into digital distribution. Mp3 is the representative of compressed sound source in online music distribution service.

Mp3 formatted sound quality is inferior as compared with CD-DA formatted sound quality, because mp3 has less information as compared to pre-compressed data. The objective of this study is by analyzing EEG to determine if people can recognize such difference as differences in sound.

In the experiment, one subject (Healthy adult, Male, Age: 22 years

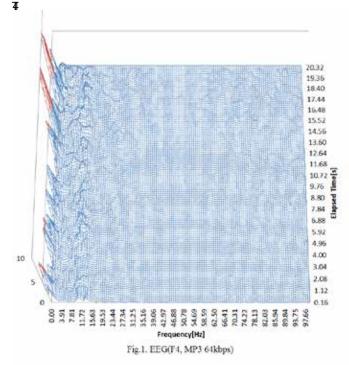

old) were studied. A 16 channel EEG amplifier which is developed in our laboratory is used in the experiment. To play sound sources, we used SE-200PCI which is a sound card for PC manufactured by Onkyo Corporation, and SRS-2050A which is a headphone manufactured by STAX Ltd. "Waltz for Debby" by Bill Evans was used as music source in the experiment.

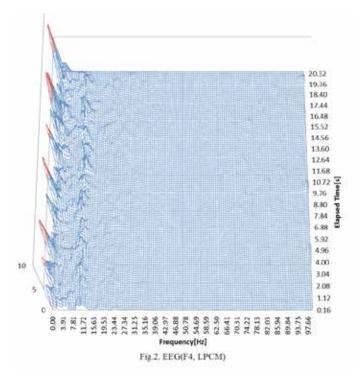

Four sound sources (LPCM, MP3 64kbps and 128kbps and 256kbps) were played sequentially. After the subject listened to each sound source for 60 seconds, sampling of EEG was carried out for 20.48seconds. (Sampling frequency: 1 kHz, Quantization bit rate: 16) We repeated this process 5 times.

Sampling data were added 5 times synchronously. Then obtained data were applied Fourier transformation.

Fig.1 and Fig.2 shows one of the results of experiments. Differences between LPCM and MP3 graphs were confirmable in Cz, F3, F4, T3, T4. In LPCM graphs, power spectral periodically increased and decreased at delta wave (0.5Hz~4Hz), otherwise, in MP3 graphs, power spectral periodically inhomogeneous increased and decreased at delta wave.

The results suggest that sound source format differences affected EEG that is come of higher cognitive function than auditory area, because differenced area were not exclusive to T3 and

PS12.029 - Evaluation of the interface pressure characteristics over a temperature regulating air-mattress under different surgical positions

Author(s): <u>Eric Tam</u>¹, Jieling Liu¹, Cindy Yip², Yu F. Chow² ¹Interdisciplinary Division Of Biomedical Engineering, The Hong Kong Polytechnic University, Hong Kong/CHINA, ²Department Of Anaesthesiology & Ot Services, Queen Elizabeth Hospital, Hong Kong/CHINA

Introduction

Intraoperative acquired pressure ulcers (IAPU) are deep tissue injury resulted from prolonged tissue compression during anesthesia. There exists clinical evidence showing that the onset of IAPU was associated with hypothermia during surgery. To maintain body core temperature, warm blankets are commonly used on the operating table. Recently, a temperature regulating air-mattress (Warmcloud, KanMed, Sweden) was introduced as an efficient patient warming system with pressure ulcer prevention. However, there are few scientific reports about the effectiveness of using Warmcloud to reduce the interfacial pressure generated during different surgical positions.

Methodology

Ten healthy volunteers (5 males, 5 females, average age 23, BMI: 22.3±5) participated in this study. Four surgical positions: supine, lateral, prone and lithotomy were evaluated at various inflation pressures of the Warmcloud system. Interface pressure was measured using a capacitive sensor mattress device (Xsensor, Canada). During the experiment, the temperature setting of the Warmcloud was set to 36°C. The average pressure, contact area, percentage of area below 33mmHg and peak pressure over bony prominences and other anatomical locations at risk of pressure ulcers were recorded. Comparisons of interfacial pressures were made between use and without use of the Warmcloud mattress on the operating table.

Results

Comparing to the operating table, contact area over the body-support interface with Warmcloud is significantly larger (p<0.05), varied

between 7 to 87% in the 4 surgical positions. The area of contact that experienced below capillary closing pressure also increased significantly (between 6-15%) when Warmcloud is in use. In terms of average pressure over the entire support surface. Warmcloud only provided significant pressure reduction during supine lying. For peak pressure loadings, different anatomical sites are involved. For supine, peak pressure was found at the scarum and the heels. Compared with lying on the operating table, use of Warmcloud significantly reduced the peak pressure by 53% and 70% at the sacrum and the heels respectively. In lateral position, while the majority (n=8) had reduction of peak pressure underneath the axilla, two subjects experienced pressure increase during the use of Warmcloud. In lithotomy position, Warmcloud significant reduced the peak pressure at the sacrum. For prone position, peak pressure at the anterior iliac spines, chest and knees varied between use and without use of Warmcloud. Furthermore, our data also showed that the recommended pressure for inflating the Warmcloud mattress may not give the best pressure reduction outcome.

Discussion

This study revealed that the Warmcloud mattress can significantly reduce the average and peak interface pressure during supine and lithotomy positions. In lateral posture, we found that gel pad used underneath the axilla may introduce unwanted high pressure loadings at the interface which could be detrimental. For prone position, as chest pad is usually used during surgery, usage of Warmcloud may not be effective. Furthermore, we also found that the recommended inflation pressure for the Warmcloud system based on patient's BMI may not give the best pressure relief characteristics. For best protection to patients, pressure measurement of the body support interface on the operating table needs to be carefully considered.

PS12.030 - Continuous cuff-less estimation of systolic blood pressure from

pulse wave transit time measured in a chair

Author(s): <u>Toshiyo Tamura</u>¹, Zunyi Tang¹, Masaki Sekine¹, Masaki Yoshida¹, Wenxi Chen²

¹Biomedical Engineering, Osaka Electro-Communication University, Neyagawa/JAPAN, ²Aizu University, Aizu-Wakamatsu/JAPAN

Introduction: To control blood pressure, especially hypertension, long-term monitoring of blood pressure at home can be effective and reliable compared with regular monitoring in a physician's office. This requires the development of more convenient blood pressure monitors to replace cuff-type sphygmomanometers. In this work, we propose a new method of non-invasive continuous cuffless estimation of systolic blood pressure (BP) at home from pulse transit time.

Principle:

The cuff-less BP monitor estimates the BP by pulse wave transit time (PWTT). Generally, if BP is higher, the PWTT is faster. The PWTT is obtained from the R wave of the ECG and the peak of the first derivative of the PPG signal. Although the blood flow and PWTT depend not only on BP but also stiffness and tonus, PWTT *is* primarily related to BP.

Systolic blood pressure is estimated with the following equation¹⁾

Pe=Pb-2/(γTb)*ΔT

where is the based blood pressure level, Tb is the PWTT corresponding to the pressure , Δ T is the change in PWTT, and γ is the peripheral resistance.

Method: The cuff-less BP monitor consists of three fabric electrodes

attached on both arms of a chair: a plus electrode for ECG installed on one side and a minus electrode and grand electrode for ECG are installed on the other arm. A PPG sensor is also installed on one arm. From ECG and PPG signals, we estimated BP. Seven healthy subjects aged 20-65 years participated in the experiments. Subjects sat in the armed chair and touched the electrodes and PPG sensor. Subjects also attached a continuous blood pressure monitor (Finometer; Finapres Medical Systems Corp.).

To evaluate the method, the continuous blood pressure monitor was used as a reference. The simultaneous recordings of the continuous blood pressure and the cuff-less BP monitor were monitored. The deviations and RMSE of the errors were calculated.

Results: Preliminary experiments showed that the errors in most results were under 10% compared with the reference. The deviations and RMSE of most results were not above 10 and the error ratios of most results were also below 10%.

Discussion: We attempted to estimate systolic BP from PWTT. The results were promising. We are satisfied with the current evaluation stage but more precise monitoring is needed to replace cuff-type sphygmomanometers and for predicting diseases related to high BP.

PS12.031 - A development of the pressure distribution display which is used in robot hand for the disability Author(s): <u>Kenya Tanaka¹</u>, Kazusige Magatani²

¹University, hiratukashi kanagawa/JAPAN, ²TOKAI University, hiratukashi kanagawa/JAPAN

We are now investigating about a robot hand control system for the amputee which is controlled by SEMG. From previous studies, it became clear that a robot hand can be controlled by SEMG which is measured from a forearm. And we also developed the robot hand control system which could measure grasping power and feedback this power to an operator. In this system, a pressure sensor for one point was used for feedback system. For this reason, our previous system could not feedback the pressure distribution on the hand surface to the operator. It is thought that if the pressure distribution of the grasping object is known, the operator will be able to know the detail of the object. So, our objective of his study is a development of the sensor which can measure pressures of multi-point.

The pressure-sensitive conductive rubber is used in order to construct a multi-point pressure sensor. In this rubber, conductive material is uniformly spread. Thus, the resistance value of this rubber changes according to the stress that is given to the rubber. A construction of the sensor is shown in Fig.1 In our developed sensor, 25mm square pressure-sensitive conductive rubber sheet was used as a sensing material. As shown in this figure, 4 conductive lines are set on each row and column. And the rubber sheet is set between these lines. This sensor can sense pressure each 16 lattice points as conductive value. In our sensor, the sensing point is changed by analog switch driven a microprocessor.

A developed sensor was set on a robot hand and tested using aluminum object. Grasping power of the robot was set from 0.8 to 3.3 kg, and the response of a developed sensor was measured. From the experiment, following results become clear. 1) The sensitivity of all sensors are almost equal. 2) There are small crosstalk at each sensing point. However, these crosstalk of each point are almost equal. From these experimental results, we have concluded that our developed sensor will be useful for the multiple sensing of the distributed pressure.

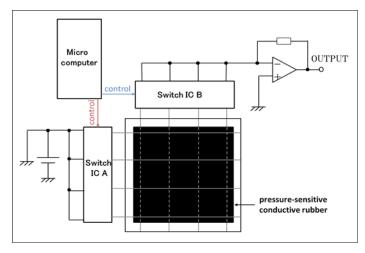

Fig1. construction of sensor

PS12.032 - Prototype Development Generating Vacuum for Treating Chronic Wounds Negative Pressure Level Laboratory Author(s): Edison Vazquez-Gordillo¹, Gerardo S. Romo-Cardenas¹, Alejandra Guillen-Peralta², Raul De La Rocha-Encizo¹ ¹School Of Engineering, Montemorelos University, Montemorelos/ MEXICO, ²School Of Health Sciences, Montemorelos University, Montemorelos/MEXICO

At present time, the medical care is being referred not only to treatment of a diagnosis disease itself, but also their complications and variations that could become chronic and therefore more devastating. With the known increase in overall life expectancy, we know that we are facing a whole different types of diseases. A case of these chronic wounds; which is a condition that has generated a very high cost both in financial perspective, and the health complications that such diseases generate. Negative pressure therapy is a procedure that has caught the attention of health professionals due to its effectiveness. But for many of them still remains unknown the biochemical process behind this therapy. On the other hand, is a process becomes costing up to \$ 40,000. As only a small percentage of the population or health systems that could afford to use a system of this type in order to treat a condition of chronic wound. For this project a methodology that involves the development of a negative pressure prototype for chronic wounds is proposed. The scope of this paper is to analyze the variables involved in the negative pressure system in order to generate models of fluids and colloids for the study of the variables that are in the process of healing of chronic wounds. This with the intention of support research and development in the area of devices negative pressure therapy inexpensive that could expand the range of use and users.

PS12.033 - Tunable Irradiation System for Corneal Collagen Cross-linking

Author(s): Victor A.C. Lincoln¹, Sidney J. Faria E Sousa², <u>Liliane</u> <u>Ventura³</u>

¹Electrical Engineering, Universidade de Sao Paulo, Sao Carlos/ SP/BRAZIL, ²Ophtalmology - Fmrp, Universidade de Sao Paulo, Riberião Preto SP/BRAZIL, ³Electrical Engineering - Eesc, Universidade de Sao Paulo, Sao Carlos SP/BRAZIL

An optical arrangement has been set up for spectroscopically measure the transmittance of UVA light through 10 human preserved corneas of over 400µm thickness during the corneal collagen cross-linking procedure under the current procedure protocol for

early stage keratoconus treatment. To enhance absorption of UV radiation, Riboflavin solution (0.1% and 400 mOsm) was applied prior to and during exposure. The UVA beam - 365nm ± 5nm at 3mW/ $cm^2 \pm 0.003 mW/cm^2$ - was focused directly onto the corneal stroma. To enhance absorption of UV radiation, Riboflavin solution (0.1% and 400 mOsm) was applied prior to and during exposure. To enhance absorption of UV radiation, Riboflavin solution (0.1% and 400 mOsm) was applied prior to and during exposure. The UVA beam - 365nm ± 5nm at 3mW/cm² ± 0.003mW/cm² - was focused directly onto the corneal stroma. Our studies on the UVA transmittance of the cornea during the cornea collagen cross-linking have shown that without Riboflavin, there is a 61.6% transmittance of UVA light toward the endothelium and at the very end of the treatment it decays to 12.6%. However, the transmittance differs in each of the stage of the treatment. In our experiments, the average transmittance in terms of energy during the 30 minutes irradiation procedure fluctuated from 0.67 to 0.38mW/cm².(figure 1). These results indicate different levels of UV transmittance during treatment and lead to the development of new technologies and consequently new protocol considering using tunable UVA irradiation system and delivering different doses at each stage of the treatment, therefore to minimize irradiation time, reducing treatment time consumption

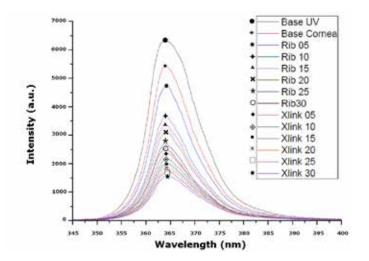

Figure 1: Transmission spectrum of a human cornea with CCT = 571mm during the collagen cross-linking procedure. (Base UV= Baseline; Base Cornea = cornea without epithelium and no application of Riboflavin; Rib = 1 drop of Riboflavin application; Xlink = Riboflavin + UVA irradiation; the numbers following the Ribs and Xlinks indicate the time interval in minutes that an event has been performed during the procedure).

PS12.034 - Electromagnetic high-hydrous gel phantom at a low-frequency band -Improvement in the electrical characteristics by using a carbon microcoil and investigation of its mechanism-

Author(s): <u>Takahiko Yamamoto</u>, Kohji Koshiji Department Of Electrical Engineering, Faculty Of Science And Technology, Tokyo University of Science, Noda/JAPAN

This paper presents an improvement in the electrical properties of a high-hydrous gel phantom by adding a carbon microcoil (CMC). A mechanism to improve the relative permittivity by the addition of the CMC is introduced. The CMC functions as an inductance at a certain frequency range. Adding a CMC to the conventional phantom is useful in improving the electrical characteristics at a frequency range of 10 MHz to 30 MHz, thereby increasing the relative permittivity.

PS12.035 - Examination of Bisphenol A Elution Concentration in Dialyzers

Author(s): <u>Yoshihisa Yamashita</u>¹, Ayako Yamashita², Isao Tsukamoto³, Yasuyuki Miwa¹, Hidetomo Nakamoto⁴, Hiromichi Suzuki⁵ ¹Faculty Of Health And Medical Care(school Of Biomedical Engineering, Saitama Medical University, Hidaka-shi Saitama/ JAPAN, ²Wakaba Internal Medical Clinic, Tsurugasima/JAPAN, ³International Medical Center(department Of Medical Engineering, Saitama Medical University, Hidaka/JAPAN, ⁴Department Of General Internal Medicine, Saitama Medical University, Irumagun Moroyama/JAPAN, ⁵Department Of Nephrology, Saitama Medical University, Irumagun Moroyama/JAPAN

[Objective]

Bisphenol A (BPA)—a chemical substance with an endocrine disruption effect—is contained in polycarbonates used in membranes, housing, constituents, etc. of dialyzers, and exposure of dialysis patients is unavoidable. We measured and examined the BPA elution concentration in various membranes used for hemodialysis therapy and dialyzers with various sterilization **methods:** here we report the results.

[Method]

RENAK PS-1.6 (AC sterilization, g-ray sterilization, and non-sterilization), APS-15SA, TS-1.6U, FDY-150GW, KF-15C, NV-1.6U, PES-15Eaeco, PES-15Saeco, VPS-15HA, PN-140, and NF-1.6H were the target dialyzers. For wet-type products, 1 ml of filling fluid was sampled first, then the blood side was cleaned using 1 L of purified water for 5 min at 200 ml/min, and 1 ml of the cleaning fluid remaining in each of the dialyzers was sampled for measurement. Portions of the hollow fiber and the housing were cut out and immersed in purified water at 70°C for 1 hr. A 1 ml aliquot of this immersion fluid was used to measure the BPA elution concentration from the constituent. High Sensitivity BPA ELISA Kit (Tokiwa Chemical Industries Co., Ltd.) was used as the measurement method.

[Results]

The BPA concentration of the filling fluid was the highest for NF-1.6H, and was equal to or less than the detection sensitivity for APS-15SA. The BPA concentration after cleaning was 0.86 μ g/L for FDY-150GW: the highest value reported. The BPA concentrations of the filling fluids for RENAKPS1.6 with the AC sterilization, the g-ray sterilization, and the non-sterilization were 0.18 μ g/L, 0.18 μ g/L, and 0.28 μ g/L, respectively. The BPA concentrations after cleaning were 0.18 μ g/L, 0.14 μ g/L, and 0.13 μ g/L, respectively. Thus, different sterilization methods did not lead to noticeable differences in results. The BPA elution concentration from the constituent was the highest for FDY-150GW for both hollow fiber and housing.

[Conclusion]

The BPA elution concentration in dialyzers was the highest for FDY-150GW after cleaning, and a different sterilization method in RENA PS-1.6 did not lead to different results. BPA was detected in both membrane materials and the dialyzer constituents. It is important to minimize the amount of eluted BPA by improving the cleaning effect on BPA while suppressing the elution of BPA.

PS12.036 - Automation of a Dispersive Raman Spectrometer Using LabVIEW Aiming In Vivo Diagnosis of Skin Cancer Author(s): Landulfo Silveira, Giovanni M. Schettino, Marcos T.T.

Pacheco, <u>Renato A. Zangaro</u> Biomedical Engineering Institute, Universidade Camilo Castelo Branco, São José dos Campos/BRAZIL

The development of optical techniques for minimally or non-

invasive diagnosis of human tumors, and consequent discrimination between malignant, benign and normal tissues, can lead to rapid tumor diagnosis in situ with high sensitivity and specificity. Integrated optical systems that perform automated collection of spectra and provide diagnostic information in vivo in real time is a challenge for modern medicine. This work aimed to automate the spectra collection of a dispersive Raman spectrometer for use in in vivo experiments of skin cancer diagnosis. The routine of data collection, storage, pre-processing and processing of spectral data was developed within the Scientific Imaging Toolkit (Roper Scientific) under the computational environment LabVIEW (National Instruments), which has virtual instruments to control the excitation parameters (laser power), spectrometer (exposure time, number of accumulations), pre-processing signals (cosmic rays filtering, removal of fluorescence background and normalization) and spectral analysis (spectral models based on PCA and tissue biochemistry) in real time. The "RamanLife" routine allowed the use of the Raman spectrometer in procedures for skin tumors removal, with the estimation of the relative amount of basal compounds that constitute the biological tissues, such as lipids, phospholipids, proteins, amino acids, nucleic acids among others, is obtained during the collection of spectra. This provided reliable diagnostic information useful to differentiate between neoplastic, benign and normal tissues, offering the possibility of routine use in clinical diagnosis and in supporting histopathological evaluation for neoplastic skin lesions in vivo in real-time, avoiding unnecessary incisional biopsies and thus enabling assessments in large population groups.

PS12.037 - Effectiveness of Ozone-Liquid Mass Transfer aiming Ozone Therapy

Author(s): Henrique C. Carvalho, Milene S. Melo, Leandro P. Alves, Carlos J.D. Lima, Landulfo Silveira, <u>Renato A. Zangaro</u> Biomedical Engineering Institute, UNICASTELO, São José dos Campos/BRAZIL

The effectiveness of ozone therapy depends on the efficiency of the mass transfer phenomenon between gas-liquid phases. Many variables are involved in this process, whose techniques aiming biological applications require constant optimization. This study aimed to compare ozone-water mass transfer held by a Venturi and a Bubble Diffuser. The results show that the turbulence associated with increased liquid velocity in the Venturi is capable of generating ozone concentration of up to 6 times higher than Bubble Diffuser, or 0.87 mg/L in 20 minutes to the Venturi, and 0.15 mg/L for Bubble Diffuser. The use of Venturi in mass transfer processes in gas-liquid phase can promote the application of ozone therapy in biological systems, since turbulent processes do not damage the fluids involved in this process.

PS12.038 - Impedance plethysmograph based on reconfigurable hardware for the study of superficial vessels Author(s): Laura L. Castro

Dept. Bioengineering, Higher Polytechnic Institute Jose Antonio Echeverria, Havana/CUBA

Impedance Plethysmography (IPG) is a simple, low cost and noninvasive method to research and assess circulatory and vascular diseases in humans. An important feature of this method is that the volume changes of the blood flow in different organs or body parts can be detected. This paper aims to develop, simulate and implement a bioimpedance measurement system for the characterization of blood flow in surface vessels. Howland's scheme is implemented for current injection. Quadrature demodulation of bioimpedance signal is used to preserve both amplitude and phase information. The bioimpedance signal processing and a user interface based only in FPGA and basic peripherals (monitor, keyboard and mouse) linking is achieved within the FPGA.

The implementation of this technique on reconfigurable hardware is a considerable advantage for the development and updating of design, allowing design flexibility and real-time processing due to parallelism offered by FPGA. The user interface greatly reduces system cost as it allows visualization and control of bioimpedance signal without using a computer.

PS12.039 - The study for bioelectric properties of tissue and organ measured by electrical impedance

Author(s): <u>Toshiaki Nagakura</u>¹, Kouya Watanabe¹, Yoshio Yasumura², Michiko Kido³, Moe Yokoyama³, Kenji Yamada³, Yuko Ohno³ ¹Department Of Biomedical Engineering, Osaka Electro-Communication University, Shijyonawate City Osaka Prefecture/JA-PAN, ²Dpartment Of Cardiology, National Hospital Organization Osaka National Hospital, Osaka City/JAPAN, ³Division Of Health Sciences, Graduate School Of Medicine, Osaka University, Suita City Osaka Prefecture/JAPAN

About 60% of weight of the human exist as various solutions with water. And the dissolved substance concentration and localization in the solution are controlled severely. Each concentration is an important parameter for diagnosis and treatment, but there is very few continuous quantitative measurement method. From the physiologic point of view ion concentration and components of the biotissue are different, electrical specification is different. Though this is well known, and also the electrical measurement has the advantage that continuous measurement is possible, there are not developed the clinically useful measurement system. Therefore we tried to study the system for clinical application to measure a living body electrically. We applied the alternating voltage (5[Vpp]) of the level not to cause macro-shock to a living body and measured a frequency characteristic of frequency 0 - 20[MHz]. We measured the electrical specification (impedance and phase) change such as solutions of an electrolyte and the protein which there was to a living body. The impedance of most material in tissue including the liquid decreases to from 0 - 1MHz approximately monotonically. On the other hand, we found that it had quantitative tendency even if we injected electrolytic solution and a protein solution into biotissue. Moreover, with the measurement under various conditions, we measured the variance condition of the electrical specification in different kind of tissue and organ.

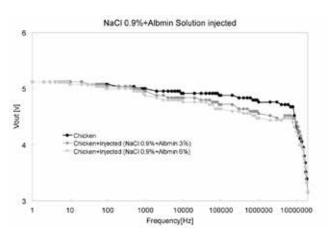

Figure 1 The relationship between the impedance of chicken muscle and concentration of solution. We were able to lead a difference and the tendency of the electrical characteristics in tissue and organ by this study. We could estimate that the solute and solvent transfer of an organ which having electric specificity of living body. We improve these results to be able to do clinical application.

PS13 - TRACK 13: INFORMATICS IN HEALTH CARE AND PUBLIC HEALTH

PS13.001 - A Method for Parental Engaged Consent in the Perpetual Secondary Usage of Health Big Data

Author(s): <u>Yvonne Choi</u>¹, Carolyn Mcgregor¹, Jennifer Heath² ¹University of Ontario Institute of Technology, Oshawa/CANA-DA, ²University of Wollongong, Wollongong/AUSTRALIA

Introduction

Knowledge discovery from the analysis of Big Data has contributed to significant breakthroughs in health care. However, personal health information is typically sensitive and identifiable thus presenting unique ethical and legal challenges when used for secondary research purposes. Our case study context, due to our recent research is Neonatal Intensive Care as the data that is generated by monitoring devices, generates a Big Data problem. In the case of neonatal research, parental engagement within the consent process is often required. Increased engagement with parents in ongoing studies requires a multileveled consent process that can be changed over time. Therefore it is important that the consent model respects their preferences and allows them to modify such preferences whenever possible and at their convenience over time.

Artemis is a platform for concurrent multipatient, multidiagnosis, and multistream Big Data analysis for clinical management and research that uses continuous physiological data streams. The Artemis platform is composed of five components consisting of the: data acquisition, online analysis, knowledge extraction and the redeployment components. Currently, the Artemis platform does not support flexible consent over time. The primary and secondary usage of physiological data collected by the Artemis platform has already contributed to new clinical discoveries related to conditions, specific to the neonatal population.

Our research focuses on engagement of the parental community who have or have had an infant in the NICU with the use of a flexible consent model which will provide researchers with the ability to integrate the patient selection process with the data mining component of the research study.

Objective

In this work we extend the current Artemis knowledge discovery component. These extensions to the current consent model will support parental preferences regarding the consent and use of their infant's physiological data over time.

Methods

To address the research aims, new tables were defined within the Artemis database model to enable parental consent. The extensions not only enable this consent to be more explicitly tied with the data, but enable the consent to be changed over time or have parents engaged regularly for consent based on their chosen degree of consent through a web based portal.

Results

The extensions to the knowledge discovery component support parental engagement in the secondary use of their child's data through a continuum of secondary use of data retrospective studies. The architecture is currently being tested as part of our research into Apnoea of Prematurity.

Conclusions

Parents are surrogate decision makers for their infant. A flexible con-

sent model will be beneficial to various stakeholders including the parental community and researchers. Engaging parents or patients empowers them in the research process and enables their consent preferences to be respected. For researchers it is a platform that allows them to maintain continuous contact with the parental community thus maintaining a pool of potential research participants for them to contact for future recruitment purposes in addition to assisting with the results dissemination process to interested parents upon completion of the study.

PS13.002 - RENEM – Brazilian National List of Equipment and Materials

Author(s): <u>Murilo Contó</u>¹, Clarice Petramale², Erlon C. Dengo², Marcio L. Borsio²

¹Health Technologies Management And Incorporation, Ministry of Health of Brazil, Brasilia/BRAZIL, ²Health Technologies Management And Incorporation, Ministry of Health os Brazil, Brasilia/BRA-ZIL

To ensure the actions of the Brazilian Unified Health System (SUS) can be achieved with universality, integrality and gratuitous, the Ministry of Health (MoH) provides investment programs for institutions to acquire equipment and materials for the operation of its services. As the budget is always limited, the MoH implemented a methodology to make improvements in their processes of adoption and investment, divided into four fronts: (1)-Adoption of a National List of Equipment and Materials (RENEM); (2)-Regulatory processes for incorporation and management of RENEM; (3)-Creation a bench of prices; and, (4)-Automation of investment analysis. RENEM was adopted after systematic standardization of nomenclatures culminating in the preparation of equipment combos distributed according to the complexity of healthcare environments, eliminating issues of requests not according to their profile service. A computerized system was developed to manage the structure of RENEM and the entire process of investment analysis, streamlining routines and paper elimination. Regulating incorporation of RENEM items established the minimum requirements of scientific evidence and deadlines for decision making. A cooperation program was created to capture economic and technic information and a function was introduced into the system that provides the technical features of the equipment in multiple choices. Each technical feature has a monetary value associated that represents the impact on the final price. Thus, the system performs a dynamic price setting which automatically adjusts to the selected specification. A tool that performs the historical search of the quantity and value of equipment financed by state, city and institution allowed the creation of ABC curves and Pareto analysis, identifying the key items of RENEM that require further attention. As a main result, the number of investments approved in 201 4 was almost four times higher than the previous year with significant improvement in projects quality.

PS13.003 - Becoming of Ubiquitous Sensors for Ubiquitous Healthcare

Author(s): Sergo A. Dadunashvili

Electrical Engineering And Elrctronics, Georgian Technical University, Tbilisi/GEORGIA

Ubiquitous healthcare has become one of the prominent areas of research in order to address the challenges encountered in healthcare environment. Ubiquitous healthcare requires networks of intelligent sensor nodes that could be deployed "anywhere, anytime, by anyone and anything" and is a permanent part of the human presence. Management of systemic diseases via technology based ubiquitous patient monitoring services has been widely proposed as a viable option for economizing healthcare resources, and providing efficient, quality healthcare. Ubiquitous sensors, devices and networks are paving the way towards a smart world in which computational intelligence is apply at all levels of the physical environment to provide reliable and relevant services to patients. This ubiquitous intelligence will change the computing landscape and environment around the patient, because it will enable new breeds of applications and systems to be developed and the realm of computing possibilities will be significantly extended. By enhancing everyday objects with intelligence, many tasks and processes could be simplified. The physical spaces where patients interact like the homes and hospitals could become more efficient, safer and more enjoyable. Ubiquitous computing, or pervasive computing, uses these many "smart things" to create smart environments, services and applications.

The Internet of Things is a new concept for telecommunication development. The Ubiquitous sensor Network is one of the general components of Internet of Things. A smart thing can be endowed with different levels of intelligence, and may be context-aware, active, interactive, reactive, proactive, adaptive, automated, sentient, perceptual, cognitive, autonomic and/or thinking. Research on ubiquitous intelligence is an emerging research field covering healthcare needs. A series of challenges exist to move from the current level of computing services in healthcare to the smart world of adaptive and intelligent services.

PS13.004 - Design and Implementation of an Application for ECG processing in Mobile Phones

Author(s): <u>René González-Fernández</u>, Margarita Mulet-Cartaya Division Of Medical Devices, Central Institute of Digital Research, Havana/CUBA

The aim of this paper is to discuss the main features implemented in an Android application for ECG processing. The software was designed to use a mobile phone, connected to a battery-powered ECG device, as a signal acquisition layer in a Telemedicine platform oriented to implement several health services such as arrhythmia follow-up and remote pacemaker evaluation. The ECG device should be able to acquire and transmit, via Bluetooth, a bipolar ECG lead; the transmission time can be set previously. A friendly user interface was implemented for data entry and to display signals and result: all input data is validated according with its type and length. Error handling is focused on ensuring data reliability and the proper application functioning. The Android application receives the ECG data according to a simple protocol defined by the authors. Each data block is composed by a header byte, signal samples, electrode status and pacemaker spike identification. When a complete ECG strip is received, the electrocardiographic signal is filtered using a FIR moving average filter. QRS complexes are detected and classified, as premature or not, RR intervals are measured and heart rate is computed. An auxiliary function based on the Teager Energy Operator was combined with two thresholds to detect QRS complexes. The same function was applied to identify P wave regions previous to each QRS complex detected. P wave were delineated combining baseline estimation, a baseline-correction algorithm and heuristic rules. ECG strips are classified as arrhythmic or not taking in count the quantity of premature QRS complexes. A SQL database was designed to store patient general data, each ECG strip with the signal processing results and the data and time when the strip was captured. All these information is uploading to a web site using GSM/GPRS network and HTTP protocol. Also, all the data is store in a database implemented in the phone; this feature allows downloading that information into a personal computer when connectivity facilities are not available. The software was programming in Java language using Eclipse SDK and SQLite database engine.

The proposed software has been tested with five models of Android mobile phones, running Android operation system version 2.3 or higher. The user interface was rated as excellent by users involved

in testing process. Errors were not reported in Bluetooth communications when the distance between the ECG device and the phone was less than ten meters. QRS complex detection algorithm was tested with MIT-BIH database and the QRS detection sensitivity was 99.24%; false positives were not identified. P waves coupled to QRS complexes were studied in fifteen ECGs of the same database; sensitivity was 92.48%. It could be considered as a good performance, but the test has to be complete with the complete database.

The developed software seems a powerful tool to convert a mobile phone, combined with the appropriated ECG device, in a medical device for several Telecardiology services.

PS13.005 - A Telemedicine System to follow-up the Evolution of Chronic Diseases in the Community

Author(s): <u>René González-Fernández</u>, Margarita Mulet-Cartaya, Juan D. Lopez-Cardona, Alejandro Lopez-Reyes, Rolando Lopez-Creagh, Rolando Lopez-Rodriguez, Hector Torres, Eyglis Ledesma-Valdes

Division Of Medical Devices, Central Institute of Digital Research, Havana/CUBA

A system was designed to follow-up three chronic diseases: cardiac arrhythmia, hypertension and diabetes mellitus. Patient evolution can be studied daily without hospitalization and the objectives are:

To document the evolution of the studied chronic diseases.
To correct medical treatment as soon as it is necessary.

- To avoid inconvenience to patients because of the frequent visit to the hospital.

Patients are registered in the system during their first visit to the physician; they are trained to make the appropriated test at home to get the necessary measurements. The medical devices will be: a commercial blood pressure device, a commercial glucometer and a one-channel ECG device designed by the authors of this paper. If alucose and blood pressure device have Bluetooth capability, data is wireless transmitted. When this feature is not available, values are entered manually using a friendly interface implemented in the mobile telephonic terminal. Two alternatives are available for that terminal: an Android mobile telephone running an application developed by the authors and a specific telephonic terminal designed by the authors too. The physiologic data is processed, when it is necessary, in the mobile telephonic terminal and the results are uploaded to a website. A web application stores the uploaded information in a SQL database. Physicians log in the web application to study their patients; specific graphic tools were developed to help this analysis. This operation mode allows medical treatment can be adjusted as soon as it is necessary and medical care is improved. The following algorithms were implemented in Java and C languages for ECG processing: a FIR moving average filter to minimize noise presence; QRS complex detection and classification based on an energy collector combined with two thresholds and heuristic rules; heart rate measuring and ectopic beat rate measuring. Two prototypes of the ECG device and one of the mobile telephonic terminal were manufactured; plastic cases and print circuit boards for that prototypes were designed using CAD-CAM tools. The first version of the Android application and the web application were ended. The ECG device was evaluated according to the IEC 60601-2-47 standard with good results in all tests. The Bluetooth communication was tested with 600 one-minute simulated ECG strips without errors; received signal were identical to those originally transmitted and never data transmission was aborted because of fatal errors. ECG processing algorithms were evaluated with twelve thirty-minute ECG strips from the MIT-BIH arrhythmia database; the sensitivity in QRS complex detection was 98.77% and no false positives were identified.

PS13.006 - Developing an Appropriate and Affordable Expert System for Medical Diagnosis (ESMD) in Developing Countries Author(s): <u>Kenneth I. Nkuma-Udah</u>¹, Gloria A. Chukwudebe², Josiah Ahaiwe³, Kennedy O. Ejeta¹, Gideon I. Ndubuka¹ ¹Department Of Biomedical Technology, Federal University of Technology, Owerri, Nigeria, Owerri/NIGERIA, ²Department Of Electrical/ electronic Engineering, Federal University of Technology, Owerri, Owerri/NIGERIA,³Department Of Information Management Technology, Federal University of Technology, Owerri, Owerri/NIGERIA

Bringing intelligent healthcare informatics to bear on the dual problems of reducing healthcare costs and improving guality and outcomes is a challenge even in countries with a reasonably developed technology infrastructure. In the developing countries, like Nigeria, introduction of intelligent healthcare informatics then becomes constrained by considerations not only of affordability but also of appropriateness of the innovation. This research sets out to develop an appropriate and affordable expert system for medical diagnosis ESMD in developing countries. ESMD is designed to enable clinicians to identify diseases and describe methods of treatment to be carried out taking into account the user capability. The ESMD was designed using the C Language Integrated Production System (CLIPS). CLIPS is rule-based expert system tool, which means that knowledge is represented in rules, based on experience. ESMD shell has four modules: the user interface, the explanation system, the inference engine and the knowledge base editor. The knowledge base of ESMD was organized among several clinical signs, symptoms and features associated to drug therapy. The prototype of the ESMD was ready for use after nine months. The system does many random guestions in order to enable clinicians make diagnosis and suggest therapy. The system is user-friendly and presented good time-response to give therapy advice. The knowledge base is editable and can be used to generate personal configuration based on population characteristics.

PS13.007 - Assessment of Mobile Health Applications

Author(s): Mary Marinou, <u>Nicolas Pallikarakis</u>, Kallirroi Stavrianou Biomedical Engineering Unit, University of Patras, Rio-Patras/ GREECE

During the last years, the usage of smartphones has rapidly infiltrated a plethora of daily functions. The health related applications which can carry out both simple functions such as recording vital signs or more complicated such as operating as computer-aided diagnosis systems, are amongst the most popular. In 2014 more than 100.000 mobile health applications (mHealth apps) have been found in the "medical" and "health and fitness" categories. It is estimated that in 2015 mHealth apps will be used by more than 500 million users worldwide, in which consumers, patients and healthcare professionals are included. This rapid development of mHealth apps revealed the need for their evaluation, assessment and regulatory compliance. This need is imposed by their particular nature, since lack of quality and specificity, or misuse of the information provided, may compromise user's health status, as well as security and privacy of the personal health data issues which are also of primary importance. The FDA and the European Commission of the EU are the only official authorities which developed regulations for apps that are classified as medical devices. Additionally various evaluation standards have been published by the private sector along with end-user assessment methods which have been also proposed.

It is expected that in the following years the adoption of the mHealth applications usage will improve the quality of the patients' lives and will promote the importance of prevention, user education and public awareness. It may also help to reduce the cost of healthcare, while increasing the frequency of interaction between patients and doctors and generally to greatly contribute to ameliorate Healthcare. Therefore it is necessary to develop a framework of adaptive evaluation and assessment, along with a well balanced regulatory system, especially in cases where an external part is attached to the smartphone that could be considered as a medical device. In this work, it is presented how mHealth apps may in some example-cases replace medical devices and in which parameters their evaluation should rely on. Applications vary from simple devices such as a simple thermometer to more complex ones like an ophthalmoscope. Applications which do not require the attachment of an additional device or sensor, are also examined such as sharing medical images or supporting management of a chronic disease, like diabetes. Concluding, the need of an evaluation framework for mHealth apps is investigated, and among the basic elements of this analysis is confidentiality, security issues, the importance of usability of mHealth apps, as well as measurements' accuracy.

PS13.008 - An Investigation into using Pulse Rate Variability to Predict Clinical Events

Author(s): <u>Usman Raza</u>¹, David Maslove², Evelyn Morin¹, Karen Rudie¹

¹Department Of Electrical & Computer Engineering, Queen's University, Kingston/ON/CANADA, ²Kingston General Hospital, Kingston/ ON/CANADA

Heart rate variability (HRV) describes the natural variation in time intervals between heartbeats, and is usually measured using R-R (peak to peak) times from the electrocardiogram (ECG). Reductions in HRV have been shown to correlate with cardiac events such as myocardial infarction and sudden cardiac death, as well as other critical illnesses such as sepsis. While ECG is the traditional method of collecting peak-to-peak data, it is expensive, cumbersome to use, and does not lend itself to ambulatory use.

It has been shown that pulse rate variability (PRV) is a sufficiently accurate estimator of HRV and can be calculated using photoplethysmography (PPG) [Schafer and Vagedes, International Journal of Cardiology, 2013]. Photoplethysmography uses two light emitting diodes, one red and one in the IR spectrum, and a light sensor to measure pulse oximetry, which can in turn be used to measure PRV. Devices that perform pulse oximetry are cheap, portable, and ubiquitous in clinical settings.

The aim of this work is to develop a prognostic system that can be used in hospital settings as a data-enabled early warning system. Using a stream of patient PRV data the system will be able to predict clinical events and alert a rapid response critical care team earlier than traditional methods. The system will be composed of two main components, the prediction software and a wireless pulse oximeter.

The prediction software will utilize a supervised training algorithm to develop a model using HRV metrics and clinical data. The large-scale incidence of PRV and HRV events will be determined using data stored in the MIMIC II database that contains clinical records and a matched set of multiple physiological signals for 2,809 ICU patients. A subset of the ICU patients that experience specific clinical events (Set A) will be identified and the PPG data in the associated waveforms will be used to calculate HRV metrics.

The algorithm will use a subset of Set A as a training sample and identify features that are highly correlated to the specific clinical events identified earlier. Once a feature-set has been determined, the remainder of Set A will be used to see whether the correlated features discovered in the training subset are also correlated in the testing subset. Iterative adjustments to the feature set and algorithm will take place until the prediction accuracy meets a satisfactory level. Once the system is accurately able to predict clinical events, it will be reconfigured to work with a live stream of clinical data collected across all 33 beds in the Kingston General Hospital ICU.

Concurrent to the development of the predictive system is the proto-

typing of an inexpensive and robust pulse oximeter that can transmit data over Bluetooth and Wi-Fi and be deployed to all admitted patients at a hospital. The current prototype can wirelessly transmit pulse oximetry data to an online database in "real-time" (~ 3 second delay). Future work on the module aims to reduce its size and power consumption and create an interface between it and the proposed predictive system.

PS13.009 - A simple device producing electrolyzed water for home care

Author(s): Koichi Umimoto

Biomedical Engineering, Osaka Electro-Communication University, Osaka/JAPAN

The prevention of opportunistic infection for the elderly is important in home care. When water containing sodium chlo-ride is electrolyzed with a electrolytic cell having two chambers of equal volume, strongly acidic electrolyzed water with strong bactericidal ability due to the available chlorine (AC) is gener-ated on the anode side. Weakly to slightly acidic electrolyzed water (WSAcEW, pH 4.0 to 6.5) is physiological pH and is suitable for biological applications. For producing WSAcEW simply and at a low cost, the present device was made of an asymmetric structure having a large anode chamber and a small cathode chamber. As a result, the pH and AC concentra-tion of conventional electrolytic device were 2.3 and 27 ppm and this water was strongly acidic water, however, those of present electrolytic device were 4.0 and 31 ppm, respectively. WSAcEW was obtained directly by this experimental device and this water showed a strong bactericidal activity against bacteria. This device is useful for producing WSAcEW as a disinfectant to employ at home care, since it returns to ordi-nary water after use.

PS13.010 - Developing predictive models using retrospective study of liver cancer patients treated with radiation therapy. Author(s): Jason R. Vickress¹, Michael Lock², Eugene Wong², Rob Barnett³, Slav Yartsev²

¹Medical Biophysics, Western University, London/CANADA, ²Western University, London/ON/CANADA, ³London Regional Cancer Program, London/ON/CANADA

Introduction: Radiation therapy is one of the primary treatments for cancer logistically providing an accumulation of information specific to each individual patient's treatment. A patient's electronic record in radiation therapy includes demographic data, diagnostic images, CT simulations, radiation planning and delivery parameters and verification imaging describing the patient's cancer treatment in great detail. Our goal is to harness this vast supply of treatment data along with outcome information in order to tailor radiotherapy treatments for future patients.

Methods: Selected radiation therapy planning parameters and outcome information were gathered for 118 patients treated for liver metastases at London Regional Cancer Program between 2004 and 2010. Planning and treatment information was available through an in-house designed system. Outcome information including patient survival, disease recurrence and blood work was collected prospectively. Multivariate Cox proportionality hazard ratio calculations were performed using SPSS version 22 (IBM) across combinations of all parameters in predicting the patient survival and disease recurrence. Patients were stratified into risk groups based on their hazard ratios of the most predictive parameters. All Kaplan-Meir curves were plotted and log rank tests of significance were performed for the patients separated by the median hazard ratio value.

Results: The most significant predictive parameters are presented in Table 1 for different numbers of covariates. Improvements of predictive power characterized by p-value were observed through the increase in significance and mean values of Kaplan-Meir curve separation for each outcome individually. The minimum number of two covariates required for optimum prediction of specific outcome was determined. Mean differences between Kaplan-Meir curves for survival were 7, 10, 11.5, and 17.5 months if 1, 2, 3, and 4 covariates (Bilirubin, Serum Albumin, BED and GTV), respectively, were considered.

Conclusions: Multivariate modeling predictions obtained on the data for 118 patients provide physicians with quantitative parameters for more reliable interpretation of the implications and foreseen outcomes for patients receiving radiation therapy based on their proposed treatment and patient's medical history. A larger patient cohort study will be performed to check the robustness of model predictions.

Table 1. Significance (p-values < 0.05 in bold) of predictions for Liver cancer treatment outcomes and mean separation (in days) between Kaplan-Meir curves when using up to 4 covariates. (Dose/fx = dose per fraction, #fx = number of fractions, BED = biological effective dose, GTV = gross tumor volume, Vx = liver volume receiving > x Gy)

Covariates	Survival	Recurrence		
		anywhere	in-field	out-field
1	Bilirubin	Dose/fx	BED	V30
2	Serum Albumin	V24	# fx	BED
3	BED	Bilirubin	Dose/ fx	n/a
4	GTV	n/a	n/a	n/a
Significance				
1	0.207	0.08	0.083	0.06
1+2	0.008	0.006	0.046	0.017
1+2+3	0	0	0	n/a
1+2+3+4	0	n/a	n/a	n/a
Mean separation (in months)				
1	7	8	10.5	12.5
1+2	10	11.5	14	15.5
1+2+3	11.5	14	23.5	n/a
1+2+3+4	17.5	n/a	n/a	n/a

PS13.011 - A Study on the Problems for People to have Colorectal Cancer Screening Tests in Japan(-From the Results of Interviews for 30 Adults-

Author(s): <u>Naoko Fujiwara</u>¹, Miki Inagaki², Kenyu Yamamoto³, Misao Yoneda⁴, Masami Azuma⁵

¹Faculty Of Health Sciences, Naragakuen University, Nara/JA-PAN, ²Baika Women's University, Ibaraki/JAPAN, ³Osaka Center for Cancer and Cardiovascular Disease Prevention, osaka/JAPAN, ⁴Suzuka University of Medical Science, Mie/JAPAN, ⁵Osaka Kyoiku University (Honorary Professor), toyonaka/JAPAN

In late years, colorectal cancer fatalities and morbidity are increasing together and the rate for people to have colorectal cancer screening tests is regrettably sluggish in Japan. For future decrease in the mortality of colorectal cancer, we performed interviews for Japanese citizens about the factors influencing their behaviors to have colorectal cancer screening tests.

The contents of interviews were organized to four categories with 7-17 subcategories. These results suggest several important factors

for people to have the screening test. They are frequent supply of concrete knowledge on the screening tests and the condition of cancer, continuous and life-related motivation to the behavior for the screening test and forming the system available for people to have the test.

PS14 - TRACK 14: INFORMATION TECHNOLOGIES IN HEALTHCARE DELIVERY AND MANAGEMENT

PS14.001 - DermApp: an application for Android mobile devices for reception and transmission of skin images

Author(s): Fabiana Garranchán¹, Samuel Ortega¹, <u>Iván Escalona¹</u>, Mayerith Torreyes²

¹Ingeniería En Telecomunicaciones, Universidad Católica Andrés Bello, Caracas/VENEZUELA, ²Dermatología, Hospital Militar Carlos Arvelo, Caracas/VENEZUELA

Unlike general practitioners, pediatricians and obstetrician-gynecologists, dermatologists are highly localized in large public hospitals or private clinics, which limit the possibilities to distant patients for care. Telemedicine is then useful for querying skin diseases.

DermApp is an application for Android mobile devices that covers the basic needs of specialists in the field of dermatology for better diagnosis, storing, transmitting and receiving skin images in any place where the doctor is present. DermApp allows a remote medical assistant to use a dermatoscope to capture images of skin lesions and select the most representative for transmission to a backup server that in turn sends the images to the dermatologist's mobile device.

A dermatoscope is a surface manual microscope widely used by dermatologists to visualize the pigmented structures in epidermis and dermal-epidermal junction for different skin phototypes. The phototype is the set of characteristics that determine whether a skin tan or not to sun exposure and the extent to which it does.

The used dermatoscope, DermLite II Red Hybrid m, has patented technology that combines non-polarized illumination with polarized light, with or without skin contact. This device offers high light output thanks to its 24 LED and a large 25mm lens.

To determine parameters for image quality, a survey was run to nine dermatologists in which images captured with mobile devices having different resolutions were presented. The minimum acceptable resolution was 3 MP. They also felt that the application had better functionality within the skin phototype III (darker white) which corresponds to a considerable percentage of the Venezuelan population.

From the evaluation of different mobile devices existing in the market we decided to use a smartphone with Android open OS for the facilities and other utilities in terms of programming offered by this operating system environment. In addition, we used a JPEG format because besides being compatible with most existing mobile devices on the market, it allows the transfer of files over a range of acceptable time without affecting markedly the image quality.

A VPN and SSH protocol were used to connect the mobile device with a backup server. Files were transferred with FileZilla program through the TCP protocol.

PS14.002 - Use of mobile devices for prevention in youngsters of risk factors common to chronic noncommunicable diseases Author(s): Franxis Castañeda¹, Fiama Rodríguez¹, <u>Iván Escalona¹</u>, María S. Tapia², Luisa Angelucci³

¹Ingeniería En Telecomunicaciones, Universidad Católica Andrés Bello, Caracas/VENEZUELA, ²Inst. Ciencia Y Tecnología De Alimentos, Universidad Central de Venezuela, Caracas/VENEZUELA, ³Centro Inv. Y Formación Humanística, Universidad Católica Andrés Bello, Caracas/VENEZUELA

Promoting behaviors and healthy lifestyles is today one of the most used mechanism for the prevention of chronic non-communicable

diseases such as cancer, diabetes and CVD, which are leading causes of mortality in Venezuela (66%) and the world.

The application of telemedicine in the field of health education provided for the prevention of these diseases through the use of advanced technologies that help disseminate information about common risk factors and unhealthy diets, physical inactivity, stress, consumption of tobacco and alcohol.

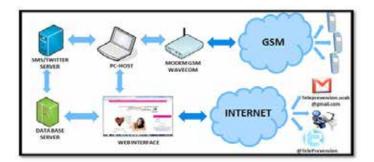

Promoting healthy behaviors through a telemedicine preventive system is sought by the use of mobile devices, based primarily on the technology of instant messaging (SMS) or social network Twitter widely used by youngsters in Venezuela and a query system via email.

Mobile phones and social networks are popular among the population. According to CONATEL (National Telecommunications Commission of Venezuela) 27 billion SMS text messages (1000 per capita) were sent in 2012. According to Semiocast (France) Venezuela was the 12th country on Twitter accounts and 6th in activity in 2012. Both media can be exploited to disseminate information about healthy behaviors and preventive factors of chronic non-communicable diseases.

The management system for instant messaging SMS and Twitter is implemented by a server to the database, a desktop application and a website. Text messages on physical activity or nutrition, prepared by students advised by psychologists, are sent to each of the mobile phones of youngsters through a modem connected to the GSM network. These youngsters can then use the system to consult psychologists and nutritionists.

Preliminary work was supported by a survey: randomly selected students were asked about their beliefs and attitudes to the risk factors of chronic non-communicable diseases and implementation of a platform for dissemination are measured content on healthy lifestyles. They were also asked about the preferred methods of communication (email, SMS, presentations, advertising) and most used social networks (Facebook, Twitter, Google+, LinkedIn, Instagram, MySpace or other) which can be used for the prevention of chronic non-communicable diseases.

The system is safe, accessible and easy to use and can be extended to different areas for the dissemination of information.

PS14.003 - Telemedicine in the Universidad Católica Andrés Bello (UCAB), Venezuela: an academic experience

Author(s): Iván Escalona¹, Jose Pirrone Puma², Mardemis Gutierrez¹ ¹Ingeniería En Telecomunicaciones, Universidad Católica Andrés Bello, Caracas/VENEZUELA, ²Esc. Ingenieria En Telecomunicaciones, Universidad Catolica Andres Bello (UCAB), Caracas/VENEZU-ELA

Universidad Católica Andrés Bello (UCAB) is the oldest private university in Venezuela (1954). The School of Telecommunications En-

gineering started its academic activities in October 2001, pioneered Venezuela in this discipline with its own profile, which emerged in cooperation with Universitat Politècnica de Catalunya (UPC), Spain. In some autonomous public universities, Telecommunications often is a specialty in the program of Electrical Engineering.

The program requirements include a one-year special project in addition to regular and complementary courses. Based on the experience made since 1998 in the Group of Medical Physics, Faculty of Sciences of Universidad Central de Venezuela (UCV), one of the authors (IE) suggested the possibility of developing some special projects in telecommunications applications to the area of health. Unlike UCV, UCAB does not have a medical school, but a health center that provides outpatient medical care in various clinical specialties as part of social work at the University.

The first project started in October 2005, the second one in March 2006. In August 2006 there was a meeting Ministry of Health - Universities to establish a "Pilot project for sustainable development of the National Telehealth Network" which contemplated five subprojects to be executed in three years: Connectivity, Standards, Medical Informatics, Tele-specialties and Tele-education. Although the national project ultimately was not implemented our School maintained the development of one-year special grade works in the area of Telemedicine.

The interest for this area quantified in 164 students in nine years, which is almost 20% of 900 graduates. These works developed two lines of investigation: Telematics and Connectivity. Telematics projects have addressed issues in areas such as Imaging, Medical Informatics and use of mobile devices with open OS for Endocrinology, Dermatology, Cardiology, Spirometry and Remote Monitoring. Connectivity Projects took place mainly in non-urban care centers in counties of various states in Venezuela, sometimes in cooperation with the Medical Informatics Center (CIM), Faculty of Medicine of UCV. Fifty-nine students have also completed short internships at the Medical Informatics Center (CIM).

In October 2008, a new sixteen-week course, Topics in Telemedicine, incorporated as an elective course in the Telecommunications Engineering program. This course is primarily a seminar and also has a five-week workshop on Introduction to Tele-radiology that involves students with programs that allow viewing of medical images, image transfer between two terminals and access them via web. Another workshop with mobile devices to capture and transfer bio-signals will be included soon.

Telemedicine has been an important experience for inter-institutional and interdisciplinary activity and in just over nine years has opened a line of applied activity in addition to the more usual lines in the telecommunications area framed in Communications Technology, Electronics and Informatics.

The main objective of our Telemedicine Group has therefore been the contribution to social welfare by implementing telecommunications networks to support medical research activities and its applications to health and the use of mobile devices. Some results have been presented in eleven national and five international events (including WCMPBE 2009 and 2012).

PS14.004 - Passage from analog to digital in radiodiagnostic processes

Author(s): <u>Giulia G. Marchesi</u>¹, Paola Freda² ¹3 B srl, Settimo Torinese/ITALY, ²S.c. Ingegneria Clinica, AOU Città della Salute e della Scienza di Torino, Torino/ITALY

The use of information technology in the medical field is becoming more and more popular, and healthcare companies recognize the benefits deriving from it and are converting themselves to digitized workflows over paper, both for economic reasons and to simplify the work of operators (administrative, clinical, health ...). Among the various analog-digital conversions, the Ris/Pacs is one of the most interesting for its complexity. Digitizing an entire radiology department requires a very careful analysis phase, in order to model workflows with adequate accuracy. Modeling workflows is of fundamental importance, as there must be absolute correspondence between model and reality. Several steps are needed before completing the final project and it is very important to satisfy all the specific requirements of the health care company in order to increase productivity and efficiency. The current computer systems allow to implement ambitious projects, however guidelines and regulations have to be respected. It is clear that the state of art about analog-digital conversion rules are several from the technical point of view, but lacking for quality management. The present study aims to analyze all the aspects related to the passage of analog-digital radiology department, carefully assessing and detailing every aspect of the whole project.

PS16 - TRACK 16: CLINICAL ENGINEERING, CLINICAL PHYSICS, AND PATIENT SAFETY

PS16.001 - Increasing the health value per dollar spent: How Human Factors can help inform procurement of healthcare technology

Author(s): <u>Sandra Ahedo</u>¹, Laura Herrero², Ana Casado³, Lourdes Escobar⁴, Jose Carlos Manuel Palazuelos⁵, Elena Rojo⁶, Andrea Cassano-Piche⁷, Patricia Trbovich⁸

¹Innovation Deparment, IDIVAL Biomedical Research Institute, Santander/SPAIN, ²Innovation Department, IDIVAL Biomedical Research Institute, Santander/SPAIN, ³Material Resources, HUMV Valdecilla University Hospital, Santander/SPAIN, ⁴Management Nursing, HUMV Valdecilla University Hospital, Santander/ SPAIN, ⁵Director Surgical Area, HvV Valdecilla Virtual Hospital, Santander/SPAIN, ⁶Teaching Departament, HvV Valdecilla Virtual Hospital, Santander/SPAIN, ⁷Centre For Global Ehealth Innovation, University Health Network, Toronto/ON/CANADA, ⁸Ibbme, University of Toronto, Toronto/CANADA

Introduction: Use of technology systems is increasingly prevalent in healthcare and important in medical providers' efforts to promote quality health care delivery. Some healthcare organizations have already realized major gains through the implementation of multifunctional, interoperable healthcare technology systems. However, as with any well-meaning and innovative medical advance, these technologies bring both intended and unintended consequences to clinicians' work practices and patient safety. *The widespread implementation and adoption of healthcare technology has been limited by a lack of generalizable knowledge about what types of healthcare technologies and implementation methods will improve care.* In Healthcare the value per dollar spent in new technology is often of little value.

Inclusion of Human Factors (HF) in the procurement of healthcare technology is new to Spain. Through collaboration with HumanEra, Canadian experts in HF, Evaltec, a newly formed HF team, based at the Hospital Universitario Marques de Valdecilla, Spain, began to apply HF.

Objective: The aim of the present study is to describe a combination of human factors (HF) assessment techniques that were used to assess technologies and inform procurement, and implementation of a next generation device in a Spanish hospital.

Method: We present a case study in which two HF techniques (i.e. ethnographic field observations and heuristic evaluations) were used to inform the procurement of infusion pumps. Specifically, ethnographic field observations were conducted to study, in situ, use of the intravenous infusion pumps currently in use in the hospital to better understand the barriers and facilitators to the use of the device. Furthermore, heuristic evaluations were conducted to uncover design deficiencies of infusion pumps that are currently in use. This information was used to better understand users' needs and the system elements that must be in place prior to the procurement and implementation of the next generation pumps.

Results: The use of HF techniques provided a new lens with which to observe the healthcare system (i.e. technology, people and environment) and revealed several issues that had not previously been identified. Ethnographic field observations provided an understanding of institutions' current practices surrounding use of intravenous infusion technologies and barriers to the optimal use (e.g. lack of a match between the physician orders and drug libraries). Heuristic evaluations were effective for quickly identifying potential user interface design problems (e.g. clarity, consistency, and familiarity in the language and labeling used on the pump interface. Together, these results identified the importance and broad impact of both usability and safety issues and informed procurement requirements.

Conclusion: From this collaboration, the Evaltec team has realized the importance of applying Human Factors methods to the evaluation of medical devices. The knowledge gained from this experience will help ensure that the imminent procurement of the next generation of infusion pumps considers the user needs, reduces the waste of consumables, increases the efficient use of the pump, and increases the health value per dollar spent. The present study demonstrates how the application of HF can help inform the design of systems and ensure that unsafe devices are not introduced to healthcare facilities.

PS16.002 - Using Heuristic Analysis to support Usability Evaluation of a low risk medical device under development process Author(s): Renata A.R. Custódio¹, <u>Ana P.S.S. Almeida</u>², João E. Côrrea³, Rodrigo M.A. Almeida⁴, Carlos H.P. Mello³, Egon L. Muller Jr² ¹Institute Of Mathematics And Computer Science, Federal University of Itajubá, Itajubá/BRAZIL, ²Institute Of Industrial Engineering, Federal University of Itajubá, Itajubá/BRAZIL, ³Institute Of Industrial Engineering, Federal University of Itajubá, Itajubá/MG/BRAZIL, ⁴Institute Of Systems Engineering And Information Technology, Federal University of Itajubá, Itajubá/BRAZIL

New technologies in the healthcare area have increased the possibilities to diagnose and treat the patients but also have added complexity and associated risks by use errors and users dissatisfaction during the use of complex machines. This paper deals with a new medical device under development in Brazil. The device is classified in the country as a low risk, but the device is intended to give comfort and to prevent futures problems to the patient under its use. The manufacture wants to evaluate the usability of the device to provide user satisfaction and efficient use of it. The heuristic analysis was the method chosen to evaluate the device, early as a prototype, in order to identify problems in the developing interface. The analysis was done by six specialists in Human Factor Engineering & Usability Lab in Federal University of Itajuba. We conclude that the heuristic evaluation was appropriate to evaluate the equipment in question, since helped identify relevant points that should be considered by the manufacturer to meet your customer and contribute with safety and efficiency in use.

PS16.003 - First Contact with Human Factors and Usability Evaluation in a Junior Research Project by a Biomedical Engineering Student

Author(s): <u>Ana P.S.S. Almeida</u>¹, Thais G. Andrade², Rodrigo M.A. Almeida¹, José A. Ferreira Filho¹</u>

¹lesti Lab Usabilidade E Fatores Humanos, Federal University of Itajuba, Itajuba/BRAZIL, ²Instituto Nacional De Telecomunicações, INATEL, Santa Rita do Sapucaí/BRAZIL

This study reports the experience of an undergraduate student enrolled at a junior research project in Human Factors Engineering (HFE) and Usability Evaluation of Medical Devices. The student was undergoing the third year of Biomedical Engineering, without any previous knowledge on HFE. The student was required made a literature review about the important concepts in the area first. The second part of the project consists on running a usability evaluation comparing two digital blood pressure monitors. A tutor, who is a human factors expert from another university, helped the student on setting up the methods, building the protocols and questionnaires.

In Brazil, Biomedical Engineering is a growing profession. The core curriculum of a Biomedical Engineer course is characterized by interdisciplinary. Although, it is uncommon to have disciplines related to HFE in undergraduate programs. HFE usually is taught as a small part of product development or in risk management related disciplines. This leads to biomedical engineering students with little knowledge on HFE, even with a high probability of working in the

development of medical devices in his career.

The junior research project was designed to give the student its first contact with HFE. It consists on comparing two digital blood pressure monitors, as if the student was required to choose and acquire one of them. Various HFE methods were presented and the student had to select the most appropriate ones. By understanding the basic functions of the equipment, with task analysis and cognitive walkthrough, the student developed protocols to perform the usability testing. There were two user groups of six participants, one for each device. Both groups had problems. The main issue was the difficulty of device installation and proper use, the clamp being one of the problems. Some of the functions, as memory, were also a source of problems. It is an important feature for patients who make a periodic pressure control, but it raised confusion on how to record and read the data, on both devices. The users pointed that they rather write down the values on a paper than using this function. The student found out that 83% of users ignored the instruction manual, even for the device that offered a quick guide. The instructions for use and the device labels were also conflicting. Another confusing point was the device alarms of high and low pressure, which caused misinterpretation.

Even though this was the first experience of the student performing the usability evaluations, she could raise a comprehensive list of considerations about the usability of the two products, with very interesting results. Unfortunately, the topic of HFE for medical devices is still unexplored in Brazil, even at academic environments for students training. With this research, the student could become aware of the importance of the issue, get to know HFE methods and applied them to the evaluation in real devices. The research also gave the student a better understanding on the importance of these topics in a product development.

PS16.004 - Non-Contact Measurement of Arterial Compliance (NCMAC)

Author(s): Delran Anandkumar, Steve Greenwald, Ragu Prakash Ratnakumaran

Blizard Institute Of Cell And Molecular Science Pathology Group, Barts and the London School of Medicine and Dentistry, London/ UNITED KINGDOM

Introduction

Increased arterial wall stiffness (especially in the aorta) is implicated in cardiovascular disease (CVD). Pulse wave velocity (PWV) as a measure of arterial stiffness is a powerful prognostic indicator for CVD morbidity and mortality. However, current methods used to measure PWV require highly trained staff undertaking lengthy procedures to obtain reliable results, making PWV assessment unsuitable as a diagnostic tool. We propose a novel non-contact reflectance photoplethysmography (PPG) method (NCMAC) of measuring PWV with the aim of making PWV assessment more accessible and therefore suitable for routine screening in a primary care environment. The device is designed to detect the pulse wave in the intercostal arteries and relies on the assumption that the timing of the wave as it reaches superficial tissue near the ribs on the subject's back closely reflects that of the wave as it traverses the descending thoracic aorta. However, this study aimed to validate the NCMAC device against simultaneous measurements of carotid radial PWV using Doppler ultrasound to detect the pulse wave. The arm was chosen as a test location as the radial artery is larger and more superficial than the intercostal arteries.

Methods

We recruited 61 healthy volunteers (37 male, 24 female) between the ages of 18 and 30. Images of the medial aspect of the right forearm were captured by an infra-red camera (Eosens CL, Mikrotron, Unterschleissheim, Germany), for 30 seconds at a frame rate of 500Hz and analysed offline with custom Matlab software. This allowed the PPG signal to be extracted from individual or groups of pixels a known distance apart, from which the time delay and hence the PWV was calculated. The Doppler signals (MD2, Huntleigh Healthcare, Cardiff, UK) were recorded from the same arm shortly thereafter with the probes placed a known distance apart at the elbow and wrist.

Results

We found a weak but statistically non-significant correlation (r = 0.045, p=0.73) between NCMAC and Doppler PWVs. A Bland-Altmann plot confirmed a lack of agreement between the methods, with a mean bias of -74.91m/s. Excluding NCMAC data clearly outside the normal physiological range (due to poor signal to noise ratio), gave a stronger and statistically significant correlation (r=0.37, p=0.04). The Bland-Altmann plot confirmed the stronger relationship between the two methods with a mean bias of -6.978m/s. However, due to the wide limits of agreement we conclude that, in its current form, the NCMAC does not produce PWV estimates that are reliably and consistently close to their Doppler derived counterparts.

Conclusion

The NCMAC device failed in measuring PWV in the relatively simple vascular anatomy of the arm. The poor results may be attributed to limitations in sensitivity of the imaging process and the ability of the software to extract a pulsatile PPG signal. Future improvements in these areas will be directed at increasing the accuracy of the device. Initially, experimental investigations and numerical modelling should be focussed on the behaviour of light as it passes through the skin and underlying tissue and interactions with the pulsating blood vessels therein.

PS16.005 - Developing a Quantitative Performance Assurance Risk Classification Model within a Generalized Risk Scoring System

Author(s): <u>Vishvek Babbar</u>¹, Agustina Krivoy², Petr Kresta², Michael Moore², Tidimogo Gaamangwe²

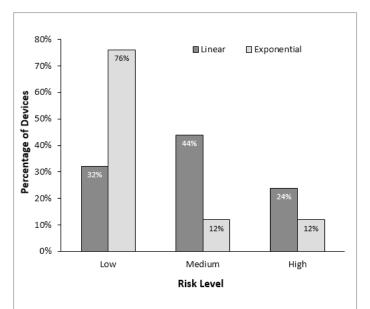

¹Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA, ²Clinical Engineering Program, Winnipeg Regional Health Authority, Winnipeg/CANADA

Risk classification is an essential process for various medical device management systems, e.g. performance assurance (PA). Several quantitative risk classification models have been developed but there is no standardized model because investigators may apply different rules to determine risk factors and risk categories. Most quantitative models also seem to assume that the distribution function for all the risk factors is the same. Therefore, the purpose of this work was to develop quantitative risk classification models within a generalized risk scoring system, taking into account the possible difference in the distribution functions. Example models, and applications are presented. The significance of the generalized system will be discussed.

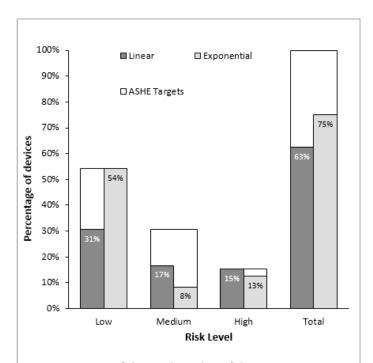

Empirical rules were used to assign risk factor weights and risk catergory scores. The risk scores were applied to 134 devices randomly selected from the regional medical device inventory. Two models, linear and exponential, were developed to transform the assigned scores to actual risk scores. The actual risk scores were then normalized to a [0,1] range. After scoring, devices were assigned to either Low, Medium or High risk levels. The distribution of the inventory between risk levels was compared with the American Society of Healthcare Engineering (ASHE) distribution for similar devices.

Figure 1 shows that the inventory distribution between risk levels is model dependent. Comparison of this distribution with ASHE (Figure

2) shows that the exponential model seems to be in better agreement with ASHE system. The results suggest model difference in sensitivity bewteen low and medium but relatively smilar for high risk devices. The significance of the model differences on applications such as PA prioritization and setting completion targets will be discussed. The next step of combining risk level with retrospective factors, such as repair history and number of missed inspections, is being explored for refined inspection prioritization.

PS16.006 - Project Management for Clinical Engineering – Considerations in the evaluation and acquisition of medical equipment for health services in Brazil

Author(s): Cleber S. Alves, Marilia M.F. Gomes, <u>Lourdes M. Brasil</u> Post-graduate Program In Biomedical Engineering, University of Brasília, Gama/BRAZIL

The public health system in Brazil must provide the population, comprehensive care and with wide availability of resources. However, the actual conditions demonstrate that available resources are not sufficient to give full attention to required health. With regard to medical devices, it is observed that its acquisition is often done without adhesion to technical criteria aiming to support the technology throughout its life cycle. The project management processes enables the clinical engineer to join the assessment team of technology to be acquired proactively analyzing the acquisition of medical equipment throughout its life cycle. The research presented involved the search for articles that deal with the project management in state of the art applied to the evaluation of medical devices focused on the incorporation of these technologies in the health care environment, addressing an adapted model of the project management processes proposed by the Project Management Institute to the activities of clinical engineer.

PS16.007 - Human Factors for Health Technology Safety: A new book on incorporating Human Factors into the work of biomedical technology professionals

Author(s): <u>Andrea Cassano-Piche</u>¹, Patricia Trbovich², Melissa Griffin¹, Ying Ling Lin¹, Anthony Easty²

¹Centre For Global Ehealth Innovation, University Health Network, Toronto/CANADA, ²Ibbme, University of Toronto, Toronto/CANADA

In healthcare, adverse events involving medical technology failures have traditionally been the primary concern of biomedical technology professionals. In contrast, incidents involving the context of use (generally classified as "use errors") have been left to clinical managers. Considering the high number of health technology-related adverse events caused by *use-error*, and the effectiveness of applying human factors principles to improve the design and safety of medical technologies, it follows that human factors methods should also be applied to technology development, evaluation, selection, implementation, training and the review of incidents, to support safe technology use.

While having a human factors professional as an integrated staff member of a healthcare facility is ideal, in reality, human factors professionals are not well established in this manner. Biomedical technology professionals, however, are well integrated within most healthcare facilities, routinely participating in evaluation, implementation, training and incident investigation related to health technologies. These responsibilities, when augmented by human factors methods, can improve the fit between a health technology and its context of use, which will lead to more effective, efficient, and safer use.

This presentation will introduce a new book, *Human Factors for Health Technology Safety*, aimed at providing biomedical technology and other professionals with the guidance required to integrate human factors methods into their tasks; acknowledging the familiar constraints of time and resources, and the complexity of the healthcare environment. The history of its development and structure of the document will be described and one or more case studies from the text will be shared to illustrate how the book can be used by biomedical technology professionals.

The text has been written based on what biomedical technology professionals know and do as core aspects of their profession. Each human factors principle and method is explained in the context of the biomedical technology professional's core activities. Human factors methods are presented in sufficient detail so the depth and nuances of the discipline are not lost, but in an accessible manner so that non-human factors professionals do not become overwhelmed. Also, recognizing that biomedical technology professionals work in health care facilities world-wide, the book is written to be applicable and adaptable to audiences with varying levels of resources.

Other guidance documents about incorporating human factors into the design of new health technology exist, and are used widely by health technology manufacturers, but very little hands-on guidance exists about applying human factors methods in a healthcare setting. This book serves to bridge this gap and expand the practice of human factors in healthcare facilities, so that staff and patients can experience safer and more efficient healthcare.

Human Factors for Health Technology Safety was commissioned by the Clinical Engineering Division of the International Federation for Medical & Biological Engineering and was written by members of HumanEra. HumanEra's core focus is on the application of human factors methods and principles to improve healthcare safety, while taking into account health care technologies, practices, and environments of use.

PS16.008 - Politics, value and risk: a system to allocate medical equipment funding

Author(s): Peter Cook, Keith Ison

Medical Physics Department, Guy's and St Thomas' Hospital, London/UNITED KINGDOM

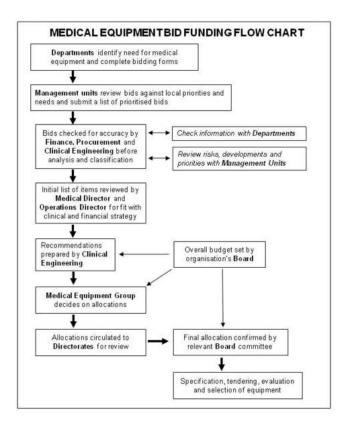

Healthcare providers seek to provide the best possible patient care, using the most appropriate medical equipment. Yet there is never enough money to go round. How does an organisation get the most from the funding it has available? What guides its purchasing priorities between replacing old equipment, buying extra items or bringing in new technology?

This poster presents a purchase prioritisation process which has been developed over 20 years and used at two large and one specialist hospital in London. This process encourages the active involvement of clinical departments, makes equipment requirements clearer and better coordinates purchasing. Although originally aimed at allocating funds to medical equipment costing over £5,000GBP, the process is easily scaleable. It supports the adoption of more elaborate systems needed to respond to economic and regulatory pressures in UK hospitals.

Important lessons learned in developing the process have included how to use risk alongside value for money in prioritisation; and the necessity of including 'soft' issues such as user preference and strategic and organisational impact alongside 'hard' measures such as return on investment and the degree of equipment standardisation.

Bids are collected from clinical departments before being checked and assessed. Purchase recommendations are drawn up, based on the relative risk of not getting equipment and/or the financial benefits of the investment and limited by available funding. These recommendations are considered by a group chaired by the hospital Medical Director that consists of several clinicians from different clinical disciplines, the senior operational manager and representatives from Finance, Estates, IT and Clinical Engineering. This group can adjust purchasing priorities in the light of clinical need and organisational strategy, with the outcome being formally approved by the relevant organisational Board committee.

A simplified flow diagram of the process is shown below. The process does not capture all bids, such as business cases for large infrastructure developments such as a new MR scanner. An amount of money is kept back each year as a contingency fund to replace equipment which fails in year; the amount spent gives some indication on how well the bidding process prevents potential service disruption. Analysis of the outcome for over 10 years of data suggests any bias in the allocation of funds is small and feedback from clinical groups has been positive.

PS16.009 - Magnetic Resonance system configuration and editing tools

Author(s): Daniel C. Pizetta, Gustavo V. Lourenço, <u>Danilo M.D.D. Da</u> <u>Silva</u>, Edson L.G. Vidoto, Mateus J. Martins, Alberto Tannús Institute Of Physics Of Sao Carlos, University of Sao Paulo, Sao Carlos/BRAZIL

Magnetic Resonance (MR) technologies play a fundamental role in medical diagnosis systems and scientific research due to their powerful versatility and non destructive characteristics.

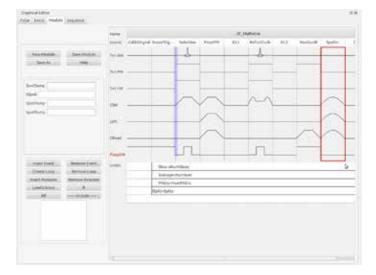

Current devices and methods require sophisticated tools not available for scientists who work with the equipment outside the manufacturer's realm. A limited number of studies, as ODIN (Object Oriented Development Interface for NMR) and DAMARIS (DArmstadt MAgnetic Resonance Instrument Software) has provided trials for meeting scientist's expectations.

This study describes tools for programming methods and MR systems. It includes a library – PyMR, an Application Programming Interface (API) and an Integrated Development Environment (IDE) with a graphical sequence editor.

The implementation of our system uses the state-of-the-art of computing technology and user's requirements. The structure includes PyMR, which acts as a front-end that generalizes its configuration and access. The API supplies the hardware-specific configuration and the IDE provides an easy way for the creation and management of MR sequences. The project was developed in Python along with PySide framework for the graphical user interface. The environment is currently in use in our onsite system CIERMag spectrometer. Besides its feasibility and quality of code structure provided by code metrics, it can be easily adapted to different devices, such as receivers and transmitters.

A new and friendly way of programming MR equipment has been developed. It provides scientists with total freedom for developing their own MR method or instrumentation device.

PS16.010 - The Unintentional Irradiation of a Live Human Fetus During a CT Scan: a case study

Author(s): <u>Jeff Frimeth</u>¹, Eduardo Galiano-Riveros², Marcelo Godin³ ¹Xspect Inc., Toronto/CANADA, ²Laurentian University, Sudbury/ CANADA, ³Hospital del Cancer, Asuncion/PARAGUAY

Purpose: The purpose of this work was to calculate the dose accidentally absorbed by a live fetus during a diagnostic CT procedure to a pregnant patient, and to assess the likelihood that the premature termination of the pregnancy was radiation-induced.

Methods: A patient underwent a diagnostic CT procedure as part of her initial clinical work up for a FIGO stage II cervical cancer. At the time of imaging - and unbeknownst to the staff – the patient was found to be 12 weeks pregnant. Approximately two weeks later, the fetus became non-viable and was surgically removed. Following established institutional procedures, the case was referred to the Physics Department for further dosimetric evaluation to determine what role - if any - the fetal dose played in the premature termination of the pregnancy. The fetal dose was determined using Wagner's CTDI Phantom Dose Reference Model method. The manufacturer's Abdomen Baby protocol was used to base the CTDIvol on, with appropriate corrections taking into account the actual scan parameters.

Results: Our estimated absorbed dose to the fetus was 19.3 mGy. Further, we estimate that the rotation of the fetus through an approximate 90° angle along the caudo-cephalic axis during imaging had no clinically relevant effect on the calculated absorbed dose.

Conclusions: The fetal dose was well below the consensus levels for negligible risk of abnormalities (50–150 mGy). At the time of exposure, the fetus was beyond the period of preimplantation; the most radiosensitive stage of pregnancy for a radiation-induced lethality. We conclude that the premature termination of this pregnancy is most unlikely to be of radiological etiology.

PS16.011 - Device reconditioning service for home-based assistance. How to choose the right approach.

Author(s): Roberta Chiarizia¹, Roberto Miniati², <u>Ernesto Iadanza²</u> ¹Clinical Engineering Department, ASUR Marche, ANCONA/ITA-LY, ²Department Of Information Engineering, University of Florence, Florence/ITALY

The home-based system's target is to give opportune responses to the problems which affect an increasing part of population. The aim of the service is to guarantee higher environmental performances and to maximize the effectiveness of these services. Starting from this, our experience was to show and suggest a method to deal with the difficulties on the management of a part of home-based service, called devices reconditioning service and identifying the best procedure to suite the needs. The critical elements and the different types of approach found, "in house" and "in outsourcing", in this health management system, were compared through Break Even Analysis. From an economical point of view this methodology points out which one, between the two presented management solutions, is the best according to collected data.

PS16.012 - Approach to the management of infusion systems in hospitals

Author(s): Roberta Chiarizia¹, Roberto Miniati², <u>Ernesto Iadanza²</u> ¹Clinical Engineering Department, ASUR Marche, ANCONA/ITA-LY, ²Department Of Information Engineering, University of Florence, Florence/ITALY

Drugs administration is the distinguishing feature of the infusion systems. They represent fundamental instruments in controlling clinical risk and in the improvement of the heath care assistance. Using infusion systems allows the continuous drugs administration, resulting in the reduction of concentration fluctuation, and, keeping the appropriate speed infusion, is the way to guarantee the desired therapeutic effect. The study presented in this paper allowed us to analyze and describe some critical points in the management of infusion systems, volumetric and syringe pumps, inside a subarea of Azienda Unica Regionale Sanitaria delle Marche (ASUR Marche). Some management solutions have been suggested such as supplementary services, in order to keep the functional continuity of the medical units, ready-to-use extra devices and their traceability. These services would allow to have extra devices in case of breakdown or in emergency situations; extra devices would belong to the so called infusion library and their handling can be both free or with a penalty. In order to decide the proper quantity of infusion systems, from the one hand, and from the other assuring the full service of the available devices, a mathematical reasoning has been done using real data from medical units. In our view this would guarantee to the hospital to save money and to get the most from the devices. In the end we suggest for the introduction of the closed-circuits for

increasing the safety of the operator during the infusion of cancer therapy.

PS16.013 - A Basic Study on the Measurement of Electromagnetic Fields in a New University Hospital Building Before and After the Hospital Opened

Author(s): <u>Kai Ishida</u>¹, Ren Hosokawa², Tetsuo Endo³, Tomomi Fujioka³, Tetsushi Fujisaki⁴, Ryoji Yoshino⁴, Minoru Hirose² ¹Healthcare Informatics, Tokyo Healthcare University, Setagaya-ku/ JAPAN, ²Medical Safety Engineering, Kitasato University, Sagamihara/JAPAN, ³Building Technology Development, Taisei Corporation, Yokohama/JAPAN,⁴Environmental Survey Office, Minato-ku/JAPAN

It is well-documented that establishing electromagnetic compatibility (EMC) is important for using medical equipment and communication devices in hospitals. To evaluate the basic electromagnetic environment, measurements should be conducted over 2 periods (before and after the opening of the hospital). We measured the electric field intensity induced by electromagnetic radiation in the broadcasting spectra coming from outside the hospital at 73 locations in our new hospital building in February 2014 (before any patients came into the hospital for the very first time) and August 2014 (6 months after the opening of the hospital). Frequency modulated radio signals, ultra-high frequency television signals, aeronautical radios, community wireless systems, and cellular phone system base stations were strongly detected at the windows of the upper floors. There was no great difference in measured levels between before and after the opening of the hospital. There were no cellular phone unit signals before the hospital opened its doors to patients, but were very strongly detected 6 months thereafter. In this study, the maximum electrical intensity was 0.28 V/m from cellular phone system base stations (2.1 GHz) observed on the south end of the 4th floor before the hospital first opened. This value was lower than the EMC marginal value of the general electronic medical equipment specified in IEC 60601-2-2 (3 V/m). Therefore, electromagnetic interference with medical equipment was extremely improbable in this situation. However, there were no cellular phone system base station signals in the elevator hall, in a portion of the corridor (located in the center of hospital), and in the hemodialysis unit. Measurements 6 months after the opening of the hospital revealed very strong cellular phone unit radio waves in the hospital. To promote greater EMC safety, the hospital should prepare countermeasures to improve these conditions, e.g., installing an interior cellular phone system base station.

PS16.014 - IAEA database of national dosimetry audit networks for radiotherapy

Author(s): Joanna Izewska, Paulina Grochowska, Ahmed Meghzifene

Nuclear Sciences And Applications, International Atomic Energy Agency, Vienna/AUSTRIA

Recently, the IAEA has undertaken a task to review the coverage and operations of national and international dosimetry audit networks (DAN) for radiotherapy. The aim was to organize the global database describing the activities of dosimetry audit networks across the world. A dosimetry audit questionnaire has been designed including information on different aspects of the dosimetry audit, such as the audit framework and resources, its coverage and scope, the dosimetry system used and the mode of audit operation, i.e. remotely and through on–site visits. In 2010, 2011 and 2013, the IAEA questionnaire was circulated to numerous institutions known for having operated dosimetry audits for radiotherapy in their countries or internationally, including members of the IAEA/WHO Network of Secondary Standards Dosimetry Laboratories.

confirm they operate dosimetry audit services for radiotherapy. The participation in audits is voluntary for a radiotherapy centre in 2/3 of responder countries and it is mandatory in the remaining. In general, audits are carried out regularly, with the frequency depending on the local circumstances; however, some organizations operate audits only by request. Most programmes verify megavoltage photon and electron beams, but some extend the audit scope to orthovoltage X rays, brachytherapy or radiosurgery. Few offer audits of tomotherapy and proton facilities. All organizations include the basic dose audit in the reference conditions in their programmes. Audits are also conducted for non-reference conditions, and for complex beam geometries, using semi- and/or anthropomorphic phantoms. Most clinical beams (85%) are checked through remote audits. Globally, approximately 2/3 of radiotherapy centres registered in the IAEA Directory of Radiotherapy Centres (DIRAC) have received some level of the dosimetry audit. However, better availability of the dosimetry audit is necessary for improving dosimetry practices in radiotherapy and for increasing safety of cancer patients undergoing radiation treatments.

The DAN database is located and maintained at the IAEA. The data from the 2010, 2011 and 2013 IAEA surveys were used to initially populate the database. When publicly available, this database can be used to provide information to international community on the availability of dosimetry audits in radiotherapy and the status of DAN activities across the world. At the same time, the information on participation in audits will be available to clinical trial organizations so that radiotherapy centres that are audited nationally and pass the national criteria are recognized as being competent to participate in international clinical trials as part of a global harmonization of clinical trial QA activities.

A concept for a DAN database was further developed to include a framework for international recognition system for national DANs activities. The introduction of such a system will be advantageous for comparing the auditing work between the various countries and regions, and to ensure that the national networks operate to the consistent internationally accepted standards and levels.

PS16.015 - Telehealth - Achieving its Promise in 2015 Author(s): Thomas M. Judd

Clinical Technology, Kaiser Permanente, Marietta/UNITED STATES OF AMERICA

Telehealth is achieving its promise in 2015. This will be demonstrated through three current case studies in which the presenter is participating:

1. US government HHS/HRSA study on evidence-based medical (EBM) tele-emergency care for rural locations

2. NGO EBM pilot for tele-neonatalogy between the national Childrens and OB Hospitals (and their key referral hospitals) based out of Skopje, Macedonia and Northside Hospital System Neonatalogy group in Atlanta, Georgia USA

3. NGO EBM tele-OB/Gyn and tele-neonatalogy as part of country-wide teaching and referral hospital development for Haiti; will bring together all parts of country as well as real-time e-consults with relevant specialists from all North America

The presentation will assess how clinical engineers can play a vital role in creating relevant solutions for use cases, partnering with other experts, such as these for and in developing countries.

In response to the IAEA surveys, 54 institutions in 45 countries

PS16.016 - The New Japanese Guidelines for Use of Mobile Phones in Hospitals

Author(s): <u>Takashi Kano</u>¹, Eisuke Hanada², Minoru Hirose³, Hidenao Atarashi⁴

¹Saitama Medical University, Hidaka, Saitama/JAPAN, ²Saga University, Saga/JAPAN, ³Kitasato University, Kanagawa/JAPAN, ⁴The University of Tokyo Hospital, Tokyo/JAPAN

The new version of "Guidelines for Use of Mobile Phones and Other Devices in Hospitals" has been published by the Electromagnetic Compatibility Conference Japan (EMCC) in August, 2014.

The Japanese hospitals have been setting their own rules for using mobile phones at their facilities, taking into account the guidelines published in 1997 by EMCC and public manners in a comprehensive way.

In the meantime, we have seen drastic changes in pertinent circumstances, such as the penetration of mobile phones into daily life, the abolishment of second-generation mobile-phone services, and the improvement of medical electrical equipment for electromagnetic immunity.

These Guidelines have been created in consideration of the above circumstances through a review by experts, medical associations, wireless service providers, and relevant ministries and agencies in order to use mobile phones and other wireless communication devices more securely and safely in hospitals.

As mobile handsets (which hereinafter mean to include smartphones and tablets with a built-in cell-phone function) have become increasingly essential to daily life in recent years, it is desirable to allow the use of mobile handsets by patients and hospital visitors in hospitals to the extent possible for improvement of convenience and QOL for patients. On the other hand, while medical electrical equipment is required to have a certain level of immunity for electromagnetic fields, their operation may be affected by mobile handsets when they are used in close proximity. Another concern is public manners, such as sounds made during phone calls, of ringtones, of incoming mail tones, of operation, and of watching TV (hereinafter called "Calls"). Therefore, it is necessary to place certain restrictions on the use of mobile handsets in hospitals and establish proper rules for using them.

Since the kinds of medical electrical equipment, the need for using mobile handsets, and the need for consideration of others appear to differ greatly among specific areas in hospitals, they need to set area-specific rules. For the areas where the use of mobile handsets is allowed, they also need to set up the conditions for use (e.g., separations, precautions for use).

It's also necessary to set rules specifically targeted at hospital staff when hospitals establish rules for using mobile handsets at their facilities. Considering that the use of mobile handsets for medical practice contributes to the swift and optimum operation of medical services, the use thereof, including Calls, may be allowed in principle, on the condition that hospital staff is fully educated about the prevention of interference with medical electrical equipment.

By establishing rules for using mobile handsets by reference to these Guidelines, hospitals are more capable to properly manage and operate wireless communication devices in their facilities. To make wireless communication devices available more safely and securely along with further development of ICT for medical services, hospitals need to pay more attention to the management of the EMC environment by reference to these Guidelines.

The English version of "Guidelines for Use of Mobile Phones and Other Devices in Hospitals" has been published in EMCC URL (http://www.emcc-info.net/info/pubcom2/2608_5.pdf).

PS16.017 - Study on Medical Equipment Location Systems that use RFID Technology

Author(s): <u>Manabu Kawabe</u>, Yasuyuki Miwa, Takashi Kano School Of Biomedical Engineering, Facculy Of Health & Medical Care, Saitama Medical University, Saitama/JAPAN

(To protect the property of the hospital and periodically check medical equipment, it is important that the hospital staff can locate medical equipment used at various places in the hospital. Therefore, we have developed a location management system for medical equipment using RFID (Radio-Frequency Identification Device) technology IT-Location.ME. Taisei Co., LtdI. In this system, an antenna is installed in the doorway of the ward, and the RFID tag, attached to the medical equipment, makes its location known when passing by the antenna. The limit of this system is that it is difficult to identify the hospital room or treatment room in which the equipment is located even though the equipment is somewhere in the ward. To compensate for this limit, we have fabricated a handheld antenna to search and find the location of the medical equipment with the RFID tag attached. Furthermore, since the electric waves emitted from the RFID tag may be transmitted to the upper and lower floors, we have examined a method to shield the electric waves emitted from the RFID tag in order to prevent false detection. Since the system specialized in identifying the location, could not store basic information on the medical equipment and periodic maintenance log, we have linked the system with the database of the commercially available medical equipment management software.

(For the search of the medical equipment with the RFID tag attached, we have fabricated a directional phased array antenna consisting of two elements. Using this antenna, we have measured time to find the 10 infusion pumps attached with the RFID tags (lined up in a room in two lines with an interval of 2.1 m and a distance between lines of 9.0 m). In this measurement, six examiners could find the pump at an average search time of 45 ± 20 s and the probability of discovery was 93.4%. In addition, we have used a metallic knit fabric to prevent the false detection of the RFID tag in the upper and lower floors. By placing the fabric on a floor from which undesirable waves are transmitted, we could prevent the false detection of the RFID tag in the upper and lower floors. The linkage with the commercially available medical equipment management software was materialized by setting up a folder in a computer to share data between the databases of the medical equipment management software and the location management system and exchanging the information on the location of equipment and the basic information. This enables the medical staff to search the information provided by the location management system through the medical equipment management software, which is simply more accessible to the staff.

(In this study, we could solve the problems with the location management system we have developed, prevent the false detection of the RFID tag in the upper and lower floors, and link the system with the medical equipment management software currently used in the hospital. We believe that the usefulness of the location management system has been enhanced through this study.

PS16.018 - Development of a Regional Prioritization Process for Diagnostic Imaging Equipment Replacements Author(s): Rebecca Austman, Petr Kresta

Clinical Engineering, Ge 512, Health Sciences Centre, Winnipeg/ CANADA

Prioritization of Diagnostic Imaging (DI) equipment for replacement in the Winnipeg Regional Health Authority (WRHA) is completed through a separate process than for other types of medical equipment. DI systems are first prioritized at the regional level, and then by a provincial committee against imaging systems throughout the province. Historically, the equipment prioritization approach within WRHA has been through a largely qualitative and subjective voting process. As a result, the final prioritization depended on how well the manager of each site/program could sell their needs. Previous studies have developed various quantitative methods for prioritizing other types of medical equipment, but no known studies have developed a method targeted for DI equipment.

The purpose of this study was to develop a quantitative prioritization method by assigning points to selected criteria, or Prioritization Factors, that should be used when considering a piece of DI equipment for replacement. Based on a literature review, four Prioritization Factors were identified that were both relevant to DI equipment and easily obtainable: Remaining Useful Life, Support Status, Condition, and Clinical Capability. Each prioritization factor was assigned a weighted score (Table 1). Determining the relative weights for each of the factors involved input from managers from each of the DI sites, using a comparative process and involving some aspects of a previously established Analytical Hierarchy Process. Each Prioritization Factor had several categories within it (Table 1), from which the managers of the site/program had to select from on their request form. The form then automatically converted the selections into a corresponding score. The sum of the scores from the four Prioritization Factors was presented as the Priority Score. Other mitigating factors could also be written in the request justification, but were not assigned a score.

Table 1: Prioritization	Eactors Used with	h Corresponding	Score Values
Table A: Frioritization	Factors Osed with	n corresponding	acore values

FACTOR	CATEGORY	SCORE	
Remaining Useful Life*	≤ 0 years	5	
	0 < x ≤ 2 years	3	
	2 < x ≤ 5 years	1	
	X > 5 years	0	
Service Support Status	Out of support	20	
	Out of support but parts still available and/or supportable by	15	
	a 3 rd party		
	≤ 2 years until EOS date	10	
	No known end of support (EOS) date; Or >2 years away	0	
Condition	Poor	15	
	Moderate	8	
	Good	0	
Clinical Capability	Lacks features/capabilities - high impact on patient care	10	
	Lacks features/capabilities - moderate impact on patient care	6	
	Lacks features/capabilities - low impact on patient care	2	
	Meets all or nearly all clinical requirements	0	

*Based on Canadian Association of Radiologists (CAR) guidelines, which incorporates both age and number of exams/yea

This method was applied during this year's replacement prioritization exercise. The numerical scores acted as a guide to aid decision-making for the managers during the regional voting process, as well as for prioritizing the equipment within their sites. Overall, the feedback received from the users of the new system was positive, and it has been well accepted. It ensured that relevant factors such as age, condition, supportability, and capability were all considered when submitting the equipment requests, so that systems could be compared more objectively. Future work includes further refining the factors and scores based on the initial experience, as well as expanding this method to be used during the province-wide prioritization.

PS16.019 - Implantable Medical Devices: more Safety with Traceability and Surveillance

Author(s): <u>Paolo Lago</u>, Ilaria Vallone, Antonio Scarso, Corrado Gemma, Federica Cardellini

Clinical Engineering Dept., San Matteo Hospital, Pavia/ITALY

Background

PRIORITIZATION

Medical Devices (MD) market produces an annual turnover of about €100 billion in Europe: 70% is produced in Germany, France, United Kingdom, Italy and Spain. Small and medium enterprises cover

95% of MD field composed by 25 thousand industries . For these reasons, there is an increasing attention to this sector in Europe. European Directives 93/42/CEE, 90/385/CEE and 98/79/CE order the main rules for the MD commercialization in Member States. The European Database on Medical Devices (EUDAMED) was instituted by European Directive 98/79/CEE in order to strengthen supervision operations and to increase market transparency.

In Italy, MD market is about €13.5 millions, with an annual growth rate of 4.7% in the period 2004-2012 and high innovation level. Italy is one of the few European Countries to create by law a MD List and to start a new data flow of MD consumption from healthcare facilities.

Objective

The aim of our work is to suggest some way to use these precious informations, already available through data flows, in order to obtain a traceability of Implantable Medical Devices. HTA analysis as well as better control on manufacturer warnings are possible too.

Methods

All official flow are analysed, identifying data and each database. Italian hospitals costs in MD are monitored through Consumption Flow. Different data flow connect patient data to implantable MD data.

In Lombardy Region, for example, the Patient Data Base is interfaced with the flow from the Hospital Discharge Forms. The implantable MD data are related to hospitalization codes. Therefore it is possible: a) to identify univocally the patient, tracing the National Insurance Number; b) to trace the whole clinic history after the implant; c) to carry out extremely detailed analyses.

Conclusions

Nowadays the major attention is about the economic and regulatory aspects of MD sector; for patient safety we correlate implantable MD with clinical events. This process could be useful for healthcare facilities (patient clinical issues and HTA) and for companies and competent authorities (post-market supervision and medical device surveillance).

PS16.020 - Using standard test methods to ensure quality and maximize supply of personal protective equipment in a time of global emergency response

Author(s): <u>Ying Ling Lin</u>¹, Adriana Velazquez Berumen², Yukiko Nakatani³

¹University of Toronto, Toronto/CANADA, ²His/emp/pau/medical Devices, World Health Organization Headquarters, Geneva/SWIT-ZERLAND, ³Ministry of Health, Labour and Welfare, Tokyo/JAPAN

The rapid spread of 2014's Ebola outbreak, in West Africa, required a stable and adequate supply of personal protective equipment (PPE) to protect healthcare workers caring for patients with suspected or confirmed haemorrhagic fever. There quickly emerged an urgent need for off-the-shelf PPE traditionally destined for much different industrial applications to meet this health care service delivery demand. Clear and specific minimum standard performance criteria for each type of protective item had to be defined within a short period of time so that countries affected by Ebola infections could procure necessary PPE, put in place procedures and prepare staff to do their work in high risk environments. In the field, there was much variability in material performance and final item construction therefore, it was necessary to choose only the most relevant performance requirements and ensure an explicit minimum standard of quality, in order to simplify procurement of complex design PPE and to maximize its quantity from major manufacturers to priority countries. However, limited studies had been found to guide recommendations of these complex items and their combinations. Technical information was combined from industrial standards with practical input from clinical teams, field logisticians, global

procurement information and researchers of major manufacturers. These evolving minimum performance standards and combinations thereof, became more stringent as supply of products to priority countries stabilized. Also, the challenging combinations of performance criteria shaped the future design need for PPE items more suitable to current demands and preparation for future outbreaks. Indeed, the USA launched "Fighting Ebola: A Grand Challenge for Development. Fighting Ebola", a design competition to address, among other themes, the specific design issues of commercial PPE. The initiation and evolution of a small and highly technical component of a greater relief effort will be presented.

PS16.021 - Creation of a system for the coding of medical devices

Author(s): Mirko Dezi¹, <u>Alessio Luschi²</u>, Ernesto Iadanza² ¹University of Florence, FIRENZE/ITALY, ²Department Of Information Engineering, University of Florence, Florence/ITALY

Medical devices have different nomenclatures for their classification. Some of the most significant nomenclatures are the Universal Medical Device Nomenclature System (UMDNS) and the Global Medical Device Nomenclature (GMDN) by the Emergency Care Research Institute (ECRI). In Italy the main are CIVAB and "Classificazione Nazionale Dispositivi Medici" (National Classification for Medical Devices – CND). The aim of this study is to create a system to automatically decode several device models from CIVAB to UMDNS code. All medical devices are coded with a table which is based on their definitions presented in these nomenclatures. The coding is lastly applied to a list of models of medical devices, developed by different companies.

PS16.022 - Establishment of Radiation Qualities for Radiodiagnostics in LCR/UERJ According to IEC 61267 and TRS 457 Author(s): Luis Magalhaes

Universidade do Estado do Rio de Janeiro - UERJ, Rio de Janeiro/ BRAZIL

The main goal of this work is to establish the radiation qualities of the Laboratório de Ciências Radiológicas (LCR) conventional X-ray equipment for calibrations in radiodiagnostics according to the recommendations of IEC 61267 and TRS 457. Tests were conducted to evaluate the homogeneity of the radiation field, high voltage applied to the X-ray tube, scattering, half-value layers (HVL) and homogeneity coefficients. The results obtained that characterize the radiation field, satisfy the conditions required by TRS 457. Invasive high voltage measures presented results compatible with the requirements of this standard. The HVL measures showed that for the first HVL the tolerance limits of IEC 61267, and the values for the homogeneity coefficients were within the limits established. The quality tests performed in this work were highly satisfactory in meeting the standard requirements. Thus, the main goal was achieved, and the methodology can be used by other similar X-ray systems.

PS16.023 - A Healthcare Facilities Qualitative and Multivariate Quantitative Assessment Methodology for Mongolia Author(s): <u>Claudio I. Meirovich</u>¹, Adiya Bold²

¹Healthcare Facilities And Medical Equipment Planning, Meirovich Consulting, Madrid/SPAIN, ²Fourth Healthcare Sector Development

Project, Ministry Of Health (fhsdp), Ministry of Health of Mongolia, Ulaanbaatar/MONGOLIA

A qualitative analysis, multivariate analysis and a scoring system is proposed as the methodology to evaluate a healthcare infrastructure and technology city network. The methodology requires visiting each facility; interviewing the staff; completing an infrastructure

checklist; assessing each room including area measurements; making pictures of each room, all the installations and all the major infrastructure elements, making a full equipment inventory including the working conditions of the equipment: identifying the exact location of all the inpatient beds of each facility and writing an evaluation report. The collected information is then cleaned to do a multivariate analysis with "R". The assessment of each facility is focused on 4 areas (dimensions): infrastructure, installations, support services and equipment. A compound score is calculated using weights for each component that builds each dimension. The weights are defined by a group of experts. The resulting scores for each dimension of each facility are then evaluated and crosschecked with the pictures and the evaluation (qualitative) report. The level of confidence of the collected information is also rated. The proposed methodology was used to assess 33 healthcare facilities of Ulaanbaatar City in Mongolia: 9 specialized hospitals, 5 District Health Alliances, 6 district hospitals, 6 secondary general hospitals, 3 maternity hospitals and 4 Village Hospitals. The obtained results were used to prioritize new investments for the health sector over the next years. Further work is required in order to adjust the proposed methodology to better identify or classify a facility's conditions, adding more answer options and including more experts in the weight definition stage.

PS16.024 - Practice of HB-HTA on the Study of HIFU Technology for the Treatment of Prostate Cancer and Uterine Fibroma Author(s): <u>Roberto Miniati</u>¹, Benjamin Latella², Francesco Frosini¹, Paolo Avezzano¹, Ernesto Iadanza¹, Fabrizio Dori¹ ¹Information Engineering, University of Florence, Florence/ITA-LY, ²School Of Human Health, University of Florence, Florence/ITALY

The aim of the study has been the development of a Hospital Based – Health Technology Assessment, study directed to analyze the clinical, social and financial aspects derived from the use of the HIFU method for the treatment of prostate cancer and uterine fibroma in comparison with the traditional therapeutic approaches.

A systematic literature review was carried out inspecting the treatment of prostate cancer through the use of HIFU technology as well as its use for the treatment of uterine fibroma. At a later stage, clinical, social and financial indicators (gathered from EUnetHTA Core Model as well as from scientific literature) were defined and evaluated and a single benefit index was drawn in the end to have a rapid and direct comparison among the various treatment methods.

For the treatment of prostate cancer, HIFU reaches good results in the clinical setting obtaining 78% of negative biopsy results post-surgery and a 68% disease-free survival rate at 5 years. It also proves efficient in the social setting and equal to traditional surgeries. For the treatment of uterine fibroma, HIFU presents an improvement of post-surgery symptomology in 80% of cases, revealing a good clinical efficacy and showing particularly convenient in the patient quality of life.

Even though the traditional techniques represent the current gold standard, the initial results for the treatment of prostate cancer, exclusive to low risk of illness, and of uterine fibroma through the use of HIFU appear positive and, therefore, encouraging for the immediate future even though it remains fundamental to have greater availability of evidence especially in the long run.

PS16.025 - A Simulation Based Model for Planning Operating Theater Activity in Complex Hospitals: Case Study in Orthopedics

Author(s): Francesco Frosini¹, <u>Roberto Miniati</u>¹, Paolo Avezzano¹, Fabrizio Dori¹, Duccio Cocchi¹, Ernesto Iadanza¹, Sheila Belli², Maria Teresa Mechi³, Vega Ceccherini⁴, Andrea Belardinelli² ¹Information Engineering, University of Florence, Florence/ITA- LY, ²Head Department, Florence Teaching Hospital, Florence/ ITALY, ³Health Department, Florence Teaching Hospital, Florence/ ITALY, ⁴School Of Hygiene And Preventive Medicine, University of Florence, Florence/ITALY

Operating theaters (OT) in hospitals represent some of the highest sources of economic expenditures since their high complexity in terms of technology equipment (integration of different complex devices and specific technical requirements), organization (multi-personnel area with complex patients flow) and usage (optimum planning between regular activity and emergency management). For the above reasons, it is essential to understand and plan the whole surgical path (patient and personnel) by avoiding foreseeable inefficiencies, delays and risks.

Hence, the aim of this study is fully modeling a generic orthopedics OT in order to support hospital decision makers in OT design and activity planning for both regular and emergency scenarios.

In order to do that and due to the complexity of the OT system, a simulation approach is fundamental for properly understanding the whole process and for clearly controlling and analyzing all the factors involved (surgical durations, types, working times and rooms availability, etc..). Discrete event models have been found reliable and accurate to simulate complex health systems (e.g. emergency management, beds management, logistic and assets estimation, etc.).

Finally, after selecting the most appropriate type of model, and using past surgical data and experts' opinions from the hospital for its development and implementation, a more precise and reliable clinical validation of the model is currently in progress, by concluding a data verification that needs a period of on-site data collection.

PS16.028 - Risk management tool in the application HFMEA in purge sector on the Material and Sterilization Centers. Author(s): <u>Sérgio S. Mühlen</u>¹, Michele C.A. Sousa¹, Maria Isabel P.

Freitas²

¹Biomedical Engineering Departament, UNICAMP, ../BRAZIL, ²Nursing Departament, UNICAMP, ../BRAZIL

Introduction: Material and Sterilization Centers in health care facilities should ensure the quality of medical instruments for safe patient care. For the sterilization process to be carried out properly, it is essential that the article to be sterilized is free from of organic matter and some inorganic substances. If the activities of receiving, cleaning, rinsing and drying of surgical instruments, located in the Cleaning sector, are incomplete or inadequate for being performed quickly, they can compromise the cleanup. These failures may have diverse origins and they determine important factors to be identified for qualifying the work process. Objective: To assess critical points in processes and identify areas for improvement in the activities undertaken in the cleaning sector, Healthcare Failure Mode and Effect Analysis (HFMEA) technique was applied to the procedures performed in that sector. Methods: The HFMEA is a toll that provides a systematic evaluation of the critical points in processes by classifying them according to the severity of the potential effects of their failures and to their probability of occurrence, allowing the prioritization of the risks to be controlled. For its implementation a multidisciplinary team was formed, the process was mapped, the risk analysis was executed and the failure modes related to the process were evaluated. Results: 89 failure modes involving the cleaning and drying of instrumentation were found, and 262 potential causes associated with these failure modes were identified. Of this total, 131 potential causes (50 %) were selected and analyzed to propose measures and actions for improvement. A guide was prepared for to help implement the proposed improvement measures. Conclusion: The application of the HFMEA tool provided a diagnosis of the critical points of the process and resulted in the proposition of improvement solutions that have been condensed into a guide action and measures that can aid the team managers of CME in incorporating safer routines in the execution of their activities and patient care.

PS16.029 - Generate health and wealth by innovation Author(s): <u>Mayur Patel</u>, Mark Humphries Cambridge Technology Centre, PA Consulting Group, Melbourn/ UNITED KINGDOM

Innovation, health and wealth – hospitals have a unique capability in these three areas. Hospitals always strive to give the best health to patients, but innovation and wealth are often a lower priority, or lack the relevant infrastructure to carve out the aspects from clinicians and standard healthcare facilities. On a positive note, there are plenty of unexplored opportunities waiting to be exploited.

An ideal way for hospitals to adopt innovation and increase participation in research is to collaborate more with industry and universities. This arrangement can be used to exploit health and wealth in hospitals through Innovation.

"Innovation" is often interpreted as discovering a new technology or method and confused with invention. Innovation often results from the integration of known elements, directed towards a change in service, process, text, modification, development or research. Invention may not be required, rather benefits can occur from creatively redeploying our existing knowledge and assets in a new way to deliver the best healthcare services to patients, whilst meeting the wealth agenda at the same time. Such assets may not always reside within the same organisation and a more open approach, enabled through collaboration with the right set of organisations, can result in optimising the contributions from each party enabling innovative solutions to be created, and more importantly, deployed in relatively short timescales.

There are numerous ways to align health with wealth by first recognising, and then making use of existing assets and resources with hospitals. Some examples are:

1) Facilities re-use: There are plenty of sophisticated devices and services in hospitals that when not in use, could be used by device and drug manufacturers to carry out research, safety or performance testing. Imaging systems and clinical laboratories are such examples.

2) Collaboration with industry by providing consulting service: Clinicians, scientists, physicist and engineers working within the healthcare services are valuable resources for requirements definition, design and development of medical devices - Usability & human factors, Imaging systems and clinical laboratories, and Clinical Trials & investigations

3) Implementation of innovative **methods:** There are numerous services in the healthcare services that can be altered with minimal expenses which can result in greater savings and efficient functioning. Some examples are Medical equipment library, standardisation of medical devices in hospitals and effective management of medical device maintenance contracts.

Obvious questions that come to our mind are: how can hospitals generate more health & wealth by exploiting such resources? Why do such centres not exist or are not well known? How much more can hospitals innovate whilst not losing its core function to deliver

patient care?

The healthcare services require the right framework, expertise and skills to find & develop such opportunities. Medical Physics departments, being a centre of these facilities and having capabilities, provide a resource to identify initiatives to explore these opportunities.

PS16.030 - Validating and comparing Methods for testing Endothelial Function

Author(s): <u>Ragu Prakash Ratnakumaran</u>, Steve Greenwald, Delran Anandkumar

Blizard Institute Of Cell And Molecular Science Pathology Group, Barts and the London School of Medicine and Dentistry, London/ UNITED KINGDOM

Background- Impaired endothelial function (EF) is strong predictor for the subsequent development of cardiovascular disease. Current EF testing involves using an expensive and technically difficult method known as Flow-mediated dilation (FMD). We are testing a simpler and more robust method known as the finger-tip endothelial function (FTEF) test, which measures the time difference between the arrival of the pulse at the middle finger of each hand (Δ PAT) before and after hyperaemic flow. As a preliminary validation of this new approach, we have compared the magnitude of the pulse arrival time difference with the maximum change in pulse wave velocity (measured in the radial and brachial arteries by Doppler ultrasound). We have also compared the time taken to return to baseline for the two methods and the area under the Δ PAT- or PWV- elapsed time curves.

Method- 48 healthy volunteers (31 male, 17 female) between the ages of 18 and 40 with no previous or current medical conditions were recruited. FTEF and the Doppler PWV measurements were performed simultaneously. Baseline data were recorded for 1 minute followed by hyperaemia induced in the left arm by 5-minute occlusion with a sphygmomanometer cuff. The response after cuff release was recorded for another 5 minutes.

Results- There was a statistically significant positive correlation when comparing relative/absolute difference in PWV against absolute difference in Δ PAT (p=0.0168/p=0.0487). A statistically significant positive correlation between the FTEF and Doppler PWV methods was observed when comparing time taken to return to baseline (p=0.0264). However, on average, Δ PAT returned to baseline significantly later than PWV (P=0.0003). A statistically significant correlation was also seen when comparing area under the magnitude time curve (p=0.0187).

Discussion- The FTEF test and Doppler PWV method of assessing EF demonstrated a correlated maximum effect, time course and area-under the magnitude time curve, thus we can assume the difference observed in Δ PAT is due to changes in brachial-radial PWV. FTEF proves to be a potentially simple and useful method for assessing EF. Comparison of FTEF with the gold standard (ultrasound FMD) is in progress to further validate the FTEF technique.

PS16.031 - Reliability Indicators in the Medical Equipment Management

Author(s): <u>Camila S. Reis</u>, William Castañeda, Renan Feltrin, Renato Garcia

Instituto De Engenharia Biomédica, Universidade Federal de Santa Catrina, Florianópolis/BRAZIL

This paper presents a study which uses reliability indicators for medical equipment management. There are considered corrective and preventive maintenance records to calculate the mean time between failures and the mean time to repair. The application of this method, the maintenance records collected refer to anesthesia equipments used in operating rooms of five health care facilities in the public network of Santa Catarina state, Brazil. The analysis of the indicators was made according brands and date of installation of anesthesia equipments. The mean time between failures of the equipment under analysis is acceptable and was 16 months for brand A and 10 months for brand B. However, it was not possible to conclude whether the periodicity of preventive maintenance performed is being effective or not for the containment of failures. It is concluded that the analysis of indicators if not describes the operational context of use and may lead to a finding of reliability of precipitated brands, not being trusted to reality.

PS16.032 - Methodology for Safety Movement of Clinical Facilities Focused in Oncology

Author(s): <u>Sandra L. Rocha Nava</u>¹, Angel Herrera Gomez², Claudia Del Carmen Cárdenas Alanís³, Guadalupe D.J. Gutierrez Sánchez¹, Erika Ramirez Lopez¹

¹Biomedical Engineering, Instituto Nacional de Cancerologia, Mexico DF/MEXICO, ²Medical Director, Instituto Nacional de Cancerologia, Mexico DF/MEXICO, ³Escala Biomedica, Mexico City/MEXICO

The National Cancer Institute in Mexico City is the leader in critical cares on Oncology, it sets the policies and programs for the cancer control in all the country. For 40 years it was hold in a space of 1.5 hectares for its operation, and in 2011 the construction of a new facility began which provides more space and safety operations to patients, visitor and medical staff.

The transfer process of 10 clinical and diagnostic services to the new facility started in 2013. The Biomedical Engineering department implemented a process for time and motion, as well as risk analysis, to perform the movement with the least impact for patients and users, delaying the minimum diagnostic studies and treatment and the minimal effects in their activities.

The services in which this methodology was implemented were: Imaging, Nuclear Medicine, Clinical Laboratory, Pathology, Emergency, Operating Rooms, Intensive Care Unit, Recovery Room, Sterilization Facility and Inpatient Units.

Moving the Imaging and Nuclear Medicine departments represented the translation of approximately \$ 20 million dollars in medical equipment, among which stand out: 1 PET-CT, 1 SPECT-CT, 1 Gammacamera, 1 MRI 1.5 T, 1 Dual CT Scan, 1 Angiography System, 2 Digital Radiographic System and 1 Digital Fluoroscopy System, 4 Digital Mammographic and 1 Stereotactic System, 1 Digital Orthopantomograph, 1 Densitometer, 7 Ultrasound, 2 complete PACS-RIS systems with 15 diagnostic stations. The total time for transfer of both departments was 40 days and studies and services were not suspended or delayed for patients, with the exception of MRI and PET-CT, for which required support from neighboring hospitals to be done.

Clinical Laboratory moved eight laboratories: Hematology, Clinical Chemistry, Urinanalysis, Bacterology, Tumor Markers, Molecular Biology, Coagulation and section sample distribution. The running time was 4 weeks.

The change in Clinical Pathology and its various services required 3 weeks for Cytopathology, Molecular Pathology, Immunohistochemistry, Histopathology and Inclusion.

In addition, eight Operating Rooms, 15 Recovery Rooms, 9 Intensive Care Rooms, 135 Inpatient beds and Sterilization facility were moved. For their flow operation and transcendence movement took place in two days each service with a strict control of the risks. All the movements were designed, documented and analyzed for a team of women biomedical engineers. The implemented methodology allowed us to conduct the transfer of the above mentioned clinical, diagnostic and treatment services with minimal impact and control risks on patient care, considering services were not suspended or delayed, their safety was always verified, the safety for the users and the 643 medical equipment as well. No device was damaged or required major repair and working properly on hospital care and equipment

PS16.033 - Design of a remote use ECG with an Optical Communication System (FSO) for Telemedicine Applications Author(s): <u>Raul Rodriguez-Aleman</u>, Yair Vazquez-Lopez, Gerardo S.

Romo-Cardenas Autoria, Antonia Mantenando Hainanita Mantenando .

School Of Engineering, Montemorelos University, Montemorelos/ MEXICO

This paper expose the current work in the development of an ECG of 12 derivations with the capability of connection through an optical communication system. Prior investigation shows that attention provided in the first minutes of a heart problem it's essential. The ECG signals are going to be transmitted into laser beam through the atmosphere to stablish communication between the ECG and the medical center, Capable to analyze the signals and give a proper diagnosis. There are a few challenges to this project; Multiplexing ECG signals into a laser Diode and effectively transmitting those signals through the atmosphere to a receptor.

This through an optical communication system which refers to the transmission of a laser beam modulated through the atmosphere to communicate between the scene to a medical center where a specialist doctor can analyze the ECG information, rate and blood pressure patient . Because the optical communication system are in recent exploration. Several techniques have not been investigated , capabilities and limitations in various scenarios and applications. An exploration of optical communication systems audio and video was performed to analyze their performance in the propagation in open space. Experiments were designed to simulate optical effects of transmission in the atmosphere by means of a base of gelatin, likewise absorption experiments and polarization of the beam is designed to better understand its operation, advantages and limitations of these communications systems. According to the Beer-Lambert law, the beam can be absorbed into the path to follow in the atmosphere having different effects on the propagation of the beam and the information is conveyed . Likewise the polarization effects generated in the intensity of the transmitted signal.

PS16.034 - Adverse events and death related to the use of the MRI equipment

Author(s): <u>Ricardo A.M. Sá</u>¹, Walter V. Mendes² ¹GerÊncia De Engenharia ClÍnica, SECRETARIA DE ESTADO DA SAÚDE DE GOIÁS - SESGO, GOIANIA/BRAZIL, ²Escola Nacional De Saúde Pública Sérgio Arouca, Fundação Oswaldo Cruz, Rio de Janeiro/BRAZIL

Objectives: The aim of this work was identify the occurence of adverse events (AE) and the death related to the use of the MRI equipment informed in incident notification system.

Background: The World Health Organization (WHO) recomends that health care systems should be able to identify,report and recalls all incidentes, especially AE. A few authors have developed a generic system risk model to search and to analyse the root causes of AE. This system can be useful for identifying these causes and improve the protection of the health and safety of patients and users by disseminating information and to prevent the occurrence of AE.

Methods: MRI is "a diagnostic technique that uses a magnetic field and radio waves to produce a detailed image of the organs, tissues and bones within body". The AE notifications were collected from the Manufacturer and User Facility Device Experience Database (MAUDE). The AEs were classified based on Shepherd's model (The Systems Risk Model). The concept of AE used in this study was "events that produce, or potentially may produce unexpected or unwanted outcomes that affect the safety of patients, users or others".

Results: We found 1487 AE related to the MRI equipment in the last 10 years (period from 01/01/2004 to 12/31/2013), being 12 related to death, and 774 of them were related to injury, 295 reports were related to "malfunction", 349 reports related to "others" and 51 reports related to "No Answer Provided". We analyzed the 12 deaths occurred. Three cases were excluded because they are repeated. From the remaining 09 reports, 07 AEs were deaths of patients and 02 AEs were deaths of professional maintenance. The causes of deaths of patients were heart attack (03 cases), respiratory arrest due to disconnection or malfunction of the anesthesia machine (02 cases), collision with ferromagnetic objects (01 case) and diagnostic error (01 case). The causes of deaths to maintenance professionals were asphyxia (01 case) and collision with the magnet (01 case).

Conclusion: We think that Shepherd model is very useful to identify causes and assess the risks of AE surveyed. For future studies, we propose to use the Shepherd's model to evaluate the AE related to the use of radiology equipment like digital x-ray and mammography.

PS16.035 - Adverse events and injuries related to the use of the MRI equipment

Author(s): <u>Ricardo A.M. Sá</u>, Walter V. Mendes Clinical Engineering, SECRETARIA DE ESTADO DA SAÚDE DE GOIÁS - SESGO, GOIANIA/BRAZIL

Background: The World Health Organization (WHO) recommends that health care systems should be able to identify, report and recalls all incidents, especially AE. A few authors have developed a generic system risk model to search and to analyze the root causes of AE.

Objectives: The aim of this work was identify the occurrence of adverse events (AE) and injuries related to the use of the magnetic resonance imaging (MRI) equipment informed in incident notification systemand to classify them accordingly to their causes following the Shepherd's model.

Methods: The AE notifications were collected from the Manufacturer and User Facility Device Experience Database (MAUDE). The AEs were classified based on Shepherd's model (The Systems Risk Model - SRM). The concept of AE used in this study was "events that produce, or potentially may produce unexpected or unwanted outcomes that affect the safety of patients, users or others".

Results: We analyzed 91 AEs related to injury occurred in the last year (period from 01/01/2014 to 12/31/2014). Three cases were excluded because they are repeated. From the remaining 88 cases, the study showed that 71 AEs were related an injuries in patients (80.7%), 11 EAs AEs were related an injuries in MRI technicians (12.5%), 05 EAS were related an injuries in MRI professional maintenance (5.7%) and 01 EA was related only to damage of device (1.1%). The causes of injuries in patients were burn skin, the most frequent one (61 cases, 69.3%), collision with ferromagnetic objects (4 cases, 4.6%), and mechanical chock between patient and magneto (3 cases, 3.4%), and others (3 cases, 3.4%). The causes of injuries in MRI technicians were mechanical chock between operator and MRI table (7 cases, 8.0%), collision with ferromagnetic objects (3 cases, 3.4%) and fall of the technologist (1 case, 1.1%). The causes of injuries in MRI professional maintenance were collision with ferromagnetic objects (4 cases, 4.6%) and helium gas escape (1 case, 1.1%). Our work classified the AEs based on Shepherd's model, being the operator component the most frequent to the direct cause (46 cases, 52.3%) and all 46 cases were related to the education/ training sub-component, the root cause. Of these AEs, 27 (30.7%) could not be analyzed because of the limited information provided in the MAUDE.

Conclusion: We think that Shepherd's model is very useful to identify causes and assess the risks of AE surveyed. For future studies, we propose to use this model to evaluate the AE related to the use of radiology equipment like digital x-ray and mammography.

PS16.036 - Investigation on solar aging in sunglasses by developing of automated prototype for sun exposure of lenses Author(s): Leonardo M. Gomes¹, <u>Homero Schiabel²</u>, Liliane Ventura¹ ¹Electrical Engineering Department – Eesc, University of São Paulo, São Carlos/BRAZIL, ²Dept Of Electrical Engineering, University of São Paulo, São Carlos/BRAZIL

The first Brazilian standard for UV protection sunglasses, NBR15111, was drafted and published in 2003, hitherto a faithful copy (mirror) of European, BSEN1836 standard. From 2010 to 2013, the School of Engineering of São Carlos (USP) made contribution in the review and drafting of this standard and the main change so far is on the extension of the UV range analysis for protection of sunglasses, i.e. from 280 - 380nm to 280-400nm and the resistance to irradiation test increased from 25h to 50h. In previous studies, there are indications that ultraviolet protection degrades with use and exposure of sunglasses to natural ultraviolet radiation. Thus, this project aims to build a prototype for irradiating sunglasses lenses, where one of the spectacles will be submitted to the solar simulator; and the other to the prototype. This prototype consists of a box for protecting mechanical and electronic systems, an automatic lid and a laser cut acrylic panel, which houses 100 lenses arranged in the use position and which will be irradiated by the sun from sunrise until sunset. The lid opens automatically; the panel is ejected by a mechanical system from inside the box and should turn towards the sun, so

that the lens will always be irradiated from the front by the sun. The data about azimuthal angular position of the Sun for the city where the prototype is located is previously calculated and recorded on the memory of the prototype. Sensors will be installed to close the cover and protect the glasses of undesirable weather conditions and to determine the ultraviolet index to which the lenses are being subjected to. The exposure time and UV index will be recorded and automatic opening or closing the lid may also be interfered by a PC by online software. Previously to the lenses being placed on the panel, spectroscopy will be performed, in the range of 280nm - 2000nm, at 5 different positions imposed by the standard at 3 different temperatures: 230C; 50C; 350C; also polarization measurements of the lenses will be performed; as well as the flammability and resistance to impact tests. Just sunglasses in compliance with the standards will be subject of the study. All these tests will be performed over again after every 30 days of exposure. Figure 1 shows the prototype's mechanical design and how it should operate. Mechanical parts are being fabricated following the illustrated design.

PS16.037 - Integral clearance of medical rooms based on the type of medical treatment ensures a safe environment upon first use

Author(s): <u>Casper Smit</u>, Bärbel Van Den Berg Medische Technologie, Medisch Spectrum Twente, Enschede/ NETHERLANDS

Aim

Patient and medical staff safety can only be guaranteed in a medical environment that is safe in terms of electricity, (ionizing/non-ionizing/ thermal) radiation, liquids, gases and particles. The specifics of each type of medical treatment, e.g. invasiveness of treatment or nature of radiation, define which safety measures are required to provide a safe environment in a medical room. As all different types of safety measures have to act simultaneously, we propose an integral and multidisciplinary approach for acceptance testing of medical rooms.

Current situation

Our institute is building a new hospital. All new medical rooms have been built over a period of five years since the first sketches and initial determination of the requirements. For several rooms the intended types of medical treatment have changed during the construction period due to advancing methods of treatments or new medical equipment. Sometime these changes require additional safety measures. We also noticed that end users and supporting staff have an incomplete overview of aspects of newly constructed rooms that have to be validated. Additionally, responsibilities but also technical documentation of medical rooms are scattered among various officers and departments within the hospital. This lack of overview of all safety measures for each single room makes it impossible for the physician or head of department to take responsibility for a safe medical procedure upon first use. In order to ensure a safe environment upon first use, but also creating a solid base to handle future changes in types of medical treatment in a room, we have used an integral and multidisciplinary approach for acceptance testing of our newly built medical rooms.

New procedure

Our procedure to check the safety measures in medical rooms is based on the intended types of medical treatment, including the used medical equipment. The intended types of medical treatment (defined by answering questions such as "Is medical electrical equipment intended to be used in direct contact with the patient?") must be agreed on by both the responsible physician and the head of the department in the initial phase of the construction period. During construction, changes in intended use are checked against the safety measures. After building the responsible officer (e.g. the radiation protection officer) must confirm that the safety measures taken in the room indeed match the intended use. The intended types of medical treatment and all checked safety measures are presented in one integral overview. Finally, the head of the department and the responsible physician share responsibility for final acceptance of the medical room based on the intended types of medical treatments.

Conclusions

Current methods for acceptance testing of medical rooms do not guarantee the safety of patients and staff. By introducing a procedure of integral and multidisciplinary acceptance testing of medical rooms based on the type of medical treatments, a safe environment upon first use is ensured. Our next steps will focus on the implementation of a change management procedure for medical rooms to guarantee the safety of a room during its life cycle.

PS16.038 - Real-Time Posture Classification and Correction based on a Neuro-Fuzzy Control System

Author(s): Leonardo P.D.D.V.M. Martins¹, Hugo Pereira¹, Bruno Ribeiro¹, Rui Almeida¹, Ana Teresa Gabriel², Cláudia Quaresma², Adelaide Ferreira¹, <u>Pedro Vieira¹</u>

¹Physics, Faculty of Sciences and Technology New University of Lisbon, Caparica/PORTUGAL, ²LIBPhys-UNL, Department of Physics, Faculty of Sciences and Technology New University of Lisbon, Caparica/PORTUGAL

Sitting position is one of the most common postures found in an office environments leading to long periods of time in that position. Assuming a poor posture in a sitting position during these long periods can even set this situation to worsen conditions, as this can lead to several health problems, namely back, shoulder and neck pain. To support the efforts in reducing such ailments, intelligent chairs are being developed in order to detect and correct poor sitting postures and alert the users to prolonged sitting behaviours. Here we describe the development of a chair prototype equipped with air bladders in the chair's seat-pad and backrest, a pneumatic circuit composed of air and vacuum pumps to respectively inflate and deflate said bladders and piezoelectric gauge pressure sensor to measure the internal bladder pressure (Figure 1). The air bladders, which were previously manually manufactured, are now industrially assembled to improve reproducibility. We use a machine learning approach by using an Artificial Neural Network Algorithm (using 15 neurons, 1 hidden layer, tansig as the transfer function, and resilient backpropagation as the training function) to classify 12 standard sitting postures (Seated postures used in the experiments and their respective class label: seated upright, leaning forward, leaning back, leaning back with no lumbar support, leaning left, leaning right, right leg crossed, right leg crossed, leaning left, left leg crossed, left leg crossed, leaning right, left leg over right, right leg over left.) with an overall score of 81%. We optimized the classification to around 87% using Decision trees and the anthropometric information of the user, such as height and weight. Fuzzy Logic was introduced to the existing Algorithm by using as input the Centre of Pressure, the Posture Adoption Time and the Posture Output from the existing Neural Network Algorithm. This new Neuro-Fuzzy Algorithm now takes into account intermediate postures between the previous standard and the time period adopted in each posture, prompting the development of a Fuzzy Control System that inflates and deflates each bladder during a specific period of time according to the Fuzzy Output.

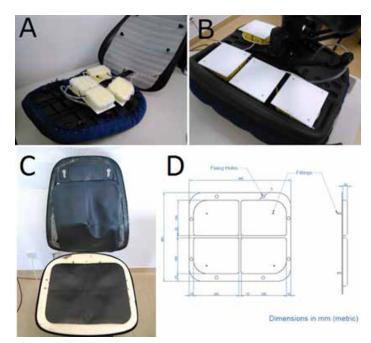

Figure 1: A – Placement of the pneumatic control modules in the back rest; B – Placement of the pneumatic control modules in the seat pad; C – Placement of the air bladders in the inside the paddings of the chair. D – Industrial design of the air bladders from the second prototype

PS16.039 - Management of electromagnetic interferences in healthcare facilities - A Review

Author(s): <u>Gnahoua Zoabli</u>¹, Nabilath A. Akimey² ¹Biomedical Engineering, CSSS du Lac-des-Deux-Montagnes, St-Eustache/CANADA, ²Institute Of Biomedical Engineering, University of Montreal, Montreal/CANADA

Management of electromagnetic interference has become a major issue in Quebec hospitals. Several discussions on this issue have been held between managers of medical technologies departments. Some hospitals tend to allow more widespread use of wireless technologies while others continue to formally ban them. As a contribution, we present a review of literature on devices that may transmit frequencies that can interfere with medical devices, such as pagers, cordless phones, cell phones, tablets, portable radio transceivers, tracking devices, laptop computers, telecommunications antennas and medical equipment. Because of its wide availability, portability and accessibility, cell phone is the most popular wireless technology. The greatest distance of immunity known to date is 6 m, excluding the combination effect of the agglomeration of several electromagnetic sources in the same area. From our literature review it is safe to allow cell phones in a health facility if the usage is made out of a nursing unit, regardless of the vocation (critical or general Medicine) or outside of a diagnostic or medical department (medical imaging and laboratories). By cons, for medical imaging technologists carrying a pocket dosimeter (immunity of 38 cm), the use of cell phones might be banned while still carrying the dosimeter. The nuisance caused by cell phones, their need for regular disinfection by their owners and the protection of privacy should be considered by healthcare facilities in preparation of regulations, procedures or policies on health and safety at work. A subsequent study should

analyze electromagnetic interference of medical equipment between them. Hospitals that have already authorized the use of cell phones on the care units would benefit requiring phones with Flight mode enabled, pending the development of a Hospital mode that inhibits, in addition, sound recording, video camera and forces the phone ring mode to vibration.

PS16.040 - Hospital Mode Design in Smartphones and Tablets for Wireless Security in Healthcare Facilities

Author(s): <u>Gnahoua Zoabli</u>¹, Akimey A. Nabilath² ¹Biomedical Engineering, CSSS du Lac-des-Deux-Montagnes, St-Eustache/CANADA, ²Institute Of Biomedical Engineering, University of Montreal, Montreal/CANADA

Despite the presence of policies and procedures regarding the regulation of the use of wireless devices in hospitals, they are hard to make effective for employees, patients and visitors. Considering many concerns related to electromagnetic interferences and patient privacy, we suggest a more realistic approach based on the design of a Hospital Mode in smartphones and tablets. Hospital Mode manages electromagnetic interference, noise nuisance, protection of privacy, sound level and inhibits video camera and forces the phone ring mode to vibration in non-clinical area. A key aspect of Hospital mode resides on its ability to switch automatically the smartphone or tablet ON and OFF depending on the area of the hospital. We recommend a regulation towards smart building integrating dedicated frequencies bandwidth to manage Hospital Mode for any compliant wireless technology.

PS17 - TRACK 17: EDUCATIONAL AND PROFESSIONAL ACTIVITIES

PS17.001 - A discipline about Human Factors Engineering and Usability applied to Medical Devices for under graduation courses using Active Learning techniques

Author(s): Renata A.R. Custódio¹, <u>Ana P.S.S. Almeida²</u>, Rodrigo M.A. Almeida³, José A. Ferreira Filho³, Alexandre C.B. Ramos¹ ¹Institute Of Mathematics And Computer Science, Federal University of Itajubá, Itajubá/BRAZIL, ²Institute Of Industrial Engineering, Federal University of Itajubá, Itajubá/BRAZIL, ³Institute Of Systems Engineering And Information Technology, Federal University of Itajubá, Itajubá/BRAZIL

This paper proposes a new discipline with hybrid methodology mixing traditional approach and Project Based Learning, using some active learning techniques as peer instruction to teach Human Factors and Usability focused on Medical Devices. This course will be offered in Federal University of Itajuba for undergrad students in Computer Sciences, Information System, Computer Engineering, Control and Automation Engineering, Electronic Engineering and Industrial Engineering. The dynamics of the classes will be guided by working in teams of students and tutoring in the proposed Project Based Learning themes. Some formal lectures about specific concepts and methods throughout the development and analysis of the proposed problems will also be held. It is expected to have a greater conceptual gain with a higher engagement by students. To evaluate the student achievement, an assessment will be applied to the end of the course, targeting both the knowledge gain and the student's motivation.

PS17.002 - The medical equipment management inside the accreditation process: a comparison with the Brazilian accredited hospitals

Author(s): João E. Côrrea¹, <u>Rodrigo M.A. Almeida</u>², João B. Turrioni¹ ¹Institute Of Industrial Engineering, Federal University of Itajubá, Itajubá/MG/BRAZIL, ²Institute Of Systems Engineering And Information Technology, Federal University of Itajubá, Itajubá/BRAZIL

This work aims to analyze the process of management of medical equipment in hospitals and compare the views of JCI, QMENTUM and ONA, a Brazilian accreditation model, on this topic. To the date these three accreditation models are the ones being used in Brazil. The survey results showed that for the Brazilian hospitals the accreditation model ONA becomes more efficient since it more in line with the reality of Brazilian hospitals.

PS17.003 - The Medical Physics M.Sc. program at the National University of Mexico:

Results and lessons learned after 100+ graduates Author(s): María-Ester Brandan

Instituto De Física, Universidad Nacional Autónoma de México UNAM, Mexico City/MEXICO

The M.Sc. (Medical Physics) program at the National Autonomous University of Mexico (UNAM) is one of two in the country. After 17 years of activities, it has graduated more than 100 students who mostly work (60%) in clinical activities. A large fraction (26%) of the graduates is presently studying, or has already completed a Ph.D. in medical physics. 8% of our former students work in non-clinical activities related to medical physics. The academic program has been revised in 3 occasions (the original 1997 curriculum, and 2003 and 2009 revisions). Accumulated experience, increased available human resources, and recently published international recommendations for educating medical physicists have determined the curricular changes. The most visible operational changes have been higher entrance requirements and promotion of a more efficient use of the time during the thesis project execution. The main obstacle for a rapid graduation has always been the thesis completion. Thanks to various strategies, graduation time including the thesis defense, has decreased from almost 4 years at the start to 2.7 years now. The areas for the required thesis have always been relatively wide and continue to expand as medical and biological physics develop in the country. Former students who get a doctorate and join Mexican universities are having an impact in the development of new research groups. Currently, the UNAM Physical Sciences Graduate program considers establishing the medical and biological physics fields of knowledge as academic options within its Ph.D. in Physics.

PS17.004 - An Experience on the dosimetry of HDR Brachytherapy Treatment Planning of Cervical Carcinoma at BPKM Cancer Hospital, Nepal

Author(s): Surendra B. Chand

Radiation Oncology, BPKM cancer Hospital, Bharatpur/NEPAL

Propose: To identify the status of Brachytherapy planning by evaluating the bladder and rectum dose of cervical carcinoma patients those undergone HRD brachytherapy for six years.

Methods and materials: Fifteen hundreds and ten patients, from 2005 to 2010, were taken for this study. In total four thousands five hundreds and thirty treatment plans were done to complete all patients' treatment. The Fletcher Suit Delclos FSD types of applicators, orthogonal radiographs were used for dosimetry. Radio opaque dye and rectal probe is used to identify bladder and rectum location respectively.

Results: 1510 patients completed all three cycle of treatments. Maximum patients, 1055 (69.87%), have received bladder dose less than 4 gray per fraction. Less than five percent patients have received bladder dose more than 71 % of prescribed dose per fraction. Similarly; In case of rectum dose, total 1324 (87.68%) pts has received rectal dose less than 57 % per cycle. 1324 (87.68%) pts have received dose less than four gray per fraction.

Conclusions: Maximum patients were treated with bladder and rectal dose less than 60 Percentages of point A dose with satisfactory pear shape. Normal organ dose should minimise, however, it should not produce a significant reduction in disease control.

Keywords: HDR Brachytherapy, Remote after loading, ICRU38, cervical carcinoma patients.

PS17.005 - Health IT Education for Clinical Engineers Author(s): <u>Thomas M. Judd</u>¹, Elliot B. Sloane²

¹Clinical Technology, Kaiser Permanente, Marietta/GA/UNITED STATES OF AMERICA, ²Executive Director, CHIRP, Blue Bell/PA/ UNITED STATES OF AMERICA

Relevant Health IT education content and opportunities for Clinical Engineers (CE) and health technology management (HTM) leaders, both in developed and developing countries, will be explored through three case studies:

1. the US Veterans Administration (VA) HTM Health IT education program in 2015

2. a global program developed by ACCE and IFMBE-CED in 2015

3. Consultations for Ministry of Health Health IT in developing countries in 2014-2015

PS17.006 - Professional Development of Medical Physicists in Radiation Oncology for the Commonwealth of Independent States

Author(s): Valeriy A. Kostylev¹, <u>Marina V. Kislyakova¹</u>, Mikhail N. Lysenko², Dmitriy V. Ulanov², Dmitriy V. Kostylev¹, Pavel V. Kazantsev¹ ¹Association of Medical Physicists in Russia, Moscow/RUSSIAN FEDERATION, ²State Atomic Energy Corporation "ROSATOM", Moscow/RUSSIAN FEDERATION

The need for the training and continuing professional development (CPD) of medical radiation physicists in Russia and CIS countries has dramatically increased lately due to the activation of the purchases of the state-of-the-art equipment and cutting-edge technologies for the modernization and reconstruction of radiation therapy departments. The efficiency of radiotherapy treatment for cancer patients and use of the state-of-the-art accelerator facilities highly depends on the qualification and number of medical physicists. There is currently an acute shortage of medical physicists in the CIS region. The qualitative professional training of medical physicists is the priority task in these countries. The fulfilment of this task has become possible due to the cooperation between the IAEA, Rosatom and Association of medical physicists in Russia (AMPR) who initiated and launched two IAEA Technical Cooperation (IAEA TC) Projects on Building Capacity for Medical Physics in Radiation Oncology for the Commonwealth of Independent States. The International Training Centre (ITC) of the Association of medical physicists in Russia based at the N.N. Blokhin Russian Cancer Research Centre is the main counterpart in the 2012-2015 IAEA TC Projects designed for the Russian-speaking medical physicists of the CIS countries to improve their knowledge and skills in the radiotherapy physics. The objective of the regional projects is to level differences in radiation oncology among CIS countries through education and training of medical physicists. ITC plays a key role in the implementation of the Projects by hosting trainees and executing training courses and practical sessions. During three years (2012-2014) of the IAEA TC projects 10 regional courses of 1-3 week duration were conducted. A 3-month group fellowship on practical aspects of medical radiation physics in radiotherapy was organized for 5 fellows from Kazakhstan, Kyrgyzstan, Moldova, Tajikistan and Uzbekistan. A total of 197 medical physicists were trained from 10 CIS Countries (Azerbaijan, Armenia, Belarus, Kazakhstan, Kyrgyzstan, Moldova, Russia, Tajikistan, Uzbekistan, Ukraine) and Lithuania. The table below shows the number of trainees from each country:

Country	Number of trainees
Azerbaijan	6
Armenia	6
Belarus	21
Kazakhstan	33
Kyrgyzstan	5
Moldova	9
Russia	67
Tajikistan	8
Uzbekistan	3
Ukraine	30
Lithuania	9
Total	197

PS17.007 - Assistive Technologies in Biomedical Engineering Education

Author(s): Lenka Lhotska¹, Tatjana Welzer²

¹Department Of Cybernetics, Czech Technical University in Prague, Prague /CZECH REPUBLIC, ²University of Maribor, Maribor/SLOVE-NIA

At present the need for interdisciplinary education supporting development and practical application of assistive technologies (AT) is continuously growing. It is given by development of demographic and age structure of the population and the need to ensure support and safety of elderly and handicapped people with increased health and other risks. Currently there is lack of graduates having interdisciplinary theoretical education in the fields of electronics and information and communication technologies and simultaneously focusing on the whole complex of practical needs of applications related to assistive technologies (AT). When we started developing courses in this area we realized that the closest and already established study program is Biomedical Engineering. The students get required courses in electronics, information and communication technologies and physiology. Thus we can relatively easily extend the curricula with new topics needed for managing the area of assistive technologies.

We are also well aware of the fact that the universities try to support education of students with special needs as much as possible. However, the requirements on support range from very simple tools up to very sophisticated systems. This area is not yet mapped very well and needs more elaborate review.

Although this area is very challenging it also offers opportunities for direct involvement of students with special needs into research projects focused on development of assistive technologies because they know the problems very well and as team members they can contribute to successful development of new more advanced tools, devices and systems.

Although it seems that all new technologies are somehow covered by existing courses in electronics, informatics, telecommunications, etc., we see and the practice proves it frequently that these courses are not properly interconnected. Nowadays we educate engineers specialized in electronics, or telecommunications, or informatics. But many of them are lacking the system view on an interdisciplinary problem. They often understand a narrow area very deeply but they do not see its connections to other neighboring fields that are necessary when developing a complex system.

In addition to purely technical courses there must be introduced courses that cover problems of handicapped people (for example their sensing limitations linked with necessity of having different computer or device interfaces, movement limitations – different design of equipment). The students must acquire knowledge about different types of handicaps and means how to compensate them. Further they must be educated in the design of tools and devices with respect to cognitive impairments, vision and hearing problems, supported communication, supported mobility; assessment and requirement analysis, and related topics. Another large area of interest is eAccessibility, namely improvement of access of handicapped people to electronic resources, including Internet. And last, but not least the legal, ethical and social issues must be considered since we are working with sensitive data similarly to medical domain.

In the paper we present examples of courses on AT and involvement of students and/or users with special needs.

PS17.008 - Future-Proofing Physics and Engineering in Medicine Author(s): $\underline{\mathsf{Kwan}}\ \underline{\mathsf{Hoong}}\ \underline{\mathsf{Ng}}$

Department Of Biomedical Imaging, Faculty Of Medicine, University of Malaya, Kuala Lumpur/MALAYSIA

Medical physicists and biomedical engineers have played a pivotal role in the development of new technologies that have revolutionized the way medicine is practised today. They have been transforming scientific advances in research laboratories to improving the quality of life for patients. Indeed innovations such as computed tomography, positron emission tomography, magnetic resonance imaging, linear accelerators, artificial hearts, robotic surgery and bionic limbs have collectively improved the medical outcomes for millions of people. The emergence of precision medicine exemplifies the potential of emerging science to improve patient outcomes and support efficient health delivery. The multi-disciplinary and cross disciplinary nature lends them an edge in research innovation. However, current emphasis tends to only enhance the specific skill development and competency at the expense of future roles and opportunities. This emphasis is largely driven by financial and political pressures for optimizing limited resources in health care. This has raised serious concern on the ability of the next generation to innovate and lead the development of new technologies. The use of nanoparticles to treat tumours, targeted radionuclide therapy, high-intensity focused ultrasound, electromagnetic wave ablation and image-guided surgery are just some areas challenging the old paradigm. We should venture into and explore non-traditional and blurred boundaries between various medical disciplines from diagnosis to treatment.

How do we future-proof the next generation? We must reform the existing curriculum by embracing contemporary sciences such as molecular biology, systems biology, nanotechnology, advanced materials, bioinformatics, spectroscopy, etc. We should encourage collaboration and interchange of ideas between medical and non-medical physicists; biomedical and non-biomedical engineers. The next-generation must be able to work or lead effectively as part of a collaborative multidisciplinary team. They should be able to participate in intelligent discussions with surgeons, neurologists, cardiologists, imaging specialists, pharmacologists, technologists, statisticians, computer scientists, spectroscopists and biologists to various extent. Furthermore, they must also engage with the public on their role in healthcare and research activities. With the right approach, the next generation will then look forward to making continued and significant contributions to the "new world" medicine. As it is, various global health challenges await the ingenuity, versatility and curiosity of medical physicists and biomedical engineers.

PS17.009 - Nuclear and Radiological Emergencies - First IAEA Training Course for Medical Physicists

Author(s): <u>Fridtjof Nuesslin</u>¹, Ahmed Meghzifene² ¹Radiooncology, Technische Universität München, Munich/GER-MANY, ²Dosimetry And Medical Radiation Physics, IAEA, Vienna/ AUSTRIA

The role of the medical physicist in preparedness and response to nuclear and radiological emergencies (NRE) has been discussed at previous joint IOMP-IAEA-WHO workshops (WC-2012, ICMP-2013). There was broad agreement that by virtue of their academic education and clinical training Medical Physicists with their expertise in radiation protection (e.g. radiation dosimetry, dose measurement, etc.) may be an added value of the workforce dealing with NRE. Most current medical physics curricula include topics relevant for NRE, like radiation dosimetry, handling radioactive materials and assessment of exposure, instrumentation, radiation monitoring, shielding, etc. However, specific training is essential – particularly in countries with no adequate emergency preparedness infrastructure - to enable a clinical medical physicist to be fully prepared to

respond efficiently in an event of NRE, within a national or local emergency response plan. To improve preparedness of the clinical medical physicists for events of NRE and to set a standard for knowledge acquirement, the IAEA developed a specific training package for medical radiation physicists. The training package consists of 14 modules, which can be delivered through a one-week Workshop. Additionally to the above topics, the course program includes specific training on protection strategies, medical management, psycho-social effects, impacts on mental health and effective risk communication. The 1st Workshop to be held shortly after theWC2015 will be organized by the IAEA and hosted by the University of Fukushima, in co-operation with the National Institute of Radiological Science (NIRS). The purpose of the Workshop is to provide the participants with a good understanding of their potential complementary roles in NRE situations, and to prepare them to contribute effectively to support the response to an NRE situation as identified in emergency preparedness plans. This pilot Workshop will target trainers who have the potential to train other medical physicists in their countries as well as other health care professionals in the response to NRE situations. Replication of this Workshop in due time is expected in order to increase the number of medical physicists who will be fully prepared to support NRE worldwide.

PS17.010 - Academic Real Time Digital Medical Image Processing Environment

Author(s): Rodolfo D.S. Ribeiro, Rianne B. Venancio, <u>Ana Cláudia</u> Patrocinio

College Of Electrical Engineering, Federal University of Uberlandia, Uberlandia/BRAZIL

In this work we developed an academic tool for teaching Digital Medical Image Processing in a Graphical interface using functions developed in MatLab. This platform makes possible the visualization of histograms, Fourier Spectra and the image in real time, with their modifications occurring as long as the user alter the image. We included the following functions in the software: brightness control, contrast control, contrast enhancement, histogram equalization, image inverse, image normalization, exponential transformation, gradient filter, logarithmic filter, Sobel filter, sum with original image, arithmetic average, geometrical average, Gaussian filter, median, maximum, minimum. We also included some noise options: exponential noise, gama noise, Gaussian noise, ReyLeight noise, Pepper noise, Salt noise, pepper and salt noise, white noise. Another interesting possibility is the comparison between the processed image and its original version besides the histogram and Fourier Spectra. A threshold tool is available to create binary images from the processing image. This process is possible anytime in the processing flow. It is possible to visualize the entire processing flow in an action log and save the image, histogram or Fourier Spectra in commercial image formats, such as .jpg or .tif. In addition, both common format images and DICOM are available in the software. In digital image processing classes in Federal University of Uberlândia, professors are already using the tool to show how some image processing functions work, besides a student who is developing his final undergraduate thesis in Biomedical Engineering in our system.

PS17.011 - Detection of Eye Movement; possibility how to control world

Author(s): Lukas Peter, Iveta Neprasova, Martin Cerny VSB - Technical University of Ostrava, Ostrava/CZECH REPUBLIC

Electrooculography is one way how to detect eye movement. Nowadays represents this method a possible compromise between the price and accuracy of equipment. Development of this method also benefits from the contemporary trend of miniaturization when electrode can be attached e.g. to the goggles. It is not necessary to have the electrodes attached on your face. Hardware solution of electrooculography and visualization software is presented. Furthermore mathematical dependency output voltage on input eye movement is determined. This work also brings the electrooculography method and principles to the awareness of students.

PS17.013 - Career Progression for Medical Physicists Author(s): <u>Wiiliam H. Round</u>

Engineering, University of Waikato, Hamilton/NEW ZEALAND

Some clinical medical physicists are employed under negotiated national/state/ provincial employment awards or contracts. These may be specific to medical physicists, or they may cover other clinical scientific professions as well. These awards often inherently define a career path for the physicists. In most countries a career path is not defined in any way, and in some countries a medical physics is not even recognised as a profession despite it being listed as such by the International Labour Organization.

But most medical physicists are not under an employment award, so they do not have a recognized career path to follow. Awards often provide guidance as to how a medical physicist's career is progressing and they often define the level of responsibility and expertise required at each stage of the structure. This provides certainty to the physicists as to what they can achieve career-wise and what they must do to progress.

A survey of existing employment structures and awards for medical physicists was carried out in early 2014. In some cases these were found to be little more than pay scales, but in some cases the documents are very detailed and run to dozens of pages. The more detailed documents define multi-level career structures with the degree of responsibility expected at each level and what must be achieved to advance through from one level to the next being explicitly defined. The more detailed awards inherently define how a medical physicist's career should progress and to offer guidance to those who employ medical physicists as to how they can develop career structures that will enable their employees to optimise their career and performance.

A well-designed award will also define minimum education and training requirements, require employers to make provision for the physicists' continuing professional development, deal with issues that arise when a physicist leaves the workforce for a period of time and wishes to re-enter it, and encourage and provide for joint clinical and academic appointments.

While regional medical physics societies are professional and not industrial organizations, they should all have career progression policies in place to offer guidance to both clinical medical physicists and their employers to ensure that the members of the clinical physics workforce can develop to their full potential. This will lead to improved medical physics professional standards and improved health care delivery.

PS17.014 - IOMP-W – the International Organization for Medical Physics Women Subcommittee

Author(s): <u>Magdalena Stoeva</u>¹, Virginia Tsapakis², Simone Kodlulovich³, Anchali Krisanachinda⁴, Nicole Ranger⁵, Teh Lin⁶, Amanda Cherpak⁷, Jamila Al Suwaidi ⁸, Efi Koutsouveli⁹, Pola Platoni¹⁰ ¹Medical Imaging Dept., Medical University - Plovdiv, Plovdiv/BUL-GARIA, ²Konstantopoulio General Hospital, Athens/GREECE, ³National Comission of Nuclear Energy, Rio de Janeiro/BRAZIL, ⁴Radiology, Faculty of Medicine Chulalongkorn University, Bangkok/ THAILAND, ⁵c/o Landauer Inc, Glenwood/IL/UNITED STATES OF AMERICA, ⁶Fox Chase Cancer Center/Temple University, Philadelphia/PA/UNITED STATES OF AMERICA, ⁷Nova Scotia Cancer Centre, Halifax/NS/CANADA, ⁸Dubai Health Authority, Medical Education Department, Dubai/UNITED ARAB EMIRATES, ⁹Ygeia Hospital, Athens/GREECE, ¹⁰Attikon Hospital, Athens/GREECE

The International Organization for Medical Physics Women Subcommittee (IOMP-W) has been recently established to meet the demands of the women in our professional society for an official representation in the governing body.

International Organization for Medical Physics

The objective of IOMP-W is in compliance with the main IOMP mission and directives to advance medical physics practice worldwide by disseminating scientific and technical information, fostering the educational and professional development of medical physicists, and promoting the highest quality medical services for patients.

IOMP-W Functions:

Develop, implement and coordinate tasks and projects related to the role of females in medical physics scientific, educational and practical aspects.

To disseminate the experiences, good practice and learning within IOMP NMOs and other relevant accessible areas/across the globe.

Popularize the role of the women in medical physics and encourage female medical physicist to advance in the profession.

Organize international cooperation in medical physics and related specialties.

Provide regular status/progress updates to the IOMP on all tasks and projects related to the IOMP Female Group.

IOMP-W has currently focused on various dissemination activities to popularize the committee among the professional society. The major dissemination activities are directed toward the development of IOMP-W section under the main IOMP website, various advertising materials, participation in scientific and professional events, establishing and strengthening our relations with other organizations. Parallel to these dissemination activities IOMP-W took a leading role in a worldwide survey to access the role of the women in the field of medical physics.

IOMP-W is also turning to the past to memorize and honor the women that contributed towards the development of Medical Physics. Special posters have been developed to present the work of Marie Curie, Irène Joliot-Curie, Goeppert-Mayer, Rosalyn S. Yallow, Harriet Brooks, Chien-Shiung Wu.

IOMP-W are planning to extend these activities to a larger scale to cover IOMP Regional societies and NMO's to popularize the role of women MP's and contribute towards the improvement of our profession worldwide.

PS17.015 - AAPM/IOMP Used Equipment Donation Program Author(s): <u>Mohammed K. Zaidi</u>

Idaho State University, Houston/UNITED STATES OF AMERICA

The objective of the Used Equipment Donation Program (UEDP) of the American Association of Physicists in Medicine (AAPM) and the International Organization for Medical Physics (IOMP) is to help developing countries acquire used equipment in good working condition through donations of used equipment made through AAPM/ IOMP. The UEDP insists that the used equipment donated is in good working condition and verifies as-far-as possible that it meets the need of the recipient developing country (DC). The guidance in the 'WHO Guidelines for Healthcare Equipment Donations' (WHO, 2000) is adhered to and relevant regulations are followed. Technical assistance is given, if need in installation or training is needed. The recipient pays for the handling and shipping and some financial help is available in special cases. UEDP reports are published in the IOMP publication Medical Physics World (MPW).

PS18 - TRACK 18: GENDER, SCIENCE AND TECHNOLOGY

PS18.001 - Bone density measurements in strontium-rich bonemimicking phantoms using quantitative ultrasound Author(s): <u>Bisma Rizvi</u>, Eric D. Silva, Jahan Tavakkoli, Ana Pejovic-

Milic Physics, Ryerson University, Toronto/CANADA

Objectives: Osteoporosis is a disease characterized by decreasing bone density and microarchitectural deterioration of bone tissue, which enhances bone fragility and fracture risk. Strontium renalate, is reported to promote bone formation and inhibit bone resorption, thus maintaining and increasing the bone mineral density (BMD) of osteoporotic individuals. Consumption of the strontium renalate for more than six months affects BMD scores, as assessed by dual energy X-ray absorptiometry (DEXA). Such DEXA-determined BMD scores often present a positive bias. Self-administration of strontium-based supplements, which is becoming prevalent, is expected to have the same impact on bone density measurements as strontium renalate.

The objectives of this work are: (1) to develop novel bone-mimicking phantoms containing different concentrations of strontium, and (2) to investigate the effect of bone strontium content on bone mineral density (BMD) obtained by a bench-top transmission-through quantitative ultrasound (QUS) system.

Materials and Methods: Preliminary investigation was performed using the bench-top QUS beam on a new generation of bonemimicking phantoms composed of hydroxyapatite and gelatin in an airtight container with dimensions of 2.5×6.5×6.5 cm³. These bonemimicking phantoms contained different concentrations of strontium and/or with a varying bone density. Using the bench-top QUS system, the broadband ultrasound attenuation (BUA) and speed of sound (SOS) of the phantoms were measured in an ultrasound frequency range of 0.5-1.3 MHz.

Results: Measurements using the bench-top QUS system showed a strong dependency of the BUA with the BMD (p < 0.001). On the other hand, dependency between the SOS and the BMD was not statistically significant (p = 0.095). Moreover, increasing bone strontium concentrations up to 3 mol% strontium showed no effect on the BUA (p = 0.749) or the SOS (p = 0.862) values measured in this study.

Conclusions: The results obtained in this study suggest that the QUS is a promising diagnostic tool capable of providing BMD scores independent of bone strontium content. This could be relevant in QUS evaluations using commercially available clinical systems in individuals who are being treated for osteoporosis using strontium-based drugs or through self-supplementation with various strontium compounds.

PS19 - TRACK 19: BIOPHYSICS AND MODELLING

PS19.001 - Numerical Modeling Of The Electrical Impedance Method Of Peripheral Veins Localization

Author(s): Mugeb B. Al-Harosh, Sergey I. Shchukin Medical And Technical Information Technology, Bauman Moscow state technical university, moscow/RUSSIAN FEDERATION

Veins in biological tissue produce electrical impedance to the alternating current passes through it. Bio-impedance method based on measuring this electrical impedance value using an array of surface electrodes has the capability of detecting peripheral veins. This paper presents the theoretical and experimental studies, reflecting the possibility of impedance method of peripheral veins localization. Mathematical model has been proposed to calculate the resistivity anomalies of vein in soft tissues and reflects the electrical impedance characteristic, depending on the location of the electrode system and the vein. A system electrode has been designed to be attached to the body in order to measure the electrical impedance value. The data obtained will determine the capabilities of the method. Experimental studies confirm the adequacy of the proposed mathematical model

PS19.002 - Modeling current density maps in the heart

Author(s): <u>Mohammadali Beheshti</u>¹, Farbod H. Foomany¹, Karl Magtibay¹, Stephane Masse², David A. Jaffray³, Kumaraswamy Nanthakumar², Sridhar Krishnan¹, Karthi Umapathy¹ ¹ryerson university, toronto/CANADA, ²Peter Munk Cardiac Centre,

toronto general hospital, Toronto/ON/CANADA, ³Radiation Physics Department, princess margaret hospital, toronto/CANADA

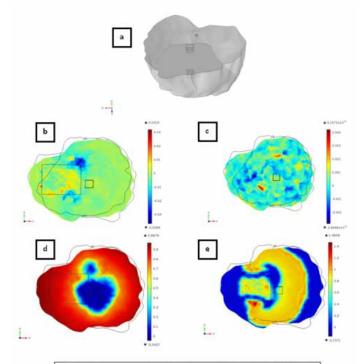

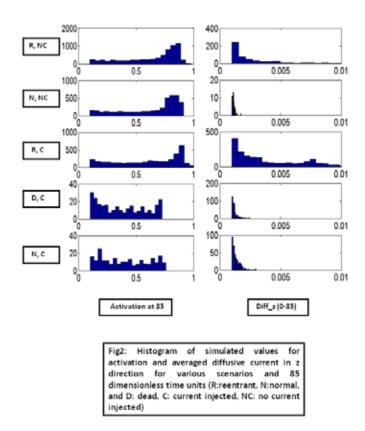

Fig1: a) Geometry of modeled heart, b) simulated diffusive current in z direction in a chosen slice for reentrant scenario, c) simulated diffusive current in z direction in a chosen slice for normal scenario, d) and e) simulated activation in the chosen slice at two different time steps for reentrant scenario (red represents active and dark blue represents cells at rest, the values are dimensionless based on Aliev-Panfilov model)

Background:

The electrophysiological state of the heart is known to vary in different heart conditions. However it is hard to measure electrical activity inside the heart tissue. Magnetic Resonance Imaging (MRI) based Current Density Imaging (CDI) is able to provide a threedimensional map of current pathways inside the tissue. However due to the experimental setup and logistics issues it is difficult to perform CDI either in ex-vivo or in-vivo hearts. Therefore generating a model that simulates CDI maps for the purpose of studying cardiac electrical activity could improve the understanding of current distributions in various heart conditions. Method:

The current density maps are simulated using Aliev-Panfilov electrophysiological model. The averaged diffusive current in the mathematical model is related to the current density and the diffusion tensor representing heart structure is extracted from Diffusion Tensor Imaging (DTI). A single source of excitation mimicking the Sinoatrial Node (small sphere in Fig1.a) is considered and two electrodes simulate the CDI electrodes (Fig 1.a). Three different heart conditions are considered for both cases of presence and absence of injected current. The condition "dead" (D) represents excitable cells while there is no natural excitation in the heart, "reentrant" (R) is created by blocking ion channels in a cubic area temporarily (Figs 1.b,d and e), and "normal" (N) in which there is natural excitation without any block.

Results & Conclusion:

Averaged diffusive current density patterns generated from the theoretical model shows the difference between states (Figs 1.b, and 1.c), Figs 1.d and 1.e show the activation maps at two time instances for reentrant scenario, the results are shown for a chosen slice. Histograms of the results (Fig 2) show the possibility of detecting various states using averaged diffusive current. This demonstrates high potential of CDI as a tool to study various heart states.

PS19.003 - Finite Element Modeling of Gelatin Phantom from Measured Impedance Spectra

Author(s): Douglas Dutra¹, Ana M.R. Pinto², <u>Pedro Bertemes-Filho¹</u>, Aleksander S. Paterno¹

¹Electrical Engineering, Universidade do Estado de Santa Catarina, Joinville/BRAZIL, ²INESC P&D Brazil, Santos/BRAZIL

Gelatin has been used as a phantom in different medical applications, as in electrical impedance spectroscopy. In this paper, the measured spectra of resistance and reactance of three gelatins with different concentrations of salt are presented. The Cole-Cole equation and the Debye model were used to fit the data by using a script written in MATLAB. The best set of these parameters offers the lower least mean square error when compared to the measured ones. The complex permittivity is then calculated as a function of frequency by using a software developed in finite element modeling (FEM), which solved the governing equations for the electrical field and potential. The measured and simulated data from FEM showed closer spectra than fitted one. It can be concluded that the FEM technique can be used to predict the impedance spectrum of gelatins as a tissue phantom. This might be a useful tool for modeling materials in biomedical, pharmaceutical and cosmetic applications.

PS19.004 - Prediction of radiation induced direct and indirect cellular damage using a novel ionisation spatial clustering algorithm

Author(s): Michael J.J. Douglass, <u>Eva Bezak</u>, Scott Penfold Medical Physics, Royal Adelaide Hospital, Adelaide/SA/AUSTRALIA

Aim:

It is accepted that clusters of DNA DSBs lead to cell death rather than individual DSBs following irradiation. Consequently, the total number of ionisation events/DSBs does not directly correlate with cell survival. A novel clustering algorithm was developed in this work to group spatially correlated ionisation events from radiation tracks to predict DSB formation.

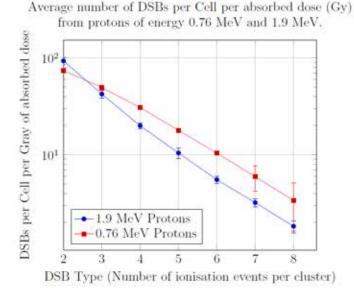

Methods:

The Monte Carlo particle interaction code RITRACKS was used to simulate ionisation track structures of various heavy ions and the corresponding production/diffusion of free radicals in water medium. A spatial clustering algorithm was developed based on a hierarchical clustering function in Matlab to group ionisation events into DSBs to predict radiation induced cell death. The definition of a DSB according to (Stewart,2001) is two or more ionisation events located on the DNA double helix within a distance of 20 base pairs (bp), corresponding to a distance of 6.8 nm. Using this DSB definition, an original ionisation clustering algorithm was applied to predict the formation of DSB clusters in a cell. It was also used to determine the relative contribution from direct and indirect radiation damage to DSB formation as a function of the LET and atomic number of the ion.

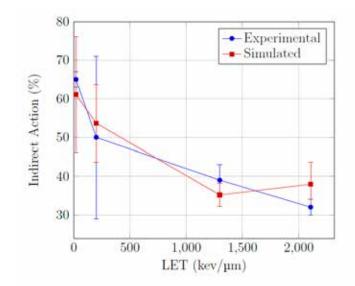

Results and Conclusions:

Figure 1 illustrates how the complexity of radiation induced DNA DSBs change with particle LET. While higher energy protons produce more ionisation events per track, the complexity of the radiation damages they produce is less compared to low energy protons.

Figure 2 shows the relative contribution from indirect radiation damage (% as compared with direct damages) with increasing particle LET. The indirect damage decreases exponentially with increasing LET. The indirect contribution from heavy ions can be as high as 70% for photons, 50% for carbon ions and 30% for iron ions in the LET range investigated.

PS19.005 - Research on Vibration of Cell Membrane of Plant Seed with Ultrasonic Excitation

Author(s): Hui Cao

School of Physics & Information Technology of Shaanxi Normal University, Xi'an/CHINA

Ultrasonic radiation for plant seed can enhance the permeability of cell membrane, which is mainly related to the mechanical effect of ultrasound. Enhancing the permeability of cell membrane improves the germination rate and production of plant seed. The shape of plant cell wall is approximately like ellipse and cell membrane as the boundary of cell is usually close to the cell wall. The elastic vibration induced by ultrasound is mainly the vibration of cell membrane from the perspective of structure and substance of cell wall and cell membrane, as cell wall can't vibrate elastically. Considering the complicated effect of cell wall and cytoplasm on the whole vibration system, it assumes that the effect can be ignored temporarily for simplifying calculation. So the cell membrane is studied as a single rectangular membrane and the frequency equation of cell

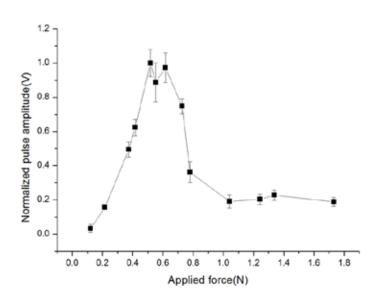

membrane under the ultrasonic excitation is obtained through the acoustical theory and biological knowledge. Provided that the cell membrane is a thin slice which is completely soft and has the same thickness. It further assumes that the cell membrane suffers uniform tension along any direction and the tension is so strong that the fluctuation of tension induced by the small deflection can be negligible in the course of vibration. Then according to the deduction of Ritz method, the vibration equation of cell membrane with ultrasonic excitation is obtained. The parameters included in the equation are the semi-major axis and semi-minor axis of ellipse, angular frequency, acceleration of gravity, surface tension and surface density. These parameters can be determined by experimental method, then the angular frequency is calculated through the equation and the resonance frequency is obtained. When the frequency of acoustic wave reaches the resonance frequency of cell membrane, it will make the cell membrane resonance and enhance the permeability of cell membrane. The vibration amplitude at this time is the largest, which makes ultrasonic energy enter the cell to the biggest extend and result in a series of biophysical effects. The conclusion of this paper is applied to the cells of gynostemma seeds and the theoretical value is found to coincide with the experiment value, thus confirming that this theoretical model has certain correctness.

PS19.006 - The Effect of Applied Force on Arterial Pulse with a New Flexible Pressure Sensor

Author(s): <u>Wenxuan Dai</u>¹, Ningqi Luo¹, Jing Liu¹, Xiaorong Ding¹, Ni Zhao¹, Yuanting Zhang²

¹Electronic Engineering, Chinese University of Hong Kong, Hong Kong/HONG KONG, ²Shenzhen Institute Of Advanced Technology, Chinese Academy of Science, Shenzhen/CHINA

Arterial pulse has always been considered as an important signal containing abundant information of human body. Thanks to the recent advancement of high sensitivity flexible pressure sensors, which are small, light-weighted and more adaptable to human skin, pulse signals can now be detected from radial or carotid artery over the skin unobtrusively and continuously. The flexible sensors can be worn on skin not only for the monitoring of health status but also for the possible early prediction of cardiovascular acute events in real time. One of the key issues regarding practical applications is to understand the interaction and adaptation of the sensors to human skin. In this work we used a resistive flexible pressure sensor made in our own research Lab to measure arterial radial pulse at wrist and studied the effects of external force applied over the flexible sensor on the measured arterial pulse signals. The signals were recorded from 10 healthy subjects under 13 increasing magnitudes of applied force (0.1-1.8N) with duration of 2 minutes for each trial. The following figure shows the normalized pulse amplitude (the amplitude of AC component of the detected arterial pulse signal) under different levels of applied force. It is observed from this study that 1) as applied force increased, the pulse amplitude of all subjects shared a same tendency-first increase and then decrease; 2) the force where the pulse amplitude reached its maxima varied among different subjects. Our experimental findings suggest that the effect of applied force should be carefully examined when applying the flexible device for physiological signal measurements. Based on this study, we are currently recruiting patients for a clinical trial and developing a model for the unobtrusive real time monitoring of the internal arterial pressure with the ultimate goal of predicting cardiovascular diseases at the early possible stage.

PS19.007 - The Art of Engineering Medicine: A New Fast Non-Invasive Method to Directly Assess Ischemia in Human Diseased Coronary Arteries

Author(s): Ivad Fayssal, Fadl Moukalled, Samir Alam, Robert Habib, Hussain Ismaeel

American University of Beirut, Beirut/LEBANON

Fractional flow reserve (FFR) is a traditional indicatory index used to assess functional stenosis severity and determine whether a stenosis causes ischemia or not. Invasively measured FFR values < 0.8 indicate that the downstream heart tissue perfused by this vessel is at risk for ischemia. Currently, measuring FFR is an invasive procedure that is expensive, time consuming, not widely available, and not without complications. Recently, comprehensive predictive techniques involving numerical methods have gained attention. In specific, the use of computational fluid dynamics (CFD) methodologies combined with patient specific data allows computing in-vivo FFR. However, these non-invasive methods are associated with high computational cost and require high performance computing technology. This study focuses on the development of new strategies to reduce computational run time of solution prediction. The first strategy is based on isolating the diseased artery and simulating it separately without implicitly integrating other arterial segments while retrieving the accuracy of in-vivo hemodynamic significance of the stenosis. Special treatment of boundary conditions at the truncated domain was done via an in-house developed methodology, allowing to directly estimating ischemia in the stenosed artery. The second strategy is based on replacing a full transient simulation by a steady state one performed under mean conditions. The value of the developed strategies lies in their potential to (i) replace the experimental method which is based on intrusive processes and (ii) be performed with low computational cost. The latter advantage can significantly impact the applicability of this method in clinical practice at large.

PS19.008 - Influence of the alteration of the flow topology during the abdominal aortic aneurysm growth.

Author(s): Joly Florian, Gilles Soulez, Claude Kauffmann Lcti, CRCHUM, Montréal/QC/CANADA

Introduction The Abdominal Aortic Aneurysm (AAA) is the 13th cause of death in the USA. Patient specific AAA growth prediction and rupture risk remains challenging but rests upon the sole measure of its maximal diameter. In order to update current diagnosis criteria, influence of the blood flow on growth mechanics should be taken into account. Knowledge of the patient geometry

and hemodynamics boundary conditions are required for a realistic numerical flow simulation. Flow can impact AAAs in several ways; here transient transport topology will be studied in the lumen. To correlate transport with morphological growth, simulations will be carried during the longitudinal study of patients with more than 4 follow-up CTA.

Methods Lumen and thrombus geometry extraction from all follow-up CTAs, volume computation and AAA growth estimation (i). Numerical simulation of the flow using FVM validated towards 4D MRI (ii). Simulation conditions: polyhedral mesh, Newtonian viscosity, transient mass flow inlet and 0D pressure outlet. Computation of the Finite Time Lyapunov Exponents (FTLE) of the flow (iii). The FTLE field is able to capture transport boundaries using data from a whole cardiac cycle.

Extraction and volume computation of enclosed stagnations zones and analysis of their progression over time, from AAA diagnosis to repair (iv).

Results Simulated flow topology showed a correspondence with MRI velocimetry experimental data. AAA lumen segmentation on seven patients over a cardiac pulse confirmed the hypothesis of a rigid wall condition on elderly patients. The transport study method allowed the isolation of stagnation zones from the circulating ones reproducibly. The volume of stagnation zones is highly correlated (r=0.98 and 0.93, resp. red and green) with AAA growth while circulation zones remains stable.

Discussion We present a numerical approach for the quantification of stagnation zones in AAAs. It takes into account the highly transient dynamics of the flow and offers a scalar Eulerian field representing a Lagrangian phenomenon. Stagnation zones are known for promoting the advection of shear-stress activated platelets to the wall leading to the apparition of ILT. More patients will be added to the study in order to better understand the relationship between transport, and AAA growth and thrombus formation. This could also give a better insight on the dynamics of the AAA growth, a step toward predicting!

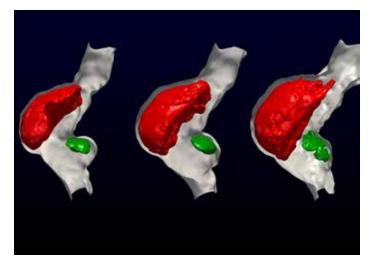

Figure: Example of the evolution over time (left to right: 2006, 2009 and 2012) and stagnation zones in a AAA. This patient presented two zones isolated in the flow.

PS19.009 - Using the DDST to Train and Test Anthropomorphic Robotic Children Author(s): Paul Frenger

A Working Hypothesis, Inc., Houston/TX/UNITED STATES OF AMERICA

Normal childhood growth and development (G&D) causes anxiety for parents, who want health care providers to examine their children, recording their progress against standards to facilitate early intervention if problems arise. The Denver Developmental Screening Test (DDST, 1967) can be utilized by doctors, nurses, teachers or other professionals with minimal G&D training. Along with its updated version (DDST II, 1992) it is the most widely used G&D measurement tool. The DDST was validated on normal children in Denver, Colorado, in the areas of gross motor, fine motor-adaptive, language and personal-social. Entries on the test sheets are organized by chronological age; i.e.: child "plays ball" at 10-12 months.

Recently, research into pediatric G&D led to models of robot-artificial intelligence (A.I.) that mimic child maturation processes. One example is the European iCub (2004-2010, Figure 1). The author's ANNIE humanoid robot-A.I. (2000-present) predated iCub by four years. Regrettably, there is no standard training and evaluation methodology to uniformly compare techniques and outcomes between robots, or between the robot models and actual children. The author is attempting to fill this gap by using the DDST as a tool to accomplish these goals, with ANNIE the test subject.

ANNIE's hardware and software have been described in detail at bioengineering and computer conferences, including CMBES. Its software relies on the Forth-language variant IEEE 1275-1994 (Open Firmware), a plug-and-play networking system. Its hardware includes analog artificial neuron circuits for its emotion engine and optical character recognition (OCR). The A.I. embeds a "subject-verb-object" format, compatible with DDST entries, in its schema-script system.

During training, modified DDST milestones in each of the four categories are input to the A.I. compiler. When ANNIE encounters objects not already known, (like "ball" or "raisin") the compiler creates a blank database entry for each via Forth's error-handling mechanisms. These unpopulated object entries are filled-in later as training progresses, including images taken from ANNIE's machine vision eyes, sounds from its microphone-ears, and text from OCR and other sources.

During testing, each DDST challenge is presented to the robot (tests are input by keyboard rather than by ANNIE's speech recognition system). The robot responds by attempting to demonstrate mastery of the test.

Result: with sufficient training, ANNIE performed every milestone except: walking, dressing, balancing, hopping-jumping (for which the robot is not yet equipped). The missing gross motor functions will be added in the future.

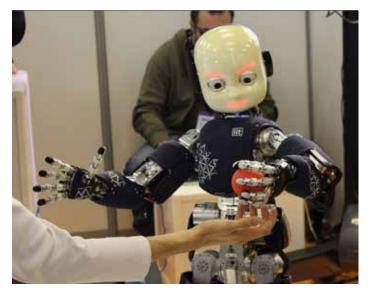

Figure 1: iCub plays ball (courtesy Wikimedia Commons).

PS19.010 - The new low-cost metaphase finder for biological dosimetry

Author(s): <u>Akira Furukawa</u> National Institute of Radiologocal Sciences, Chiba/JAPAN

Biological dosimetry is to estimate one's dose by biological phenomena. Most popular and "gold standard" phenomenon is the appearance of dicentric chromosomes in one's metaphase cells among white blood cells. Metaphase finder is a tool for biological dosimetry that finds metaphase cells on slide glasses. It consists of automated microscope, auto-focus system, X-Y stage, camera and computer. It does the image diagnosis of the microscopic images of the slide glasses, and displays the positions of metaphase cells. A metaphase finder is used for the personnel worked at Fukushima nuclear plant to know how much dose they irradiated.

The author and colleagues have already reported a low-cost metaphase finder system, using commercially-available products (1). Its software was application of mathematical morphology. But the system was a combination of multiple manufacturers and then it requires much knowledge and skill to the resellers and users. This system was more compact and less price than commercial products. The system would be another choice for resellers and users, but its speed was needed to faster.

Then, the author has collaborated with a software company to start new project to make another system. This system is using new special software is expected to be faster than non-custom made system. We used Nikon Eclipse Ni-E microscope with motorized X-Y stage, 4x objective lens and 1920 x 1024 pixels color camera for hardware. The software added the new function to compare the color of the image. The new system was also compact and low– price.

Now, the system was completed and we tested its speed. It was 13 minutes and 56 seconds per one slide, while capturing 1,333 images. We accomplished the aim of the project. The dicentric-dose curve will be shown in this presentation.

This research is supported by The Japan Science and Technology Agency.

PS19.011 - Concentrated photoactivation: focusing light through scattering

Author(s): <u>Ana Teresa Gabriel</u>¹, Jorge Machado¹, Ricardo Gomes², João Coelho³, Catarina Silva⁴, Catarina Reis⁴, José Paulo Santos¹, Pedro Vieira¹

¹LABPhys-UNL, Departamento de Física, Faculdade de Ciências e Tecnologia, Universidade Nova de Lisboa, Monte da Caparica/POR-TUGAL, ²Laboratório de Óptica Lasers e Sistemas, Faculdade de Ciências, Universidade de Lisboa, Lisboa/PORTUGAL, ³Instituto de Biofísica e Engenharia Biomédica, Faculdade de Ciências, Universidade de Lisboa, Lisboa/PORTUGAL, ⁴CBiOS - Centre for Research in Biosciences & Health Technologies, Universidade Lusófona,, Lisboa/PORTUGAL

Light has long being used in medicine; however, the high scattering of biological tissues always hindered its use. The aim of this work is the development of methodologies to focus light inside biological tissues. Geant4/GAMOS Monte Carlo platform was used to simulate the possibility of parameterize the time delay of multiple sources of external light, offset in time, as a function of the interest region position in order to create constructive interferences in a breast sample. A computational model was implemented and the platform was configured in order to perform these simulations. Preliminary results using a single light source were performed. It was concluded that scattering in adipose tissue is very high which is consistent with previous studies.

PS19.012 - Steered Molecular Dynamic Simulation Approaches for computing the Blood Brain Barrier (BBB) Diffusion Coefficient

Author(s): Maysam Pedram¹, Amir Shamloo¹, Aria Alasti¹, <u>Ebrahim</u> <u>Ghafar Zadeh²</u>

¹Sharif University of Technology, Tehran/IRAN, ²York University, Toronto/CANADA

In the recent years a great attention of research deals with different physical and biological aspects of the BBB structure, a robust shield that separates the blood and brain, a recent research held by the authors of this paper has focused on figuring out computing the diffusion coefficient of endothelial cell membrane. In this study, the major efforts have been concentrated on calculating a standardized measure for the amount of permeability and diffusion of this barrier. As a result, this work is dedicated to molecular dynamics (MD) simulation of calculating the interaction force between nano-particle and BBB membrane. data is recorded by using steered molecular dynamics simulation and crossing nano-particles with constant velocity for many times on both sides of the membrane. This data help to find diffusion coefficient in order it can convert the discrete medium simulation into continuum medium.

PS19.013 - The study of the relationship between the scatterer particle size of soft tissue in ultrasonic focal region and the frequency offset of backscattered signal

Author(s): Jianzhong Guo, Shuyu Lin, Hui Cao

School of Physics & Information Technology of Shaanxi Normal University, Xi'an/CHINA

The traditional B mode ultrasonic imaging equipment utilizes the information of amplitude envelope of ultrasonic backscattered RF signal to construct the soft tissue image, while other information such as frequency and phase is not fully utilized which is related to the microstructure of tissue. When the biological soft tissue have some pathological changes, its attenuation coefficient⊡elastic properties, particle size or concentration (the number of scatterers per unit volume) of ultrasonic feature scatterers will be changed accordingly. The power spectrum of ultrasonic backscattered RF signal of the soft tissue is related to the particle size, geometric shape, concentration and elastic properties of ultrasonic feature scatterers.

Based on the ultrasound propagation property in biological soft tissues, it was studied that the relevance between the central frequency offset of ultrasonic backscattered RF signal and the particle size of ultrasonic feature scatterer. The interreaction of attenuation coefficient of tissue in the focal region of ultrasonic transducer, concentration of ultrasonic feature scatterer, as well as the central frequency, bandwidth and focusing properties of ultrasonic transducer on the central frequency offset was explored by means of the computer simulation.

Four experimental imitations with different particle sizes of scatterer were made, and the frequency characteristics of these fore types of ultrasonic backscattered signals were studied by the statistical signal process method. Experimental imitation was made by gelatin, glass bead, glycerin, distilled water, antiseptic and glutaral-dehyde. The glass beads are special solid glass beads of 2#II3#II4# and5#provided by Qinhuangdao QinHuang glass beads Co. LTD. Their average effective scatter radiuses are 36.25 mm, 47 mm, 55.25 mm and 64.25 mm, respectively.

The results of computer simulations reveal that the frequency shift of ultrasonic backscattered signal of soft tissues would increase with the particle size of ultrasonic feature scatterer increasing, and approximately shows a linear growth relationship. The frequency offsets is different with the different parameter of transducer such as the central frequency, bandwidth and focusing property ,and the number concentration of ultrasonic feature scatterer and focusing property of transducer have not significant effect on the frequency offset .

The results of imitation experiments indicate that, with the increase of the effective scatter radius of ultrasonic feature scatterer, the central frequency of ultrasonic backscattered RF signals of experimental imitation would shift to the low frequency and is more and more close to the central frequency of ultrasonic exciting signal.

It can be concluded that the information of frequency and phase of ultrasonic backscattered RF echo signal may be used to study the microstructure characteristics of soft tissue and explore the application of ultrasonic diagnosis technology in the physiological pathology diagnosis of biological tissue.

PS19.014 - Dynamic Model for Shear Stress-Dependent NO and Purine Nucleotide Production from Endothelial Cells Author(s): <u>Patrick L. Kirby</u>, Donald G. Buerk, Kenneth A. Barbee,

Dov Jaron

School Of Biomedical Engineering And Health Sciences, Drexel University, Philadelphia/UNITED STATES OF AMERICA

We developed a dynamic mass transport model for a parallel-plate flow chamber apparatus that predicts concentrations of nitric oxide (NO) and purine nucleotides (ATP, ADP) produced by cultured endothelial cells (ECs). The flow chamber, which was designed and fabricated in our laboratory, permits real time *in vitro* measurements of NO produced by ECs at different levels of wall shear stress (τ_w) (Andrews et al., Nitric Oxide, 23(4):335-42, 2010). From steady-state NO measurements with bovine aortic ECs cultured in this chamber, Andrews et al. (2010) found that a hyperbolic function provided the best fit for the τ_w -dependent rate of NO production (R_{NO}).

$R_{NO} = R_{basal} + R_{max}(\tau_w/(\tau_w + A))$

More recent studies with this flow chamber (Andrews et al., Cellular and Molecular Bioengineering, 7(4):510-20, 2014) investigated the role of τ_w -dependent release of ATP in modulating R_{No} . In order to analyze data from these studies, we modified a previous model that characterizes the spatial distribution of NO in the chamber (Fadel

et al., Annals of Biomedical Engineering, 37(5):943-54, 2009). The modified model predicts how the net release rates and mass transport for NO, ATP, and ADP vary with changes in τ_w . Two prevous models in the literature for ATP release and ADP formation were implemented. The first model (John and Barakat, Annals of Biomedical Engineering, 29(9):740-51, 2001) predicts a rapid rise in ATP and ADP to steady-state values within a few sec. The second model (Qin et al., Biomechanics and Modeling in Mechanobiology, 7(5):345-53, 2008) predicts a slower increase, reaching peak ATP and ADP values at different τ_w , followed by a slow decline in concentration, attributed to "receptor desensitization" (a reduction in the response with a longer stimulus).

Experimental data obtained after altering ATP and ADP concentrations with apyrase (Andrews et al., 2014) were analyzed to quantify changes in R_{NO} using this model. Apyrase is a calcium activated plasma membrane-bound enzyme that catalyzes the conversion of ATP to ADP, followed by conversion of ADP to AMP and inorganic phosphate. A reduction in τ_w -dependent R_{NO} was found when 1 Unit/mL apyrase was added to the media in the chamber, presumably due to lower ATP and ADP at the EC cell surface. The 2 ATP release models were used to predict effects of different isoenzymes of apyrase on ATP and ADP concentrations in the chamber, although the exact composition of apyase used experimentally was uncertain. We explored different functional relationships to describe experimental changes in $R_{_{NO}}$ with $\tau_{_{W}}$ due to changes in ATP and ADP. A reasonable fit was found with an apyrase isoform of Desiree which predicts the largest decrease in ATP and ADP. Further experimental data is required to validate the model and obtain better estimates for the model parameters. The dynamic model simulations provide a greater understanding of experimental results obtained with parallel-plate flow chambers and allows quantitative analysis of the relationship between τ_{w} , purine nucleotide concentrations, and NO produced by ECs.

PS19.015 - Mechanism of Phospholipase as a Potential Anti-Bacterial Drug Revealed by Nonlinear Spectroscopy Author(s): Xiaolin Lu

School Of Biological Science And Medical Engineering, Southeast University, Southeast University, Nanjing/CHINA

Lipids play a fundamental role in diverse biological processes for energy storage, compartmentalization, and signaling, etc. In this respect, it is of great importance to understand the pathways and mechanisms of lipid metastasis triggered by phospholipase. Recently, it was found that the local enrichment of negatively charged lipids into biomembrane domains can lead to high activity of phospholipase A₂ (PLA₂), suggesting a potential anti-bacterial application of PLA, [1]. Here, we apply the 2nd-order nonlinear optical spectroscopy – sum frequency generation vibrational spectroscopy [2] to investigate the hydrolysis process of model lipid biomembranes catalyzed by PLA_a. Two types of phospholipases and two types of phospholipids were used including secretory human phospholipase A₂ type IIA (PLA2-IIA), venom PLA₂, 1,2-dipalmitoyl-sn-glycero-3-phospho-(1'-rac-glycerol) (sodium salt) (DPPG, negatively charged) and 1,2-dipalmitoyl-sn-glycero-3-phosphocholine (DPPC, neutrally charged). Nonlinear spectroscopic results indicate, compared to PLA, PLA2-IIA can strongly bind to the negatively charged DPPG biomembrane with certain specific orientation and trigger the fast hydrolysis process, confirming its anti-bacterial function.

PS19.016 - Cancer stem cells in a hierarchical model of tumour regrowth in five head and neck carcinomas Author(s): Loredana G. Marcu¹, David Marcu², Sanda M. Filip² ¹School Of Chemistry And Physics, University of Adelaide, Adelaide/

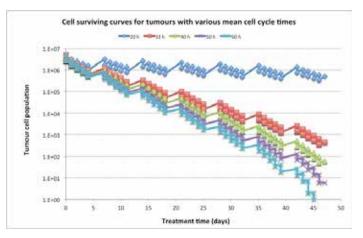

SA/AUSTRALIA, ²Department Of Physics, University of Oradea, Oradea/ROMANIA Introduction: Locally advanced head and neck carcinomas (HNC) are aggressive due to several tumour-related factors such as: hypoxia, elevated levels of the endothelial growth factor receptor and tumour repopulation during treatment. There is a growing body of evidence towards the existence of cancer stem cells (CSC), which represent a subpopulation of tumour cells that hold the ability to proliferate indefinitely, are tumorigenic and also more quiescent than non-cancer stem cells. Due to their ability to respond to triggers these cells are considered to be accountable for treatment resis-

tance and failure, as well as tumour recurrence. However, there is insufficient quantitative information in the literature regarding the kinetics and behaviour of CSCs in order to assess their impact on tumour control. The aim of this work is to simulate the possible mechanisms behind CSC generation and contribution to tumour regrowth during treatment on five virtual HNC with different growth kinetic parameters.

Methods: A hierarchical model of HNC has been grown using probabilistic methods starting from one tumour-initiating cell. The model written in C++ has generated a virtual tumour of 10^7 cells having biologically real parameters. The radiation software module kills cells according to surviving fractions defined for each phase of the cycle. A fraction of 20% cells are recruited after irradiation as CSCs (which proliferate via symmetrical division) or non-CSCs (asymmetrical division). The fraction of CSCs is limited to 25% of total cells.

Results: The model has shown that tumours growing with different kinetic parameters (mean cell cycle time, volume doubling time) respond differently to conventional radiotherapy. Due to the repopulation ability of CSCs, tumours with shorter mean cycle times (20h – 40h) cannot be cured with 70Gy given in 2Gy/fraction, 5 days a week, over 7 weeks (see figure). A typical HNC with 33h mean cycle time would need an additional 26Gy, or a 6 day/week treatment to be cured, considering that the tumour is non-hypoxic. Tumours with mean cycle time of 20h exhibit a drastic resistance through repopulation, as the interfraction interval (24h) is larger than the time for cell division.

Conclusions: Differences in treatment response of various HNC models due to CSCs and their interplay with growth kinetics show the importance of CSC identification within the tumour. The need for accurate markers for CSC labelling is therefore imminent. Both quantitative and qualitative knowledge on CSC are needed to describe the resistant subpopulation and to design treatment regimens accordingly.

PS19.017 - Effects of interaction with electromagnetic field on cell culture of Saccharomyces cerevisiae

Author(s): <u>Aracely Martínez</u>, Julio C. Villagómez, Modesto A. Sosa-Aquino, Francisco A. Horta, Teodoro Córdova-Fraga Departamento De Ingeniería Física, División de Ciencias e Ingenierías, León/MEXICO

Saccharomyces cerevisiae has been regarded as a convenient target for investigating effects of electromagnetic fields, such as cell proliferation, given that it has wide applicability in industry. At the same time, the relationship between cell growth and form culture, could be an indicator of the conditions of their environment where it is growing. In this work, we studied the change in the rate of cell reproduction and changes in the pattern of growing of a cell culture of Saccharomyces cerevisiae when it's stimulated magnetically. The magnetic field used for stimulation was generated with a Rodin coil in the range of approximately 1 to 4 mT, at frequencies of 60, 100, 800, 1500 and 2450 Hz. The yeast was grown in liquid medium YPD, and stimulated for 8 hrs. For frequencies of 60 and 800 Hz the cell culture was a decrease in the rate of cell proliferation, relative to the control sample. The frequencies of 100 and 1500 shown an increase in the rate of cell proliferation, while the stimulated sample to 2450 didn't show a significant change. For the study about changes in the pattern of growth, it was performed a fractal analysis of the growing culture. Samples of Saccharomyces cerevisiae in YPD medium, was stimulated for 8 hours with the same Rodin coil at frequencies of 100, 800 and 1500 hz. The observation was performed by a microscope and the fractal dimension analysis was performed during the first two hours after stimulation. The box counting method was used for the determination of the fractal dimension. The results suggest that there are no changes in the pattern of crop growth.

PS19.018 - Obstructive and Sclerotic Disorders affecting Carotid Blood Flow to the Brain

Author(s): <u>Onaizah Onaizah</u>¹, Tamie L. Poepping², Mair Zamir³ ¹Medical Biophysics, University of Western Ontario, London/ CANADA, ²Physics And Astronomy, University of Western Ontario, London/ON/CANADA, ³Applied Mathematics, University of Western Ontario, London/ON/CANADA

Stroke remains one of the leading causes of death in North America. A large number of strokes are a direct result of carotid artery disease. Physiological and pathological changes in the carotid artery can result in obstructive and sclerotic disorders. The internal carotid artery (ICA), one of the branches of the common carotid artery (CCA), is a major route for blood supply to the brain. Thus, obstructive changes such as stenosis due to plaque development can impede blood supply to the brain. Sclerotic changes associated with the hardening of the artery result in changes to the pressure and flow relationship thus reducing blood supply to the brain.

An experimental in vitro flow loop was employed in combination with a lumped parameter (LP) model to study changes in blood supply to the brain as a result of obstructive or sclerotic disorders of the carotid artery. An LP model is an electrical analogue to the experimental in vitro flow loop, consisting of a pump supplied with an idealized carotid artery waveform. A family of carotid artery phantoms with varying compliances and stenosis severity were used. Simultaneous pressure and volumetric flow-rate waveforms were measured using flowmeters (EP620/625, Carolina Medical Inc.) and a pressure catheter (SPR 350S, Millar Inc.). The pressure waveform is as an input to the LP model to generate a predicted flow-rate waveform, which is then matched to the measured flow-rate waveform by varying the LP model parameters.

An LP model, specifically designed to match an in vitro flow loop, was validated and parameter values were extracted for five different phantoms by matching waveforms. The increased resistance associated with the stenosis and the differences in the phantom compliances are shown in Fig. 1. Mean flow rates through the ICA were calculated using the experimentally measured flow-rate waveforms. Obstructive disease had minimal impact on mean flow-rate up to a certain threshold (70% stenosis) before it became significant (p<0.05). A decrease in compliance on the other hand had a significant effect on mean ICA flow-rate (p<0.05). While obstructive disease does not directly have a large impact on blood supply, it is still considered important due to its role in the development of thrombotic events.

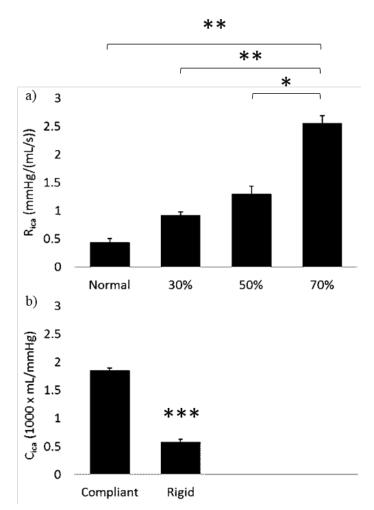

Fig. 1 The parameter values extracted from the LP model are shown: a) phantoms with increasing stenosis (R_{ica}), changes are significant (**, p<0.01) for a severe (70%) stenosis, b) phantoms with decreasing compliance (C_{ica}), changes are significant (***, p<0.001).

PS19.019 - Estimation of Tissue Temperature in Tumor Hyperthermia Using Ultrasonic Methods

Author(s): Xiao-Jian Wang¹, Xiao-Hui Qiu²

¹Department of Chemotherapy, Ganzhou Tumor Hospital, Ganzhou, China, Ganzhou/CHINA, ²Information Engineering Institute, Gannan Medical University, Ganzhou/CHINA

Estimation of tissue temperature in Tumor Hyperthermia is an extremely important assurance of therapeutic safety. In all kinds of measuring methods, ultrasonic nondestructive techniques are the safest and the most promising one. The main ultrasonic methods of temperature measurement are based on ultrasonic echo signal,

acoustic transmission signal, the characteristic parameters of ultrasonic image, theoretical model simulation and so on. The theories of various ultrasonic methods adopted for measuring tissue temperature are introduced in this paper with their application, limitation and research status analyzed respectively.

PS19.020 - Modeling of a Photosensitzer Distribution Relevant to Photodynamic Therapy of Malignant Non-Pigmented and Pigmented Tumors

Author(s): Marta Wasilewska-Radwanska¹, Zenon Matuszak² ¹Faculty Of Physics And Applied Computer Science, AGH University of Science and Technology, Faculty of Physics and Applied Computer Science, Krakow/POLAND, ²Medical Physics And Biophysics, AGH University of Science and Technology, Faculty of Physics and Applied Computer Science, Krakow/POLAND

Photodynamic therapy (PDT) is a branch of phototherapy and it is among many available methods used in clinical practice to treat cancer. PDT is approved procedure for treatment of many types of cancer such as esophageal. lung and skin cancer. Research investigation show that the PDT technique can also be effective against melanoma. Generally speaking, three crucial elements in the PDT must cooperate to cause therapeutic effect of PDT: photosensitzer (PS), oxygen (O₂) and light. The PDT's therapeutic effect depends on many factors involved in the PDT: accumulation of PS and oxygen availability in the treatment region, absorption of light by PS (activation) and efficiency of production of cytotoxic reactive oxygen species (ROS), mainly singlet oxygen (10,). The main mechanism of cell death occurs by photogenerated ¹O₂ that attacks important parts of the cells (membranes) causing oxidative damages and cells death. To make the PDT a more effective treatment modality, an appropriate dosimetry is required. Two main factors must be controlled: PS accumulation within target tissue and optical penetration depth of light used (photon density). Because many of PS are fluorophores, monitoring PS fluorescence play significant role in localizing of PS and quantifying its concentration within tissue. The optical parameters of tissues (absorption and scattering properties) significantly influence both the intensity and shape of PS fluorescence, because the intensities of fluorescence excitation as well as emission light are modulated by the tissue. Additionally, melanin present in pigmented tumors strongly absorbs light, and it modifies both the propagation of excitation light and the resulting fluorescence emission. The goal of the present work is to model fluorescence measurements used for determining the PS concentration in non-pigmented and pigmented tissue. Monte Carlo (MC) method was used to simulate propagation of photons (exciting PS and emitting by PS) within tissue. The influence of melanin tissue concentration on distribution of the excitation and the emission light was estimated. Optical properties of tissue used in simulations are based on reported values for normal and pigmented skin. Computational model of skin consists of seven layers. The simulations were done for PS from porphyrin family since these compounds emit light at near 650 nm.

Spatial distribution of the fluorescence excitation and emission were simulated as functions of the tissues' optical properties. It was demonstrated that the model is able to predict the spatial distribution of the porphyrin type PS fluorescence excitation/emission pattern within skin and PS concentration. The results of MC simulations were compared with the experimental images of skin fluorescence textures.

CONTINUING EDUCATION

BMEE01 - GENERAL BME EDUCATION

BMEE01.1 - Biomaterials - Cell-Material Interactions: Biochemistry & Physics

Author(s): <u>Dennis E. Discher</u> Molecular & Cell Biophysics Lab, University of Pennsylvania, Philadelphia/PA/UNITED STATES OF AMERICA

Tissue cells and implants all interact with the innate immune system, especially phagocytes that try to 'eat' everything. However, 'Self' cells are spared, and it turns out that a polypeptide found on all cells marks cells (as well as engineered particles and surfaces as 'Self'), limiting their phagocytic interactions in vitro and in vivo [Rodriguez Science 2013]. If an injected cell thus survives and if it has stem-like properties, the tissue microenvironment can in principle influence its differentiation. We have focused on how matrix elasticity can direct stem cell lineage, recognizing that tissues can be very soft like fat and brain, or increasingly stiff like striated muscle and rigid like bone [Engler Cell 2006]. Stem cells feel and respond to such elasticity differences together with soluble factors [Discher Science 2009], and we now find such signaling propagates all the way into the nucleus, which adjusts its mechanics to tissue stresses but also feeds back on gene expression [Swift Science 2013]. What unifies these mechanisms of interest in immune recognition and in matrix-regulated stem cell differentiation is a convergence of decision-making pathways on cytoskeletal force generation.

BMEE01.2 - Radiology 101: Intro to X-Ray tubes (manufacture & maintenance)

Author(s): <u>Phillip Bogolub</u>, Cindy Friesen xxx, xxx/UNITED KINGDOM

Dunlee presents, "X-Ray 101 & Working Together"

The presentation will begin with where X-ray tubes are used. This entails a brief overview of the different types of tubes.

We will then move onto what a tube does and what the outcome is.

The next section goes into detail of how an X-Ray and CT tube is made which includes the manufacturing process, the different varieties as well as the tube design itself.

We will show the anatomy of a tube and the various parts and what the specific functions of those parts are.

We will then go into the operation of the tube and what types of failures can be experienced.

We will also discuss why preventative maintenance and training is important.

We will conclude with questions and answer section.

BMEE02 - MEDICAL DEVICE DEVELOPMENT AND COMMERCIALIZATION

BMEE02.1 - Med-Tech Commercialization – A Research Hospital's Perspective Author(s):

How do you define 'success' of your med-tech research? Seeing a commercialized product on the market available for use in patients around the world is arguably the most relevant, impactful and satisfying end-point for anyone in this field. However, the med-tech commercialization process is far from being a 'cookie-cutter' approach. What works in one field, falls short in others. What works at one institution, isn't optimal for others. What works for one technology, completely misses the mark for another. How one industry partner prefers to work, is not uniform across all partners. It is a dynamic environment requiring flexibility and optimization of the various factors. A research hospital's view on this exciting area will dive deep into the dynamics through a series of actual start-up and licensing examples demonstrating some of the approaches that have been implemented at the University Health Network, Toronto. A brief intellectual property primer will also be included to provide the attendee with a functional understanding of what is needed to succeed in some of the most common commercialization scenarios. How do you define 'success'?

BMEE03 - BIOINFORMATICS, TELEMEDICINE AND HOSPITAL INFORMATION SYSTEMS

BMEE03.1 - DICOM & PACS: Managing Digital Imaging Networks Author(s): <u>Marvin Mitchell</u>

Healthcare, N/A, Barrie/CANADA

What does it really take to manage a Digital Network consisting of DICOM and PACS? The objective of my talk will answer this question. Many of you may have already been exposed to the words "DICOM" and "PACS". Although these words are normally used together, they are very different in achieving the goals they were designed for. Both technologies can exist together as well separate from each other.

Our conversation will begin with a short talk on the beginning, and continued evolution of "DICOM" and "PACS". We will have a look at Conformance Statements and how to effectively use them.

Our conversation will then continue with how to effectively manage a Digital Network containing both DICOM and PACS. Throughout my experience, I have had the pleasure in being a part of successful executions of Digital Network management and as well as being part of projects that had "lessons learned". The management of a DICOM and PACS Digital Network is continued work in progress that starts with Planning phase and ends with Decommissioning of the product. The topics we will explore to get a richer sense of what it takes to manage such Networks are:

Planning and Integration

Workflow considerations

A typical DICOM and PACS Network

People/Education

Scalability

Support Process

Disaster Recovery

Business Administration Challenges

BMEE04 - GENERAL BME EDUCATION

BMEE04.1 - Biomaterials - Polymer/Organic Coatings Author(s): <u>Min Wang</u>

Department Of Mechanical Engineering, The University of Hong Kong, Hong Kong/CHINA

Many biomaterials currently in clinical use were originally developed for engineering applications and surface modification is thus needed for their biomedical applications. The biomaterials specifically designed and developed for certain medical application(s) may require another set of surface characteristics that are suitable for the material to be used in another clinical environment; or surface modification is required for enhancing the clinical performance of the biomaterial in its targeted application(s). What our body "sees" and deals with when an implant is placed in our body is the surface of the implant. Therefore, surface properties of materials or biomaterials are of paramount importance, which can determine the success or failure of a material for its intended biomedical applications. Different types of biomaterials - metals, polymers, ceramics and composites - are now used in various biomedical applications. As these substrates are drastically different from each other, different coatings and surface modification techniques are used for implantable metals, biopolymers, bioceramics and biomedical composites (porous composite scaffolds in particular in recent years). And coatings themselves can be polymeric, metallic, ceramic or even composite in nature. Polymer coatings are very attractive for the surface modification of biomaterials because they provide great versatility in chemical groups on the surface for controlling the cell-biomaterial interactions. They are relatively easy to form/produce, using simple techniques such as dip-coating or solvent casting. Coatings can also be made via chemical grafting of molecules onto the biomaterial surface. Techniques/structures such as self-assembled monolayers (SAMs) and layer-by-layer (LBL) assembly are extensively investigated in the biomedical field due to their distinctive advantages. For example, PEGylated SAMs are formed for controlling the surface interaction of biomaterials with proteins, and drugs are incorporated in LBL-formed polymer coatings for their controlled release in vivo. In the area of metal implants, NiTi shape memory alloys (SMAs) becomes a focus of research because they possess unique properties of shape memory and superelasticity. However, metals are bioinert and NiTi SMAs cause concerns over their long-term biocompatibility due to toxic ion release. Investigations have been performed to use the plasma immersion ion implantation and deposition technique to modify the NiTi SMA surface, yielding encouraging mechanical and biological results. For tissue regeneration, tissue engineering scaffolds play a crucial role but scaffold alone is not sufficient for regenerating functional body tissues. Growth factors are needed for prompting specific cell behaviors and functions. Additive manufacturing technologies such as selective laser sintering (SLS) may not be able to produce growth factor-incorporated scaffolds directly, but SLS-formed polymer scaffolds can be surface modified for incorporating growth factors for their controlled release later. One example is SLS-formed PHBV scaffolds with the surface modification of heparin onto which rhBMP-2 is incorporated. These advanced scaffolds have exhibited enhanced ability for bone tissue regeneration in vivo. This lecture will (1) briefly review clinical requirements (mainly surface requirements) for biomedical materials, (2) give an overview of coatings and surface modification techniques for different types of substrates, and (3) present and discuss the performance of some surface-modified biomaterials and indicate future trends.

BMEE05 - CLINICAL ENGINEERING/TECHNOLOGY MANAGEMENT

BMEE05.1 - Introduction to Medical Technology Management (Clinical Engineering Practice)

Author(s): Saide Calil1, Anthony Chan2

¹Department Of Biomedical Engineering, Unicamp, Campinas/BRA-ZIL, ²Biomedical Engineering, British Columbia Institute of Technology, Burnaby/CANADA

The term "Management of Medical Technology" is widely used today but not many people really know its range. Some limit "Management" to maintenance services and consider only preventive maintenance and repair activities; some add other activities, such as technical training and quality control. The fact is many other activities can be added to "Medical Technology Management", including risk management, cost assessment and control, equipment procurement, installation, discarding, and reporting to the hospital managers. The proposal here is to present and discuss:

1 – What activities are performed today by Clinical Engineers within what is called Management of Medical Technology?

2 – Which of these activities are really part of Management of Technology and which ones can be transferred to other subject such as; Financial Management

3 – Define what kind of knowledge is necessary for Technology Management to guide training courses on Clinical Engineering.

BMEE07 - BIOINFORMATICS, TELEMEDICINE AND HOSPITAL INFORMATION SYSTEMS

BMEE07.1 - E-medicine and Remote Medical Consultations Author(s): <u>Gilad Epstein</u> OTN (Ontario Telemedicine Network), Torornto/CANADA

Learning objectives

Overview of current Telemedicine programs

Trends in virtual care

Technology trends enabling new models of care

Telemedicine is growing in popularity and is moving from a pioneering stage into mainstream.

Innovative models of care leveraging technology are creating new opportunities in the healthcare industry.

In this session we will review the current state of Telemedicine in Ontario, and provide insights to future virtual care trends and the impact on patients and providers.

BMEE08 - GENERAL BME EDUCATION

BMEE08.1 - Biomechanics - Implant design Author(s): Cheng-Kung Cheng

Department Of Biomedical Engineering, National Yang Ming University, Taipei/TAIWAN

Biomechanics - Implant Design

In order to reasonably assure the implant's safety and effectiveness, the two major concerns of medical devices, computational models and biomechanical tests are conducted in the design phase. The computational models, including finite element model and kinematic model, are usually performed firstly because it is relative cost efficiency and easy to modify design parameters. In addition, using these models can quickly estimate the stress and strain distribution or kinematic performance of the implant. The biomechanical tests then take steps in to simulate the performance of implants under real-live mimic loading by following the ASTM and ISO standards. The research outcomes of the implants are essential for premarketing approval.

Although most of the orthopedic implants were initially developed in Europe and North America, the substantial differences between Asian and Western population should be considered for implant designs nowadays. Not only the bone quality, size, and geometry differences but also the epidemiology of disease and lifestyle can greatly affect the design concept. For example, the high prevalence of avascular necrosis of femoral in Asia leads to total hip arthroplasty while osteoarthritis in Western is the top indication of total hip arthroplasty. Furthermore, demands of high flexion is much more important for Asian patients after total knee arthroplasty for achieving activities like prayers kneeling, cross-legged sitting, and Japanese proper sitting. Therefore, understanding the discrepancies among different populations is beneficial in unique implant design to the target market.

Customized implant has become another growing category of implant design with the development of novel technology, which resolves the difficulties of manufacturing in the past and lowers the cost of production. The revolutionary 3D printing with metal material has elevated implant design from prototyping to practical scenario.

BMEE09 - BIOINFORMATICS, TELEMEDICINE AND HOSPITAL INFORMATION SYSTEMS

BMEE09.1 - Medical Device Network Connectivity Author(s): Ryan Forde

Research And Development, Drager, Andover/UNITED STATES OF AMERICA

Medical device networks are becoming nearly ubiquitous in the developed world. These networks allow medical devices to share information with other devices, archive and store information for later access and warn caregivers about potentially hazardous situations before they occur. This talk will focus on patient monitoring networks and how they relate to hospital Information Technology networks and discuss some of the challenges of integrating the two. We will cover different communication technologies and when each might be used. Finally we will discuss some of the current efforts to create a standards landscape that will allow medical devices to interoperate and improve care for patients.

At the conclusion of the program, attendees will be able to:

1- Describe different communication protocols used by medical devices and explain what each might be used for.

2- Understand how patient monitoring networks can work with hospital IT networks and what some of the advantages, and challenges of connecting the two might be.

3- Understand the basic reasons why standardized medical device interoperability is important and how we might get there.

BMEE10 - GENERAL BME EDUCATION

BMEE10.1 - Multiscale Biomechanics in Deep Tissue Injury Author(s): <u>Arthur F. Mak</u>

Division Of Biomedical Engineering, The Chinese University of Hong Kong, Shatin/HONG KONG

LEARNING OBJECTIVES

1) Acquire a basic understanding of the problem of deep tissue pressure ulcers;

2) Review the recent literatures on in-vivo and in-vitro studies related to deep tissue injuries

3) Learn how computational biomechanics can be applied to study the formation of deep tissue injuries and their propagation to become clinical ulcers

ABSTRACT

Damages occur when cells and tissues are subject to excessive physical stresses. Such damage thresholds depend on the exposure duration of these physical forces. Deep tissue injury due to prolonged excessive skin/skeletal loadings can lead to clinical pressure ulcers, affecting millions of persons with physical disability. In this short course, we will review recent literatures on (1) the transmission of skin/skeletal loadings to muscle tissues around bony prominences, (2) how mechanical stresses at tissue level invoke cellular damages, (3) the involvements of the vascular and lymphatic systems, (4) the effects of post-ischemic oxidative reperfusion might affect the load-carrying capacity of the involved tissues and their sub-cellular and molecular mechanisms, and (5) how damages in the deep muscles can propagate towards the skin, resulting in a clinical through-thickness ulcer. Relevant In-vitro, in-vivo, and insilico studies will be summarized.

BMEE11 - CLINICAL ENGINEERING/TECHNOLOGY MANAGEMENT / GENERAL BME EDUCATION

BMEE11.1 - Trends in Medical Device Certification and improving Patient Safety through Evolving Standards Author(s): <u>Dale Morgan</u>

Certification & Test, CSA Grouup, Toronto/CANADA

The medical device chain consisting of development, manufacture, approvals, distribution/service and patient care use is generally considered to be governed by a highly regulated industry – presumably to assure safety, effectiveness and electrical compatibility for the care environments and infrastructures where the devices are used. Despite this, patient safety concerns and adverse events continue to occur and healthcare innovations have many hurdles before reaching the caregivers and patients. The regulatory processes for medical devices generally have 3 parts: Safety Technical File, Clinical Review (Licensing), and Quality Systems Registrations. Together these parts should be sufficient to ensure the aspects of safety and best practices are used in all phases of the medical device chain. These parts have also long been considered separate regulatory and compliance aspects involving different expertise, people and services.

Traditionally, the Safety Technical file is comprised primarily of electro-medical certification and test reports/certificates according to the use of recognized international and harmonized medical device standards (note- must include electrical code and other deviations in Canadian adopted Standards for Health Canada). The key electro-medical device standards are the IEC 60601 /ISO 80601 Family of Standards. Since the 2005 version of the 60601 standards (3rd edition) and recently the 2012 version (3.1 edition) there has been a remarkable evolution of scope and complexity. Focus has moved from inherent electrical safety (2nd edition) to a broader focus on Safety, Essential Performance, Risk Management, Software Life Cycle processes, Usability, Alarms, and new use environments such as Home Healthcare and Emergency Medical Services.

The application, knowledge and science of certification engineering and test for the evolving family of 60601 standards is now crossing the boundaries into the other 2 parts of the medical device regulatory processes – clinical and quality systems. All 3 processes have their separate requirements and roles in Regulatory approvals for sure. However, the trend is that a holistic approach in understanding all of the processes in the refinement and application of standards has the great ability to safely fast track innovation, advance safety and open global markets for med tech companies here and abroad.

A few of the substantial developments in the 60601 standards will be examined to illustrate the trend of evolving standards to improve safety and ultimately enabling better and safer patient care. For example, one of the most significant and challenging changes in 60601 standards is the use of the Risk Management process to facilitate rapid technology developments and clinical feature benefits. This is a knowledge area steeped in clinical applications and engineering, risk assessment, process design, and quality management.

Understanding these trends can enable healthcare and clinical engineering professionals to better to gage the safety and limitations that new medical technology will bring into their already sophisticated and evolving care environments.

BMEE11.2 - Quantitative Musculoskeletal Ultrasound Author(s): <u>Yong-Ping Zheng</u>

Interdisciplinary Division Of Biomedical Engineering, The Hong Kong Polytechnic University, Hong Kong/CHINA

Leaning Objectives:

1. To understand methods and applications of ultrasound elasticity measurement and imaging for musculoskeletal soft tissues

2. To understand what is sonomyography and its applications

3. To learn how to use 3D ultrasound imaging for musculoskeletal assessment, particularly for spinal deformity

This talk will introduce three different approaches for quantitative musculoskeletal assessment using ultrasound. Ultrasound imaging has been widely used for musculoskeletal tissue assessment, but mainly qualitatively and subjectively by operators. Only some simple parameters such as length and area may be obtained for static ultrasound images. Musculoskeletal ultrasound has been rapidly developed recently due to the reduced size and cost of ultrasound scanner, and a number of quantitative musculoskeletal ultrasound approaches have also been developed.

Elasticity and viscoelasticity of different musculoskeletal soft tissue plays a very important role in muscle contraction, motion, force transfer and load bearing. The change of elasticity may be associated with different diseases, such as osteoarthritis (cartilage tissues), spasticity and atrophy (muscle), diabetic foot (plantar tissue). Furthermore, muscle may changes its elasticity during contraction, making it a useful parameter to indicate muscle quality. Muscle elasticity cannot be measured but also imaged, thus it can be used to for diagnose some local tissue problems. In this study, different methods for the measurement and imaging of tissue elasticity will be introduced, including ultrasound indentation, acoustic radiation force impulse, supersonic shearwave imaging, etc. Applications for muscle, tendon, and articular cartilage assessment will be introduced.

The second quantitative musculoskeletal ultrasound method to be introduced is developed for muscle assessment, named as sonomyography (SMG), in relation to its counterpart electromyography (EMG). SMG is derived from real-time ultrasound images and represents the architectural changes of muscle during contraction. The architectural parameters include muscle thickness, cross-sectional area, pennation angle, fascicle length, etc. They are detected automatically from real-time ultrasound images continuously thus forming signals, which can then be used for muscle functional assessment as well as for control. In this talk, the development of this area will be introduced together with recent achievements by different groups.

3D ultrasound imaging has been commonly used for fetus assessment. The third topic is to introduce how to use 3D ultrasound imaging for quantitative musculoskeletal assessment, including how an 3D ultrasound image is form formed. The focus will be on the recent development of using 3D ultrasound for radiation-free assessment of spinal deformity, such as scoliosis. It has been demonstrated that 3D ultrasound is feasible to measure the spine curvature for scoliosis patient, including the lateral deformity as well as spinal rotation. 3D ultrasound imaging shows a promising future for scoliosis screening, monitoring for curve progression and assessment for treatment outcome. The potential applications of this new quantitative musculoskeletal ultrasound technique will be discussed.

Figure 1. Assessment of musculoskeletal tissue biomechanical properties using tissue ultrasound palpation sensor (TUPS).

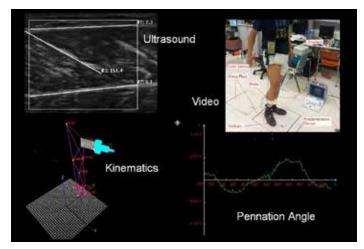

Figure 2. Compound motion analysis using conventional optical kinematic tracking method and sonomyography, which represents architectural change of muscle extracted from real-time ultrasound images during muscle contraction.

Figure 3. 3D ultrasound imaging for the measurement of spinal deformity for scoliosis patients. (a) Virtual 3D spine model formed using spinal bony landmarks detected on ultrasound images; (b) 3D ultrasound imaging system (Scolioscan) being used for assessing the spine of a body; (c) A coronal-view ultrasound images formed using the Scolioscan.

BMEE12 - CLINICAL ENGINEERING/TECHNOLOGY MANAGEMENT

BMEE12.1 - Clinical Engineers & Biomedical Engineering Technologists Certification - International Perspective

Author(s): Larry Boyce¹, Petr Kresta²

¹Clinical Technology Management, Sodexo Canada, Woodstock/ CANADA, ²Clinical Engineering, Winnipeg Regional Health Authority, Winnipeg/CANADA

Certification of Biomedical Engineering Technologists and Clinical Engineers – International Perspectives

Abstract

The session addresses contemporary issues in the certification of clinical engineers and biomedical engineering technologists through presentations and panel discussion with audience participation.

The need for certification of Biomedical Engineering Technologists and Technicians (BMET) is examined after 33 years of operating the Canadian Board of Examiners under the International Certification Commission (ICC). In that time little has changed, certification remains voluntary while a license to cut hair is mandatory in the province of Ontario. Currently in Canada there is no law or regulation that prevents the "talented maintenance mechanic" from maintaining medical equipment. The fundamental question is, "Is the public protected?" The current Canadian process is reviewed in an attempt to determine if it is working well enough to ensure that the public is protected. Should BMET certification be voluntary or mandatory? What are other countries doing?

The dissolution of the International Certification Commission in favour of the newly formed AAMI Credentials Institute (ACI) eliminated the International component of certification. Why this happened, the impact on technologists and the future of certification is examined?

Certification in Clinical Engineering is examined in several jurisdictions globally including the United States, Canada, and China. Responsibility for the Certification in Clinical Engineer program in the US and Canada shifted recently from the Healthcare Technology Foundation to the American College of Clinical Engineering. The current structure and status of the Certification Program is reviewed. The emergence of new clinical engineering related certification programs sponsored by the AAMI Credentials Institute, is examined and their potential impact discussed.

Clinical Engineering Division of the International Federation for Medical and Biological Engineering (CED/IFMBE) has been working for several years on a project looking at developing an international umbrella under the CED/IFMBE for the programs of certification in clinical engineering (CCE). Since the latest International Standard Classification of Occupations of the International Labor Organization explicitly considers biomedical/clinical engineers (CE) as an integral part of the health work force, it stands to reason that formal career paths of CE should be demanding similar, if not the same, as career paths of other health professionals with commensurate duration and level of university education.

The objective of this paper is to present current project status and activities, together with the proposal for CCE from the CED/IFMBE perspective. The CED/IFMBE, in cooperation with other interested parties, advocates the regulation of the CE profession and is currently establishing the mechanisms and structures for the CCE. IFMBE should ask all national governments to adopt and follow this model.

Learning Objectives:

1) The attendee will be able to explain the need for certification of Biomedical Engineering Technologists (BMETs) and describe the basic steps involved to become certified in Canada.

2) The attendee will be able to explain the need for certification of clinical engineers (CEs) and describe the basic steps involved to become certified in the United States and Canada.

3) The attendee will be able to discuss the status of certification nationally and internationally.

BMEE13 - CLINICAL ENGINEERING

BMEE13.1 - Patient safety and Optimal Performance: A Holistic Framework for Medical Devices

Author(s): Michael Cheng¹, Saleh Altayyar², Hal Hilfi³, Julie Polisena⁴ ¹Biomedical Engineering, ottawa/ON/CANADA, ²King Saud University, Riyadh/SAUDI ARABIA, ³Biomedical Engineering, Ottawa/ON/ CANADA, ⁴Canadian Agency for Drugs and Technologies in Health, Ottawa/CANADA

The stated purpose of medical device regulations is to ensure the <u>safety and performance</u> of medical devices. However, many health care professionals and users of medical devices may not know the scope and limitations of medical device regulations; often they have unrealistic expectations about the device regulators' ability to protect public health. While literature and guidelines on medical devices abound, they were written in different contexts by different medical device groups employing diverse terminologies. For a policy-maker or a health care worker, the task of navigating and digesting enormous amount of information becomes very difficult.

This session will present a simple, three-stage framework summarizing three essential steps (regulation, contextualized assessment, operation management) and the key elements in each step to ensure the ultimate <u>patient safety and optimal performance</u> for any medical device. This three-stage framework, which also reflects World Health Assembly Resolution WHA60.29, is useful for medical device policy and management planning; it can serve as a common reference framework among stakeholders for education, communication, and collaboration. Its components can be linked to all levels of activities in the lifespan of a medical device. Guidance on how to execute these three steps is available in the worldwide literature; one can search for details without losing the "big-picture" relevance, and then choose the right tools appropriate to one's situation.

An insight from this framework is that, at present, medical device regulation, assessment, and management professionals tend to work in isolated groups; but the framework suggests a system with interconnecting components, through which there could be well-designed, functional interaction and collaborative activities among groups to enhance effective and efficient outcomes. Participants are encouraged to brainstorm on improving this situation.

At the conclusion of this presentation, attendees will be able to

1. know the unique difference between medical devices and drugs

2. clarify the differences between the general regulatory statement of "safety and Performance" and the ultimate healthcare objective of "patient safety and optimal performance" of medical devices

3. first do no harm.....identify the three essential steps to ensure patient safety with medical devices

4. expand the same three stages to include health technology assessment (HTA) and health technology acquisition and management (HTM) for optimal performance

5. know the basics of medical device regulations (HTR) and the essential elements for managing medical devices (HTM) (good management practices) in a healthcare facility

6. relate the widely available literature on medical devices to components of the big-picture holistic framework

7. use this simple three-stage as common framework to educate, communicate and collaborate with all stakeholders including the non-technical public as well as other healthcare professionals including the decision makers

8. hear the personal viewpoints on the importance of a holistic approach to medical device safety from the former Chair of the Asian Harmonization Working Party (http://www.AHWP.info, a medical device regulators' forum of 24 countries/economies in Asia, Africa and South America).

9. your turn: questions, comments, suggestions

10. take home challenges in enhencing the outcome of medical device utilization in your local environments.

BMEE14 - NEURAL & REHABILITATION ENGINEERING

BMEE14.1 - Neuro-robotics – Neurally Interfaced and Inspired Prosthesis Author(s):

Prosthesis technology, such as dexterous upper limb, has advanced greatly in sophistication. Not only are the motor mechanisms advanced, capable of extensive dexterous manipulation, but the more advanced prostheses also possessing sensors for feedback. However, controlling the prostheses remains a significant challenge. Here the need and the challenge is the neural interface, whether to the peripheral or the central nervous system, and deriving or providing the information for motor control and sensory feedback respectively. This talk will present the current state of the art of neural interface for dexterous upper limb prosthesis and how neural control may be achieved. Neural interface technology may be noninvasive or invasive, and utilizes micro to macro electrodes for signal acquisition, and decodes spiking information from neurons and cortical rhythms from brain surface or the scalp. Sophisticated decoding of neural population and signal processing of EEG and Electrocorticogram can derive information needed to the control dexterous movement of the prosthesis. However, sensory information is not as readily relayed to the nerves or the brain and thus sensory prosthesis are not yet as advanced. Biologically inspired tactile sensors that take into consideration receptors and the nerve code may help achieve suitable sensory feedback via microstimulation of nerves or the brain of the amputee. Future research and development will be directed towards closing the loop, deriving cortical or peripheral nervous system information to control the prosthesis and return the sensory information to the subject. This vision of Neuro-robotics or Neuro-prosthesis calls for a chronically interface implanted or seamlessly integrated with the limb and the nervous system.

BMEE15 - CLINICAL ENGINEERING/TECHNOLOGY MANAGEMENT

BMEE15.1 - Introduction to Root Cause Analysis (RCA) and Failure Modes and Effects Analysis (FMEA) to Support Medication Safety Initiatives

Author(s): Kim Streitenberger, Julie Greenall

N/a, Institute for Safe Medication Practices Canada, Toronto/CANADA

Recently media attention has been focused on serious errors involving medications occurring in various healthcare settings. Often these reports express concern about lack of accountability of individual healthcare providers involved in these errors; however understanding the science of error helps us to realize that most errors are not related to individual competence but rather a complex interaction between the healthcare provider and numerous underlying system factors. This one-hour presentation will provide an overview of two structured analysis techniques, one prospective and one retrospective, that will assist individuals and organizations to improve their approach to safe medication management.

At the conclusion of this presentation, participants will understand:

the importance of incident analysis in organizational safety efforts

the impact of system factors on error potential in the medication use process

the need to apply human factors engineering principles in error analysis and system redesign

when to use retrospective analysis (root cause analysis) and prospective analysis (failure mode and effects analysis)

The Institute for Safe Medication Practices Canada (ISMP Canada) is an independent national not-for-profit organization committed to the advancement of medication safety in all healthcare settings. Our goal is the creation of safe and reliable systems for managing medications in all environments. For more information about ISMP Canada, please visit www.ismp-canada.org.

BMEE15.2 - Biomechanics - Computational Modeling and Analysis

Author(s): Yubo Fan

School of Biological Science and Medical Engineering, Key Laboratory for Biomechanics and Mechanobiology of Ministry of Education, National Key Lab of Virtual Reality Technology, Beihang University, Beijing/CHINA

The learning objective is to understand:

(1) the basic concept of computational modeling and analysis in biomechanics,

(2) the applications of these computational methods,

(3) the development direction of the computational methods.

Biomechanical factors extensively participate the life activity of living organism. Mechanical environment involves the proliferation, differentiation and apoptosis of the cell, the growth and remodeling of the tissue, and the coordination of different physiological systems. Mechanical factors also play critical roles in the diseases and therapies. For example, wall shear stress participates the formation of atheromatous plaques; post-operative stress distribution affects the outcome of interventional surgery. The integration of biomechanics and microbiology has become the indispensable parts in the fields of physiology and medicine. Computational simulation has been an important method for biomechanical investigation. Computational method can anticipate the irregular and complicated biological structure, predict and analyze the responses under extreme conditions. Despite that the simulations must follow by experimental validation and computational verification to ensure accuracy. We have conducted series of computational investigation in the areas of orthopedics, orthodontics, and injury prevention. These include:

(1) The protective mechanism of woodpecker's head for absorbing impacts was discovered. The special functions of beak and hyoid provided bionic insight in protective designs. (2) The finite element eyeball was simulated with an injury process, revealing the mechanism of amotio retinae. (3) Significant achievements on different orthopedic research and clinical application were also obtained, such as knee, cervical spine, wrist, fetal head, ankle, and osteoadaptation in space.

Computational technology has advanced the biomechanical researches in physiology and medicine. With the development of the computer technology and numerical algorithm, computational technology will continue to promote the interdisciplinary and multiscale studies in biomechanics and mechanobiology.

Acknowledgment

The present study was supported by grants from National Natural Science Foundation of China (NSFC 11421202, 11120101001), and National Science & Technology Pillar Program of China (2012BAI18B07, 2012BAI22B02).

BMEE16 - BME TECHNICAL/SERVICE COURSES

BMEE16.1 - Surgical Laser: Technology and Safety Issues Author(s): <u>Murray Greenwood</u>

Biomedical Engineering, Trillium Health Partners, Mississauga/CANADA

With the recent updates to standards ANSI Z136.1 Safe Use of Lasers and CSA Z386-14 Safe Use of Lasers in Healthcare, the requirements for the administration of the hospitals' laser safety program will require updating.

At the conclusion of the program, attendees will be able to:

Apply the laser standards to various surgical active lasing mediums

Understand various safety challenges with different active lasing medium and their delivery systems

BMEE17 - MEDICAL DEVICE DEVELOPMENT AND COMMERCIALIZATION

BMEE17.1 - Technology Commercialization - Road Map and Precautions Author(s):

This lecture will discuss the process of technology commercialization and provide cautionary advise to entrepreneurial scientists and engineers in bioengineering and medical physics. Technology commercialization begins by making sure scientists and engineers are aware of the opportunities afforded by commercialization and the requirement to have the intellectual property (IP) properly secured. Disclosing an invention or a trade secret in a public talk invalidates IP rights. Industrial contracts must carefully spell out the IP rights. University technology transfer offices only file patents that have a high likelihood of licensing. Existing corporations typically license technology with high reward and low risk. Startup companies are left with higher risk technology. The startup process is fraught with difficulties related to lack of skill of founders, inadequate governmental and investment funding, poor choice of corporate partners, and affordable experienced management. Offering the right product at the right time with excellent development, operations, marketing, sales, and service are the key factors to the success of startup companies.

BMEE18 - GENERAL BME EDUCATION

BMEE18.1 - BioMEMS - Microsensors; Microactuators; Microfluidics; Micro-Total Analysis Systems (e.g., Genomics and Proteomics)

Author(s): David Weitz

Physics & Seas, Harvard University, Cambridge/MA/UNITED STATES OF AMERICA

This talk will describe the use of drop-based microfluidics to perform very large numbers of experiments using small, picoliter-sized drops in an inert carrier fluid. This technology enables many new classes of experiments and applications. Both the underlying science and the applications will be described.

BMEE19 - BME TECHNICAL/SERVICE COURSES

BMEE19.1 - Rechargeable Batteries: Characteristics, Performance, and Maintenance Author(s): <u>Isidor Buchmann</u> Cadex, Richmond/CANADA

Topic As the reliance on the battery grows, so does the need for robust battery management standards and practices in healthcare. This is not happening uniformly and the *Association for the Advancement of Medical Instrumentation (AAMI)* rated battery management as one of the top 10 challenges for hospital's biomedical departments. An US FDA survey says that "up to 50% of issues in hospitals are related to the battery."

At a debriefing with the FDA at their Maryland HQ at which Mr. Buchmann participated, three shortcomings were identified with batteries in medical devices. Each of these will be discussed at the IUPESM World Congress, and are:

 Deficiency in quality assurance in batteries by device manufacturers

2. Lack of understanding in battery system integration

3. Not knowing the end of battery life

Presentation Equipment manufacturers base the runtime of a device on a new battery, but this is a temporary state. Once rubberstamped and approved by the authorities, the users are on their own. Little guidance is provided to assure continued performance and hints as to when to replace the battery.

A battery has a relatively short service life and will require several replacements during the life of the host device. Batteries are difficult to test and often escape the scrutiny of inspection. To assure reliability, a battery must be treated like any other serviceable part in a medical device.

When asking users of a battery-operated medical devices, "When should the battery be replaced?" no clear answers are given. Without a strategic management plan, a battery may stay in service too long, compromising reliability, but most are changed too early, increasing operational cost and stressing the environment.

Mr. Buchmann will give an overview of basic battery technology, discuss typical behaviors in healthcare, how their life can be optimized, pros and cons of a smart battery, when a battery should be replaced, and methods of analyzing batteries as part of maintenance systems.

Presenter Isidor Buchmann is the founder and CEO of Cadex Electronics Inc. and author

of www.BatteryUniversity.com. For three decades, Buchmann has studied the behavior of rechargeable batteries in practical, everyday applications, has written award-winning articles including the best-selling book "Batteries in a Portable World," now in its third edition.

Company Cadex Electronics specializes in the design and manufacture of battery chargers and analyzers, as well as advanced rapid-test and monitoring systems. Sold in over 100 countries, Cadex products are known for their robust design, reliable service and long product life. During the 30 years of operations, Cadex has secured several patents in the field of battery diagnostics and monitoring.

Battery University www.BatteryUniversity.com is an education website that addresses strengths and limitations of batteries in the hands of the everyday user. The papers evaluate different battery types and offer the best choice for an application. The information offers busy professionals a crash course on batteries; it helps engineers find a battery for a new product; students seeking answers for an academic project; and the everyday battery users wanting to prolong battery life.

BMEE20 - HUMAN FACTORS AND MEDICAL DEVICE SAFETY

BMEE20.1 - Clinical Alarms Management (incl. IHE Alarm Communication Mgt)

Author(s): Yadin David¹, Tobey Clark², Marjorie Funk³ ¹Health Technology Foundation, Biomedical Engineering Consultants, LLC, Houston/TX/UNITED STATES OF AMERICA, ²Instrumentation & Technical Services, University of Vermont, Burlington/ UNITED STATES OF AMERICA, ³School Of Nursing, Yale University, Orange/CT/UNITED STATES OF AMERICA

Background

The use of an instantaneous attention-getting feature, like an alarm, to improve management of a patient's health condition has been used for many years. Alarm systems, ranging from simple alerts to complex alarm systems, are found on many medical devices. Alarms are intended to protect patients, however, they also contribute to noise, error, and the phenomenon of "alarm fatigue", which can lead to adverse events.

Alarm fatigue results from staff being overwhelmed by a cacophony of non-actionable alarms, leading to a delayed response to the actionable alarms or to alarms being ignored or turned off. A high percentage of alarms are not actionable – they do not lead to changes in patient management.

Due to significant adverse events related to clinical alarms, the Healthcare Technology Foundation (HTF) began an initiative in 2004 to improve the management of alarms. A task force of clinical engineering professionals wrote a seminal white paper in 2007 summarizing the literature, adverse event data, and a national survey of 1,327 healthcare staff, which included observations and recommended improvements.

Between 2005 and 2009, the Food and Drug Administration received 566 reports of deaths related to alarms - over 100 deaths each year. The devices associated with the highest number of deaths were physiologic monitors and ventilators.

In 2011, the HTF administered a second national survey, to which 4,278 clinicians responded. The results of this survey were presented to the attendees at the 2011 AAMI Clinical Alarms Summit and distributed nationally. Little progress in alarm hazard reduction was found between the two surveys, with false alarms still comprising the most serious issue related to alarms. Almost 20% of the respondents reported that adverse events occurred in their hospital in the prior 2 years.

The ECRI Institute, an independent, non-profit health technology safety organization, identified alarm hazards as the #1 Health Technology Hazard for the past 4 years.

Effective January 1, 2014, the Joint Commission issued a National Patient Safety Goal (NPSG.06.01.01) requiring hospitals to establish alarm management as an organizational priority. Accordingly, organizations must design a systematic and coordinated approach to better manage this important safety issue. Policies, procedures, and education related to alarms will be required beginning in 2016.

Deliverables

This session will address quantitative and qualitative findings from the HTF alarm surveys. Results showed the impact of clinical alarms on patient safety, clinical perceptions of alarms, and alarm improvement efforts. Results of roundtables held at the 2015 AAMI annual meeting will be presented, along with current HTF activities, such as the development of an "Alarms 101" document for patients and families.

Care providers' views of the issues and best practices for meeting patient management goals and the Joint Commission NPSG.06.01.01 will be discussed, including a case study. Also, the development of unique educational tools, including online clinical alarms orientation and training, will be covered.

Objectives

1. Describe the problem of alarm fatigue and its impact on patient safety.

2. Identify effective strategies for alarm management.

3. Discuss attitudes and practices related to clinical alarms as revealed in the Healthcare Technology Foundation's national surveys.

BMEE21 - GENERAL BME EDUCATION

BMEE21.1 - Biomaterials - Cell-surface Interaction Author(s): <u>Caroline Loy</u>, Diego Mantovani Lab Biomaterials And Bioengineering, Laval University, A/QC/CANADA

Cell-Materials Interactions for the Replacement and the Regeneration of Tissue and Organs

Caroline Loy and Diego Mantovani

Canada Research Chair I for Biomaterials and Bioengineering for the Innovation in Surgery, Dept of Min-Met-Materials Engineering & Research Center, University Hospital Center, Laval University, Québec City, Canada

Over the last 50 years, biomaterials, prostheses and implants saved and prolonged the life of millions of humans around the globe. The main clinical complications for current biomaterials and artificial organs still reside in an interfacial mismatch between the synthetic surface and the natural living tissue surrounding it. Today, nanotechnology, nanomaterials and surface modifications provides a new insight to the current problem of biomaterial complications, and even allows us to envisage strategies for the organ shortage. Advanced tools and new paths towards the development of functional solutions for cardiovascular clinical applications are now available.

In this CE program, we are therefore proposing to present and discuss with English, French and Spanish speakers the past, present and future challenges of cell-material interactions. At the conclusion of this program, attendees will be able to:

Describe and discuss the principles of the host-response that any foreigner body generate when in contact with human cells and tissues;

Define and determine how to assess and predict in vitro the cell-materials interactions in the cardiac, vascular, neurological and orthopedic system, including those generated and the bone and blood interface;

Demistify the myth of the bionic man, and understand how diseased tissue and organs can be replaced, reconstructed or are envisaged to be regenerated.

BMEE21.2 - Biomaterials - Plasma Medicine

Author(s): <u>David B. Graves</u>¹, <u>Michael Keidar</u>² ¹Chemical And Biomolecular Engineering, University of California at Berkeley, Berkeley, CA/CA/UNITED STATES OF AMERICA, ²The George Washington University, Washington/UNITED STATES OF AMERICA

A new field of cold atmospheric plasma (CAP) processing associated with biomedicine has emerged in the last 5-10 years. [1] CAP can be used to shrink tumors, promote wound healing and sterilization, and treat dermatological and dental disease, among other things. This presentation will focus on the role of reactive oxygen species (ROS) and reactive nitrogen species (RNS). ROS and RNS (or RONS), in addition to a suite of other radical and non-radical reactive species, are essential actors in an important sub-field of aerobic biology termed 'redox' (or oxidation-reduction) biology. Evidence will be presented that RONS generated by plasmas are probably responsible for much their observed therapeutic effects. [2,3]

At the conclusion of the CE program, attendees will be able to:

1- Describe and discuss the emerging field of cold atmospheric plasma biomedicine.

2- Understand some of the physical and chemical characteristics of the plasma sources as well as typical tools used by plasma scientists to measure and compute key quantities.

3- Recognize some of the emerging connections between reactive species in aerobic biology and the therapeutic mechanisms of CAP.

BMEE22 - GENERAL BME EDUCATION

BMEE22.1 - Biosensors and Signal Processing - Signal Analysis and Processing

Author(s): Sri Krishnan

Electrical And Computer Engineering, Ryerson University, Toronto/ CANADA

Abstract:

In this talk the characteristics of biomedical (physiological) signals will be covered followed by the techniques and algorithms needed for processing, analysis and intrepretation of these signals. Timedomain, frequency-domain, joint time and frequency domain, and sparse domain approaches will be covered in detail for applications related to body sounds' signals, ECG, EMG and gait rhythm.

Learning objectives:

1) design of biomedical signal analysis system

2) intrepretation and quantification of biomedical signals for various applications related to health ICT and emerging mobile health applications

3) algorithms for processing of biomedical signals

BMEE22.2 - Cellular and Biomolecular Engineering - Nanoparticles in Diagnostic Therapy

Author(s): Mukesh Harisinghani

Radiology, Massachusetts General Hospital, Boston/MA/UNITED STATES OF AMERICA

Magnetic nanoparticles have been used for imaging oncologic and immune disorders as they provide a means of assessing macrophage activity. conventional imaging in these areas is limited to anatomical depiction of abnormality, the use of magnetic nanoparticles provides the functional component and has been a poster child for bench to bedside application.

At the conclusion of the proposed program, attendess will be able to

1. Understand the mechanism by which magentic nanoparticles provide functional informaton on MRI

2. Understand the clinical utility of imaging with nanoparticles and how it could profoundly influence patient care

3. Understand what some of the technical challenges are when imaging with magetic nanoparticles

BMEE23 - CLINICAL ENGINEERING/TECHNOLOGY MANAGEMENT

BMEE23.1 - Clinical Engineering Standards of Practice – Canadian New Edition and Other Countries Author(s): Anthony Chan¹, <u>Bill Gentles</u>²

¹Biomedical Engineering, British Columbia Institute of Technology, Burnaby/CANADA, ²Vice President, BT Medical Technology Consulting, Toronto/CANADA

Learning Objectives: At the conclusion of this session program, attendees will:

Understand the process of developing a Standard of Practice that is appropriate for their particular healthcare environment.

Understand the value of the discussions that take place during the development of a standard of practice.

Understand the main sections to include in a standard that is written to conform to ISO guidelines.

Understand how a standard of practice can be used as the basis of a peer review or accreditation process for Clinical Engineering services.

Abstract

Clinical engineering is one of several professional disciplines contributing to safe, effective and economical health care. The role and primary responsibility of a clinical engineering service is management of medical device technology, including adherence to recognized safety, quality, cost and efficiency standards.

The first Clinical Engineering Standards of Practice (CESOP) for Canada was published in 1998. The CESOP has since gone through 2 revisions, with the latest being published in 2014. Each revision was developed by a working group with broad representation from across the country. The working group for the 2014 revision met on a monthly basis for over a year, and produced 17 drafts before the final draft was presented to the membership for approval.

The CESOP is widely adopted by clinical engineering departments across Canada to establish scopes and practice; referenced by health care accreditation bodies; and used to formulate evaluation guidelines in peer review process.

Examples of standards of practice from other countries will be presented and compared to the Canadian standard.

BMEE23.2 - Emerging Medical Technologies - What to Expect, How to Prepare for it Author(s):

Medical technologies are evolving at a rapid pace. This change is significantly impacting how healthcare organizations and their technology managers should plan for, procure, support, and update their technologies. This presentation will review new and emerging technologies that are expected to have the most impact on the healthcare technology management profession. It will also discuss the operational and mindset changes that healthcare technology management professionals must make to best prepare for their emerging and future roles. This discussion will include a review of the processes used by ECRI to assess and make judgments about new and emerging technologies with commentary on how these processes can be applied at healthcare organizations. At the conclusion of this program attendees will be able to: 1. Describe important new and emerging trends in healthcare technologies

2. Discuss key operational changes that healthcare technology management programs should be making to prepare for new and emerging medical technologies

3. Develop a methodology for evaluating and planning for new and emerging medical technologies

BMEE24 - MEDICAL DEVICE DEVELOPMENT AND COMMERCIALIZATION

BMEE24.1 - The Product Development Cycle

Author(s): Lahav Gil Ceo, Kangaroo Group, Toronto/CANADA

Learning objectives:

1. Understand the nomenclature of medical devices product development and how it corelates with the (business) language of commercilaization of a medtech company

2. Anderstand the key steps of development that a clinical technology goes through, from technology-transfer all the way to commercial grade, validated and appproved medical device, based on the FDA recomendations for product realization

3. Understand how to assess and evaluate technology rediness, and where it currently is on the product development map

Abstract:

The presentation will provide a clear map and the milestones of medical devices product development starting with requirments gathering and product definition and ending with a validated medical device ready to ship. We will cover each step and explain the content of the inputs and outputs along the progress path.

Some of the topics that will be covered, amongst others are: Business jusification, requirements gathering and needs assesment, stakholders analysys and value drivers, feasibility studies, user feedback, system SPECs and architecture, diferent kinds of prototypes, alpha prototype, preproduction build, design controls, serial manufacturing, V&V, DHF, DMR, DHR, NPI, ISO 13485 QMS, tracability matrix, labeling, change controls

BMEE25 - CLINICAL ENGINEERING/TECHNOLOGY MANAGEMENT

BMEE25.1 - Clinical Engineering Best Practice and Bench-marking

Author(s): Binseng Wang

Quality & Regulatory Affairs, Sundance Enterprises, Inc., White Plains/UNITED STATES OF AMERICA

While debated for over 30 years, productivity and efficiency (cost) measurements and benchmarking continue to be a challenging topic for the clinical engineering (CE) community. At the core of this challenge is the lack of reliable indicators substantiated by actual data. An attempt was made to evaluate some traditional and newer indicators using data collected from two distinct sources in the USA, each with >150 hospitals. Results confirm early concerns that worked hours self-entered by CE staff are subject to misuse and, thus, should be avoided as a productivity benchmark. Likewise, the cost-of-service ratio (COSR) is easily manipulated and, thus, not reliable as an efficiency benchmark. In contrast, good statistical correlation was found for both staffing and cost data with several hospital indicators that are consistently collected for reimbursement and financial reporting purposes. Good correlation with CE department indicators was more difficult to find, apparently due to the lack of reliable records and consistent accounting of all CE resources and expenditures. While no single, easy to measure and understand indicators emerged as replacements for the worked-to-paid-hours ratio and COSR, it was possible to build multi-dimensional models for both productivity and cost efficiency. However, these models, while accurate, are not precise, so the results need to be interpreted carefully. Furthermore, anecdotal data obtained from other countries showed that there are substantial differences in both staffing and efficiency metrics, even though there are numerous similarities in technical metrics. In essence, benchmarking of staffing and cost can be good starting points for a more detailed analysis of the differences among organizations that could reveal substantive causes such as service scope and strategy, organizational characteristics and geographical challenges as well as opportunities for major productivity improvements and cost reductions.

BMEE26 - CLINICAL ENGINEERING

BMEE26.1 - Collaboration on Healthcare Technology Decision-Making

Author(s): Julie Polisena¹, Hal Hilfi², <u>Michael Cheng</u>³ ¹Canadian Agency for Drugs and Technologies in Health, Ottawa/ CANADA, ²Biomedical Engineering, Ottawa/ON/CANADA, ³xxx, xxx/UNITED KINGDOM

This education session will discuss two types of collaboration on healthcare technology decision making, both of which emphasize a multidisciplinary approach. Firstly, we will briefly describe a simple checklist that guides the routine assessment of any request for the purchase of medical devices in a healthcare facility. Secondly, , we will outline the application of formal HTA (health technology assessment) to support informed decision making for new technologies, a large scale technology acquisition and/or complex technologies. We shall devote a major part of this presentation to describe the collaboration of hospital-based HTA network to support informed healthcare technology decision making.

HTA is a form of analysis on health technologies that provides decision makers with information on their clinical effectiveness, safety, cost-effectiveness, and encompasses patient preferences, and ethical, societal, organizational and other considerations. It is a principle component of the holistic framework, (presented yesterday) to enhance the optimal performance associated with the use of medical devices. More specifically, we will elaborate on how HTA in a network of healthcare providers can assist in making decisions on the purchase, use and discontinued use of medical devices in their institution. In addition, we describe how local HTA units can collaborate to facilitate information sharing, avoid unnecessary duplication of effort, and provide equal access to timely evidence-based information to decision makers. This network of HTA producers would allow their work to contribute fully to ensure the sustainability at all levels of healthcare.

Many jurisdictions continue to face hospital budget cuts that force them to look at innovative ways to address these shortfalls, while still managing health care technologies. HTA at the hospital and regional levels is gaining recognition and importance in many parts of Canada and Europe given its potential for greater impact on hospital policies and clinical practice by involving the end-users in the assessment and decision-making. More could be achieved through effective collaboration or networking to combine efforts and experiences.

At the end of this education session, attendees will be able to:

1- learn more details of the Stage 2 (assessment function) of the Holistic Framework for Medical Devices presented yesterday (11 June 2015)

2 appreciate how multidisciplinary collaborations in healthcare technology decision making are crucial in contributing to the safety, quality, and sustainability at all levels of healthcare.

3- use a checklist to guide routine assessment on simple requests for the purchase of medical devices in a healthcare facility

4 understand how HTA for more complex casescan enhance the optimal performance on the use of medical devices

5- understand how an HTA collaborating network can facilitate information sharing on purchasing, implementing, managing, and decommissioning of medical devices.

BMEF01 - GESTION EN GÉNIE BIOMÉDICAL/CLINIQUE

BMEF01.1 - Exemples de Donnes Pratiques en Génie Clinique et Indicateurs

Author(s): Mohcine El Garch

Groupe Biomédical Montérégie, Agence de la Santé et des Services Sociaux de la Montérégie, Brossard/QC/CANADA

Objectifs d'apprentissage: A l'issue de ce programme de la session, les participants pourront:

1. Comprendre les éléments requis pour mettre en place une démarche qualité dans un service de génie clinique.

2. Comprendre les éléments requis pour mettre en place une stratégie d'entretien des équipements médicaux

3. Identifier les éléments principaux d'une démarche de planification d'entretien préventif pour les équipements médicaux

4. Comprendre les éléments principaux d'un projet d'acquisition de technologie médicale

5. Identifier quelques indicateurs pertinents pour un service de génie clinique et les intégrer au sein d'un tableau de bord.

Exemples de bonnes pratiques en génie clinique et indicateurs

Le génie clinique est l'une des disciplines professionnelles qui contribuent à la sécurité et l'efficacité des systèmes de santé tout en contribuant à l'optimisation des coûts associés à l'utilisation des technologies. Le rôle et la responsabilité première d'un service de génie clinique est la gestion de la technologie des dispositifs médicaux, y compris le respect des normes de sécurité, de qualité, et les standards de gestion de coût et d'efficacité reconnus.

Cette session va présenter dans un premier temps les principaux éléments d'une démarche qualité pour un service de génie clinique. Cela nous permettra de constater que l'implantation d'une démarche qualité dans un service de génie biomédical ne constitue pas une fin en soi. C'est un outil pour améliorer l'efficacité de l'organisation d'un service de génie biomédical afin de répondre encore mieux aux attentes du personnel clinique, des patients et des administrateurs d'un établissement de santé. En utilisant les guides de pratiques reconnus dans le domaine du génie clinique, cette session présentera également des pistes pour revoir les principaux aspects de gestion des technologies de santé en hôpital tel que la stratégie d'entretien des équipements médicaux, la planification des entretiens préventifs des équipements, la gestion des projets d'acquisitions ou encore la mise en place d'indicateurs et de tableaux de bords.

ENGLISH

TITLE: Examples of standards of practices in clinical engineering, improvements and metrics - Exemples de bonnes pratiques en génie clinique, amélioration et indicateurs.

ABSTRACT: Clinical engineering is one of the professional disciplines that contribute to the safety and effectiveness of health systems and contribute to the optimization of costs associated with the use of technology. The role and primary responsibility of a clinical engineering department is the management of medical device technology, including compliance with safety standards, quality, and cost management recognized standards.

This session will present main elements of a quality system approach for clinical engineering departments. This will allow us to see that the implementation of a quality approach in a Clinical Engineering department is not an end in itself. It is a tool to improve the efficiency of the organization to better meet the needs of clinical staff, patients and administrators of a health facility.

Using standard recognized practices in the field of clinical engineering, this session will also present ways to review key aspects of healthcare technology management in health technology such as maintenance strategy of medical equipment, planning of preventive maintenance equipment, management of acquisition projects or the development of performance metrics and dashboards.

Learning Objectives:

At the end of the program of the session, participants will:

1. Understand the elements required to implement a quality approach in a clinical engineering department.

2. Understand the elements required to implement a maintenance strategy of medical equipment

3. Identify the key elements of a preventive maintenance planning process for medical equipment

4. Understand the main elements of a medical technology procurement project

5. Identify some relevant indicators for clinical engineering services and integrate them within a dashboard.

BMEF02 - GESTION EN GÉNIE BIOMÉDICAL/CLINIQUE

BMEF02.1 - Clinical Engineering Standards of Practice – Normes de Pratique en Génie Clinique- Nouvelle Edition Canadienne en Français

Author(s): Mohcine El Garch¹, Bill Gentles²

¹Groupe Biomédical Montérégie, Agence de la Santé et des Services Sociaux de la Montérégie, Brossard/QC/CANADA, ²Vice President, BT Medical Technology Consulting, Toronto/CANADA

Le génie clinique est l'une des disciplines professionnelles qui contribuent à la sécurité et l'efficacité des systèmes de santé tout en contribuant à l'optimisation des coûts associés à l'utilisation des technologies. Le rôle et la responsabilité première d'un service de génie clinique est la gestion de la technologie des dispositifs médicaux, y compris le respect des normes de sécurité, de qualité, et les standards de gestion de coût et d'efficacité reconnus.

Le premier guide des pratiques en génie clinique (CESOP) pour le Canada a été publié en 1998. Le CESOP a depuis traversé deux révisions, la dernière ayant été publiée en 2014. Chaque révision a été développé par un groupe de travail avec une large représentation de partout au pays. Le groupe de travail pour la révision 2014 s'est rencontré sur une base mensuelle depuis plus d'un an, et a produit 17 avant-projets avant que le projet final soit présenté aux membres pour approbation.

Au cours de l'année 2015, le comité Bilingue du CMBES a entrepris la traduction du guide anglophone afin de pouvoir le partager avec la communauté en génie clinique francophone au Canada.

Le CESOP est largement adopté par les départements de génie clinique à travers le Canada pour établir les champs d'activité de la pratique professionnelle. Il est référencé par les organismes d'accréditation de soins de santé et il est également utilisé pour formuler les lignes directrices d'évaluation dans le processus d'examen des départements de génie clinique par les pairs.

Au cours de la session, des exemples de guides de pratiques d'autres pays seront présentés et comparés au référentiel canadien.

Objectifs d'apprentissage: A l'issue de ce programme de la session, les participants pourront:

1. Comprendre le processus d'élaboration d'un guide de pratiques qui est approprié pour leur environnement de soins de santé particulier.

2. Comprendre les principales sections du guide qui est rédigé en vue de se conformer aux lignes directrices de l'ISO.

3. Comprendre comment un guide de pratique peut être utilisée comme standard de base d'une revue du fonctionnement d'un service de génie clinique par les pairs ou dans le cadre d'un processus d'accréditation.

ENGLISH

Clinical engineering is one of the professional disciplines that contribute to the safety and effectiveness of health systems and contribute to the optimization of costs associated with the use of technology. The role and primary responsibility of a clinical engineering department is the management of medical device technology, including compliance with recognized safety standards, quality, and cost efficiency management standards.

The first Clinical Engineering Standards of Practices (CESOP) for Canada was published in 1998. The CESOP has since gone through two revisions, the latest having been published in 2014. Each revision was developed by a working group with broad representation across the country.

During 2015, the Bilingual Committee CMBES undertook the translation of the English-speaking guide in order to share it with the francophone clinical engineering community in Canada.

The CESOP is widely adopted by clinical engineering departments across Canada to establish the scopes of professional practice. It is referenced by the health care accreditation bodies and it is also used to formulate the assessment guidelines in the review process for clinical engineering departments peer.

The session will be an introduction to the CESOP French translation with some comparison with examples of other countries standards of practices.

Learning Objectives: At the end of the program of the session, participants will:

1. Understand the process of developing a practical guide that is appropriate for their particular health care environment.

2. Understand the major sections of the guide that is written in order to comply with ISO guidelines.

3. Understand how practice guidelines can be used as standard based on a review of the functioning of a clinical engineering department peer or as part of an accreditation process.

BMEF03 - GESTION EN GÉNIE BIOMÉDICAL/CLINIQUE

BMEF03.1 - Impacts de la Technologie Médicale sur la Santé de la Mére et de l'Enfant

Author(s): <u>Gnahoua Zoabli</u>¹, Akimey A. Nabilath² ¹Biomedical Engineering, CSSS du Lac-des-Deux-Montagnes, St-Eustache/CANADA, ²Institute Of Biomedical Engineering, University of Montreal, Montreal/CANADA

Objectifs:

- 1. Santé et sécurité au travail
- 2. Santé de la mère et du bébé

3. Outils pour se prémunir des effets néfastes de la technologie médicale sur l'humain

4. Prévention en milieu de travail pour les professionnels de la santé

Résumé:

L'environnement hospitalier comporte continuellement pour les employés différents risques selon la nature des tâches réalisées quotidiennement: proximité de patients infectés, exposition au bruit ambiant, exposition aux rayonnements ionisants, manipulation de produits chimiques ou biologiques, effort physique de manutention, risque d'éraflure ou de piqure accidentelle. Des mesures préventives et des directives appropriées permettent de minimiser ces divers risques et d'assurer aux employés des conditions de travail assez sécuritaires durant l'exercice de leur profession au sein de l'hôpital. Les dispositions mises en œuvre pour garantir une maternité sans danger ne sont pas appliquées de façon uniforme dans les établissements de santé, voire sur le même département. La présente formation est une mise à jour des connaissances qui a pour but de renseigner les professionnelles de la santé qui planifient d'être enceintes, qui le sont déjà, ou sont nouvellement mamans, sur les risques biologiques, chimiques et physiques induits par la proximité technologique ou les horaires de travail en milieu clinique. Des recommandations sont faites aux gestionnaires pour faciliter l'harmonisation des tâches et des congés connexes à la condition de grossesse ou d'allaitement chez la professionnelle exerçant en milieu clinique.

ENGLISH

Hospital environment has continuously presented different risks to the employees depending on the nature of the tasks performed daily: being close to infected patients, exposure to environmental noise or radiation, handling chemicals or biologicals, physical effort or ergonomics, risk of scratching or accidental needlestick injuries. Preventive measures and appropriate guidelines will minimize these various risks and ensure to employees fairly safe working conditions within the hospital. Procedures implemented to ensure safe motherhood at work are not applied consistently in health facilities or on the same department. This training is an update of knowledge which aims to inform health professionals who are planning to be pregnant, who already are, or are new moms. The risks studied here are related to biologicals, chemical and physical hazards induced by technological proximity or work shifts in clinical or medical areas. Recommendations are made to clinical and medical managers to facilitate the harmonization of tasks and optimize pregnancy or lactation leave conditions for female professionals working in a hospital.

Learning Objectives:

- 1. Occupational safety and health
- 2. Health of mother and baby

3. Tools to protect against adverse effects of medical technology on the human

4. Prevention workplace for healthcare professionals

BMEF04 - GESTION EN GÉNIE BIOMÉDICAL/CLINIQUE

BMEF04.1 - La Gestion de Projets et de Portefeuille de Projets en Technologies de la Santé

Author(s): Mohcine El Garch

Groupe Biomédical Montérégie, Agence de la Santé et des Services Sociaux de la Montérégie, Brossard/QC/CANADA

L'objectif de ce cours est de donner des pistes de réflexion aux participants pour :

Définir la gestion de projet dans un contexte hospitalier

Réaliser la planification de leurs projets (petits ou grands)

Établir la charge de travail du ou des professionnels

Gérer la performance et les risques associés à un projet

Communiquer de façon efficace l'avancement des projets

Utiliser le logiciel MS Project pour réaliser la gestion d'un projet

Partager des projets et des ressources en mode multi-projets avec MS Project

La gestion de projets et de portefeuille de projets en technologies de la santé.

Les activités du service de génie biomédical dans un hôpital sont plus souvent qu'autrement réalisées en mode projet. Travaillant seul ou en équipe, le professionnel est souvent amené à développer des outils lui permettant de suivre ces activités. Que ce soit dans le cadre de petits projets ou de projet de grande envergure, la connaissance des méthodes de projets et des outils pratiques sont un incontournable.

Ce cours présente les éléments principaux de la gestion de projet en général, les enjeux, les risques et les outils à mettre en place pour mieux gérer ses projets. Des exemples de projets et de situations rencontrées spécifiquement dans le domaine du génie clinique seront présentés et des outils pour gérer les projets et les portefeuilles de projets seront également abordés.

ENGLISH

TITLE: Project management and program in health technology projects - La gestion de projet et de portefeuille de projet en technologies de la santé

ABSTRACT: The activities of the Clinical Engineering department at a hospital are more often than not carried out in project mode. When working alone or in teams, the clinical engineer needs to develop tools to monitor these project activities. Knowledge of standard practices and tools of project management are a necessity in the context of large-scale project or even with the small projects.

This course presents the main elements of project management, issues, risks and tools to put in place to better manage its projects. Examples of specific projects and situations encountered in the field of Clinical Engineering will be presented and tools to manage projects and program will be discussed.

Learning objectives:

The objective of this course is to give food for thought to the participants to:

- · Define project management in a clinical engineering perspective;
- Plan their projects (whether small or large);
- Establish workload for clinical engineers;
- · Manage the performance and risks associated with a project;

- · Communicate effectively the progress of projects;
- Use MS Project to achieve the project management;
- \cdot Share projects and resources in multi-mode projects with MS Project

BMEF05 - GESTION EN GÉNIE BIOMÉDICAL/CLINIQUE

BMEF05.1 - Implantation du Guide des Bonnes Pratiques de L'ingénierie Biomédicale en Etablissement de Santé Author(s): Fabienne Debiais¹, Christine Lafontaine² ¹Génie Biomédical, Hôpital général juif, Montréal/CANADA, ²Génie Biomédical, Haelys, Terrebonne/QC/CANADA

Résumé:

Cet atelier présentera le guide des bonnes pratiques de l'ingénierie biomédicale en établissement de santé et proposera une démarche d'implantation ainsi que des outils et méthodes pour y parvenir.

Cette session comportera un partage d'expériences variées provenant de plusieurs établissements de santé et faisant appel à diverses méthodologies (LEAN, ISO 9001...).

Objectif #1:

S'approprier le guide des bonnes pratiques de l'ingénierie biomédicale pour mieux le maîtriser et en tirer le maximum pour répondre aux exigences du milieu de la santé.

Objectif #2:

Découvrir différentes techniques de priorisation des bonnes pratiques de l'ingénierie biomédicale afin de maximiser l'impact des actions mises en oeuvre.

Objectif #3:

S'initier à des méthodes de gestion de la qualité (LEAN, ISO 9001) en découvrant des projets concrets réalisés en milieu hospitalier.

ENGLISH

TITLE: IMPLEMENTATION OF BIOMEDICAL ENGINEERING BEST PRACTICE GUIDE IN HEALTHCARE INSTITUTIONS

ABSTRACT : This workshop will introduce the biomedical engineering best practice guide in healthcare institutions and will suggest an implementation process as well as tools and methods to achieve this. This session will include a sharing of varied experiences from several healthcare facilities and using various methodologies (Lean, ISO 9001 ...).

BMES01 - INTEROPERABILITY IN HEALTH TECHNOLOGY

BMES01.1 - Interoperability - Profiles - IHE Author(s): <u>Vladimir Quintero</u>

Universidad Simaon Bolivar, Barranquilla/COLOMBIA

Learning objectives

1- Why Interoperability is needed?

2- The role of IHE

3- Origin, purpose and use of Interoperability Profiles

ABSTRACT

The rapid advance of Information and Communications Technology, ICT, has produced, among other effects, the multiplication of data related to the health of a patient, data that is produced by the increasing amount of diagnosis, monitoring and treatment equipment available today to the medical science. Along with this development of technology-based data, models of care have evolved towards offering integrated services, often produced by different suppliers, with the consequent need for exchange and integration of clinical and financial information. Finally, the prioritization of patient-centered care has increased the number of actors, both users and producers of information in the processes of health care delivery.

The convergence of these three trends has exponentially increased the volume of data available for any patient, without simultaneously having developed a strategy to ensure that all such data, produced by different sources, can be seamlessly exchanged, integrated, processed, and used.

We have arrived to a paradoxical situation in which potential users of the information, like physicians, policymakers, researchers, and even the patients themselves, are surrounded by a sea of data, without being able to use it in an integrated and efficient way. What is needed is the implementation of interoperability between all those equipment, devices and systems.

According to HIMSS (Health Information Management Systems Society): in healthcare, interoperability is the Ability of different information technology systems and software applications to communicate, exchange data, and use the information that has been exchanged. Data exchange schema and standards should permit data to be shared across clinicians, lab, hospital, pharmacy, and patient regardless of the application or application vendor. Interoperability means the ability of health information systems to work together within and across organizational boundaries in order to advance the health status of, and the effective delivery of healthcare for, individuals and communities.

By the end of the 90's, the Radiology Society of North America, RSNA, the National Electric Manufacturer Association, NEMA and HIMSS came together to create a new organization to deal with this challenge of interoperability, the IHE: Integrating the Healthcare Enterprise.

IHE is an international initiative designed to encourage and promote the integration of medical devices and information systems that support the operation of modern health institutions. Its main objective is to ensure that in the care of patients, all required information for medical decisions is correct and available to healthcare professionals.

The strategy proposed by IHE articulates the needs of producers and users of equipment, devices and systems, from the viewpoint of Use Cases in which information exchange requirements are determined, and a solution that fits all participants needs is developed. The methodology begins with the identification of priority situations of information exchange by users: Clinics and Hospitals, independent Doctors, research centers, etc. These requests are converted into use cases by a technical team of development engineers from major manufacturer of health equipment and systems in the world.

After identifying the particular characteristics of the exchange of information in each use case, they proceed to identify the most efficient standards for structuring this exchange (DICOM, HL7, ISO, IEEE, etc.) and with them they design and build a profile of interoperability, which is then published and implemented in equipment and systems by those producers who participated in its development, and finally tested under real conditions during the massive testing event: the Connectathon, held annually in various countries.

This scheme collaborative competition ensures that the solutions offered by the interoperability profiles, integrated into 'Technical Frameworks' which are also published free of cost, have the widest possible coverage and can facilitate the exchange of information between the maximum number of equipment and systems, regardless of their origin.

Production of IHE is structured in 14 'Domains' or thematic areas, to meet the different specialties and user needs. To date, the IHE has National Committees in 19 countries.

BMES02 - INTEROPERABILITY IN HEALTH TECHNOLOGY

BMES02.1 - Business Opportunities

Author(s): <u>Mario Castañeda</u> Health Care Technology, Healthitek, San Rafael/CA/UNITED STATES OF AMERICA

The very existence of Health Care Technology departments, programs, and projects is at risk during times of organizational political and technical turmoil. Elections, reorganizations, austerity mandates, and disruptive technologies bring changes that impact the Health Care Technology leader. The leader's ability to demonstrate added value during organizational transitions is vital. Successful designing, delivering, and sustaining programs during turmoil can be itself transformational and in line with the changes.

Our approach recasts the problem into an opportunity for economic growth. Under uncertainty, one of the major challenges is to design a program that motivates other key stakeholders to provide support. We designed a successful program in Colombia and will describe the factors that made this possible: 1) adopting **the continuum of health model** as a foundational framework, 2) building a coalition of public, private, and academic organizations for support, and 3) developing and implementing a new facilitation model to distill the ideas of 40 participant thought leaders from local business, industry, health care, and academia.

Learning objectives

The participant will

1) Identify opportunities brought about by organizational change, turmoil, and disruptive technologies.

2) Learn from the success of the Colombian Case study how to apply success factors to solve their own challenges.

3) Learn about how to identify opportunities for business, academia, and government to obtain support of their leaders.

BMES03 - INTEROPERABILITY IN HEALTH TECHNOLOGY

BMES03.1 - Trends on IT and Health Technology Author(s): <u>Antono Hernandez</u> ACCE, GHIA USA, Potomac/UNITED STATES OF AMERICA

The healthcare sector has experienced fast evolution due to the convergence of information technologies and communications with the health technologies. We will present an overview of medical technology in healthcare facilities: standalone equipment, networks of medical devices (analog and digital), technology in public health servicing communities. Also, we will address the current trend in the use of mobile communication platforms for personal monitoring and auto management of health (people responsible for their own health). Parallel to this will be the evolution of epidemiological information systems, the clinical information systems and the information generated by mobile technologies. We will highlight some aspects of the integration and convergence of these technologies and the way they have impacted the workflow in healthcare facilities. This evolution brings benefits but also risks associated that are inherent to the use of technologies as well as some others made (intentionally or unintentionally) by the people. Also, this change of the healthcare delivery model gives more responsibility to the people in the management of their own health and well-being.

Topics include:

- · The evolution and trend on healthcare technology
- \cdot The convergence of Health Technologies and Information and Communication Technologies

BMES03.2 - Healthcare Continuum

Author(s): <u>Vladimir Quintero</u> Universidad Simon Bolivar, Barranquilla/COLOMBIA

Learning objectives

- 1- What is the Healthcare Continuum
- 2- Challenges and opportunities
- 3- Where Healthcrae Continuum and Interoperability meets

ABSTRACT

Traditional health delivery is structured to meet patients' specific and acute complications. It is focused on intervention and associated diagnoses. This system consolidates in the twentieth century in response to a large increase in demand for timely cure of diseases, especially infectious and viral. This business model requires companies able to make large investments in infrastructure and specialized equipment, as well as highly specialized personnel capable of performing complex surgeries. Therefore, it is a business that consumes a lot of resources (doctors, hospital beds, technology, medicine, etc.) contributing to increase the financial pressure on the health system. Besides being timely, it is a reactive health delivery to a patient's need. In this sense, offered products and services are a response to a specific complication in the patient's health. Therefore, consumers of products and health services that typically do not have such complications are not a target for companies in this business.

What is the necessary evolution of this way of delivering health given the significant changes in demand and environment? The need to provide a continuum of care to a population with further and further growing care needs is imposed. The aim of continuing care goes beyond the cure of a disease. It seeks to accompany the patient's or consumer's health throughout his/her life. In the continuous delivery of health intervention still exists, but is limited to what is necessary, the population most in need. That is only a small part of a much more complex whole, where prevention, early disease detection and remote monitoring of patients play a key role. The consumer (and no sickness or hospital) is the center of this business. On the one hand, it supports the value chain by sending data on their health through proactive use of mobile or remote technology. On the other hand, the consumer is the key element of the proposed value chain, which seeks to provide a "complete solution" for health, promoting the establishment of lasting (and not one-time) relationships over time.

The main differences between the traditional value chain of health delivery and that of continuous healthcare delivery are reflected in the benefits of this new way of looking at health:

- · Increased business opportunities
- Better health for patients
- · Optimization of costs for companies and the system

This paradigm shift in the delivery of health services brings a significant multiplication of the actors involved, of the offered services, and of the corresponding integration mechanisms.

Finally, all that change must be supported by information, which now more than ever must be standardized to ensure "the ability of different information technology systems and software applications to communicate, exchange data, and use the information that has been exchanged" which corresponds exactly to the definition of interoperability.

JT01 - IMAGING

JT01.1 - SPECT and Gamma Camera State-Of-The-Art Technology and Current Research Author(s): <u>R Glenn Wells</u> Physics, Carleton University, ottawa/CANADA

Dedicated cardiac SPECT cameras were recently introduced into the market. These cameras represent a significant departure from traditional Anger-camera designs. They employ novel collimators and acquisition strategies, large numbers of detectors, and solidstate cadmium-zinc-telluride detectors. These features produce a 4-8 fold increase in camera sensitivity which can be used to significantly improve image quality, reduce acquisition times or reduce patient radiation exposure. Some of these systems are also guasi-stationary, opening the door to exciting future applications in dynamic imaging. This presentation will describe the design features of the more popular dedicated cameras, the DSPECT system (Spectrum Dynamics) and the Discovery NM530c (GE Healthcare) and highlight how the new cameras achieve their improvements in sensitivity. As with any new technology, there is a learning curve associated with its use: familiar artifacts like those from attenuation have changed their appearance and prevalence, and new concerns arise such as image truncation due to a limited field of view. Therefore, I will also discuss some of these and other limitations and challenges inherent in the designs and some implications for their integration into a clinical environment. I will present some of the evidence supporting the use of these systems to reduce acquisition times and patient exposures. Finally, I will discuss the use of these cameras for dynamic imaging. Once solely in the domain of Positron Emission Tomography (PET), the improved sensitivity and temporal resolution of the new cameras make it possible to acquire dynamic cardiac SPECT studies with clinically practical protocols. This will allow measurement of absolute myocardial blood flow which PET studies have shown will improve diagnostic and prognostic accuracy over standard relative perfusion imaging. I will describe some of the research being done by my group and others to bring these novel capabilities to the clinic.

At the conclusion of the CE program, attendees will be able to

Understand the novel features of these dedicated cardiac cameras and how they provide improved performance.

Describe and discuss how these new cameras can be integrated into a clinical environment and how this may alter clinical protocols and workflow.

Describe some of the novel capabilities of the new cameras and potential for future applications.

JT01.2 - Magnetic Resonance Imaging State-Of-The-Art Technology and Current Research

Author(s): Richard Frayne

Radiology And Clinical Neurosciences, University of Calgary, Calgary/AB/CANADA

Magnetic resonance (MR) imaging continues to be a rapidly changing field, with a clear connection between technologic innovation and clinical imaging enhancement. MR technology has been in near constant evolution since before the installation of the first clinical MR imaging units. The first clinical MR images in Canada were obtained in 1982; since this time advancements have been made in all facets of clinical MR imaging. These advances can be conveniently divided into hardware and software developments.

MR hardware has seen increases in main magnetic field strength, improvements in gradient performance, and tremendous advances

in imaging coil design. Today's leading edge clinical systems operate at 3 T (with some centers now exploring systems operating at 7 T and higher), with gradient performance often limited to established physiological safety limits, and adoption of flexible multi-channel (32 or more) receive coils and, most recently, multi-channel transmission. These developments have been used to increase signal-tonoise in acquired images, improve patient throughput, and maturation of a wide range of application-specific imaging coils.

MR software has arguably seen an even more explosive growth in both new approaches and applications. Most clinical MR scanners have research environments that can be accessed by user at vendors-approved research sites. This access has allowed softwarebased innovations to occur not only at vendor R&D facilities; but also at ever increasing rates at universities and academic medical centers. Advanced approaches include ongoing development of fast imaging approaches (that are often coupled with clever under-sampling schemes and matching image reconstruction strategies), artifact suppression strategies (e.g., motion, fat), as well as new image contrast mechanisms. New MR applications have extended clinical MR imaging from purely anatomical/structural imaging to include the assessment of brain activation, diffusion, perfusion, relaxation rates, velocity and other functional/physiological parameters. Techniques are also under development to image molecular phenomena. An emerging concept, related to these new assessment methods, is the application of quantitative imaging techniques to patients.

At the conclusion of this presentation, participants will:

Understand the historical pattern of advances in MR imaging and their impact on clinical care.

Describe and discuss the relevance of state-of-the-art MR hardware advancements.

Described and discuss the relevance of state-of-the-art in new MR software approaches and applications.

Have an enhanced appreciation of the relationship between technologic innovation and clinical imaging enhancement.

JT02 - PROCUREMENT AND EQUIPMENT SELECTION

JT02.1 - UNICEF's Approach to Medical Device Selection and Procurement for Low-Resource Settings

Author(s): Shauna Mullally¹, Ludo Scheerlinck²

¹Health Technology Centre, UNICEF Supply Division, Copenhagen/ DENMARK, ²Health Technology Centre, Medical Devices Unit, UNI-CEF Supply Division, Copenhagen/DENMARK

UNICEF works in over 190 countries to promote the rights of children and is a major source of health, nutrition, education, water and sanitation and child protection supplies in low-resource settings. In 2013, for example, UNICEF procured \$2.8 billion worth of supplies for development programs and humanitarian emergencies in 130 different countries, of which approximately \$142 million was medical devices and kits for maternal, newborn and child health (MNCH).

The medical devices team within UNICEF's supply headquarters in Copenhagen leads the selection and procurement of 800 medical and clinical laboratory devices that form our standard product portfolio. Many are stored in our supply warehouse where kits are packed for rapid response during emergencies and to facilitate distribution to end users. In addition to our standard device portfolio, we supply personal protective equipment, assistive health technologies for children with disabilities, and vocational training products for healthcare workers for MNCH interventions.

Our procurement is guided by UN and public procurement rules that ensure clear segregation of duties for technical and contracting staff during the tendering process. Quality assurance is also a critical aspect of the process, and is managed by an in-house team that runs a test laboratory and audits manufacturers' quality systems. We have developed quality policies for in-vitro diagnostics and medical devices, and work with the World Health Organization (WHO) on pre-qualification of rapid diagnostics tests.

In addition to managing medical device procurement, we advise on supply chain management and health technology management in-country, beginning with needs assessments. We work closely with the WHO and other partners to foster product innovation, produce guidance for medical device selection in low-resource settings and harmonize specifications for essential supplies for MNCH. We also conduct fit for purpose evaluations and research on the markets of our essential, strategic devices.

Some examples of our current work include:

Strengthening MNCH services in the Democratic Republic of Congo through the supply of medical devices to equip 200 hospitals and 1,000 health centres nationwide

Leading two projects to foster innovation for child wheelchair solutions for use in emergencies and for improved acute respiratory infection diagnosis for children in their communities

Working with partners to evaluate new point of care HIV diagnostics in seven African countries

Working with the WHO and UN partners on a list of essential medical devices for MNCH services at different levels of care

Supplying a large percentage of the Ebola personal protective equipment to affected countries; developing technical specifications, leading an industry consultation and developing guidance

At the conclusion of the session, attendees will be able to:

Describe and discuss UNICEF's approach to device selection and procurement and incorporate some principles of the approach into their own work

Describe and discuss medical device selection and procurement challenges in low-resource settings and identify tools produced by UNICEF, the WHO and partners to address the challenges

Provide examples of UNICEF's current medical device projects and identify opportunities for collaboration with UNICEF on medical device innovation, selection and procurement and health systems strengthening work

JT02.2 - Equipment Donation and Disposal - Goodwill vs. Risk Author(s): <u>Mario Ramirez</u>¹, Bill Gentles²

¹Medical Engineering, The Hospital for Sick Children, Toronto/CAN-ADA, ²Vice President, BT Medical Technology Consulting, Toronto/ CANADA

Learning Objectives: At the conclusion of this session program, attendees will:

Meet other participants who are involved in medical equipment donations and share contact information to promote further information sharing.

Understand the reasons for the failure of donated medical equipment in developing countries.

Understand the necessary 'best practices' related to people, processes, and metrics to most effectively donate medical equipment to developing countries

Understand the essential role of recipient organizations in improving the success rate of donations.

Abstract:

Previous studies conducted in the United States and Europe have shown that as much as 70% of medical equipment that is donated to low-income countries is never put into use in these countries[1]. As a result an unnecessary burden is created, and many of the recipients' equipment deficiencies remain unresolved.

Responses to natural disasters also generate a flood of donated medical equipment, which is often sent with a lack of understanding of what is really needed. A study of seven hospitals in Haiti found only 30 percent of the 115 pieces of medical equipment donated after the 2010 earthquake were working and 14 percent of the equipment could not be repaired. [2]

To address this ongoing problem, numerous articles and guidelines have been published. A recent guideline published in the UK includes a thorough examination of the reasons for the lack of success of medical equipment donations, and exhaustive recommendations to correct the problem. [3]

In this session we will review the current knowledge on the complexities of donating medical equipment to developing countries, and discuss possible approaches to improve the effectiveness of these donations.

JT03 - IMAGING

JT03.1 - CT State-Of-The-Art Technology and Current Research Topics

Author(s): <u>Ting-Yim Lee</u>¹, Aaron So², Esmaeil Enjilela² ¹Imaging, Lawson Health Research Institute, London/ON/CANADA, ²Imaging Research Laboratories, Robarts Research Institute, London, ON/CANADA

Learning Objectives

1. State-of-art technology in CT - wide detector cone beam, iterative reconstruction, dual energy

2. Researh applications of dual energy

3. Research applications of dynamic contrast enhanced scanning - perfusion imaging in stroke, cancer and heart attack

Abstract

The advent of slip ring, dual energy, cone beam acquisition with wide detector array and iterative image reconstruction have revolutionized the applications of CT in both the clinical and research arena since the 1990's. This presentation will discuss these different technological advancements and their implications in clinical and research applications. For clinical applications, examples will be drawn from dual energy material selective imaging, high resolution imaging and dose reduction. For research applications, perfusion imaging in stroke, cancer and heart attack and compressed sensing reconstruction for ultra-low dose perfusion imaging will be discussed.

JT03.2 - Review of PET State-Of-The-Art Technology and Current Research Topics, Including PET/CT and PET/MR Author(s): Roger Lecomte

Sherbrooke Molecular Imaging Center, Research Center of CHUS (CRCHUS), Sherbrooke/CANADA

Positron emission tomography (PET) is a medical imaging modality using positron-emitting isotopes to investigate the fate of radiolabeled molecules in living organisms. By measuring the uptake, biodistribution and washout of the radiotracer, it is possible to obtain information about in vivo molecular processes involved in normal physiology, as well as in diseases such as cancer, neurological disorders, heart and cardiometabolic diseases. Major advances in PET technology have widened the range of applications of PET in both biomedical research and clinical diagnosis. Examples of these technological advances include very diverse and clever detector designs, sophisticated signal processing techniques, 3-dimensional imaging with iterative reconstruction algorithms, the introduction of time-of-flight measurement, and the combination of PET with X-ray computed tomography (CT) or magnetic resonance imaging (MRI). Whereas PET technology has made huge progress in the last decades, it has not reached its performance potential. This review will describe the basic principles, state-of-the-art technology and current developments of PET, including PET/CT and PET/MR dual-modality imaging. The overview will be concluded by detailing a few key research and clinical applications of PET imaging and by discussing some promising new ideas in the field.

At the conclusion of the CE program, attendees will be able to:

1- Describe and discuss PET imaging principles, technologies and applications used in diagnostic nuclear medicine and biomedical research.

2- Understand the underlying physical limitations and areas of potential advances of the PET imaging modality. 3- Explain the various advantages and limitations of different multi-modality imaging approaches.

JT04 - ETHICS

JT04.1 - Ethics for Biomedical Engineers and Medical Physicists Workshop

Author(s): <u>Monique Frize¹</u>, <u>Jean-Pierre Bissonnette²</u> ¹Systems And Computer Engineering, Carleton University, Ottawa/ CANADA, ²Radiation Physics, Princess Margaret Cancer Centre, Toronto/CANADA

Learning objectives: (1) Become familiar with ethical theories, codes, and ethical decision-making; (2) learn the application process for obtaining ethics clearance for research projects; (3) explore various ethical dilemmas and how to deal with these.

Health professionals are concerned with a variety of questionable behavior and professional and ethical misconduct, especially when a patient's life is at stake. The workshop discusses the ethical decision-making process, including ethical theories and ethical codes, experimentation with humans and animals, clinical studies for prototype testing, and how to obtain ethics clearance for this type of research. The impact of technology and science on people, society, and the environment and means of minimizing harm are discussed. Ethics regarding gender and culture is also an important aspect to consider. For clinical practitioners, ethics regarding incident reporting, fairness, access to resources and skills, and educational practice are of concern. Ethics education and training is a must for anyone working in these two fields related to health care.

Format of the workshop :

The main ideas, concepts, and references will be presented (20 minutes). Groups of 4-5 persons will prepare an application to an Ethics Research Board for a research project of their choice; some ideas will be provided (30 minutes). Groups will review another group's application (20 minutes). Comments and ideas originating from participants will be collected and included in a report that follows the workshop (15 minutes). Although discussions will be conducted in English, groups preferring to submit their work in French will also be considered.

JT05 - LEADERSHIP

JT05.1 - What is Leadership? A Roundtable from Recognized Leaders

Author(s): David Jaffray¹, Kin-Yin Cheung², Ratko Magjarevic³, Tony Easty⁴, Herbert Voigt⁵

¹Ontario Cancer Institute / Princess Margaret Hospital, Toronto/ CANADA, ²Medical Physics & Research Department, Hong Kong Sanatorium & Hospital, hong kong/HONG KONG, ³University of Zagreb Faculty of Electrical Engineering and Computing, Zagreb/ CROATIA, ⁴University Health Network, Centre for Global eHealth Innovation, Toronto/CANADA, ⁵Biomedical Engineering, Boston University, Boston/UNITED STATES OF AMERICA

Leadership, and the dynamics of leadership, is one of the most complex topics in the workplace. Almost everyone has had the experience of being led by people they admired and respected and by people they did not. Since most leaders would prefer to be judged as belonging to the former group, it is useful to examine the attributes of a leader that engender admiration and respect and deconstruct them as a framework for us all to strive for.

In my opinion, very few people are natural leaders, and so for most of us, leadership takes work and effort. It is useful to regularly examine the ways in which we attempt to lead, to determine whether we are being effective. That said, what are some of the key attributes of effective leadership:

Know where you are going: It is hard for team members to follow you if you yourself haven't thought carefully about what you intend to achieve and how you intend to get there.

Communicate regularly: Most of us assume that those around us know more about our plans than they really do. It is easy to forget that key pieces of information have not been shared with team members, so try to make sure that this happens. It can be quite informal. It does not require endless memos and meetings.

Allow involvement and dissent: Not everyone agrees on how an issue should be tackled, and good leaders allow ideas to come forward from team members without fear of criticism or punishment. Ultimately, the leader may take the final decision on an approach, but the team is more likely to commit to it if it represents the collective talents and knowledge of the team. Good leaders should allow their ideas to be challenged and should be prepared to change if a team member proposes something better.

Provide support and encouragement: Sometimes things don't go well, and it is important for a leader to be open about what is happening since everyone usually knows anyway, but at the same time encourage the team to see a way forward and do the best that it can in the circumstances.

Avoid playing favourites and public humiliation: Every team member deserves to feel needed and valued. If the leader has clear favourites, everyone will see that and the team dynamic is affected. Public humiliation of a team member for poor performance may be tempting but should be avoided. Even if the other team members agree that their performance is poor, they will not enjoy seeing a colleague be humiliated, and will wonder when it will be their turn for such treatment.

Try to make it fun: It seems like a cliché to speak of work as fun. Most people work to earn a living, after all. However, many jobs can provide great satisfaction when something goes well and there is a good outcome, even if there is no direct reward for the team.

Learning Objectives:

Presentation of the above attributes will stimulate discussion among participants, and provide a framework for considering leadership.

Participants will have the opportunity to comment on whether they agree with this list or identify other attributes as more relevant to their experience.

At the end of the session, participants will be able to take this material, enhanced with their own experiences and insights, and apply it in their own work environments.

JT06 - LEADERSHIP

JT06.1 - Hosting and Organizing an International Meeting Author(s):

For many professionals hosting an international meeting can elevate their career to a different level. Engagement in professional associations and organizations provides an excellent networking opportunity that helps support research and create general best practices.

Attending an international conference, one sometimes wonders what it takes to run an international conference yourself and what you need in place in order to do so. In this session we will be exploring

- · How to attract/bid on a scientific/medical conference
- \cdot Creation of a bid team and the necessary committees
- \cdot Financial investments and liabilities
- \cdot Planning process and time commitment

· Stakeholders and team members of successful conferences

The session is designed to give a comprehensive overview of the process involved based on practical examples such as the IUPESM World Conference and other meetings.

A special focus will be given to financial concerns and how to mitigate the risk of a meeting by involving professional groups and setting the conference up properly in a legal and tax-accounting matter. Finally there will be time for specific questions.

Learning Objectives:

· How to successfully bid on hosting a professional conference

· Designing a Continuing education programme that delivers value

 \cdot Properly assess financial risk and overall planning and budgeting for a professional conference

JT06.2 - Social Media in Science and Medicine

Author(s): Parminder Basran

Medical Physics, BC Cancer Agency- Vancouver Island Centre, Victoria/CANADA

The use of websites and applications that enable users to create, share, and discuss content is not new to medical physicists and biomedical engineers, but how one might adopt modern social media tools and technology for these purposes may well be. In this session, we explore social media in science in medicine with a particular focus towards medical physicists and biomedical engineers. We will explore how modern social media tools might be used in clincial activities, as a tool for research, as an educational tool, and as a means of public outreach.

Key learning objectives of this presentation are:

1. To provide a brief description of key social media channels and technology relevant to the medical sciences;

2. To provide some examples of how social media may be used in clinical, research, education and outreach activities;

3. To explore personal and institutional privacy concerns when using social media in a professional setting.

JT07 - HUMAN FACTORS AND MEDICAL DEVICE SAFETY

JT07.1 - FMEA and Root Cause Analysis Author(s): Eric Ford

Department Of Radiation Oncology, University of Washington, Seattle/WA/UNITED STATES OF AMERICA

Of the systematic tools available for improving the safety and quality of care in radiation therapy, two have proven particularly useful: Failure Mode Effects Analysis (FMEA) and Root-Cause Analysis (RCA). These two techniques offer complimentary methods for analyzing error pathways. FMEA provides a method of quantifying hazards before they occur, while RCA offers a means understanding the drivers of error through in-depth analysis of events that have already occurred. Recent data demonstrates that these two tools are most effective when used in combination with one another. This presentation will provide an overview of FMEA and RCA with reference to the concepts and methods established in AAPM Task-Group 100 (FMEA) and the RO-ILS: Radiation Oncology Incident Learning System in the US. A series of case studies will be included which illustrate the practical operational aspects of both FMEA and RCA.

At the conclusion of the CE program, attendees will be able to:

Describe the fundamental concepts behind FMEA and RCA

Understand in detail the methods used for each

Incorporate each tool into the quality management program of their own clinic

JT07.2 - Human Factors and Usability Assessment Author(s): Patricia Trbovich

Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA

Learning Objectives:

At the end of the session participants will:

1. Appreciate the importance of understanding systems issues and intrinsic human limitations in improving patient safety

2. Understand Rasmussen's model of migration to boundaries to explain the mechanism by which deviance occurs, stabilizes, regresses, or progresses to harm. This model assesses how accidents occur and helps to understand the human and system contributions to adverse events

3. Have a general understanding of usability assessment and key concepts that help protect against dangerous errors that could lead to patient injury

4. Understand the "Hierarchy of Effectiveness" in developing solutions to safety problems

Healthcare organizations depend on human beings to perform safety critical tasks in complex work environments. Consequently, it essential for these organizations to effectively address human factors and human performance considerations, to reliably achieve safe and successful outcomes. Human Factors (HF) is a discipline concerned with the study of how people interact physically and psychologically with products, tools, procedures, and processes. HF takes into account human capabilities, limitations, and characteristics and aims to make the environment function in a way that is safe and seems natural to people.

In this presentation, we will begin with a review of Human Factors and the relationship that exist between the high rate of preventable adverse events in healthcare and the pace, and increase of new technology and approaches. We will discuss Rasmussen's model of risk management in a dynamic society, which addresses the dynamic aspects of safety, and consequently is well suited to understanding current conditions in modern healthcare delivery and the way conditions may lead to accidents. When errors involving medical devices occur, people typically blame the users rather than investigate broader systems factors that are likely contributing, such as a poorly designed interface

between the medical device and the user, or inadequate user training. We will discuss how usability assessment can help fulfill the need to understand how to better ensure that (a) medical devices are designed for optimum capability and ease of use, and (b) clinician training is thorough and effective. Finally, we will discuss the crucial role that healthcare professionals, including biomedical technology professionals, play in selecting the appropriate strategy to reduce and remedy medical error. It is often not obvious nor clear, which error prevention tool to use, even when system-based causes have been identified. We will discuss various error prevention tools and their respective effectiveness for creating lasting changes in the healthcare system.

JT08 - SCIENCE AND RESEARCH

JT08.1 - How to get Grants: Tips for Success Author(s): <u>Aaron Fenster</u>

Imaging Research Laboratories, Robarts Research Institute, London/ON/CANADA

Success for obtaining a grant for research is getting increasingly more difficult as the number of applicants is rising and funds for research is not keeping pace. Thus, for research grants to be successful, they must be outstanding, or at the very least, nearly outstanding. While the current state for research funding appears to be highly intimidating, complex, and with challenges that are overwhelming, the steps to produce a successful grant are highly logical and follows a regular pattern. Never-the-less, the current research funding environment causes many research applicants to avoid starting their grant until it is too late to produce the level of the grant that would make it successful.

The current research funding in Canada is quite complex with funding sources that include Federal, Provincial, disease-based foundations and private sources (e.g., philanthropists). Grants can be written for funding to support operating costs of research, equipment, infrastructure and individuals' salaries. Details of the documents to be filled and submitted are usually different, requiring different types of information. However, the process for writing these grants follows the same steps: preparation, writing the grant, refinement, and submission of grant.

A successful grant writer would have these steps in mind and start their grant allowing sufficient time for each step. For example, while the most critical step is the preparation step, most researchers do not spend enough time or don't quite understand what is needed. Specifically, this step requires substantial investments in time to generate the "idea" that would be considered transformative and/ or meeting an unmet need that would have a significant impact on their field (e.g., significant impact on diagnosis, treatment or understanding of a disease). Since the "idea" generation is critical to success, the grant writer must steer away from ideas that are just "interesting", "would be useful" or "somebody should do this". The "idea" must be of significant importance to the community or field that it would evoke the comments such as "I wish I though of that" or "if the applicant can accomplish this task, it would change the way XXX would be done" or "if anyone in Canada (the world) can do this, this applicant has the best chance for accomplishing this goal". Clearly, evoking these type of comments and reviews are difficult to achieve, so the question is how to generate the "idea" that would evoke these types of comments.

In this paper, I will describe the process for writing a successful grant and the steps and timelines needed to achieve this. The information that will be provided is based on a personal experience of writing successful and unsuccessful grants over the past 30 years as well as the experience and discussions with the scientists at the Robarts Imaging Research Laboratories in London.

Learning Objectives:

1) Planning steps used to write a succesful grant.

2) How to allocate sufficient time to write a succesful grant.

3) What constitutes an "idea" that will be the basis of a succesful grant and how to achieve this.

JT08.2 - How to Write and Review Research Articles Author(s): <u>David Thwaites</u>¹, David W.O. Rogers²

¹Institute Of Medical Physics, School Of Physics, University of Sydney, Camperdown, Sydney/AUSTRALIA, ²Physics, Carleton University, Ottawa/CANADA

Learning objectives:

1. To understand the basics of writing a scientific paper for submission to a peer-reviewed journal and the requirements of the journal.

2. To understand the importance of clear presentation of results for publication and how to achieve this.

3. To understand the reviewing process, to help in writing papers, as well as when/if invited to be a reviewer.

Publication of your work is necessary to move the research field forward, (and for your career!). Using our experience as authors, reviewers, editorial board members and editors, we summarize some observations on writing and reviewing scientific papers for a peer-reviewed journal.

i) For writing and submitting a paper: assuming the work is good as a starting point, the focus here is on what makes a clear paper. This is also likely to maximise the chance of it being acceptable. First, consider your main message and hence material selection and writing flow so that this is clear. Make the introduction relevant to where the work fits into the current state of related published research, going quickly from generalities to specifics. Even good well-presented work will not get into high-impact-factor journals unless it is clearly novel and/or significant. Methods should allow the work to be repeated; ask yourself if they are clear and complete. Explain acronyms. Results should clearly tie figures and tables to text. Conclusions should relate back to the key message and be verifiably supported by results. Discussion and conclusions should not just be re-stated results!

Ask a colleague, unconnected with the work, to read the 'final' draft paper and comment on clarity. If they can't understand it, neither will the referees! Re-read it yourself after a time gap. Check journal requirements and comply! Hastily prepared submissions are usually poorly prepared! Badly written papers, not complying with requirements and including mistakes, e.g. in references, give the impression that the work may also be poor. Work with experienced authors initially (e.g. supervisor). Look critically at papers you read and note what you think works well. New writers *can* learn good practice by example. Good luck!

ii) One area that needs really careful attention is the *clear presentation of results in tables, graphs and figures* and this is often not well done in submitted papers. Specific advice on this will be summarized.

iii) One potentially difficult issue regarding writing a paper is the question of '*Who should be an author?*' Various guidelines regarding this issue will be presented.

iv) *For reviewing papers* (important to think about for authors to help foresee potential issues that can be dealt with up front, as well as if invited to review), this **summary** will outline the review process at several major journals and discuss the role of the reviewer. The obvious central role is to ensure the scientific accuracy of the paper being reviewed and to ensure it properly situates the paper in the current state-of-the-art without becoming a review paper. It is also important to ensure the paper properly reports the results of others and to identify plagiarism if at all possible. The role is not to have the paper written the way the reviewer would write it, but to help the author make their paper clearer and unambiguous. The issue of a referee's potential conflict of interest will be addressed.

MPE01 - MEDICAL PHYSICS EDUCATION AND PROFESSIONAL ISSUES

MPE01.1 - Workforce Models for Medical Physicists Author(s): Julian Malicki

Medical Physics, Greater Poland Cancer Centre, Poznan/POLAND

Learning objectives

- To present the elements that make up a workforce model for medical physicists.

- To describe approaches to quantifying staffing levels.

- To show current trends in shifting duties from direct clinical obligation to a supervisory role with more safety-related tasks.

Given the ongoing changes in the field of medicine and physics, numerous factors must be considered in any analysis of the duties performed by medical physicists. For the last century, the main focus of their activity has long been on clinical work, along with research and, to a lesser extent, radiation protection and quality assurance. In recent decades, however, medical physicists have slowly become further removed from direct clinical responsibilities. This distancing first occurred in diagnostic radiology and it is now evident in radiotherapy.

Can a model be analytically derived and quantified?

A workforce model should be described both qualitatively and quantitatively; that is, the number of physicists needed, the types of activities required, and the time needed to perform these. To estimate the number of positions that need to be created, we could use a bottoms-up approach. However, such an approach tends to overestimate the number of physicists needed. Another approach is to survey the current situation, and to extrapolate from this to create a more economically-feasible model.

Clinical obligation

The rapid development of science has had a large impact on medical practice. More sophisticated equipment, such as modern CT or MRI scanner, does not require the presence of a physicist during the procedure nor for its interpretation. The only discipline in which medical physicists are still clinically active with duties for individual patients is radiotherapy. However, the emergence of new techniques require more time for quality assurance. This situation presents a challenge for medical physicists, who have had to give up part their of routine, easier clinical duties.

Interactions between various groups of staff

An important factor that influences the workforce model is how specific duties are allocated among the major staffing groups (physicians, medical physicists, and radiographers) involved in medical imaging and therapys. In countries with a shortage of medical doctors or physicists, more clinical duties are performed by radiographers (for example, ultrasound examinations, overseen by radiologists) and radiotherapy technologists (e.g., radiotherapy planning, supervised by physicists).

Research and teaching

The workforce model can vary if the institution carries out teaching and research activities along with clinical work. Clearly, physicists with teaching obligations cannot perform the same amount of clinical work as those who do not teach. However, there is no direct formula to calculate the proportion of clinical to teaching activity.

<u>Quality</u>

Quality control and assurance are becoming ever more important in light of the increasing complexity of modern devices that use ionizing radiation. In most large hospitals, a staff member is designated as the quality officer. Clinical audits are considered more effective than ISO 9001 audits, mostly because the auditing team is comprised of peers rather than administrative personnel. An emerging area is risk assessment, reporting and analysis of events. In the future, these obligations may take up a larger portion of the time available to medical physicists.

Radiation protection

Unlikely other medical disciplines, regulations on the safety of medical uses of ionizing radiation are stricter. In many countries, this increases the burden on medical physicists to contribute to radiation protection.

Conclusion

Guidelines and actual staffing levels create not one but a number of workforce models that describe how many posts are associated with different aspects of medical diagnostics and therapy.

The model is constantly changing, although the ongoing trend is towards a diminishing share of direct clinical work, with more emphasis on supervisory, safety-related, and quality control/assurance tasks with a commensurate decrease in medical physics research.

MPE01.2 - International Educational Standards: Can We Define a Common Medical Physics Curriculum?

Author(s): <u>Raymond K. Wu</u>¹, Colin G. Orton², Tomas Kron³, Ahmed Meghzifene⁴

¹Radiation Oncology & Cyberknife Department, University of Arizona Cancer Center, PHOENIX/UNITED STATES OF AMERICA, ²Radiation Oncology, Wayne State University, Grosse Pointe/UNITED STATES OF AMERICA,³Physical Sciences, Peter MacCallum Cancer Center, Melbourne/AUSTRALIA, ⁴Dosimetry And Medical Radiation Physics, IAEA, Vienna/AUSTRIA

1. What are the common requirements to be considered a qualified clinical medical physicist

2. How do IOMP and IMPCB collaborate on maintaining and upholding the standards

3. Who are the stakeholders

4. When do we expect to reach the different milestones

Abstract

The IOMP in May 2012 approved two policy statements: The Medical Physicist: Role and Responsibilities, and Basic Requirements for Education and Training of Medical Physicists. Earlier, the International Medical Physics Certification Board (IMPCB) was established on May 23rd, 2010 after many years of discussions and planning. The Constituting Panel of the IMPCB asked the same question as the caption title and wrote into the Bylaws and the Model Certification Program the goals to establish requirements for general and medical physics education, and clinical training. The publication of the two IOMP policy statements helped IMPCB to move forward and enabled its Accreditation Committee to develop the requirements for certification and accreditation. In 2013 the International Atomic Energy Agency (IAEA) published the Human Health Series No 25 with the endorsement of IOMP. The comprehensive collection of international data and the publication point to the fact that it is possible to harmonize the roles and responsibilities of clinically engaged

medical physicists and the education and training requirements in many parts of the world. Further plans are being developed for collaborations between IMPCB and the IAEA to consider conducting special certification examinations for a group of medical physicists from regions not likely to create their own certification bodies in the near future. Recent initiatives of IOMP indicated the interest of collaborations between IOMP and IMPCB to work on medical physics certification matters. It has been proposed that the IOMP be assigned a special designation of Supporting Organization of IMPCB, with three members of the Board of Directors appointed by IOMP. In addition, the IMPCB is considering amending the Bylaws to reflect the leading role of IOMP. IMPCB will adopt the IOMP standards, and clarify that other certification models are acceptable. The IMPCB recognizes that there are national/regional variations to certification in medical physics based on differences in national/ regional legislation and educational traditions, so it gives to national and regional certification bodies considerable freedom to decide on the manner in which a given organization seeking IMPCB accreditation conducts the certification process. However, minimum education and clinical training criteria as well as continuing education and professional development are required for all IMPCB certified medical physicists.

MPE03 - RADIATION THERAPY INVITED SPEAKER

MPE03.2 - In Vivo Dosimetry

Author(s): Ben Mijnheer

Department Of Radiation Oncology, The Netherlands Cancer Institute, Amsterdam/NETHERLANDS

The rationale for *in vivo* dosimetry (IVD) is to provide an accurate and independent verification of the overall treatment procedure. It is used to detect clinically relevant differences between planned and delivered dose, to record dose received by individual patients, and to fulfill legal requirements. It will enable the identification of potential errors in dose calculation, data transfer, dose delivery, patient setup, and changes in patient anatomy. The relation between IVD and other parts of the quality assurance (QA) process, such as the commissioning and QA of the treatment planning system and machine QA, will be elucidated.

After discussing briefly the main characteristics of the most commonly used (point) detector systems, the rapid development of EPIDs for 2-D, 3-D and even 4-D, patient dosimetry during advanced treatment techniques such as IMRT and VMAT, will be elucidated. The various ways of dose determination and dose reconstruction inside a patient will be reviewed. Methods to quantify differences between measured and predicted dose distributions will then be clarified, as well as tolerance and action levels when deviations are outside clinical criteria.

A number of examples will be given to illustrate the possibilities of different types of commercially available and in-house solutions of hard- and software used for IVD. Clinical experience of IVD during external beam radiotherapy showed that most errors were due to the properties of a specific plan, human errors in the clinic, and anatomical changes. These types of error can often not be traced by means of pre-treatment dose verification using phantom measurements or independent dose calculations. Anatomy changes and modification of patient setup can generally be observed by means of in-room imaging. However, 3D IVD can compliment IGRT because it quantifies the dosimetric effects of these variations. Follow up actions, including inspection of in-room imaging data, followed by phantom measurements and improvement of procedures, if required, will be discussed.

Specific problems related to the use of IVD during brachytherapy, such as the use of a detector with a small volume and a well-defined position with respect to patient anatomy and source configuration, will be elucidated. The role of IVD in proton and ion radiotherapy by measuring the decay of radiation-induced radionuclides will also be discussed.

Large scale introduction of IVD requires implementation of a fully automated process that is integrated in the clinical workflow. Several approaches yielding alerts without or with limited human intervention will be compared.

Finally recent developments and future approaches such as realtime IVD, enabling the linac to halt in case of serious delivery errors, time-resolved dose verification, and the use of IVD during adaptive radiotherapy techniques will be discussed.

Learning objectives

1. To elucidate the rationale and type of errors that can be detected with in vivo dosimetry

2. To describe the instrumentation and techniques applied for in vivo dosimetry

3. To review the current clinical experience and future developments of in vivo dosimetry

MPE04 - QUALITY AND SAFETY

MPE04.1 - Quality Framework: The Canadian Partnership for Quality Radiotherapy

Author(s): Michael Milosevic

Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/CANADA

Radiotherapy is an important curative and palliative treatment for cancer that is indicated in 40-50% of patients. Quality assurance plays a critical role in radiation treatment planning and delivery. Driven by an urgent need to harmonize radiation treatment quality and safety in Canada, the Canadian Partnership for Quality in Radiotherapy (CPQR) was established through collaboration with national professional associations involved in radiation treatment delivery. CPQR has focussed its efforts on the creation of guidelines to measure and support programmatic quality assurance, maintain high quality radiation treatment technologies, and support incident learning and management. CPQR has uniquely incorporated a patient perspective into all of its activities, and developed a national guideline to motivate patient engagement in radiation treatment quality and safety at the individual program level.

Moving forward, priority will be placed on incorporating key CPQR deliverables into national accreditation programs, defining pan-Canadian system performance metrics for radiation treatment quality and safety, and strengthening international collaboration to support global harmonization of best practice.

At the conclusion of this program, attendees will:

Understand the stakeholder engagement model used by CPQR to build a national program of radiation treatment quality and safety

Understand how key CPQR initiatives in programmatic quality assurance, equipment quality control and national incident learning have harmonized practice across Canada and improved system resilience

Be aware of opportunities to collaborate with CPQR to improve radiotherapy quality and safety, either at the level of individual treatment programs or on a regional or national scale

MPE04.2 - Radiation Oncology Practice Accreditation in the United States

Author(s): Steven De Boer

Radiation Medicine, Roswell Park Cancer Insitute, Buffalo/NY/UNIT-ED STATES OF AMERICA

Learning Objectives:

After attending this presentation the attendee should 1. Have an understanding of the accreditation process for Radiation Oncology facilities.

2. Know the importance of attaining practice accreditation.

3. Know the different regulatory requirements for practice accreditation.

Accreditation of a Radiation Oncology practice in the United States consists of the evaluation of an entire practice by an independent accrediting body, ensuring that it meets or exceeds guidelines.

The process varies between the different accrediting bodies, but commonly consists of ensuring that

-The policies and procedures are adequate and enforced.

- There is acceptable quality of treatment prescriptions, design, and delivery.

-The quality assurance of all equipment is in compliance with recognized standards.

- The facility is in compliance with state and federal regulations.

- There is appropriate review of patient status, progress and documentation.

In most centers, obtaining practice accreditation is a voluntary process. However, many centers have chosen to obtain practice accreditation for many reasons. These include

-Improving the quality and safety of the medical practice.

-Providing confidence in the quality and safety of current practice to administration, staff, peers and patients.

-Providing a learning experience to the entire staff through the accreditation process.

-Allow for marketing advantage for the practice.

-Providing a legal confidence that appropriate measures are being taken to provide safe and quality treatment.

Practice Accrediation is a valued service which has the goal of increasing treatment quality and patient safety.

MPE05 - COMPUTERIZED SYSTEMS

MPE05.1 - Database Rudiments and Clinical Use Author(s): John Kildea

Medical Physics, McGill University Health Centre, Montreal/CANADA

Electronic databases are found everywhere in modern society, nowhere more so than in a radiotherapy department. However, few people understand how databases store data and even fewer are equipped with the tools to extract them. With just a little guidance it is possible to delve into any modern database and extract useful information. This workshop will cover the basics of database design and describe the tools available to extract useful data.

At the conclusion of the CE program, attendees will be able to:

1) Describe how a modern database is structured and how data is stored in relational tables

2) Download and install simple software to connect to adatabase

3) Write simple SQL queries.

MPE05.2 - Modern Radiotherapy Treatment Planning: Capabilities, Commissioning, and Clinical Use Author(s): <u>Benedick A. Fraass</u>

Department Of Radiation Oncology, Cedars-Sinai Medical Center, Los Angeles/CA/UNITED STATES OF AMERICA

Learning Objectives:

1. Describe capabilities of modern radiation therapy treatment planning systems.

2. Summarize the clinical commissioning process and how that information can be used.

3. Illustrate ways to incorporate modern treatment planning methods into clinical use.

Modern radiation therapy treatment planning systems incorporate many advanced tools for planning, including automated segmentation (contouring), fusion of imaging datasets from multiple modalities, use of multileaf collimators, intensity modulated radiation therapy (IMRT) and volume modulated arc therapy (VMAT), image guided radiation therapy (IGRT) and advanced dose calculation algorithms. Appropriate clinical use of these advanced capabilities requires detailed and careful clinical commissioning of a multitude of functions and capabilities, followed by use of that commissioning information to educate planners, physicians, physicists about the proper use of those tools and algorithms. This presentation will summarize available modern radiotherapy treatment planning functionality, describe clinical commissioning of these complex systems, and make comments about ways to incorporate these capabilities into safe and effective clinical use.

MPE06 - IMAGING

MPE06.1 - 4D Imaging

Author(s): Stewart Gaede

Physics And Engineering, London Regional Cancer Program, London/CANADA

At the conclusion of the CE program, attendees will be able to

1. Understand 4D-CT reconstruction methods.

2. Recognize motion artifacts in a 4D-CT dataset and understand methods to reduce them.

3. Determine how to implement 4D-CT clinically and how to address practical solutions to common problems, including management of irregular breathing patients and construction of the PTV for 4D-ra-diotherapy.

Four-dimensional computed tomography (4D-CT) imaging has become a staple for providing 3D dynamic anatomical information used in modern radiotherapy of tumours influenced by respiratory motion. A 4D-CT dataset is composed of a time series of 3D images at multiple phases of the patient's breathing cycle. This is accomplished by acquiring multiple projections of the same anatomical space under free breathing conditions and retrospectively binning either the projection data or sequentially acquired 2D axial slices according to a breathing trace that was acquired simultaneously. For projection binning, the CT scanner operates in low-pitch helical mode, where the pitch is related to the patient's breathing period. For image binning, the CT scanner operates in ciné mode, where time series of images are acquired over an entire breathing cycle at one fixed couch position then reacquired at sequential couch positions until the intended scan range is imaged. While 4D-CT scanning improves image quality compared to free-breathing 3D imaging, artifacts are still present, mostly due to irregular breathing patterns exhibited by many patients. As a result, sorting algorithms combine volumes from temporally misaligned respiratory phases into a single volume. Many methods have been proposed to improve 4D-CT sorting methods for irregular breathing patients, including phase tagging adjustment, respiratory trace manipulation, amplitude-based sorting methods, and non-linear image registration. Despite these improvements, motion artifacts can also be induced due to poor correlation between the motion of the internal anatomy and that of the respiratory surrogate. Retrospective binning of 4D-CT data in the absence of an external surrogate has been proposed and has shown to reduce motion artifacts. The resulting 4D-CT dataset can be used to define an envelope of the gross-tumour volume (GTV) for conventional free breathing treatment delivery or one or more phases can be chosen for respiratory-gated radiotherapy. In both scenarios, multiple methods have been proposed that utilize the 4D-CT dataset to construct the internal target volume (ITV), including manual delineation, auto-segmentation, or maximum intensity projection (MIP) generation via registration to the planning CT, which in itself can be a single 4D-CT phase, an average of the 4D-CT dataset, or ideally, the entire 4D-CT dataset. In the latter case, dose calculations are performed on each respiratory phase and through deformable registration the dose is summed over all phases. Although the advantages of 4D-CT imaging in modern radiotherapy of mobile tumours is clear, implementation into routine clinical practice is not necessarily straightforward. We are, therefore, proposing a CE program that is intended to address 4D-CT imaging technology, reconstruction methods, and practical solutions to common problems such as clinical implementation of 4D-CT, interpretation of 4D-CT for irregular breathing patients, construction of a planning target volume (PTV) for 4D-radiotherapy, and 4D-treatment planning considerations. Extension of 4D imaging to positron emission tomography (PET) and magnetic resonance imaging (MRI) will also be presented.

MPE06.2 - Dose from X-Ray Imaging Procedures Author(s): John M. Boone

Radiology Snd Biomedical Engineering, UC Davis, Sacramento/ UNITED STATES OF AMERICA

The learning objectives of this talk are to acquaint the attendees with:

(1) the way in which radiation dose is estimated in radiography

 $(\ensuremath{\mathcal{Z}})$ the use of Monte Carlo methods for determining dose and dose distribution

(3) Radiation dose assessment in computed tomography and several of the controversies associated with some dose metrics.

The estimation of x-ray dose is a basic requirement of a diagnostic medical physicist. In this presentation, x-ray dosimetry methods will be discussed for radiography, mammography, and computed tomography. For the projection imaging procedures, the entrance air kerma is used with conversion coefficients which are produced using Monte Carlo methods. In computed tomography, the entrance surface of the patient is ill-defined due to scanner rotation, and therefore the air kerma at isocenter of the scanner can be used. The acquisition of air kerma data at the scanner isocenter using various phantoms is also an important component of CT dosimetry, and these metrics include CTDI-100, CTDI-w, and CTDI-vol. In CT as with projection imaging modalities, Monte Carlo methods are used to generate coefficients useful for estimating radiation dose. While the dose methods used in radiography and mammography are relatively stable, there have been a number of important changes in the methodologies associated with CT dosimetry. These newer methods take into consideration both the size of the patient in the XY plane (using the size-specific dose estimate, SSDE, methodology), and the length of the scan in the z-dimension also has an impact on the radiation dose estimate. Recent activity with respect to dosimetry methods in computed tomography include AAPM task groups 111, 200, 204, and 220, as well as Report 87 from the International Commission on Radiation Units (ICRU). The general message from each of these reports will be discussed. In recent years, there has been a move to require dose reporting for some x-ray imaging procedures, especially computed tomography. The utility of fully automated CT dose reporting will also be demonstrated in this tutorial. While the use of effective dose as a metric has been used in certain circles of the radiology community, some of the pitfalls of effective dose as a dose metric will also be explored.

MPE07 - RADIATION SAFETY

MPE07.1 - What can IAEA do for the Clinical Medical Physicist? Author(s): <u>Joanna Izewska</u>, Ahmed Meghzifene

Nuclear Sciences And Applications, International Atomic Energy Agency, Vienna/AUSTRIA

Learning objectives: (1) to learn about IAEA activities in dosimetry and medical radiation physics; (2) to get acquainted with IAEA educational material and training opportunities; (3) to learn about IAEA technical assistance for medical physicists.

Shortage of medical physicists, insufficient education and training opportunities, and lack of professional recognition exist in several countries. To address these issues the IAEA conducts systematic and comprehensive activities in support of medical radiation physics worldwide. They are related to education and training, scientific advice and guidance, research and development and also include technical services.

Recently, an IAEA report has been published that defines the roles and responsibilities of a clinically qualified medical physicist in radiotherapy, diagnostic radiology and nuclear medicine. The document, endorsed by IOMP and AAPM, also recommends minimum requirements for the academic education and clinical training, and for continuous professional development. It also addresses other topics of interest for the profession.

Three IAEA handbooks for teachers and students provide the basis for education of medical physicists initiating their university studies in radiotherapy, diagnostic radiology and nuclear medicine. These volumes are supplemented by a collection of slides prepared for all book chapters. The IAEA also developed training packages for clinical residents in medical physics. This teaching material has been adopted by many universities and hospital training centres worldwide. Multiple technical reports, guidance documents and advisory books are a useful resource for medical physicists in specific areas of their activities. 'Human Health Campus' website serves as an educational resource for professionals and students involved in radiation medicine.

For long time, the IAEA has maintained an interest in standardization and development of Codes of Practice (CoP) for dosimetry with several publications in the field. One important example is the TRS-398 CoP that is in use in most world regions. A new CoP for small radiotherapy fields is under preparation. There is also a long tradition of organizing conferences and symposia in dosimetry and medical radiation physics to foster the exchange of information among professionals and to highlight developments in the field.

Regional and national training courses, workshops and fellowships are available for medical physicists to upgrade their skills and practices. These activities lead to improvement of the professional status, enhance specialist capabilities and strengthen medical physicists' contributions to radiation medicine developments. Opportunities exist for participation in co-ordinated research efforts, with some projects leading to a doctoral degree.

The IAEA support to medical physics also includes technical assistance for implementing and reviewing QA programmes at hospitals. Traceable dosimetry calibration services are provided through the IAEA/WHO Network of SSDLs to promote accurate measurements of radiation doses. Dosimetry audits in radiotherapy and comprehensive clinical audits are offered by the IAEA to radiation medicine clinics. In particular, the IAEA/WHO postal dose audit service for radiotherapy dosimetry has been in operation for over 45 years and checked radiotherapy beam calibrations in 2000 hospitals in 130 countries. levels, which help in the development and growth of the medical physics profession worldwide.

MPE07.2 - Safety Learning and Safety Management to Prevent Radiotherapy Incidents Author(s): <u>Ola Holmberg</u>

Radiation Protection Of Patients Unit, IAEA, Vienna/AUSTRIA

Radiation protection of patients must deal with the issues of not having dose limits, purposely exposing sensitive subgroups, and purposely using doses that could cause deterministic effects. While medical uses of ionizing radiation have been of tremendous value to the global population for nearly 120 years, it could be noted that radiation accidents involving medical uses have accounted for more deaths and early acute health effects than any other type of radiation accident, including accidents at nuclear facilities.

Safety reporting in radiotherapy can be mandatory or voluntary. There may be mandatory reporting to health authorities and/or radiation regulatory authorities in a single country, depending on the regulations in place. There are two types of events to consider in relation to mandatory safety reporting to the authorities. First, there are the recordable events that are errors that do not meet regulatory reporting requirements, but could indicate a gap in patient care. These are usually reviewed by the regulatory authority during an inspection or audit. The second type are the reportable events, or those events that have exceeded some threshold defined by a regulatory agency. The reported events should be focused on incidents with serious actual or potential outcomes, such as injury or death. Mandatory reporting should focus on these serious events in order to avoid obscuring the incidents that need to be investigated.

On the other hand, voluntary reporting systems are often confidential and focus on events and outcomes, instead of regulatory sanctions. They can capture "less serious" and near miss events with the purpose being to share knowledge on safety-related events and conditions and on lessons learned to improve the safety environment and patient outcomes. These reporting systems encourage institutions to focus on improvement of the safety environment; protect institutions from the legal system, handle information with confidentiality and allow for anonymous reporting of errors or circumstances that could lead to errors. An incident in another hospital can lead to identification of the hazard before a similar incident is realized locally. By collecting data from a large pool of events, better defined "lessons to learn" can be created that may improve patient safety.

The IAEA has developed a voluntary safety reporting system for radiotherapy. This is called Safety in Radiation Oncology (SAFRON). The system has incorporated data from other international, national and local reporting systems, and data directly from SAFRON participants, in order to make radiotherapy safety information more accessible. In addition, this database also provides links to publications of interest in the evaluation of incidents, lessons learned, and corrective actions. The system is designed to educate facilities about incidents and corrective actions.

In addition to looking at the characteristics of this system, such as severity scales and process steps, the seminar will also look at some other database elements forming the structure of safety reporting and learning systems in practice, such as safety barriers, causes and contributing factors. Additionally, practical operation of the system and dissemination of information will be discussed.

At the conclusion of the CE program, attendees will be able to

1. Understand differences in objectives and characteristics of mandatory and voluntary safety reporting in medical uses of ionizing radiation

To conclude, multiple IAEA projects are in operation at various

 Define and describe the different elements needed to form the structure of safety reporting and learning systems in practice, such as severity scales, process steps, causes and contributing factors
 Apply safety barriers (equipment or processes) to radiotherapy in practice, in order to strengthen safety and prevent unintended irradiation of patients

MPE07.3 - Equipment Standards and Performance Measurements for Radiotherapy Systems

Author(s): Jean M. Moran

Radiation Oncology, University of Michigan, Ann Arbor/MI/UNITED STATES OF AMERICA

Equipment standards continue to evolve with the increased complexity of treatment delivery systems. Guidance from the American Association of Physicists in Medicine (AAPM), such as that defined in Task Group 142, will be presented with respect to quality assurance (QA) standards and test frequency for linear accelerators. Mechanical, dosimetric and system safety checks will be described. In addition, Medical Physics Practice Guidelines are also becoming available from AAPM. These publicly available reports differ from Task Group reports and some impact radiotherapy system QA. The elements of the available guidelines will be presented. Finally, the evolving tools and techniques for performing QA will be discussed.

At the conclusion of the CE program, attendees will be able to

Describe the major elements of a radiotherapy system QA program

Learn about the different types of guidance available from the AAPM

Learn about evolving techniques and tools for performing QA measurements

MPE08 - QUALITY AND SAFETY

MPE08.1 - Quality Systems in Radiotherapy Author(s): <u>Mary Coffey</u> Radiation Therapy, Trinity College Dublin, Dublin/IRELAND

Quality and safety are inextricably linked in radiotherapy. This is clearly expressed in the European SocieTy for Radiotherapy and Oncology (ESTRO) Vision statement 1.1: 'Optimal individualised patient care will be achieved by integrating new clinical and preclinical evidence from biology, molecular/functional imaging and the use of new systemic agents together with the delivery of high precision radiation therapy in a safety aware environment'.

In many instances the failures in radiotherapy, which have had catastrophic outcomes, are the result of system failures involving one or more steps in the radiotherapy process. Quality in radiotherapy is multifaceted and encompasses the full spectrum from referral to follow-up addressing both technical and clinical aspects: 'total quality management'.

Technical quality commences with the equipment purchase decision and subsequent commissioning procedures. Clinical quality commences with accurate diagnosis including staging and grading and review at a multidisciplinary meeting. These first stages can be influenced by a range of external factors and are often outside the direct control of the radiotherapy team. Comprehensive clinical audits, such as the IAEA QUATRO programme can identify problems within the process and, as such, can directly influence quality.

Following referral to radiotherapy the radiotherapy team has a responsibility to ensure that the treatment prescribed is the treatment that the patient receives. From a technical perspective assurance that the dose set is the dose delivered is controlled by practices such as daily output measurements, in vivo dosimetry and dose verification for procedures such as IMRT coupled with the routine quality assurance procedures.

Peer review is an important factor in ensuring clinical quality and can include peer-to-peer discussion, chart review prior to first treatment and peer review of volume delineation. A recent paper by Tol et al describes how different treatment planning protocols can lead to large differences in organ at risk (OAR) sparing and other publications previously have identified the importance of adherence to protocol in minimizing dose to the OARs.

Ensuring accurate treatment delivery requires care and attention to positioning and immobilisation. This includes correct selection of the immobilisation method, regular monitoring of equipment and verification of the treatment delivered.

Quality systems in radiotherapy must also include human factors and the impact of the rapid changes currently taking place in our discipline. "Change is creating new paths for failure and new demands on worker(s) ... revising their understanding of these paths is an important aspect of work on safety ... missing the side effects of change is the most common form of failure for organisations and individuals"

Learning Outcomes

To be able to discuss the spectrum of quality aspects in radiotherapy

To be able to describe the process of an external comprehensive clinical audit and its role in quality

To be able to review quality processes in their own department

MPE08.2 - Cost and Resource Management of Radiotherapy Author(s): <u>Peter Dunscombe</u>

Oncology, University of Calgary, Calgary/CANADA

The cost of health care in the 34 countries of the Organisation for Economic Cooperation and Development had been rising twice as fast as GDP up until 2009. The financial events of 2008 have tempered this growth with a third of OECD countries now reporting a decrease in per capita expenditure on health care over the period 2009-2011. Particularly as we continue to be beset with financial uncertainty, many over indebted countries and many more facing continuing negative growth, we can expect downward pressures on health care budgets to continue. Analyses suggest that the direct costs of cancer care to the health care system are around 5%. Societal costs of cancer including lost productivity and informal care actually exceed direct health care costs - a fact that we often lose sight of. However, considering the magnitude of the cancer problem, which can only increase with an aging population across the globe, cancer treatment still represents a relatively small part of the overall health care budget. And within the cancer treatment budget, radiotherapy represents less than 10%. Although the contribution of radiotherapy to overall direct health care budgets is small, <1%, we would be naïve in thinking that its relative financial insignificance will shield radiotherapy from the economic realities of today's world. In order to justify budgets and to maintain accessible, high quality radiotherapy for the benefit of the 50% of cancer patients for whom it is indicated we need to have a much better idea of the costs and benefits of this essential modality.

In this presentation we'll look at the economic data that support the contentions made above, search the literature for radiotherapy costing studies and examine a few relevant studies in more detail. The presentation will conclude with a brief overview of ESTRO's Health Economics in Radiation Oncology project.

At the conclusion of the CE program, attendees will be able to:

1. Identify sources of data on health care funding and its distribution.

2. Discuss the literature on radiotherapy costing studies.

3. Appreciate ESTRO's Health Economics in Radiation Oncology initiative.

MPE09 - RADIATION THERAPY

MPE09.1 - The Modern Physicist Tool Box: How to Choose Between Current Dosimeters Author(s):

Learning Objectives

To review the basic principles of radiation detector dosimetry

To review the dosimetry protocols for conventional and small radiation fields

To provide an overview and a suitability discussion of dosimeters for a particular clinical applications including conventional and small fields

Dosimetric accuracy remains of paramount importance in a context of image-guided radiation therapy using clinical protocols that increasingly make use of hypofractionation with high doses per fraction. Over the past decade radiation dosimetry has seen developments including novel radiation standards for absorbed dose to water, unprecedented accuracy in the determination of correction factors for detectors and new formalisms for dosimetry of small static and dynamic radiation fields. At the same time, manufacturers have brought new water-equivalent and perturbation-friendly detectors on the market. This presentation reviews some basic aspects of detector dosimetry, new detectors and their suitability for measuring absorbed dose in challenging dosimetric conditions.

MPE09.2 - Radiobiology Applications for Clinical Physicists: Isoeffective dose calculations; Hypofractionation; TCP/NTCP; Peripheral doses and secondary cancers Author(s): <u>Michael Joiner</u>

Department Of Oncology, Wayne State University, Detroit/MI/UNIT-ED STATES OF AMERICA

The Linear-Quadratic (LQ) formulation deals specifically with the relationship between total dose and dose per fraction, and with interfraction interval using the Incomplete-Repair derivative model. The LQ description has been thoroughly tested in the clinical domain, but almost always in the "conventional" range of dose per fraction below 6 Gy. LQ is the simplest mathematical description of a non-linear relationship and though empirical in nature, it has nevertheless been subject to many attempts to connect with our understanding of how radiation injury is produced and repaired at the cell and molecular level. Yet any meaningful and clinically useful link in this respect has remained elusive. The relationship between total dose and overall treatment time is an even more complex relationship dependent on the different underlying radiobiology of different tissues even within the apparently same category of early-reacting or late-reacting tissues, distinguished by respectively a "high" or "low" ratio of α/β in the LQ equation. Overall time is therefore better handled independently of LQ.

A straightforward but untested hypothesis for the different α/β values for early- and late-reacting tissues, is that a naturally low α/β for a target cell population is smoothed out to a higher value as the sum of the responses of different proliferative subpopulations, and different phases of the cell cycle that these are in. This explanation could be applied to the responses of malignancies in the lung and head and neck, also adding in the additional response variation of cells at various levels of hypoxia in these sites. Of note is the connection between outcome of radiotherapy and HPV status in oropharyngeal cancers, which implies a possible difference in treatment strategy between these tumor subtypes and could also explain the high α/β of head and neck cancer overall as the sum of the responses of the different cancer subtypes (HPV + and –) which could

both have low α/β but different radiosensitivity. In some malignancies, notably prostate and breast, clinical data do indeed indicate a low α/β which might also reflect more uniformity in response perhaps more characteristic of lower proliferative or early-stage disease. This has resulted in new efforts to test hypofractionation which have also been enabled by better dose localization achievable with image-guided Volumetric Modulated Arc Therapy.

There is evidence that the LQ model becomes less reliable at doses per fraction < 1 Gy, due to possible low-dose hyper-radiosensitivity, and also at > 6 Gy per fraction for reasons not yet understood though increasing vascular damage and immunological/inflammatory effects occur at higher doses per fraction. It is axiomatic that LQ must indeed overestimate effect at very high doses per fraction because the effective D0 would become unrealistically low. This makes the outcome of hypofractionated regimes less predictable: using LQ at high doses per fraction would be playing safe in predicting toxicity of hypofractionation, while overestimating the effect on the target malignancy, noting that possible hypoxia in a tumor could also limit the effectiveness of large dose fractions.

Learning Objectives

1. Understand that the simplest two-parameter LQ model is a utility for describing the relationship between total dose and dose per fraction for isoeffect

2. Know the dose range of 1-6 Gy per fraction over which using the LQ model can be most relied upon

3. Be aware of the underlying radiobiology which may explain responses at low or high dose per fraction to be inadequately predicted by LQ extrapolation of the response to 1-6 Gy per fraction

MPE10 - COMPUTERIZED SYSTEMS

MPE10.1 - Dose Computation Algorithms, Including Monte Carlo

Author(s): Tommy Knoos

Radiation Physics, Skane University Hospital and Lund University, Lund/SWEDEN

Learning Objectives for *Dose modelling in external photon beam* radiotherapy

Separation of beam modelling and dose engine

Classification of dose calculation engines

The role of measured data in model based

Modelling of absorbed dose to patients during external photon beam radiotherapy will be reviewed. This will include the modelling of the radiation source i.e. the linac head (beam modelling) and the various dose calculation algorithms applied within the patient (dose engine).

For the beam modelling, the different sources e.g. target, filters and collimators etc will be defined as well as their importance for the photon and electron fluence reaching the patient. The consequences of removing the flattening filter, which several vendors now have made commercially available, will also be shown.

The pros and cons regarding different dose engines ability to consider density changes within the patient will be covered (type a and b models). Engines covered are, for example, pencil-beam models, collapsed cone superposition/-convolution models and combinations of these, as well as a glimpse on Monte Carlo methods for radiotherapy. The different models possibility to calculate dose to medium (tissue) and/or water will be presented.

Finally, the role of commissioning data especially measurements in today's model based dose calculation will round of the lecture.

MPE10.2 - Treatment Planning Optimization: IMRT and VMAT Author(s): Jan Unkelbach

Radiation Oncology, Massachusetts General Hospital, Boston/MA/ UNITED STATES OF AMERICA

Learning objectives:

Understand the concepts of fluence map optimization (FMO), leaf sequencing, and direct aperture optimization (DAO), which form the components used to assemble modern IMRT and VMAT planning algorithms.

Understand the formulation of VMAT planning as an optimization problem that aims to determine the trajectories of multi-leaf collimator leaves while the gantry rotates around the patient.

Understand the state-of-the-art in VMAT planning from an algorithmic perspective in the research literature and in commercial implementations.

Abstract:

Treatment planning for external beam radiotherapy is formulated as a large-scale mathematical optimization problem, which determines the machine parameters of the treatment device to achieve a desired dose distribution in the patient. Treatment plan optimization for intensity-modulated radiotherapy (IMRT) was historically developed as a two-step approach. In the first step, the fluence maps of incident beams are optimized; in the second step, a leaf sequencing algorithm converts the fluence maps into a sequence of apertures that can be delivered using a multi-leaf collimator (MLC). These two steps, fluence map optimization (FMO) and sequencing, are still important components in modern treatment planning systems (TPS). However, advanced TPS adopt direct aperture optimization (DAO) methods, which aim at directly optimizing the shape and intensity of MLC openings. DAO methods partially overcome some of the drawbacks of the two-step approach, such as degradation of the FMO dose distribution during the sequencing step.

Over the past years, volumetric modulated arc therapy (VMAT) has found widespread clinical application. In VMAT delivery, the gantry continuously rotates around the patient while the treatment beam is on and delivers radiation, promising shorter delivery times compared to step-and-shoot IMRT. Many treatment planning studies have since compared VMAT and IMRT in terms of plan quality and delivery time. In contrast, publications on the mathematical optimization algorithms used in VMAT planning are scarce. VMAT planning ultimately aims at optimizing the trajectories of MLC leafs while the gantry rotates around the patient. Unlike FMO, this represents an inherently non-convex optimization problem. Most VMAT algorithms, including the commercial implementations, use the concepts of FMO, leaf sequencing, and DAO that were originally developed for IMRT, and adapt these methods to VMAT. VMAT implementations differ in the component they rely on the most and the exact implementation of each step.

The presentation will briefly review basic concepts in treatment plan optimization, but will subsequently focus on the state-of-the-art in IMRT and VMAT planning from an algorithmic perspective. Implementations in commercial systems are explained and approaches suggested in the research literature are presented.

MPE11 - RADIATION THERAPY

MPE11.1 - Linear Accelerator Technology Author(s): <u>Malcolm R. Mcewen</u> Measurement Science And Standards, National Research Council, Ottawa/ON/CANADA

Learning objectives:

Understand how an electron linear accelerator works to produce electron and photon beams.

Understand the commonalities between different manufacturers' machines and also the important differences.

Understand what is physically being controlled by the software running on the linac workstation.

Electron linear accelerators are the workhorses of today's radiation therapy clinics. This presentation will aim to take the covers off a modern linac and show the different components that are required to produce, accelerate and deliver the primary electron beam to the treatment head. Clinical users are often quite familiar with the treatment delivery 'end' of a linac (target, flattening filters, MLC, *etc*) so the focus of this presentation will be on the other parts of a linac, where perhaps the medical physicist has the least day-to-day experience – the electron gun, modulator, rf source, waveguide and bending magnets. The aim is to open up what has perhaps become a black (or more often, white) box. The presentation will trace the history of linac development since the 1950s to the present day and show that the modern machines of 2015 have more in common with those early accelerators than one might think.

The following systems will be dealt with in some detail:

rf sources/amplifiers (magnetron and klystron)

high-power modulator design

vacuum components

electron gun (diode and triode)

beam transport and bending magnets

The intention is to cover the designs from the major manufacturers of rotational gantry-based linear accelerators.

Although this session is aimed primarily at clinical medical physics involved in using linear accelerator technology it has been designed to be accessible to those without a highly technical understanding of linacs.

MPE11.2 - Reference Dosimetry and its Uncertainties

Author(s): <u>David W.O. Rogers</u>¹, Malcolm R. Mcewen² ¹Physics, Carleton University, Ottawa/CANADA, ²Measurement Science And Standards, National Research Council, Ottawa/ON/ CANADA

Learning objectives

to understand the advances in photon beam reference dosimetry since 2000 (i.e., since publication of TRS-398 and TG-51).

to be aware of the implications for reference dosimetry when using FFF (flattening filter free) linac beams.

to understand the uncertainties in calculated values of kQ (= kQ,Qo).

to understand which ion chambers are suitable for reference dosimetry.

to be able to assess the various corrections needed (ion recombination, polarity, beam non-uniformity, etc).

to understand the uncertainties associated with reference dosimetry.

"Best Practice" reference dosimetry requires two components to obtain the calibration of an external beam radiation device:

1. Accurate input parameters (calibration coefficients, conversion factors), and

2. Accurate detector measurements in the radiation therapy clinic.

Calibration coefficients are determined by the primary, or secondary, standards laboratory and would be a presentation in themselves, so this session will look at conversion factors (e.g., k_{α} factors, perturbation factors) and ion chamber measurements. Although the presentation will focus on the two most widely-used external beam protocols (IAEA TRS-398 and AAPM TG-51) the issues discussed will be applicable to other national protocols and codes of practice currently in use.

Part 1 - Conversion factors and beam quality specifiers.

Since 2000 there have been studies (mostly Monte Carlo) which demonstrated that the data used then for the various correction factors making up $k_{_{\rm O}}(P_{_{\rm wall}}, P_{_{\rm repl}}, P_{_{\rm cel}})$ were individually wrong by up to 1%. Fortunately the calculated $k_{_{\rm O}}$ factors ($k_{_{\rm O,Qo}}$ in TRS-398) only depend on ratios of these factors and the errors in $k_{_{\rm O}}$ were therefore somewhat less. One study showed that the %dd(10)_x and TPR_{20,10} beam quality specifiers were equivalent for clinical beams with flattening filters. However, since then it has become common to use linacs without flattening filters and this leads to complications which will be discussed.

To overcome issues with the individual correction factors, it is possible to calculate k_{o} values directly using Monte Carlo techniques with an uncertainty of 0.4% to 0.5%. When compared to measurements of k_{o} for 26 different ion chamber models (with uncertainties of 0.3% for reference class chambers), the agreement was excellent, with $\chi^{2/}$ df values less than 1. The calculated values fall on smooth curves as a function of %dd(10)_x except for chambers with high-Z electrodes, which are not suitable for reference dosimetry for other reasons as well. The talk will present the experimental and calculated values to demonstrate each of the above statements.

Part 2 - uncertainty and the clinical medical physicist

As part of any measurement it is essential to estimate the uncertainty in the result obtained. Development of an uncertainty budget is not just a matter of obtaining a value; the steps followed to construct an uncertainty budget are, in fact, a process review that feeds directly into the quality documentation and procedures used by each institution.

This part of the session will examine the primary components of uncertainty in an absorbed dose to water measurement and describe how they depend on the user's experimental method, the choice of chamber, *etc.* We deconstruct the basic measurement equations found in dosimetry protocols to understand what is required to obtain an accurate and precise determination of D_w . Issues that become apparent in doing this include the correct choice of ion chamber type, the errors that can arise from inadequate detector characterization, and the importance of understanding the performance of all systems that contribute to the final measurement.

Carrying out this analysis will demonstrate that the clinical medical

physicist is not simply someone following a recipe, but is actively involved in impacting the overall uncertainty in reference dose measurements.

MPE12 - COMPUTERIZED SYSTEMS

MPE12.1 - Image Registration

Author(s): Michael Velec Techna Institute, University Health Network, Toronto/ON/CANADA

Multiple imaging modalities are now commonly used to diagnose and classify disease. For radiation oncology in particular, tumor representations from several images need to be combined to define the treatment target and serial imaging is then used to guide therapy. Registration is the process by which the information in these images is combined into one model of the patient and exploited. Algorithms differ widely in how they function and therefore each have specific clinical scenarios were they are better suited. Recently deformable registration algorithms are being adopted for more advanced applications, adding further complexity to treatment processes. Understanding methods to assess if image registration is performing accurately, and techniques to apply when it is not, are essential to ensure that treatment accuracy is maintained.

At the conclusion of this session, attendees will be able to:

1) Describe fundamental components of image registration using common rigid and deformable algorithm examples

2) Understand quantitative and qualitative methods to perform validation and quality assurance for image registration

3) Discuss strategies to make tradeoffs between image registration limitations and clinical goals, using examples scenarios

MPE12.2 - Automated Segmentation of Images for Treatment Planning Purposes

Author(s): Greg Sharp

Radiation Oncology, Massachusetts General Hospital, Boston/MA/ UNITED STATES OF AMERICA

Automatic segmentation holds great promise for improving radiotherapy practice. Although it is primarily regarded as a method for increasing efficiency, automatic segmentation can also play a role in improving standardization and consistency. The application of segmentation to clinical research is also of interest, because it can easily scale up to large numbers of patients for retrospective studies. This CE session is intended to provide a gentle, but complete, introduction to the algorithms and expected performance of radiotherapy auto-contouring software.

The goals of the CE session are to provide understanding of

- Algorithms commonly used in automatic image segmentation software

- Methods for evaluating segmentation accuracy

- Expected segmentation accuracy for commonly segmented organs-at-risk

MPE13 - MEDICAL PHYSICS EDUCATION AND PROFESSIONAL ISSUES

MPE13.1 - Advocacy for Physicists and How to Deal with Government, Unions, Regulators, and Employers Author(s): Jerry J. Battista¹, Wayne Beckham²

¹Medical Biophysics, Western University, London/CANADA, ²Medical Physics, BC Cancer Agency - Vancouver Island Centre, Victoria/ BC/CANADA

Learning Objectives:

To understand that a medical physics career evolves to the point of requiring administrative and negotiating skills

To recognize the need to interact with governments, regulators, unions, and employers

To understand the "hot buttons" in dealing with non-scientific interactions

Medical physicists are fortunate to enjoy a career with such wide diversity in activities but the priority of each activity changes over the course of a career. Early career is focused on acquiring necessary clinical skills in the safe administration of diagnostic or therapeutic medical procedures. If there is a concurrent university appointment, this also requires some level of activity in teaching and research, initially supported by internal grants and potentially growing to nationally peer-reviewed levels. In time, the physicist is assigned progressively more supervisory roles and significant administrative duties. Interactions with hospital administrators, legislative agencies at the provincial and federal levels, and employee unions expand. The role then requires an abrupt mental shift for scientists as discussions extend beyond having good data and logic. In dealing with hospital executives, a delicate balance of budget restraint, excellent patient services, and risk management must be struck. In dealing with government regulators, attention to procedural details and a population (macroscopic) perspective is needed for justifying acquisition and assuring safety compliance of all technology. In dealing with unions, fair play of the employee and relationship with the employer is the focus, under all foreseeable circumstances. Endless hours are expended in interpreting, applying or editing collective agreements for word precision describing "what if" scenarios such as displacement of employees by technological advances. In summary, medical physicists working in hospital environments must be prepared to advocate well beyond their core scientific know-how. A stronger background in budgeting, presentation of proposals and arguments at the lay level, understanding legislative language, and "big picture" viewpoints is needed. Without such preparation, future leadership of medical physics programs may be assigned to non-physicists.

MPE14 - RADIATION THERAPY

MPE14.1 - Radiotherapy Units: Cobalt-60 Units and Gamma Knife Units

Author(s): Steven Goetsch

Medical Physics, Dade Moeller Health Group, Solana Beach/CA/ UNITED STATES OF AMERICA

The original Leksell gamma unit was conceived and built in 1967. Since that time hundreds of such units have treated an estimated 1 million patients worldwide for brain tumors and other neurological diseases. In times of increasingly tight health care budgets single fraction Gamma Knife radiosurgery and 3 to 5 fraction stereotactic radiotherapy become increasingly attractive options for treatment of patients with intracranial disease. Over the last 48 years treatment times have become much shorter and treatment plans have become far more sophisticated. New radiotherapy units continue to be introduced to the U.S. healthcare system.

At the conclusion of the CE program, attendees will be able to:

Describe in detail how the Leksell Gamma Knife and other similar gamma radiosurgery (GSR) units work

Compare and contrast the methods and results of clinical applications of the gamma unit with those of competing technologies

Become familiar with new advances in GSR technology

MPE14.2 - Brachytherapy: Overview of State-Of-The-Art and New Developments

Author(s): <u>Nicole Nesvacil</u>, Christian Kirisits Department Of Radiation Oncology, Medical university of Vienna, Vienna/AUSTRIA

The main learning objectives of this presentation are:

To get an overview of the uncertainty budget in modern 3D IAGBT

To understand the correlation between dosimetric uncertainties and reporting of total treatment doses for different clinical sites and treatment schedules

To improve understanting of the consequences of uncertainties in the delivered dose for the usability of dose-response models in clinical decision making (definition of planning aims and decisions for/against use of IGABT vs IGBT without re-imaging before each irradiation, for individual patients)

Increasing availability of 3D image guided adaptive brachytherapy (IGABT) treatment techniques, allow us to tailor dose distributions for each individual patient to the specific anatomy and reduce risks of side effects, while increasing the dose to the tumour. However, individual dose plan optimization is always affected by dosimetric uncertainties that may lead to a difference between prescribed and delivered dose.

In this presentation we will review the most recent reports on uncertainties in brachytherapy and discuss the impact of different types of uncertainties on our understanding of dose-response analysis.

The sources of uncertainties can be of technological nature (source calibration, dose calculation and dose delivery), or due to the clinical workflow and anatomy of the patient (applicator movement, delineation uncertainties, anatomical changes (inter-/ or intra-fraction variations)). Recent reports highlight the magnitude of different types of uncertainties for different BT treatment sites (Tanderup et al. 2013, Radiother Oncol 107:1-5, Kirisits et al. 2014, Radiother Oncol 110:199-212, and references therein).

Uncertainties can be classified as systematic (e.g. source calibration) or random (e.g. interfraction variations). Recently, a lot of effort has been made to analyze dosimetric variations occurring due to anatomical changes, within and between different BT fractions for cervical cancer. For example, a multicenter study (Nesvacil et al. 2013, Radiother Oncol 107:20-25) revealed random intra- and inter-fraction uncertainties of the order of 10% for D_{g0} of HR CTV and 20-30 % for D_{2cm^3} for organs at risk, for the physical dose of each BT fraction. In this case inter-/intra-fraction variations can be considered as the main contributors to the total uncertainty of the delivered BT doses. While dosimetric variations for the target appear to be dominated by contouring uncertainties, variations for OARs are also influenced by their changes in location and filling, as well as movements of the applicator and target in relation to the OARs.

In a hyperfractionated BT treatment protocol observed uncertainties of physical fraction dose will also lead to an accumulated uncertainty of the whole BT treatment dose (in EQD2) – which (including contributions from EBRT to the overall treatment) is used to analyze clinical dose-response relationships.

Comparison of examples for different types of uncertainties for various BT applications, tumour sites, OARs, and different treatment schedules, might help to define future goals and strategies to further increase precision in modern IGABT, and to better understand dose constraints for BT planning.

MPE15 - COMPUTERIZED SYSTEMS

MPE15.1 - Managing Respiratory Motion in Radiation Oncology Author(s): Paul Keall

Radiation Physics Laboratory, University of Sydney, University of Sydney/AUSTRALIA

Learning objectives

1. Understand the clinical drivers for respiratory motion management in radiation oncology

2. Understand how respiratory motion management occurs at multiple stages of the patient treatment cycle

3. Understand the current status of respiratory motion management technology in radiation oncology

Presentation Description

One of the most exciting and dynamic areas of academic and clinical radiation oncology is the management of respiratory motion in radiation oncology. New technologies are being invented, innovations are occurring on existing technology and the growth of clinical data and findings is staggering.

Respiratory motion management in radiation oncology can be broadly classed into the four interconnecting areas where technology and the patient interact: (1) Imaging for treatment planning; (2) Treatment planning; (3) Pre-treatment imaging and (4) Treatment delivery.

In this talk the clinical drivers for respiratory motion management and associated technological development drivers will be described. Current clinical standards for the four broad respiratory management motion areas will be explained. Near and long term directions for respiratory motion management, including the interaction of respiratory motion management technologies with other emerging cancer imaging and treatment modalities will given.

MPE15.2 - RadOnc Treatment Management Systems and the Paperless Treatment Process

Author(s): Benedick A. Fraass

Department Of Radiation Oncology, Cedars-Sinai Medical Center, Los Angeles/CA/UNITED STATES OF AMERICA

Learning Objectives:

1. To describe differences between the traditional treatment process and the treatment process in a paperless environment.

2. To discuss the differences between paperless and truly electronic medical record and treatment management systems.

3. To discuss the issues involved in integrating quality assurance and safety concerns into our paperless and/or electronic treatment process.

Over the last decade, the radiation therapy planning and delivery process has morphed from a manual paper-chart-based process to one which is implemented with computerized treatment management systems (TMS) and electronic medical record (EMR) systems. The paperless process has numerous advantages over the older paper-based system as well as some disadvantages, especially when old techniques are carried over into the paperless environment. This presentation will discuss differences between traditional and paperless approaches and describe some of the quality assurance and safety concerns which must be properly handled in the new environment. The progress that the field of radiation oncology has made from "paperless" to fully implemented computerized TMS and EMR systems will be reviewed and evaluated.

MPE16 - RADIATION THERAPY

MPE16.1 - Specialized Units: Tomotherapy and CyberKnife Systems

Author(s): Martina Descovich¹, Robert J. Staton²

¹Radiation Oncology, University of California San Francisco, San Francisco/UNITED STATES OF AMERICA, ²Radiation Oncolgy, UF Health Cancer Center - Orlando Health, Orlando/UNITED STATES OF AMERICA

The continual advances in radiation therapy technology lead to the development of specialized treatment units. The design and function of TomoTherapy & Cyberknife systems is significantly different than traditional medical linear accelerators. This session will provide an overview of the TomoTherapy and Cyberknife systems covering design and operation, available image guidance techniques, and quality assurance recommendations. Treatment workflow, clinical applications, and treatment planning techniques will also be discussed and compared.

Educational Objectives:

1. Understand the core concepts of Tomotherapy & Cyberknife treatment delivery.

2. Understand the image guidance options for Tomotherapy & Cyberknife machines.

3. Understand the QA procedures for Tomotherapy & Cyberknife.

MPE16.2 - Heavy Particle / Light Ion Therapy

Author(s): <u>Oliver Jäkel</u> Medical Physics In Radiation Oncology, German Cancer Research Center, Heidelberg/GERMANY

Proton beam radiotherapy celebrates it's 60th birthday in 2015, but already 2 years after the first proton treatment in Berkeley, also helium was introduced for radiotherapy. Heavier ions like carbon, nitrogen, neon, silicon and argon have also been used for radiotherapy at Berkeley between 1977 and 1992.

After the Berkeley trials ended, the first clinical treatment facility started its operation in Chiba, Japan in 1994 with carbon ions. In Germany an experimental facility opened in 1997 and was the first facility to establish intensity modulated beam scanning for carbon ions. In the meantime five clinical centers are existing in Japan, four in Europe and two in China. One of the most advanced facilities opened in 2009 at Heidelberg University: it is the only facility with an isocentric scanning gantry for ions and also offers beams of helium and oxygen ions for pre- clinical research.

In the presentation the physics and radiobiological rationale for ion beam radiotherapy is outlined. Some current research topics in the field of medical physics will be highlighted and the status of ion beam therapy in the world as well as the current clinical evidence will be summarized.

At the conclusion of the CE program, attendees will be able to

1- Describe the physics and radiobiological rationale for using ion beams in radiotherapy

2- Describe how the physics of ions is connected to the biological effectiveness

3- Describe the most important research directions for ions and the existing clinical evidence for carbon ions

MPE17 - RADIATION THERAPY

MPE17.1 - Chemotherapy and its Influence on Radiotherapy: Basics for Clinical Physicists

Author(s): Eva Bezak¹, Michael P. Brown² ¹School Of Physical Sciences, University of Adelaide, Adelaide/SA/ AUSTRALIA, ²Cancer Clinical Trials Unit, Royal Adelaide Hospital, Adelaide/AUSTRALIA

In this lecture the following learning objectives are aimed at:

1. To revise the role and basic principles of chemotherapy in cancer treatment.

2. To develop understanding of biological rationale for combined radiation and chemotherapy.

3. To review most common chemotherapy agents in current clinical use.

Cancer therapy of the last two decades has been marked by rapid development of combined therapies, especially of conventional chemotherapy (CHT) drugs with radiotherapy (RT).

While a complete understanding of biological mechanisms behind combined therapies is still being investigated, clinical trials have demonstrated improved survival for a number of cancers, including head and neck, stomach, oesophagus, lung, pancreas, colon, breast, glioblastoma multiforme and others. Some of the main chemotherapy agents are cisplatin, gemcitabine, tirapazamine (TPZ), temozolomide (TMZ) and 5-Fu (Fluorouracil) and analogues (1, 2).

The basic rationale for combined chemo/radio therapy lies in socalled spatial cooperation of the two modalities; with RT affecting the local tumour and systemic chemotherapy sterilizing the disseminated clonogenic cells (3). Additionally, the main objective is to enhance tumour response without enhancing normal tissue complications (the process known as radiosensitization). Chemotherapeutic agents target different physiological characteristics of the tumour, including hypoxia that is generally associated with tumour radioresistance. Other group of drugs (so-called radioprotectors) are used to reduce/mitigate normal tissue injury without compromising the tumour response (4).

The enhanced tumour response or radioprotection can be achieved with varying degrees of additivity, depending on the mechanisms of interaction of the drug and radiation and their interplay. Clinical data suggest that many of the enhanced tumour effects result from simple additivity; i.e. there is no direct interaction between the chemotherapy agent and radiation. Normal tissue protection, on the other hand, is often most pronounced when drugs are administered more closely to irradiation. The optimum scheduling and combinations are, however, still being investigated. Currently used scheduling has been in general developed from clinical trials and supported by modelling (1, 5).

The main/known mechanisms of interaction between drugs and radiation and the resultant additive and synergistic effects include: enhancement of DNA damage (i.e. change in the slope of the dose-response curve), formation of additional DNA adducts, interference with DNA repair processes (e.g. inhibition of repair of sublethal damage), enhancement of apoptosis, inhibition of proliferation, perturbation of cell kinetics (e.g. an increase of a number of cells in the sensitive cell cycle phase), hypoxic cell sensitization, inhibition of angiogenesis, and interference with signalling pathways.

The interaction between a chemotherapy agent and radiation is dose and time dependent, including drug dose and scheduling, time sequencing between drug and radiation delivery, radiation dose doserate as well as fractionation schedule. There seems to be lesser dependence on the tumour/tissue type.

MPE17.2 - Models of Delivery of Radiation Therapy (Private, Public, BCCA/CCO, etc).

Author(s): Michael Sherar¹, Thomas Mcgowan²

¹Cancer Care Ontario, Toronto/ON/CANADA, ²Oncology, The Cancer Centre Bahamas & The Cancer Centre Eastern Caribbean, Nassau/ BAHAMAS

Around the world, the mix of private and public delivery of radiation therapy services varies. The challenge for any model of payment for and provision of services is the assurance of and continual improvement of quality, including equitable access to services for the entire population. An examination of where the public and private sectors have been successful, and the challenges each type of model faces in different parts of the world is useful as we look to the problem of how to expand access to high quality radiation services globally.

Cancer Care Ontario (CCO) oversees the planning of and public payment for publically provided radiation therapy services in Ontario. There is no private involvement. Interestingly, the private sector did have a role in the evolution of Cancer Care Ontario to it's current state. In the latter part of the last century long waiting lists in Ontario required sending 1,000 patients a year to the United States for care. A short term private sector contract (but using public hospital facilities) was put in place to eliminate out of country rereferrrals, and bring the waiting list down. This wait times crisis was a key factor in changing CCO's role from being a provider to become a purchaser and quality improvement agency. Provision of services was reintegrated with local hospitals. Quality improvement according to provincial standards is driven as part of the Ontario Cancer Plan. Provincial and regional clinical leaders work with Regional Cancer Program Vice Presidents to drive quality improvement across all facilities. The benefits of a strong public provincial program including central capital planning and a population level approach are described as well as an analysis of some of the key challenges facing the Ontario system.

In contrast, The Bahamas provides an example of where the private sector played an essential role as it was able to provide the capital, and management expertise to build and operate a radiation facility in an environment where the government could not realistically afford to do so. Through a partnered care model, the private facility treats both public and private patients to the same standard, but provides radiation services to public patients at a reduced cost. This partnered care model is successful enough that the same private sector provider, at the request of the government of Antigua and Barbuda, is building a similar facility to provide care for the population of The Eastern Caribbean.

The global problem of access to radiotherapy will be not solved through a single approach. We will need to learn from best practice in a variety of environments to tailor a solution to each environment.

Learning Objectives:

1. Understand the benefits and challenges of the both public and private payment and delivery models for radiation therapy.

2. Understand the challenges of improving global access to radiation therapy in the context of public, private or mixed payment and service delivery solutions.

3. Understand how the mix of public and private involvement in a radiation therapy delivery model can be dependent upon the local political and economic environment.

MPE18 - MEDICAL PHYSICS EDUCATION AND PROFESSIONAL ISSUES

MPE18.1 - Curriculum Design: How to Train the Next Generation of Physicists?

Author(s): John Damilakis

Medical Physics, UNIVERSITY OF CRETE, HERAKLION/GREECE

The International Organization for Medical Physics states in its Policy Statement No. 2 that 'Medical Physicists working as health professionals shall demonstrate competency in their discipline by obtaining the appropriate educational qualification and clinical competency training in one or more sub-fields of medical physics. Basic knowledge of the other sub-fields is also required. Medical Physicists practicing in hospital/clinical environments shall also participate in a continual professional development program'. Recommendations on the minimum levels of education and training for medical physicists are given in the same document. This lecture will present guidelines and recommendations developed by international organizations on the requirements for the education and training necessary for a physicist to become a clinically qualified medical physicist. These guidelines can be used for the development of the local curriculum for medical physicists.

An increasing number of higher education institutions have in recent years started to offer courses on Medical Physics. Moreover, Continuing Professional Development (CPD) for medical physicists is of great professional interest. CPD courses is an excellent way to ensure that Medical Physicists become knowledgeable about all current issues in their field and to provide the necessary knowledge, skills and competences for certified Medical Physicists to become Medical Physics Experts. However, external assessment of the quality of education or training provision is needed. Accreditation is the formal recognition that education and training on medical physics provided by an institution meets acceptable levels of quality. Accreditation should be based upon standards and guidelines. Requirements for accreditation of a training programme should take into account several aspects including facilities, staff, educational material and teaching methods.

EUTEMPE-RX is a European Commission (EC) funded project which aims to provide training opportunities to medical physicists in diagnostic and interventional radiology to become Medical Physics Experts i.e. to reach level 8 according to the European Qualification Framework (EQF). A network of excellent teaching centers in medical physics has been set up to develop a set of modules. The courses will achieve their learning objectives combining online with face-to-face teaching. More information about EUTEMPE-RX can be found at www.eutempe-rx.eu.

Learning Objectives

1. To present curricula for postgraduate education program on Medical Physics

2. To present guidelines and recommendations developed by international organizations on the requirements for the education and training necessary for a physicist to become a clinically qualified medical physicist

3. To discuss issues related to accreditation of the education and training in Medical Physics

MPE18.2 - Professional Standards and Certification of Qualified Individuals

Author(s): <u>Matthew Schmid</u>¹, Geoffrey Ibbott² ¹Medcial Physics, BC Cancer Agency - Southern Interior, Kelowna/ CANADA, ²Radiation Physics, UT MD Anderson Cancer Center, Houston/UNITED STATES OF AMERICA

Learning Objectives: 1. Understand the 4 underlying principles that form the basis for a certification program: a. Providing an examination process b. Providing a maintenance of certification (recertification) program c. Providing a public registry d. Providing a disciplinary process 2. Be familiar with the specifics of the CCPM and ABR certification processes (eligibility requirements, exam process) 3. Be familiar with the CCPM recertification process and the ABR maintenance of certification process Abstract: The Canadian College of Physicists in Medicine (CCPM) exists to protect the public by: (a) establishing standards of competence for those involved in the application of the physical sciences in the medical field in Canada. (b) identifying individuals who meet the established standards and maintaining a registry of these individuals. Similarly, the American Board of Radiology (ABR) has as its mission: To certify that our diplomates demonstrate the requisite knowledge, skill, and understanding of their disciplines to the benefit of patients. This talk will focus on how the CCPM and the ABR meet these objectives. By way of introduction, a brief description of the structure and governance of the CCPM and of the ABR will be presented. The core business of any certification organization is centered around its examination process. The eligibility requirements for membership in each board will be detailed, along with a description of the examination process. After initial certification has been obtained, both the CCPM and the ABR require that all members meet the requirements of an on-going maintenance of certification (recertification) program in order to maintain their certification status. The structure of the MOC programs will be presented. Members of the CCPM are required to comply with the Code of Ethics stated in the Regulations of the College, and this will be briefly discussed, along with a description of the disciplinary process in place to ensure member compliance with the Regulations of the College. The ABR is not a membership organization, but certification carries with it the expectation that the diplomate meet appropriate professional standards.

MPE19 - RADIATION THERAPY

MPE19.1 - Commissioning, Clinical Implementation and Quality Assurance for Stereotactic Body Radiation Therapy Author(s):

Stereotactic Body Radiotherapy (SBRT) has been applied clinically for over two decades. The accumulation of published technical and clinical studies currently available have has offered insights into both the efficacy and special concerns associated with the delivery of SBRT to different sites. The safe and effective delivery of SBRT requires careful attention to many unique technical aspects, including dosimetry of small photon fields; management of respiratory motion; immobilization, localization and image guidance; accurate dose calculation; quality assurance; and understanding of normal tissue constraints to high dose irradiation. This session will provide an overview of these important technical considerations, guidance on safe and effective implementation in the main disease sites, and a survey of reported clinical outcomes.

At the conclusion of the CE program, attendees will be able to:

 Describe key elements of initial SBRT equipment commissioning, patient-specific QA, and routine periodic machine performance QA;
 Describe and discuss processes for small field dosimetry, and understand limitations in available algorithms for dose calculation;
 Describe and discuss practical issues associated with patient immobilization, motion management, use of image guidance for accurate localization;

4. Describe and discuss standard treatment regimens and normal tissue dose constraints, to incorporate clinical and technical principles into their disease site-based programs of their own.

MPF01 - IMAGERIE

MPF01.1 - Tomodensitométrie: Les Nouveaux Développements et Avenues de Recherche

Author(s): <u>Philippe Després</u> Département De Physique, De Génie Physique Et D'optique, Université Laval, Québec/CANADA

Objectifs d'apprentissage

1) Apprécier l'évolution technologique de la tomodensitométrie depuis l'avènement des appareils multicoupes.

2) Comprendre les enjeux de radioprotection associés à la tomodensitométrie et reconnaître l'apport de diverses approches pour réduire la dose.

3) Découvrir de nouvelles applications en tomodensitométrie ainsi que les avenues de recherche actuelles, notamment en imagerie biénergie et en reconstructions tomographiques avancées.

La tomodensitométrie (TDM) n'a pas connu de bouleversements majeurs depuis l'avènement des appareils multicoupes et des acquisitions hélicoïdales. Cependant, cette technologie n'a pas cessé d'évoluer pour autant. L'évolution de la TDM au cours des dernières années sera abordée durant cette présentation selon différents points de vue: technologique, social et médical. D'un point de vue technologique, la TDM peut désormais compter sur une puissance de calcul numérique bonifiée, permettant l'exécution d'algorithmes de reconstruction plus performants en des temps raisonnables. Les processeurs graphiques (GPU) à architecture hautement paralèlle, notamment, permettent aujourd'hui l'exécution rapide d'algorithmes itératifs où un modèle physique de détection est utilisé durant la reconstruction. Cette approche peut mener à des images de meilleure qualité acquises à des doses inférieures pour le patient. D'un point de vue social, le recours de plus en plus fréquent à la TDM et son accessibilité toujours grandissante ont soulevé des questions importantes en radioprotection. Les manufacturiers d'appareils TDM, bien conscients de ces enjeux, proposent aujourd'hui des technologies destinées à minimiser la dose au patient; celles-ci seront revues et discutées. D'un point de vue médicale, la TDM permet aujourd'hui davantage d'applications grâce à certaines innovations technologiques. Le cas de l'imagerie bi-énergie sera revu et discuté. Finalement, les avenues de recherche actuelles en TDM seront abordées, tant d'un point de vue technologique que médical.

ENGLISH

Computed Tomography: new developments and research avenues Learning objectives Appreciate the technical evolution of Computed Tomography (CT) since the advent of multislice devices. Understand the radiation safety challenges associated with CT and recognize the role of various approaches to reduce the dose to the patient. Discover new applications in CT as well as current research avenues, notably in dual-energy imaging and advanced tomographic reconstruction. Computed Tomography did not change significantly since the advent of multislice devices and helical acquisitions. However, this technology did not stop evolving altogether. The evolution of CT during the last few years will be reviewed from different points of view: technological, social and medical. From a technological perspective, CT can nowadays rely on unprecedented computing power, allowing the execution of advanced reconstruction algorithms in a reasonable time. Massively parallel Graphics Processing Units (GPUs), for instance, allow the used of complex physical models in iterative reconstruction. These approaches can yield better images acquired at lower patient exposures. From a public health perspective, the steadily increasing number of CT studies performed each year has drawn attention from the media and radiation safety authorities. CT manufacturers, well aware of this situation, nowadays propose technologies aiming at reducing the radiation dose to the patient. These technologies will be reviewed and discussed. From a medical perspective, CT nowadays allow new applications thanks to technological developments. The case of dual-energy imaging will be reviewed and discussed. Finally, current research avenues in CT will be reviewed, from a technological as well as medical point of view.

MPF01.2 - Résonnance Magnétique: les Nouveaux Développements et Avenues de Recherche

Author(s): Martin Lepage

Nuclear Medicine And Radiobiology, Université de Sherbrooke, Sherbrooke/QC/CANADA

The field of magnetic resonance imaging continues to develop both in terms of technological innovations and of novel clinical applications. Higher magnetic field strengths along with the development of accelerated acquisition methods have led to unforeseen applications because of previously unexploited contrast mechanisms. For example, the large susceptibility contrast available at fields of 3T and above has produced exquisite images of the human brain vasculature. Radio-frequency field inhomogeneity at high field was overcome by parallel transmission and this has led to the design of parallel excitation enabling faster image acquisition. Those are becoming useful in the clinical characterization of pathologies and may help tailor better treatment options. Meanwhile, combining information from multiple imaging modalities has the potential to refine the information extracted from images by highlighting the vascular and metabolic aspects of pathologies. This is expected to translate in improvements in diagnosis, treatment planning and therapy response.

At the conclusion of this presentation, attendees will be able to

Identify novel technological developments and novel contrasts in magnetic resonance imaging

Identify recent clinical application of magnetic resonance imaging

Identify where magnetic resonance imaging, alone or in combination with other imaging modalities, may further improve tissue characterization

MPF02 - SYSTÈMES INFORMATISÉS

MPF02.1 - Éléments de Base: Réseaux Informatiques, Serveurs, et Standards de Communication Author(s): <u>Stefan Michalowski</u> Radiation Oncology, CHUM, Montréal/QC/CANADA

Objectifs d'apprentissage

 Comprendre l'environnement informatique dans le milieu médical, plus spécifiquement en radio-oncologie et radiologie.
 Connaître les technologies de communication utilisées en radio-oncologie et radiologie.
 Établir les liens entre les besoins cliniques et la technologie.

Résumé

Dans ce cours, les notions de base en informatique nécessaires aux physiciens médicaux opérant dans les secteurs de radio-oncologie et de radiologie seront expliquées. Ce cours, basé sur mon expérience de plus de 10 ans dans l'administration des systèmes d'information du département de radio-oncologique du CHUM, se découpe en trois sections: format de fichiers, communication, et infrastructure.

Dans la première section, en débutant par une explication des concepts de la numérisation, la compréhension des formats de fichier sera démystifiée. Utilisant ces nouvelles notions, le format de stockage des images médicales utilisé par DICOM sera expliqué. L'extension radiothérapie de DICOM (DICOM-RT) sera aussi détaillée. Par l'utilisation d'exemples pratiques, le cours touche les problèmes qui peuvent survenir lors de la manipulation et de l'échange de fichiers DICOM entre divers logiciels et systèmes afin de permettre aux participants de mieux comprendre et résoudre ces problèmes.

Dans la deuxième section, une explication de la réseautique standard (TCP/IP) sera abordée en plus des technologies de communication spécifique au milieu médicale tel que celles utilisées par DICOM et les standards couvert par l'organisme HL7. Une explication des concepts derrière la réseautique IP et des technologies de transport de donnée (Ethernet). Un des aspects très importants de la communication est la sécurité, surtout dans le contexte actuel. Les notions d'authentification et d'autorisation seront abordées. De plus, le chiffrement et les communications sécurisées seront expliqués. Ces notions vous permettront de comprendre la configuration des infrastructures réseautiques.

L'échange d'informations qui fait partie de la communication comporte des dangers qu'il faut surveiller, surtout lorsqu'on échange de l'information entre deux systèmes différents, que ce soit deux versions d'un logiciel ou deux logiciels différents. L'exportation et l'importation comporte des transformations qui peuvent modifier les données. Le cours couvrira ce sujet avec quelques exemples.

Finalement, la troisième section fera un survol des équipements et infrastructures nécessaires pour faire fonctionner les systèmes d'information radiologique (PACS) et radio-oncologique (ROIS). Cette section couvrira les concepts de base de donnée relationnelle en plus de se concentrer sur les infrastructures physiques nécessaires pour faire opérer les système d'information (serveur, SAN, RAID).

ENGLISH

Learning Objectives

 Understand the information technology environment in the Healthcare sector, more specifically in Radiation Therapy and Radiology.
 Learn about the communication technologies used in Radiation Therapy and Radiology.

3) Establish the links between clinical needs and technology

Summary

In this presentation, the essential notions in IT necessary for Medical Physicists and Engineers operating in Radiation Therapy and Radiology will be explained. This presentation, based on my more than 10 years of experience in the management of CHUM's Radiation Oncology Information System, is composed of three sections: file formats, communication and infrastructure.

In the first section, through the introduction of the elements and concepts surrounding information digitisation, understanding of file formats will be demystified. Using these new notions, the image file format for DICOM will be explained. The Radiation Therapy extension to DICOM (DICOM-RT) will also be covered. Through the use of practical examples, the difficulties and issues that can arise when manipulating and transferring DICOM files between information systems and applications will be touched upon, this will allow participants to better understand and solve these issues.

In the second section, an explanation of the most common network technology (TCP/IP) will be discussed, in addition to the communication technologies specific to the Healthcare sectors such as those used by DICOM and the standards covered by the HL7 group. In more detail, the concepts of IP networking and transport technologies such as Ethernet will be explained.

As one of the most important aspects of communication is security, especially in today's context, the course will adress this subject by covering the notions of authentication and authorisation. In addition, encryption and secured communications will be explained. All these notions should help participants understand the basics of configuring a safe network infrastructure.

There are important factors that have to be analysed when information is exchanged between two different systems, be it two different versions of the same software application or two different software applications. Because data can be modified by these exchanges, an information system manager has to understand these issues. Thus, this presentation will include a few examples of the dangers users are exposed to when exporting and/or importing data from one system to another.

Finally, the third section will overview the hardware and infrastructure required to run a Radiology Information System (RIS/PACS) and a Radiation Oncology Information System (ROIS). This section will cover database concepts as well as the technical details of the physical hardware to run such information systems (server, SAN, RAID).

MPF03 - RADIOTHÉRAPIE

MPF03.1 - Appareils Spécialisés: Tomotherapy, CyberKnife, Brainlab, Gamma Knife

Author(s): Veronique Vallet

Ira, Centre hospitalier universitaire vaudois, Lausanne/SWITZER-LAND

La radiothérapie 3D, par modulation d'intensité (IMRT) ou d'arcthérapie volumétrique modulée (VMAT), font de plus en plus partie des techniques habituelles de traitement. En revanche, d'autres installations de traitement, comme la Tomothérapie, le CyberKnife, le Novalis (Brainlab) et le GammaKnife, sont des systèmes moins couramment utilisés dans la pratique clinique. Ces installations permettent des traitements hautement spécialisés et ont un véritable potentiel d'amélioration des traitements. Les spécificités de ces installations impliquent d'autres manières de préparer et de délivrer les traitements.

Les objectifs de ce cours sont les suivants:

1. Décrire ces installations et mettant l'accent sur les différences par rapport à des accélérateurs linéaires "conventionnels".

2. Montrer et décrire des plans de traitement typiques qui peuvent être obtenus avec ce type d'installations.

3. Décrire les avantages et les inconvénients de tels systèmes.

ENGLISH

3D conformal radiotherapy, intensity modulated radiotherapy (IMRT) or volumetric modulated arc therapy (VMAT), are increasingly used as standard treatment techniques. However, other treatment machine, such as TomoTherapy, CyberKnife, Novalis (Brainlab) and GammaKnife are less commonly used in clinical practice. These machines allow highly specialized treatment and have real potential to improve treatments quality. The specificities of these machines imply other ways to prepare and deliver treatments.

The objectives of this course are:

1. Describe the different treatment units focusing on their differences from "standard" linear accelerators

2. Show and describe typical treatment plans that can be achieved with this type of machines.

3. Describe the advantages and disadvantages of such systems.

MPF03.2 - Curiethérapie Guidée par l'image

Author(s): Luc Beaulieu

Radio-oncologie, CHU de Quebec, Quebec/CANADA

Objectifs d'apprentissages

- Identifier la ou les modalités d'imageries les plus appropriées selon le type de procédure de curiethérapie visé.

- Connaitre les forces et les limitations des diverses modalités.

- Reconnaître les nouveaux besoins dans le cadre d'un programme de contrôle de la qualité.

- Identifier les nouvelles techniques d'imagerie pertinentes au domaine

La curiethérapie a connu une évolution importante grâce à l'apport de l'imagerie dans le processus de préparation (positionnement d'aiguilles, de cathéters et d'applicateurs) ainsi que dans celui de la planification des traitements. Dans ce dernier cas, le passage d'une planification de traitement 2D basée sur la localisation des cathéters et applicateurs vers une planification 3D basée sur la délimitation de volumes cibles et des organes à protéger a profondément transformé la pratique clinique. Pour un site comme la prostate, l'utilisation de l'imagerie en temps réel pour le guidage de l'insertion d'aiguilles ou encore de cathéters a révolutionné la curiethérapie pour ce site pour en faire une procédure rapide, précise et efficace, au plus grand bénéfice des patients.

Cette présentation, faite dans le cadre d'une session de formation continue, fera un survol des modalités d'imagerie les plus courantes en curiethérapie, notamment la tomodensitométrie, l'imagerie par ultrasons, l'imagerie par résonance magnétique ainsi que le tomographie par émission de positron comme modalité de support. Les avantages et inconvénients de chacune de ces modalités seront présentés. La question des besoins supplémentaires en terme contrôle de la qualité de ces modalités pour assurer une planification de traitement optimale sera abordée.

Finalement quelques avancées en imagerie, telle que l'IRM multiparamétrique, ayant de fortes probabilités d'influencer la pratique de la curiethérapie à court et moyen terme seront discutées.

MPF04 - LA FORMATION ET LE CHEMINEMENT DE CARRIÈRE DES PHYSICIENS MÉDICAUX

MPF04.1 - Les Standards Professionnels et la Certification des Physiciens Médicaux

Author(s): Clément Arsenault

Medical Physics, Dr. Leon-Richard Oncology Centre, Moncton/ CANADA

Learning Objectives:

1. Understand the 4 underlying principles that form the basis for a certification program:

- a. Providing an examination process
- b. Providing a maintenance of certification (recertification) program
- c. Providing a public registry
- d. Providing a disciplinary process

2. Be familiar with the specifics of the CCPM certification process (eligibility requirements, exam process)

3. Be familiar with the CCPM recertification process

Abstract:

The Canadian College of Physicists in Medicine (CCPM) exists to protect the public by:

(a) establishing standards of competence for those involved in the application of the physical sciences in the medical field in Canada.

(b) identifying individuals who meet the established standards and maintaining a registry of these individuals.

This talk will focus on how the CCPM meets these objectives.

By way of introduction, a brief history of the CCPM will be presented, followed by a description of the current structure and governance of the CCPM.

The core business of any certification organization is centered around its examination process. The eligibility requirements for membership in the CCPM will be detailed, along with a description of the examination process.

After initial certification has been obtained, the CCPM requires that all members regularly demonstrate that they continue to meet certification requirements. The structure of the recertification program will be presented.

Members of the CCPM are required to comply with the Code of Ethics stated in the Regulations of the College, and this will be briefly discussed, along with a description of the disciplinary process in place to ensure member compliance with the Regulations of the College.

MPF05 - QUALITÉ ET SÉCURITÉ

MPF05.1 - Le Partenariat Canadien pour la Qualité en Radiothérapie

Author(s): <u>Normand Frenière</u> Radio-oncologie, CSSSTR - CHAUR, Trois-Rivières/CANADA

Learning objectives:

1) Understand who the Canadian Partnership for Quality Radiotherapy is, its organizational structure and the opportunities to contribute

2) Be up-to-date with four priorities determined by CPQR which constitute the four main programs

3) Understand the process developed for the creation and revision of Technical quality control guidelines. Be up-to-date with guidelines published and those to come

Radiotherapy benefits to approximately 50% of cancer patients at some point in their cancer journey, either as curative treatment or to palliate symptoms. Currently, there are 42 radiotherapy programs across Canada. In 2010, national professional organizations involved in the delivery of radiation treatment in Canada founded the Canadian Partnership for Quality Radiotherapy (CPQR) with the objective to support the universal availability of high quality and safe radiotherapy for all Canadians. Professional organizations are: Canadian Association of Radiation Oncology (CARO), Canadian Organization of Medical Physicists (COMP) and Canadian Association of Medical Radiation Technologists (CAMRT). Strategic and financial support are provided by the Canadian Partnership Against Cancer (CPAC).

Four programs have been identified as offering the greatest potential to improve quality and safety and mitigate risk.

Quality assurance guidance and indicators

The intent of this program is to provide national guidance and indicators to motivate continuous quality improvement in a radiation treatment program. The published document outlines the overarching organizational structure and processes that are required to assure high quality and safe radiotherapy, along with key quality indicators for programmatic assessment.

In 2014, CPQR, CPAC and Accreditation Canada partnered to develop a Radiotherapy module for the Accreditation Canada's Qmentum program which uses a range of standards to focus on quality and safety. This module will adopt many of the indicators contained within CPQR's document and will help assure long-term sustainability of quality and safety measures in radiotherapy. Performance will be publicly reported to motivate utilization across Canada.

Technical quality control guidance

The intent of this program is to provide direction for assuring optimal performance of radiotherapy equipment in programs across Canada. Several guidelines are published and others are to come. A structured process was developed in the creation or revision of each guideline. It includes an expert review and revision, a broad community consultation to assure relevance and practicality, validations in real-world clinical environment, endorsement by the Quality Assurance Radiation Safety Advisory Committee of COMP, and a sustainability plan to assure continued relevance over time.

National reporting system

The intent of this program is to provide radiotherapy programs with a national reporting system which will provide a tool to report, track and analyze incidents from their own center and anonymously from other Canadian centers. Learning from near misses and incidents that occur during treatment planning and delivery is a key element of quality assurance. CPQR is partnering with the Canadian Institute of Health Information (CIHI) on this project.

Patient satisfaction

The intent of this program is to establish an approach for measuring and reporting the patient experience in a meaningful way. A patient perspective will be integrated with each of the three other programs described above. In addition, new indicators of patient satisfaction and patient experience will be developed and incorporated into Qmentum program accreditation. We should not forget that the Patients and Canadian public are the ultimate beneficiaries of safe and effective radiation treatment.

MPF05.2 - L'ingénierie des facteurs humains Author(s):

L'augmentation constante des possibilités technologiques entraine une complexification de l'interaction avec les équipements et les logiciels utilisés en physique médicale et en génie biomédical. L'ingénierie des facteurs humains peut être mise à contribution pour réduire, et prévenir, cette complexification. Cette présentation décrira diverses méthodes, pratiques et normes pour y arriver. On illustrera le tout au moyen d'une étude de cas.

À la fin de cette présentation, vous serez en mesure de (d')

Décrire et discuter de moyens pour améliorer la performance et à réduire l'erreur humaines

Identifier des activités où il est possible d'intervenir pour réduire l'erreur humaine

Tenir compte de normes et de pratiques appropriées lors de la conception, l'achat ou la sélection d'équipement ou de logiciels

Abstract - English

Title: Human Factors Engineering

The constant increase in technological possibilities leads to a complexity of the interaction with the equipment and software used in medical physics and biomedical engineering. Human factors engineering can be used to reduce and prevent this complexification. This lecture will describe methods, practices and standards to achieve this. A case study will be presented to illustrate how to integrate those elements.

At the end of this lecture, you will be able to:

- 1. Describe and discuss means to improve human performance and reduce human error
- 2. Identify activities where it is possible to intervene to prevent human error
- 3. Consider appropriate standards and practices when designing, procuring or selecting equipment and software.

MPF06 - IMAGERIE

MPF06.1 - La Boîte à Outils du Physicien Moderne: Instruments de Contrôle de Qualité

Author(s): Alain Gauvin

Medical Imaging, McGill University Health Center, Montréal/CANA-DA

La pratique du physicien œuvrant en imagerie médicale a beaucoup évolué au cours des dernières années. Ceci est évidemment en grande partie attribuable à l'évolution des technologies d'imagerie médicale, en particulier le passage au mode numérique. Certaines autres technologies ont aussi inauguré de nouvelles catégories dans l'instrumentation de mesure et de test, comme les dispositifs d'affichage. Toutefois, l'instrumentation de mesure a elle-même fait l'objet de changements substantiels. Il est donc utile donc de présenter l'appareillage de test utilisé dans la pratique contemporaine du physicien médical.

Une classification des tests sur la base du type de mesure est proposée. La construction de cette classification est effectuée de façon à se rapprocher de la quantifié physique mesurée plutôt que de la composante de la chaîne d'imagerie faisant l'objet de la mesure. Cette facon regrouper les différentes mesures par type permet de bien faire ressortir les caractéristiques de l'instrumentation du physicien, et l'impact qu'ont ces caractéristiques sur les différentes mesures produites. Les situations où certaines caractéristiques des appareils de mesure ont un impact sur l'interprétation, voire la pertinence de certains tests sont discutées en détail. De plus, certains changements technologiques qui sont en cours sont aussi discutés, qu'il s'agisse de changement au niveau de l'appareillage de mesure, ou au niveau de la technologie de la chaîne d'imagerie faisant l'objet de cette mesure. De plus, il existe de nombreuses méthodes de mesures utilisant des objets de tous les jours pour mener à bien certains tests, souvent sans compromis au niveau de la qualité des mesures. Il est important d'identifier ces solutions de mesure simples et peu onéreuses en fonction de l'objectif recherché.

Finalement, les outils logiciels occupent un rôle croissant dans la pratique du physicien en imagerie médicale. Dans beaucoup de cas, il s'agit de méthodes d'appoint pour certains tests, par exemple en permettant l'analyse des valeurs obtenues. Dans d'autres cas, il s'agit plutôt de méthodes logicielles dont la portée est plus globale, comme pour la collecte, l'organisation ou la présentation des résultats du contrôle de la qualité. Finalement il devient de plus en important pour le physicien de disposer de visibilité sur certains aspects de la connectivité de l'appareil. En effet, certaines mesures obtenues par le physicien sont souvent présentées à l'opérateur et expédiées par l'appareil vers d'autres systèmes, par exemple le produit dose-aire. Puisqu'il était déjà important pour le physicien d'assurer le bon fonctionnement de tels dispositifs, la communication des mêmes résultats doit naturellement elle aussi être scrutée par le physicien, ce qui introduit une nouvelle classe d'outils logiciels.

En somme, l'appareillage utilisé par le physicien médical est typiquement très onéreux en acquisition, mais aussi en entretien. La compréhension du fonctionnement de cet appareillage doit être attentivement recoupée avec la finalité des différents tests effectués par le physicien afin que l'investissement engendre une valeur concomitante en termes de qualité et d'efficacité.

Au terme de cette session, les participants seront en mesure de

1- Comprendre la classification proposée pour les mesures effectuées par le physicien.

2- Comprendre le fonctionnement des différentes technologies utilisées pour chaque type de mesure de la classification, et certains enjeux découlant de ces technologies. 3. Connaître les outils logiciels employés par le physicien et la place croissante qu'ils occupent dans la pratique du physicien.

ENGLISH

The toolbox of contemporary medical physicists: quality control instruments.

The practice of medical physics in diagnostic radiology has evolved substantially in recent years. Obviously, this is largely due to changes in medical imaging technologies, in particular the transition to digital imaging. However, the development of some other new technologies has also led to the introduction of new categories of measurement and testing, for example display monitors. Moreover, the measuring instruments have themselves undergone substantial changes. Therefore, it is useful to present the test equipment used in the contemporary practice of medical physicists.

A classification based on the type of measurement is proposed. The construction of this classification is in contrast to an imaging system based approach, since the measurement of a given physical quantity can be required for many types of system. This in turn allows for a greater emphasis on the characteristics of measurement instruments, and on the impact that they have on the various types of use. In particular, some situations for which some of these characteristics have an impact of the interpretation, or even or the relevancy of some of the tests are described. In addition, some technological changes that are under way are also discussed, be it change in the measuring apparatus, or at the imaging chain technology. Furthermore, there are many methods of measurements using simple and inexpensive test objects to carry out certain tests, often with no compromise in the quality of the measurements. It is pertinent to identify these simple measurement solutions and their adequacy as a function of the survey objective.

Finally, software based tools occupy an increasingly important role in the practice of medical physicists. In some cases, these methods are used as an adjunct to some tests, for example for analyzing the values obtained. In other cases, they can be used for survey data collection and management. It is becoming more and more important for physicists to have some visibility on certain aspects of the connectivity of imaging systems. For example, some measurements obtained by the physicist are often also available to the operator and sent by the device to other systems, such as the dose-area product. Since it is important for the physicist to verify that imaging systems operate properly, the communication of the data pertaining to its operation must naturally also be verified by the physicist, which introduces a new class of software based tools in the physicist's toolbox.

In **summary**, the equipment used by the medical physicist is typically expensive to acquire and maintain. Understanding how this equipment operates allows for the physicists to maximize the quality and the efficiency of the survey.

After this session, participants will be able to

1- Understand the proposed classification for the measurements carried out by the physicist.

 Understand how different measurement technologies are used and some of the issues arising from the use of these technologies.
 Know the software tools used by the physicist and the growing position which they occupy in the practice of the medical physicist.

MPF06.2 - La Radiologie Interventionnelle, Incluant un Survol des Nouvelles Technologies et Approches

Author(s): <u>Cécile Salvat</u>, Jérémie Ragot, Annick Gotti, Antonella Jean-Pierre

Medical Physics, Paris Hospital, Paris/FRANCE

La radiologie interventionnelle est définie par un consensus d'experts français comme l'ensemble des actes médicaux invasifs diagnostiques et/ou thérapeutiques ainsi que les actes chirurgicaux utilisant des rayonnements ionisants à visée de guidage perprocédure, y compris le contrôle.

La radiologie interventionnelle se développe considérablement depuis quelques années. Les applications cliniques de plus en plus audacieuses se multiplient tant sur le plan des équipements vasculaires dédiés qu'au bloc opératoire sur des arceaux de bloc. Le nombre d'actes de radiologie interventionnelle à visée thérapeutique, le plus souvent possible en ambulatoire pour améliorer la prise en charge du patient, croit chaque année en France au détriment d'autres actes chirurgicaux souvent plus invasifs et plus lourds pour le patient.

Les domaines de la cancérologie, de la cardiologie, de la neuroradiologie, de la pédiatrie, sans oublier les applications viscérales et ostéo-articulaires, tous sont concernés par les nombreuses innovations technologiques que proposent les constructeurs visant à améliorer la qualité de l'image. Les avancées technologiques concernent à la fois les matériels (capteurs, tubes, filtration...), les protocoles d'acquisition et les logiciels. Par conséquent, les procédures cliniques se réalisent avec des technologies de plus en plus complexes (acquisitions bi-plan, angiographie rotationnelle, roadmap 3D, acquisitions hybrides...) nécessitant des temps d'acquisition parfois très longs sous rayons X avec une formation des opérateurs de plus en plus pointue et évolutive. Les études en France constatent une augmentation globale de la dose patient en imagerie ces 10 dernières années et notamment dans le cadre des nouvelles approches thérapeutiques interventionnelles. Les accidents ou incidents en radiologie interventionnelle déclarés à l'Autorité de Sureté Nucléaire française ne représentent que 3 % des évènements significatifs en radioprotection déclarés mais sont les plus graves enregistrés avec des effets déterministes importants chez le patient.

Nous présenterons les innovations technologiques proposées par les constructeurs ainsi que les paramètres qui sont à l'origine, en permanence, du compromis entre la dose et la qualité image nécessaire à l'élaboration du diagnostic et/ou des gestes thérapeutiques. Nous aborderons l'optimisation des protocoles et les outils de réduction de dose ainsi que l'arrivée récente sur le marché des DACS, logiciels de suivi et de cumul de dose patient dont le rôle est devenu incontournable.

Nous détaillerons le rôle essentiel que doit jouer le physicien médical, à l'interface entre les équipes médicales et les constructeurs, aidé par des outils désormais disponibles et de plus en plus performants, dans l'intérêt de la radioprotection du patient mais également des opérateurs.

MPF07 - RADIOTHÉRAPIE

MPF07.1 - Nouvelles Technologies et Approches en Curiethérapie

Author(s): Luc Beaulieu Radio-oncologie, CHU de Quebec, Quebec/CANADA

Objectifs d'apprentissages

- Identifier des problématiques clés de la pratique courante en curiethérapie qui bénéficieraient d'avancées technologiques.

- Identifier des technologies habilitantes.

- Saisir les bénéfices et les limitations des nouvelles technologies présentées.

- Extrapoler leurs utilisations pour de nouvelles approches de traitement

Cette présentation, faite dans le cadre d'une session de formation continue, veut porter un regard sur les sujets chauds de R&D en curiethérapie. Plusieurs avancées technologiques sont présentement considérées pour implémentation en curiethérapie. Ces avancées offrent des possibilités de changements significatifs à la façon dont seront planifiés ou traiter les patients.

Pour cette présentation, cinq de ces avancées seront abordées. Première nous aborderons l'introduction de nouvelles méthodes de calcul de la dose et son impact sur la planification de traitement. Par la suite, nous brosserons un portrait des efforts liés à la conception de nouvelles sources et de nouveaux applicateurs qui pourraient permettre de nouvelles approches de traitements. Une nouvelle technologie pour le suivi en temps réel d'aiguilles, de cathéters et des applicateurs a été récemment proposée. Nous en regarderons à la fois l'impact et les limitations. Nous regarderons comment les technologies d'impression 3D pourraient personnaliser davantage les procédures de curiethérapie. Finalement, nous couvrirons la question de la robotique comme aide au médecin en curiethérapie interstitielle.

Pour chacune, nous allons aborder les problématiques physiques ou cliniques visées par leur introduction, les implications de leur utilisation ainsi des perspectives entre termes de modification possible par rapport à la pratique courante.

D'autres avancées, en particulier du côté de l'imagerie 3D et 4D, sont aussi d'importance, mais seront couvertes par d'autres présentations.

MPF07.2 - Protontherapy

Author(s): <u>Alejandro Mazal</u>¹, Farid Goudjil¹, Remi Dendale² ¹Physique Médicale, Institut Curie, Paris/FRANCE, ²Radiation Oncology, Institut Curie, Paris/FRANCE

Protontherapy is one of the most promising conformal approaches for radiation therapy and the number of operational facilities is increasing all over the world (around 40 centers en operation and more than 40 en preparation).

The rational of its use is based on physical properties of accelerated protons in media, in particular the dose deposition by ionization in depth with the shape of a peak (the Bragg peak). Adding different energies (energy modulation) produces a spread out Bragg peak (SOBP) to cover a target volume in depth with a homogeneous dose, but this also increases the entrance dose.

The main advantages of a proton beam compared to photons are the distal fall off and the lack of exit dose (reducing the integral dose to the patient), a homogeneous dose to the target, an homogeneous dose at the entrance path and a small penumbra at the entrance. There are some limits such as the skin dose, the uncertainty in the range, the large penumbra in depth (related to multiple scattering) and the neutron dose (related to nuclear interactions. A clear evolution is seen in the technology, mainly in the accelerators (cyclotrons, synchrocyclotrons, synchrotrons, planes linacs and new approaches) as well as in gantries to propose compact and cheaper solutions, including single room approaches (as with electrons-photons). Ancillary tools include specific solutions in treatment planning software, patient positioners, dosimetry and range verifier devices. The present tendency is to use pencil beam scanning to treat with intensity modulated proton beams, in combination with conventional methods of image guided radiation therapy, management of organ movements and adaptive therapy.

Clinical protocols include well accepted but rather rare locations (uveal melanoma, base of skull chordomas and chondrosarcomas, pediatrics, radiosurgery for intracranial targets) and more common clinical sites including lung, breast and prostate, with a tendency to include all targets treated in radiation therapy with photons. There are also comparative studies with the use of heavier ions (e.g. Carbonne), which add radiobiological advantages to their physical specifications.

Research and development in the field include physical and engineering aspects (detectors, micro-beams, delivery systems, models and optimizations, robotics for positioning,...), radiation biology (equivalent doses, effects of dose rate, LET, neutrons, radiosensitizers...), and clinical research (combined treatments, hypofractionation, ...). The main limit to spread protontherapy today is the investment cost.

At the end of the CE program, attendees will be able to:

1- Describe the main physical interactions and dosimetric characteristics of clinical proton beams and define the existing technology and its evolution.

2- Understand the rational for existing and upcoming clinical protocols

3- Have a scope of the research and development programs in the field.

MPF09 - IMAGERIE

MPF07.2 - Dosimétrie et Radioprotection en Radiologie Author(s): <u>Sylvain Deschênes</u> Medical Imaging, CHU Sainte-Justine, Montreal/CANADA

Objectifs pédagogiques:

1. Connaître les radiations ionisantes et mieux comprendre leurs effets.

2. Mieux connaître les risques reliés à la radiation ionisante.

3. Connaître les bonnes pratiques en matière de radioprotection en imagerie diagnostique et interventionnelle.

Abrégé:

Au cours des quinze dernières années, plusieurs publications ont traité des risques reliés aux radiations ionisantes lors d'examens de radiologie diagnostique et interventionnelle. Dans la même veine, des campagnes comme*lmage Gently* et *Image Wisely* ont vu le jour afin de sensibiliser à cette réalité les institutions utilisant l'imagerie médicale. Or, de façon générale, les méthodes proposées afin d'évaluer quantitativement le risque associé à ce rayonnement s'accompagnent d'une certaine ambiguïté pour les niveaux de doses rencontrés en imagerie médicale. De plus, à l'heure d'une approche personnalisée de la médecine, cette estimation dosimétrique rencontre plusieurs embûches : indicateurs de dose non standardisés, passage vers une dose à l'organe complexe, etc.

Parallèlement, on voit apparaître plusieurs articles de loi, notamment aux États-Unis, qui obligeront prochainement les établissements de santé à tenir un registre des doses reçues par leurs patients. Dans cette foulée, plusieurs logiciels sont apparus dans les dernières années afin d'offrir la possibilité d'effectuer un tel suivi.

Dans cette présentation, nous tâcherons de mieux comprendre les effets de la radiation ionisante sur le corps humain. Par la suite, les différents indicateurs de dose rencontrés en imagerie médicale diagnostique et interventionnelle seront présentés. L'emphase sera mise sur les deux types d'examens les plus irradiants en radiologie : la tomodensitométrie (CT-scan) et la radioscopie interventionnelle. Dans le cas du tomodensitomètre, les indicateurs proposés sont le Computed Tomography Dose Index (CTDI), le Size-Specific Dose Estimate (SSDE) et le Dose Lenght Product (DLP). La radioscopie, de son côté, présente la dose sous forme de produits dose-surface (Dose Area Product ou DAP) et de doses accumulées à la peau. Nous verrons comment ces différents indicateurs peuvent être utilisés pour évaluer une valeur personnalisée sous forme de dose aux organes et de dose effective. Nous verrons aussi comment ces métriques permettent de calculer les niveaux de référence diagnostiques (NRD) aident à identifier les examens où la dose est potentiellement problématique, à optimiser les protocoles et à se comparer aux autres dans notre gestion de la dose. Des pistes de solution afin d'optimiser les procédures seront également présentées.

ENGLISH

Learning Objectives:

1. To understand the nature and effects of ionizing radiation.

2. To better understand the risks associated with ionizing radiation.

3. To learn good radioprotection practices in diagnostic and interventional imaging.

Abstract:

In the past fifteen years, there has been a growing interest for assessing the risks incurred by radiation exposure during diagnostic and interventional radiology procedures. As a result, campaigns such as *Image Gently* and *Image Wisely* have raised awareness regarding such issues. However, the information provided by radiological systems is oftentimes ambiguous, hindering the efforts to assess such risks. For example, in this age of personalized medicine, dose estimates have to address issues such as non-standardized dose indicators, the need for more accurate organ doses, etc.

Meanwhile, legislations have been or soon will be passed in North America regarding dose monitoring and reporting. For example, Bill 1237 is now enforced in California and it is a matter of time before such laws proliferate in many other states and countries. Accordingly, several software solutions are now offered to perform this monitoring.

In this talk, we will cover the nature of ionizing radiation and its effects on the human body. Then, we will introduce various dose indices describing patient's exposure for diagnostic and interventional imaging modalities. Emphasis will be placed on CT-scan and interventional radioscopy since they deliver substantial radiation to the patient. For CT-scan, the relationship between Computed Tomography Dose Index (CTDI), Size-Specific Dose Estimate (SSDE) and Dose Length Product (DLP) will be explored. For radioscopy, we will show how Dose-Area-Product (DAP) and cumulative entrance skin dose describe patient's irradiation.

We will finally see how these indices may be used to compute personalized dose reports where organ dose and effective dose are used to evaluate the risk for a specific patient. We will also see how computing Diagnostic Reference Levels (DRL) may help optimizing institutions protocols and identify exams where excessive dose has been delivered to a patient. Some tips will be provided to help minimize dose during procedures.

MPF08 - SYSTÈMES INFORMATISÉS/ QUALITÉ ET SÉCURITÉ

MPF08.1 - Algorithmes de Calcul de Dose, Incluant Monte Carlo Author(s): <u>Raphaël Moeckli</u>

Institute Of Radiation Physics, CHUV, Lausanne/SWITZERLAND

Les systèmes de planification jouent un rôle fondamental et central en radiothérapie. Le coeur du système est l'algorithme de calcul de la dose. L'algorithme de convolution/superposition est actuellement le plus utilisé, mais de nouveaux algorithmes, basés sur Monte Carlo ou sur les équations de transport, apparaissent progressivement sur le marché.

Les objectifs de ce cours sont les suivants:

1. Décrire les principaux composants des systèmes de planification.

2. Décrire les principaux algorithmes de calcul de la dose utilisés actuellement (convolution/superposition, Monte Carlo, équations de transport).

3. Décrire les avantages et les limitations des différents algorithmes.

MPF08.2 - Utilisation de la Maîtrise Statistique des Processus en Milieu Hospitalier

Author(s): <u>Karine Herlevin (Gérard)</u>, Vincent Marchesi, Océane Mougel, Isabelle Buchheit

Medical Physics Unit, Institut de Cancérologie de Lorraine, VAN-DOEUVRE-LES-NANCY Cedex/FRANCE

3 learning objectives:

1. Understand variability, its impact and behavior (differentiate random and special causes).

2. Describe the DMAICS method to introduce a SPC (Statistical Process Control) analysis.

3. Understand how to use control charts and performance indicators in the management of your department.

Quality indicators have been developed quite recently in health, compared to industry, but considerable progresses have been made. Indeed, we moved from an era where data was almost non-existent, to the current period where data has become abundant.

So, there is a need in health, to find a quality management method that can monitor quality indicators over time to facilitate a continuous and measurable improvement of quality.

One of the methods allowing this is the Statistical Process Control (SPC). SPC has made proves in industry and has been widely used since 1950 in Japan and since 1970 in the USA and in Europe. Concerning health, the first papers introducing SPC have appeared in 2005 and its use is still increasing. This method aims at controlling and improving the quality of a process through a statistical analysis, by using two main tools: performance indicators and control charts.

Performance indicators rate the ability of a process to produce data that are within predefined specifications, at a precise moment. So, performance indicators depend on the specifications that are often chosen empirically, based on practice and experience.

On the contrary, control charts monitor the results over time and do not take into account the specifications. They are only based on statistical rules. So, the aim of control charts is to monitor the process over time, by using statistical control limits that distinguish random (natural) variations (i.e values within the control limits) from significant changes (special causes) that disturb the process. Thanks to the statistical control limits, the effects of special causes can be detected, and then actions can be undertaken to reduce or eliminate their effects. A process that is only subject to random causes of variation is statistically under control and thus statistically predictable.

In the presentation, we will develop a practical example of the use of SPC in the field of Radiotherapy. We will show how SPC can be used to monitor the IMRT (Intensity Modulation Radiation Therapy) pre-treatment quality controls and to make the dose delivery process under control. The aim is to increase the security of each patient's treatment while controlling the whole dose delivery process, without increasing time devoted to the analysis.

To conclude, SPC is a method that helps reducing the variability of a process, and thus decreasing the number of data out of specifications.

We are convinced that SPC should secure and improve quality of many processes in radiotherapy and in health in general. It could serve as a common language to evaluate processes' performance. Moreover, the ultimate goal of SPC is, considering a process is under control, to streamline the amount of quality control in a safe statistical environment by taking objective decisions to balance resources and quality.

MPF09 - IMAGERIE

MPF09.1 - TEP: Les Nouveaux Développements et Avenues de Recherche

Author(s): Roger Lecomte

Centre D'imagerie Moléculaire De Sherbrooke, Centre de recherche du CHUS (CRCHUS), Sherbrooke/CANADA

La tomographie d'émission par positrons (TEP) est une modalité d'imagerie médicale utilisant des isotopes émetteurs de positron pour suivre le devenir de molécules radiomarqués dans les organismes vivants. En mesurant la captation, la biodistribution et l'élimination du radiotraceur, il est ainsi possible de tirer des informations sur les processus moléculaires in vivo aussi bien en condition physiologique normale que dans des états pathologiques comme le cancer, les désordres neurologiques et les maladies cardiovasculaires ou cardiométaboliques. Des avancées technologiques majeures ont permis d'élargir les domaines d'applications de l'imagerie TEP, que ce soit en recherche biomédicale ou pour le diagnostic clinique. Des exemples de ces avancées technologiques se retrouvent dans la multitude de concepts de détection et de techniques sophistiquées de traitement des signaux, en imagerie tridimensionnelle avec reconstruction tomographique itérative des images, l'introduction de la mesure du temps-de-vol, et la combinaison de l'imagerie TEP avec la tomodensitométrie par rayons-X (TDM) ou l'imagerie par résonance magnétique (IRM). Malgré d'énormes progrès au cours des dernières décennies, la technologie TEP n'a pas réalisé tout son potentiel. Cet apercu passera en revue les principes de base de l'imagerie TEP, l'état actuel de la technologie et les développements en cours dans le domaine, incluant les réalisations en imagerie multimodale utilisant les approches TEP/TDM et TEP/IRM. En conclusion, nous discuterons quelques applications marguantes de l'imagerie TEP en recherche et en clinique et nous commenterons quelques nouvelles idées prometteuses offrant des perspectives intéressantes dans le domaine.

À la fin de ce programme d'éducation continue, les participants seront en mesure de :

1- Décrire et discuter les principes de l'imagerie TEP, les technologies et les applications utilisées en médecine nucléaire diagnostique et en recherche biomédicale.

2- Comprendre les limitations physiques sous-jacentes et les possibilités d'amélioration de la modalité d'imagerie TEP.

3- Expliquer les divers avantages et limitations des différentes approches d'imagerie multimodales.

MPF10 - RADIOTHÉRAPIE PT 1

MPF10.1 - La Radiothérapie Guidée par L'image, Incluant Doses et CQ

Author(s): Gregory Delpon¹, <u>Myriam Ayadi-Zahra</u>², Frédérique Lafay², Albert Lisbona¹

¹Medical Physics, Centre René Gauducheau, NANTES/ FRANCE, ²Radiotherapy Physics, Centre Léon Bérard, LYON/ FRANCE

Learning objectives:

- To define errors occurring during the treatment ant their clinical impact

- To list the different technologies currently available for the IGRT and their specific QA / to define the concept of adaptive radiotherapy

- To discuss the dose delivered by the different devices

Abstract:

Radiotherapy consists in delivering ionizing radiation to the tumor while avoiding the surrounding normal tissue. Treatment efficacy is often limited by the resistance of tumors and the toxicity of healthy organs. Then prescription must represent a trade-off between risks and benefits. The dose-response curves for tumor control and normal tissue complications determine the therapeutic window that is the possibility of delivering a sufficient dose with an acceptable level of side-effects. The development of imaging modalities and treatment techniques aims at improving this therapeutic window. 3D and 4D imaging modalities allow to describe tumors and normal tissues and their motions. Intensity-modulated radiation therapy with static beams (IMRT) or arcs (VMAT), stereotactic body radiation therapy (SBRT) allow to deliver accurately highly conformal doses to the tumor and to spare a large volume of normal tissue. These developments that are changing the clinical practice are made possible thanks to the emergence of image-guided radiotherapy (IGRT).

IGRT is based on the acquisition of frequent in-room images during a course of radiotherapy. These images are used to verify the position of the target volume and/or the organs at risk with a higher frequency and a greater accuracy than portal images, more irradiating and of lower quality. IGRT integrates various imaging modalities that allow either direct visualization of the tumor by two-dimensional or three-dimensional images or indirect visualization of the tumor using surrogates such as implanted markers or bony structures. The anatomical data acquired during those imaging sessions lead to two types of decisions: the correction of the positioning and the modification of the treatment plan. After a rigid registration between planning images and in-room images, positioning of the tumor target can be corrected by moving the couch. This is done daily in radiotherapy departments. The treatment plan modification taking into account the anatomical deformations is more complex. It may impose one or more replanning during the course and requires the development and validation of tools not yet fully mature to date for clinical routine use. This is the concept of adaptive radiotherapy.

IGRT requires a close collaboration between physicians, technicians and physicists. Specific training should be put in place to help decision making when registering images. Depending on the therapeutic goal, the treatment site and the equipment, IGRT strategies may differ in terms of imaging modality and frequency. Each department should define its own protocols specifying the roles of each professional. The commissioning of the imaging systems should be performed by the physicists, whatever the modality (ionizing or non-ionizing, 2D or 3D, ...). In addition a quality control program should be implemented based on the international publications such as AAPM reports. The use of ionizing radiation devices raises the problem of the additional dose delivered to patients. The dose due to in-room imaging sessions should be estimated by measurements or calculations to be reported. The management of this extra dose should be part of on site IGRT protocols.

IGRT offers new treatment opportunities such as toxicity reduction, dose escalation, hypofractionation, voxelization and adaptation. But the clinical implementation requires the staff to perfectly define the goals (positioning and/or replanning) and the roles.

MPF10.2 - Dosimétrie in Vivo

Author(s): Louis Archambault Radio-oncologie, CHU de Quebec, Quebec/CANADA

Objectifs d'apprentissage: (1) décrire les différents outils permettant de faire de la dosimétrie in vivo; (2) identifier les champs d'application et les avantages potentiels de cette pratique; (3) se familiariser avec différentes approches pour faire l'implantation clinique d'une stratégie de mesure in vivo.

En radiothérapie, la dosimétrie in vivo est généralement définie comme la mesure de la dose de radiation faite au moment même où un patient reçoit une fraction de son traitement. L'attrait de la dosimétrie in vivo est grand, puisqu'elle est la seule manière de connaître réellement la dose de radiation administrée au patient. Toutefois, malgré cet avantage notable, ce type de mesure n'est toujours pas utilisé à grande échelle. Dans de nombreuses cliniques en Amérique du Nord, la dosimétrie in vivo n'est utilisée que marginalement ou pour des cas très particuliers. Des sondages ont démontré que l'apparente lourdeur clinique de la dosimétrie in vivo est un obstacle majeur à son adoption généralisée.

Dans un premier temps, nous ferons l'inventaire des différents détecteurs pouvant être utilisés pour faire la mesure de dose in vivo. Nous présenterons les forces et les faiblesses d'un grand nombre d'instruments, allant des appareils embarqués servant à faire la mesure de la dose à la sortie du patient (imageur portal) jusqu'aux appareils implantables directement au voisinage d'une tumeur ou d'un organe à risque. Nous porterons aussi une attention particulière à l'utilisation de ces instruments dans des conditions non standard telles que les mesures hors du champ primaire de radiation, les mesures de très faibles doses de radiation ou les mesures de patrons de dose fortement modulés. À moins que des précautions ne soient prises, la mesure dans des conditions non standard peut introduire une erreur systématique dans l'évaluation de la dose.

Deuxièmement, nous ferons un survol des champs d'application où la dosimétrie in vivo offre un grand potentiel tel que le contrôle de la qualité et le suivi des patients tout au long de leur traitement par imagerie portale; l'évaluation des doses reçues par des appareils cardiaques implantables (pacemakers) et la protection des organes à risque dans la radiothérapie hautement conforme. Nous discuterons aussi des avantages d'intégrer un programme de dosimétrie in vivo avec une approche de radiothérapie adaptative.

Finalement, dans un troisième temps, nous verrons comment il est possible d'implanter une stratégie de mesure in vivo tout en minimisant son impact négatif sur le flot des opérations cliniques. Nous passerons en revue des exemples de centres ayant implanté de telles stratégies et nous présenterons les rôles et responsabilités de chaque intervenant (physicien, technologue, etc.) ainsi que les besoins de formation. Nous discuterons aussi des outils logiciels et autres systèmes de bases de données nécessaires pour stocker et analyser l'information recueillie et garantir un suivi et une rétroaction efficace.

MPF11 - RADIOTHÉRAPIE PT 2

MPF11.1 - Stéréotaxie Extra-Crânienne: Techniques et CQ Author(s): <u>Myriam Ayadi-Zahra</u>, Guillaume Beldjoudi, Jean-Noel Badel, Claude Malet

Radiotherapy Physics, Centre Léon Bérard, LYON/FRANCE

Learning objectives:

- To list the different technologies currently available for SBRT

- To discuss about the crucial points in the implementation of SBRT(dose measurements, algorithm, ...) and the periodic QA to perform

Abstract:

Stereotactic Body Radiation Radiotherapy (SBRT) is rapidly expanding. This rising treatment strategy shows comparable clinical results with surgery concerning primitive tumors local control (Non-Small Cell Lung Cancer). SBRT can also significantly increase the overall survival of oligometastatic patients. This advanced technique classically delivers single or few fractionated large dose to tumors located in various sites of the body (thoracic, paraspinal, abdominal and pelvic sites). The treatment principle is based on the use of small size photon beams, providing high target conformity and narrow dose fall-off for better critical organs sparing. Consequently, this special treatment strategy requires a high level of accuracy, first, in the beam commissioning (dose measurements) and then, at each step of the treatment process, i.e simulation, treatment planning, delivery. The global uncertainty of the process must be kept as low as possible in order to keep clinical benefits without increasing the toxicity probability.

Key linac features that determine the SBRT feasibility are the beam collimation that allows a sharp beam penumbra and complex target management, and reliable image guidance. Various technologies can currently perform SBRT: conventional linac with appropriate image guidance, Tomotherapy™, Cyberknife™ and Vero™. In case of moving targets, additional systems exist to manage the patient breathing (breath hold, abdominal compression, Gating) in order to minimize the uncertainty due to target motion. Other solutions monitor the breathing patient combined with image guidance, and thus can allow a real time tumor tracking.

Imaging is crucial in SBRT because it helps to define the more precisely the target volume and position in the patient and it also guarantees the correct tumor targeting before and/or during the treatment delivery. Acquisitions parameters of the reference CT scan have to be optimized so that the best quality image is obtained (spatial resolution, contrast). 4D CT scan is necessary for all moving tumors as it gives the spatio-temporal position and deformation of the target. Multi-modality imaging, such as MRI, PET-CT and contrast-enhanced-CT, is mandatory too, to improve the tumor and critical organs delineation.

Concerning beam commissioning, critical aspect is the detector used for measurements. Caution must be paid to its resolution, volume and response considering the very small size beam. Performance of dose calculation algorithm is important especially in low density media because it can have a large impact on the isodose prescription. The periodic tests of Quality Assurance depend on the treatment delivery used for SBRT. For each new localisation to be validated, and regularly, End-to-End (E2E) tests are recommended. Many commercial E2E phantoms exist and help physicists to validate the overall workflow of the treatment.

The SBRT implementation in a clinic needs a robust educational program followed by all professionals involved in the patient treatment. These latter must refer to the recent published guidelines (AAPM Task Group 101 report, etc...). In parallel, an "a priori" risks analysis should be done to refine the workflow and patient safety. Then, incidents have to be reported as part of an Experience Feedback Committee program.

MPF11.2 - La Radiothérapie Adaptative

Author(s): <u>Bernard Lachance</u> Radio-oncologie, CHU de Québec, Québec/QC/CANADA

Objectifs d'apprentissage:

Acquérir une définition de la radiothérapie adaptative et comprendre les motivations justifiant son développement.

Connaitre les processus techniques ainsi que les divers éléments technologiques qui sont nécessaires au déploiement de la radiothérapie adaptative.

Apprendre les diverses stratégies d'adaptation du traitement de radiothérapie externe aux besoins spécifiques du patient.

La radiothérapie a connu de multiples développements technologiques au cours des deux dernières décennies. Ces développements ont conduit en premier lieu à une importante amélioration au niveau de la précision, de la rapidité ainsi que de la fiabilité des appareils de traitement. Deuxièmement, le grand avancement des capacités informatiques a permis le développement de logiciels toujours plus performants pour calculer et optimiser les distributions de dose dans le patient, pour gérer et faire circuler de grande quantités d'informations entre les divers systèmes et pour manipuler les images médicales. De plus, la planification des traitements de radiothérapie fait maintenant usage sur une base régulière de plusieurs modalités d'imagerie telle que la tomodensitométrie, l'imagerie par résonance magnétique (IRM) et la tomographie par émission de positron (TEP-CT) qui permettent aux radio-oncologues de définir les volumes cibles ainsi que les organes à risques (OAR) avec beaucoup de précision.

Ces avancées technologiques ont permis le développement de diverses formes de radiothérapie conformationnelle avec modulation d'intensité des faisceaux (RCMI). Les techniques de modulation d'intensité peuvent être divisées en deux grands groupes : les techniques utilisant des faisceaux stationnaires, appelées techniques « step and shoot » et « sliding window », et les techniques utilisant un déplacement continu de la source de rayonnement autour du patient selon un ou plusieurs arcs, appelées IMAT pour « intensity modulated arc therapy », VMAT pour « volumetric modulated arc therapy » ou tomothérapie sérielle ou hélicoïdale, selon la technologie employée.

Ces techniques de RCMI nous offrent la possibilité de conformer avec grande précision la distribution de la dose à des volumes cibles toujours mieux définis par les radio-oncologues à l'aide de multiples modalités d'imagerie. Un traitement plus conforme ouvre la porte à l'escalade de la dose dans l'objectif d'augmenter le contrôle local de la maladie. Toutefois, il existe divers facteurs limitant qui nous empêchent encore de tirer le plein potentiel de la RCMI à cibler avec précision les volumes du médecin. Par exemple, la position du patient n'est pas parfaitement reproductible d'une fraction à l'autre, il y a des mouvements des organes internes dus à la respiration ou au péristaltisme, il y a des changements au niveau du remplissage de la vessie et/ou du rectum, etc. Il s'agit là de facteurs reliés au patient, il y en a d'autres reliés à l'appareillage et à l'interprétation de l'anatomie. L'approche traditionnelle pour prendre en compte ces variations quotidiennes est d'adopter des marges de sécurité autour des volumes cibles définis par le radio-oncologue, ce qui conduit nécessairement à irradier plus de tissus sains.

L'idée de la radiothérapie adaptative a été introduite en réponse à

cette problématique des variations quotidiennes de la position du patient ainsi que de ses changements anatomiques. Les diverses stratégies d'adaptation visent à gérer le traitement d'un individu en identifiant et en quantifiant les variations propres au patient au cours de sa série de traitement et en utilisant ces informations pour optimiser le processus de planification et de délivrance du traitement. Toutes ces stratégies reposent sur l'utilisation d'une forme ou d'une autre d'imagerie embarquée, nous permettant d'obtenir des images planaires et/ou volumétriques du patient au moment même du traitement. C'est le développement récent de diverses technologies d'imagerie embarquée qui a rendu possible l'émergence de la thérapie adaptative.

Dans sa forme la plus simple, la thérapie adaptative se réduit à la radiothérapie guidée par l'image (IGRT : *image guided radiation therapy*) qui consiste au repositionnement quotidien du patient sans modification du plan initial. Des images planaires ou encore des images volumétriques sont comparées à des images de références acquises et/ou produites lors de la planification du traitement. Sur la base de cette comparaison, le patient est déplacé en translation et potentiellement aussi en rotation pour conformer sa position le plus possible à la position de planification.

En thérapie adaptative, on utilise l'information obtenue par l'imagerie embarquée pour modifier la planification initiale. Le processus d'adaptation peut-être relativement simple : modifier les marges de sécurité initiales après quelques observations et créer un second plan de traitement; ou encore très complexe : créer un nouveau plan en temps réel avant chaque fraction.

Un survol des diverses stratégies d'adaptation sera présenté. Les processus techniques impliqués ainsi que les outils technologiques nécessaires seront discutés. L'expérience du CHU de Québec dans le traitement adaptatif au niveau pelvien (traitement de l'adénocarcinome de la prostate et du cancer de la vessie) et au niveau de la sphère ORL sera en autre utilisée pour illustrer le propos.

MPS01 - RADIATION THERAPY

MPS01.1 - Radiobiology Applications for Clinicians - Isoeffective Dose Calculations, Hypofractionation, TCP/NTCP Author(s): Beatriz Sánchez-Nieto

Instituto De Física, Pontificia Universidad Católica de Chile, Santiago/CHILE

Learning objectives:

To understand the relationship between dose and dose per fraction in the dose response curves of late- and acute- response tissues as well as for tumours.

To learn how to do isoeffective calculations in clinical practice

To learn the basic of commonly used TCP and NTCP biological models and how they can help in clinical decisions

ABSTRACT

Isoeffective dose calculations

It is well known that the biological effect of a given absorbed dose of ionizing radiation depends on how this is distributed over time. Moreover, the steepness of the isoeffective curves obtained for different combinations of total dose and fraction size strongly vary among different tissues [1]. The Linear Quadratic (LQ) model has been extensively used to quantify the relationship between total isoeffective dose and dose per fraction in fractionated radiotherapy [2]. And so, parameters such as BED, EQD2, TE, NTD have been used in order to allow comparisons between different treatment schemes or, for example, to predict the effect on tumours/normal tissues of changes in fractionation. These concepts have regained interest in the last years with the new radiotherapy techniques which allow a better sparing of normal tissues and so larger fraction sizes can be explored. From the point of view of isoeffective dose calculations, the current status of modified fractionation schemes (with the respect to the conventional 1.8-2Gy fraction size) will be revised (hypo-, hiper- and acceleration fractionation).

And yet, the problem is more complex. The inhomogeneous dose distributions usually delivered during radiotherapy, imply different fraction sizes for the different sub-volumes and consequently an inhomogeneous biological response throughout the irradiated volume (double-trouble effect) [3]. The above problem can be addressed by using BED distributions or, the more compact, Biologically Effective DVHs (BEDVHs). This approach is compulsory, for example, if external RT and brachytherapy techniques are going to be combined.

TCP/NTCP models

The end points which are truly relevant in radiotherapy are the probabilities of tumour control (TCP) and of toxicity of the normal tissues (NTCP). There are several reasons which justify why TCP and NTCP models are desirable [4]. The Marsden TCP model [3] and the Lyman model [5] will be presented as example of models which, correctly parameterized, reproduce the sigmoid shape of the dose-response curves. Clinical applications of those models will be also presented together with description of some freely available software (BIO-PLAN and BioSuit) [6,7].

MPS02 - COMPUTERIZED SYSTEMS

MPS02.1 - Radiation Treatment Planning Systems and Dose Computation Algorithms (including Monte Carlo)

Author(s): <u>Antonio Leal Plaza</u>¹, Ana Ureba¹, Elisa Jiménez-Ortega¹, José Antonio Baeza¹, Rita Pereira Barbeiro¹, Sergio García-Gómez², Rafael Linares³, María Perucha³, Juan Carlos Mateos⁴, Santiago Velazquez⁴

¹Fisiología Médica Y Biofísica, University of Seville, Seville/ SPAIN, ²Hospital Univeristario Virgen de la Candelaria, Tenerife/ SPAIN, ³Servicio De Radiofísica, Hospital Infanta Luisa, Seville/ SPAIN, ⁴Servicio De Radiofísica, Hospital Universitario Virgen del Rocío, Seville/SPAIN

Learning objectives:

Discuss about the actual requirements for dose calculation for complex radiotherapy techniques.

Discuss the different dose calculation algorithms and Monte Carlo simulation, and how the latter is implemented in commercial treatment planning systems.

Presenting full Monte Carlo simulation as alternative for treatment planning.

Abstract:

Several studies show that a prescription dose deviation of 5% may compromise tumor response and morbidity. Although the accuracy of dose delivered to the patient depends on multiple factors involved in the radiation therapy process, it is considered that the criterion of acceptability for dose calculation algorithms ranges between 2% and 5% in dose. The dose calculation is performed with different degree of success by means of analytical algorithms such as convolution methods, collapsed cone, pencil-beam with corrections, convolution/superposition or anisotropic analytical algorithm. Apart from the electron beams, the dose distribution with photon beams can be calculated accurately enough in most of cases by means the planning system based on analytical algorithms. Nevertheless, when the radiotherapy techniques use a highly conformed radiation treatment, the media heterogeneities in the path of the photon beam has to be incorporated on the planning algorithm. For the pencil beam model, the necessary heterogeneity corrections are based on dose values calculated in a water equivalent material multiplied by a heterogeneity correction factor generated from an electron density matrix derived from a CT value matrix. It has been probed that the pencil-beam convolution algorithm does not work well in regions of electron disequilibrium, particularly when the field size is small. Other algorithms take into account satisfactorily the 3D scatter such as convolution/superposition, so the drawbacks linked to the heterogeneities in the patient are solved for most cases, although they present limited accuracy under certain circumstances due to several approximations used. Anisotropic analytical algorithm is a pencil-beam convolution/superposition algorithm which uses a multiple-source model to represent the beam and a patient scatter model represented by density scalable poly-energetic kernels. Regardless of the differences that have each other semi-analytical or analytical algorithms, all have in common the fact of having been tested with Monte Carlo (MC) simulations.

The dose calculation with MC is considered the most accurate technique today. MC has been used to validate these algorithms for complex techniques, such as intensity modulated radiotherapy (IMRT) where there is a significant amount of nonstandard conditions and where the beam modifiers play an important role in the characterization of the beams composing the modulated fields. Commercial companies have made efforts in the implementation of MC as alternative to analytical treatment planning systems. They try to maintain the MC advantages about the precision, while reducing

simulation time, but not always is easily to achieve the adequate compromise. For some radiotherapy plans or techniques, the level of approximation of the transport or the low number of sampling may end up making unjustified the implementation of MC.

The most complex techniques are being more and more frequent in the clinical practice. These techniques based on intensity modulation involve an important role of the beam modifiers. The contribution of scattered and transmission radiation from the collimators can represent a fraction of the dose in the organs at risk (OAR). In this scenario, MC could be an excellent tool in order to consider the particle transport and scattering, not only in the patient, but also along the linac head. Full MC (fMC) simulations, in addition to the dose calculation based on the physical heterogeneities in the patient, make possible to consider MLC transmission, scattering and secondary particles contributions in order to take into account the physical characteristics of the beam. Unfortunately, fMC based on an explicit radiation transport can be inefficient due to the time required to get a low statistical uncertainty.

The use of variance reduction techniques and parallel computing could overcome the problem of time consuming, whether it is performed also together with the implementation of algorithms along the optimization process which are especially appropriate to the characteristics of the MC simulation. The necessary number of histories to reach a precise dose distribution is related to the total number of voxels (dose points) defined in the CT patient and to the total number of incident beams (beamlets). A reduction of the number of beamlets and/or voxels will mean simplify the initial problem and will make possible to decrease the overall treatment planning time.

The approach of Direct Aperture Optimization (DAO) has been applied to both IMRT as well as VMAT with the main purpose of incorporating MLC properties directly into the optimization process. The reduction of involved geometries seems to be a convenient approach for the explicit transport by means of the MC simulation of the linac head.

On the other hand, it is also possible to reduce the size of the initial optimization problem by reducing the set of dose points. Usually, all the voxels composing the structures of interest are considered, since all of them are included when dose-volume constraints are implemented in the inverse planning optimization process. A selection could be done randomly or considering only those voxels directly involved in the complexity of the relative dose distribution, for example, the voxels in the intersection of PTV and a specific OAR. Linear functions and piecewise linear convex objectives and constraints can be solved with linear programming (LP). Optimization model can be written under LP formulation, in which each voxel can be identified in the objective function. If this voxel reduction is combined with few apertures the number of equations involved in a LP formulation can significantly reduce the computation time inherent to fMC in the optimization process. Furthermore, this formulation could make possible to take advantage of considering the problem at the voxel scale, what could be especially suitable for a dose painting approach to be applied according to functional and molecular information assessed by combined PET/CT imaging. It seems appropriate to make matching the more accurate dose calculation with the challenge of heterogeneous dose, as proposed with the application of dose painting, for both modalities by contour or by number.

MPS03 - RADIATION THERAPY

MPS03.1 - Protontherapy

Author(s): <u>Alejandro Mazal</u>¹, Farid Goudjil¹, Remi Dendale² ¹Physique Médicale, Institut Curie, Paris/FRANCE, ²Radiation Oncology, Institut Curie, Paris/FRANCE

Protontherapy is one of the most promising conformal approaches for radiation therapy and the number of operational facilities is increasing all over the world (around 40 centers en operation and more than 40 en preparation).

The rational of its use is based on physical properties of accelerated protons in media, in particular the dose deposition by ionization in depth with the shape of a peak (the Bragg peak). Adding different energies (energy modulation) produces a spread out Bragg peak (SOBP) to cover a target volume in depth with a homogeneous dose, but this also increases the entrance dose.

The main advantages of a proton beam compared to photons are the distal fall off and the lack of exit dose (reducing the integral dose to the patient), a homogeneous dose to the target, an homogeneous dose at the entrance path and a small penumbra at the entrance. There are some limits such as the skin dose, the uncertainty in the range, the large penumbra in depth (related to multiple scattering) and the neutron dose (related to nuclear interactions.

A clear evolution is seen in the technology, mainly in the accelerators (cyclotrons, synchrocyclotrons, synchrotrons, planes linacs and new approaches) as well as in gantries to propose compact and cheaper solutions, including single room approaches (as with electrons-photons). Ancillary tools include specific solutions in treatment planning software, patient positioners, dosimetry and range verifier devices. The present tendency is to use pencil beam scanning to treat with intensity modulated proton beams, in combination with conventional methods of image guided radiation therapy, management of organ movements and adaptive therapy.

Clinical protocols include well accepted but rather rare locations (uveal melanoma, base of skull chordomas and chondrosarcomas, pediatrics, radiosurgery for intracranial targets) and more common clinical sites including lung, breast and prostate, with a tendency to include all targets treated in radiation therapy with photons. There are also comparative studies with the use of heavier ions (e.g. Carbonne), which add radiobiological advantages to their physical specifications.

Research and development in the field include physical and engineering aspects (detectors, micro-beams, delivery systems, models and optimizations, robotics for positioning,...), radiation biology (equivalent doses, effects of dose rate, LET, neutrons, radiosensitizers...), and clinical research (combined treatments, hypofractionation, ...). The main limit to spread protontherapy today is the investment cost.

At the end of the CE program, attendees will be able to:

1- Describe the main physical interactions and dosimetric characteristics of clinical proton beams and define the existing technology and its evolution.

2- Understand the rational for existing and upcoming clinical protocols

3- Have a scope of the research and development programs in the field.

MPS03.2 - Nanoparticles and Radiotherapy Author(s): <u>Yolanda Prezado</u>

Imagerie Et Modelisation Pour La Neurobiologie Et La Cancerologie, CNRS, Orsay/FRANCE

Learning objectives of the lecture:

1. To provide an introduction to nanoparticles as radiosensitizers and its theoretical basis

2. To give an overview on the existent multi-disciplinary research on nanoparticles in radiotherapy

3. To understand the prospects for future studies and innovations and the potential for applications of nanoparticles in radiation therapy

Radiotherapy is one of the most important methods for cancer treatment. The major limitation to be able to deposit a tumoricidal dose is the deleterious side effects in the surrounding normal tissues. Therefore, the study of radiosensitizers has emerged as a persistent hotspot in radiation oncology as a means to enhance the biological effect of the deposited dose. Nanoparticles, especially noble metal nanoparticles (NPs), may be useful in enhancing the efficacy of radiotherapy because of their unique physical and chemical properties [1]. To date, several different NPs have been successfully applied as potential tumor-selective radiosensitizers in vitro and in vivo studies. Among them, the pioneer work of Hainfeld et al. [2] reached a factor 4 increase in one-year survival rate of mammary tumor-bearing mice injected with 1.9 nm gold nanoparticles prior to irradiation.

Understanding of the underlying nanoparticle-radiation interactions still demands further research, since there is a disconnect between the theoretically predicted increases in cell killing and experimentally observed results. Although Monte Carlo simulations of high-Z nanoparticles have demonstrated significant local dose enhancement in low energy photons of ¹⁹²Ir brachytherapy sources and also X-rays in kilovoltage range [3], some biological studies found comparable sensitization effects at kilovoltage and megavoltage X-ray energies [4]. Therefore, it was suggested that physical dose enhancement based on increased X-ray absorption could not be the main mechanism of sensitization.

In this lecture, an overview the existent, multi-discipline research on nanoparticles in radiotherapy, will be presented. The principles behind NP radiosensitization will be discussed. Special emphasis will be put to physics studies assessing the dose-enhacement effects and their limits. Relevant results of related in vitro and in vivo experiments will be reviewed. An outline of new combined strategies like theragnostics, that takes advantage of the ability of a nanoplatform to ferry cargo- both therapeutic and imaging agents will be sketched. Other approaches like the use of magnetic NPs for hyperthemia plus RT or luminescent NPs for RT followed by photodynamic therapy will be briefly described. A reflection on the prospects for future studies and innovations and the potential for applications of nanoparticles in radiation therapy will conclude the lecture.

MPS04 - IMAGING

MPS04.1 - CT Basics

Author(s): <u>Caridad Borrás</u> School Of Medicine And Health Sciences, George Washington University, Washington/DC/UNITED STATES OF AMERICA

Learning objectives

Understand the processes involved in CT image formation

Become familiar with the definition and typical values of the parameters in CT image acquisition protocols

Learn the basics about CT image quality assessment and patient dosimetry

Abstract

The course will start describing the general principles of x-ray image formation. A historical review of early (1972) images of the EMI Mark I scanner will be presented. The processes involved in CT image formation, image acquisition (scanning), image reconstruction and display, will be explained. The characteristics of the x-ray generator and the x-ray tube, including common x-ray spectra used, and typical values of tube potential (kV) will be displayed. The CT number definition and the Hounsfield Scale of CT numbers will be presented. The different motions of the x-ray tube around the patient and the various components of the CT system: gantry, x-ray tube, patient table and detector array will be described. The historical evolution of the various generations of CT scanners with different types of detector arrays and their physical characteristics, including flat panel detectors, will be reviewed. Various detector configurations in multiple-row detector CT will be shown. The differences between sequential (axial) and helical scanning will be discussed. The concept of cone beam CT will be introduced. The process of image reconstruction using filtered back projection and iterative reconstruction algorithms, the number of views required to form an image, the role of antiscatter grids, the use of shaping (bow) filters and the need for x-ray tube z-axis oversampling in helical scanning will be examined. Common terms used in CT, such as pixel, voxel, matrix size, ray, view, reconstruction slice thickness, x-ray beam collimation, pitch, acquisition field of view and detector settings will be defined. The final CT imaging process which will be covered is the conversion of the digital data into a visible image represented by different shades of gray or brightness levels that can be displayed on a video monitor and controlled selecting the CT level, CT window width and display field of view (zoom). The images can then be recorded, stored and transmitted to a PACS system, as needed. CT image quality will be expressed by assessing the presence of artifacts and measuring spatial and contrast resolutions. The effect of kernels used to soften or sharpening an image will be illustrated. The impact on image quality of various acquisition, processing and displaying factors, collectively referred as CT protocols, can be assessed subjectively by discriminating geometric patterns embedded in phantoms, such as contrast-detail structures or bar line-pairs, or objectively, by measuring noise power spectra and modulation transfer functions. Although a full presentation on patient dosimetry is outside the remit of this lecture, basic CT dosimetry terms will be outlined: computed tomography dose index (CTDI), multiple scan average dose, volumetric computed dose index (CTDI_{vo}), dose length product, size specific dose estimate, and CT organ doses. Dose reduction techniques such as tube current modulation will be mentioned. The lecture will finish with a statement on health risk-benefits in CT scanning.

MPS05 - COMPUTERIZED SYSTEMS

MPS05.1 - Managing Respiratory Motion, Including 4D and Gating Techniques; QC Author(s):

El manejo del movimiento respiratorio es de gran importancia en localizaciones de tórax y abdomen, siendo especialmente relevante en los tratamientos de SBRT de pulmón e hígado. Existen diferentes sistemas para poder realizar estos tratamientos, desde los sistemas de compresión diafragmática con indicadores analógicos o digitales de la presión realizada al paciente, hasta los sistemas de respiración libre empleando marcadores fiduciales internos.

La adquisición de imágenes mediante TC se obtiene mediante respiración libre con métodos de Slow CT scan, Breath-hold CT o bien TC 4D. Estos últimos tienen dos métodos de adquisición de imágenes: sistemas prospectivos o sistemas retrospectivos.

Los métodos de irradiación pueden variar desde los que permiten realizar respiración libre y controlar el movimiento del tumor con CBCT 4D hasta los sistemas que emplean gating para realizar los tratamientos. Entre estos podemos diferenciar entre los que el paciente controla la respiración con un espirómetro y permiten la irradiación solamente en la fase de expiración y los que emplean sistemas de infrarrojos externos y marcadores internos. Estos sistemas disponen como método de IGRT radiografías estereocopicas y se relaciona cada par de imágenes con una fase del ciclo respiratorio, de tal manera que se determina el movimiento del marcador (relacionado con el tumor, al estar en las proximidades de este) seleccionándose la fase del ciclo respiratorio donde el paciente se va a irradiar.

Los controles interfracción e intrafracción, es necesario en este tipo de tratamiento, es recomendable los CBCT de kilovoltaje para pulmón e hígado siendo aconsejable disponer de CBCT 4D. Los sistemas de radiografías estéreoscopicas son favorables en SBRT siempre que se empleen marcadores internos, estos pueden ser bolas de oro o bien hilos de oro, [] ya que pueden permitir: correcciones en 6D, control intrafracción y una mayor rapidez en la adquisición de imágenes comparado con el CBCT.

Los sistemas de QC son imprescindibles en este tipo de técnicas, siendo muy variados en función del equipamiento empleado. Entre los procedimientos mas relevantes podemos encontrar los siguientes: -espiración vs inspiración + espiración, localización del isocentro en un volumen blanco móvil, -correcta localización del isocentro independientemente de la fase del ciclo respiratorio elegida para tratamiento, -medida de dosis absorbida en irradiaciones con control respiratorio, medida de distribución de dosis absorbida en irradiaciones con control respiratorio.

1) Conocer los beneficios que aporta el control respiratorio en los tratamientos de radioterapia especialmente en los de SBRT. Entre ellos podríamos destacar la reducción de los márgenes entre GTV y PTV que trae como consecuencia la disminución de los tejidos sanos irradiados. También la necesidad de realizar el Tc de simulación con un control del ciclo respiratorio.

2) La exactitud con que deben ser administrados los tratamientos de SBRT mediante la IGRT y el control de la irradiación durante la irradiación. Para ello se deberán conocer los diferentes sistemas de irradiación: respiración libre, compresión diagramática, ABC y gating

3) Realizar el control de calidad del equipamiento empleado en el control respiratorio. Para ello se verán los diferentes sistemas para cada método de control respiratorio. ENGLISH Respiratory motion management has shown its importance at chest and abdomen radiotherapy treatments, being particularly relevant for lung and liver stereotactic body radiotherapy (SBRT) treatments. Several systems are available to consider respiratory motion, such as systems involving abdominal compression with analogic or digital pressure indicators or free breathing gating systems using internal fiducial markers.

Image acquisition with computed tomography (CT) can be performed through several solutions: slow scanning, breath-hold or prospective and retrospective 4D CT.

Irradiation techniques include free breathing and tumor motion control with 4D CBCT and gated treatments. Among them, it can be found techniques where patient controls breathing with a spirometer and irradiation is only allowed at exhalation phase. Or systems based on infrared external markers and internal fiducial markers. These systems use stereoscopic X-Ray as imaging system and each pair of images is related to a phase of the respiratory cycle, in such a way that the fiducial marker motion is defined (which is linked to the tumor, since it is located nearby) and therefore allowing the selection of the phase of the respiratory cycle for the irradiation.

Interfraction and intrafraction control is necessary. Kilovoltage (kV) cone-beam CT (CBCT) is highly recommended for lung and liver treatments and 4D CBCT would be an advantage. Stereoscopic X-ray imaging systems are also valid for SBRT if internal fiducial markers are used, such as gold seeds or cylinders, as they enable 6D corrections, intra-fraction control and a faster image acquisition compared to the CBCT system.

Quality assurance is extremely important at these techniques. Quality tests vary depending of the equipment. Among the most relevant we could highlight: exhalation vs exhalation + inhalation, isocenter localization at a moving target volume, correct isocenter localization, independent of the phase of the respiratory cycle chose for treatment, absorbed dose and dose distribution measurements when irradiation with breathing control.

Goals:

1 - Benefits of the respiratory control in radiotherapy treatments, mainly in SBRT. Among others, margin reduction between GTV and PTV with the consecuence of a decrease in normal tissue irradiation. Also the need of a respiratory control during the simulation CT.

2 - SBRT treatments accuracy by means of IGRT and respiratory control. For that purpose all systems in respiratory control will be reviewed: Free breathing, Gating, ABC and diaphragmatic compression.

3 - Respiratory control equipment and Quality Assurance. Review of the different systems in respiratory control.

MPS05.2 - Computerized Systems Basics: Servers, Data Standards (DICOM, HL7), Virtual Machines, Portable Devices Author(s): Armando Alaminos-Bouza

Development, Mevis Informática Medica - BRAZIL, São Paulo/BRA-ZIL

In the realm of medicine, Radiotherapy was a pioneer specialty in the use of computer technology, in particular for therapy planning. The first International Conference on the Use of Computers in Radiation Therapy (ICCR) took place in 1966 (Cambridge, UK). Since 1966, seventeen editions of ICCR took place, and the next, in London 2016, will celebrate the 50th anniversary of ICCR. Today, several radiotherapy modalities are as entangled on computer infrastructure as with radiation treatment machines. This presentation will focus on a subset of the computerized framework on which modern radiotherapy depends, including hardware and software elements. Major breakthroughs in the computer industry with influence in radiotherapy will be mentioned, such as massive parallelization and portability. Two standards for handling, storing and transmitting digital medical information will be introduced: DICOM and HL7.

Learning objectives:

1 – Know the purpose and main modalities of the DICOM standard, in particular those supporting Radiotherapy workflow.

2 - Define the scope and purpose of HL7.

3 – Explain the role of informatics support infrastructure, such as servers, workstations, portable devices, networks, virtual machines, etc., in the context of the radiotherapy department.

MPS06 - COMPUTERIZED SYSTEMS

MPS06.1 - Optimization: IMRT and VMAT

Author(s): <u>Antonio Leal Plaza</u>¹, Rita Pereira Barbeiro¹, Ana Ureba¹, José Antonio Baeza¹, Elisa Jiménez-Ortega¹, Sergio García-Gómez², María Perucha³, Rafael Linares³, Juan Carlos Mateos⁴, Santiago Velazquez⁴

¹Fisiología Médica Y Biofísica, University of Seville, Seville/ SPAIN, ²Hospital Univeristario Virgen de la Candelaria, Tenerife/ SPAIN, ³Servicio De Radiofísica, Hospital Infanta Luisa, Seville/ SPAIN, ⁴Servicio De Radiofísica, Hospital Universitario Virgen del Rocío, Seville/SPAIN

Learning objectives:

Discuss the usual procedures for planning of treatments based on the intensity modulation radiotherapy treatments.

Estimate the different sources of uncertainty associated with IMRT and VMAT techniques.

Evaluate MC simulation as alternative for planning with the higher accurate as possible under an efficient way.

Abstract:

Recent technical developments and the ongoing pursuit to achieve an optimal dose distribution have led to the routinely use of modern techniques in the treatment of cancers, including intensity-modulated radiotherapy (IMRT). More recently, the interest in arc-based IMRT techniques (IMAT) is growing, in an attempt to overcome some of the limitations associated with conventional IMRT, such as increased treatment times and considerable rise in number of monitor units (MUs) delivered. These techniques involve delivering dose by means of a sequence of continuously evolving apertures with associated intensities as the gantry moves around the patient in one or more arcs. Additionally to the dynamic multileaf collimator (MLC) movement, the dose rate and gantry rotation speed may vary simultaneously during irradiation for volumetric modulated arc therapy (VMAT), as opposed to the original IMAT definition, VMAT has the theoretical potential to offer similar dose distributions in shorter treatment times compared with conventional static field IMRT, and is currently commercially available as either RapidArc[™] (Varian Medical Systems, Palo Alto, CA) or VMAT[™] (Elekta AB, Stockholm, Sweden).

It could be argued that the high complexity of VMAT presents a revolutionary treatment delivery, generating two different sources of uncertainty:

The classical issue linked to the dose calculation accuracy performed by commercial software. This is a dual problem concerning both, patient heterogeneities consideration and the beam modifiers contribution to the final dose.

The potential differences between the planned and delivered treatment, due to the discrete calculation of a continuous technique.

On the theoretical definition of VMAT presented by Otto, Monte Carlo was already proposed as an effective and necessary tool. Analytical algorithms cannot take into account the dose with the same accuracy as it is done with Monte Carlo. Moreover, the analytical algorithms are based on previous experimental measurements performed in different dosimetric conditions to those present in VMAT treatment. Consequently, MC has been used to validate these algorithms for techniques such as IMRT, where there is a significant amount of non-standard conditions and the beam modifiers play an important role in the characterization of the beams composing the modulated fields. The scenario for VMAT is similar to IMRT, and even more complex, due to the increment of parameters for the optimization process involved. The fundamental challenge of applying MC to solve these techniques is to enable the explicit consideration of all geometries implicated and perform the dose calculation in operating times for clinical practice. To this end, approaches based on parallel computing solutions are implemented in addition to the application of variance reduction techniques, allowing the use of Monte Carlo simulation in reasonable times. Apart from these points, radiotherapy techniques with many incidence beams, such as VMAT and dynamic IMRT approaches based on sliding windows, do not necessarily require a time longer for MC simulation than the time spent for simple treatments with fewer beams, while analytical algorithms take a longer time when increasing number of incidence beams. In these cases, a limited number of histories are required for each individual beam contribution, as it is the final dose due to the sum of all beams that should provide enough statistics. Nevertheless, MC never will be efficient enough, if we face the optimization problem in the same way as traditionally it has been done with the analytic algorithms.

In general, a reduction of the number of beamlets and/or voxels simplifies the initial problem and makes it possible to decrease the overall treatment planning time. Specific combination of mathematical algorithms along the optimization process will be discussed in order to establish the more appropriate set to the characteristics of the MC simulation. Actually, some of these approaches could be exported to the systems based on analytic dose calculation engines.

On the other hand, the accuracy assurance of the predicted dose distribution could be compromised by the possible differences between the discrete apertures proposed by the TPS and the finally delivered by the linac. If there are dramatic changes in the aperture shapes from one control point to the next, the linac can execute a different configuration to the parameters combination that was planned by the TPS. The mechanical limitations related to the relative speed between leaves and gantry and also the required changes in the dose-rate can generate these discrepancies. Therefore, the estimation of the patient dose based on information from the treatment delivery log files (e.g. MLC DynaLog files in Varian RapidArc), in which the MLC leaf and jaws positions, fractional MUs, and gantry angle are recorded, is essential for VMAT QA. In fact, it is necessary to know what is actually being performed by the linac during the VMAT treatment delivery.

Definitively, MC provides an adequate tool for the verification of the dose distribution within the patient geometry, allowing the verification of the dose calculated from the complex MLC apertures commonly used in the delivery of VMAT treatments. Furthermore, MC simulation of log files, recorded during treatment delivery, should be considered for a general VMAT QA able to cover both type of uncertainties commented above.

We will try to expose the essential characteristics that we believe the optimization algorithm has to fulfill to achieve a treatment planning system based on explicit MC simulation that could be used efficiently in the clinical routine.

We will also present an alternative VMAT QA system, based on an automated MC simulation of the explicit transport through the linac head and patient heterogeneities and experimental measurements with Gafchromic EBT3 film within a cylindrical phantom specifically developed to host the films rolled at different depth, available for a 3D and continuous dosimetric verification.

MPS06.2 - Automated Contouring

Author(s): Armando Alaminos-Bouza

Development, Mevis Informática Medica - BRAZIL, São Paulo/BRAZIL

Contour delineation remains one of the most time consuming process in Radiotherapy planning. Contouring depends on a computer vision technique called "image segmentation" that has continuously evolved since 1965. Image segmentation is commonly used to locate objects and boundaries. Automated methods for segmentation and contouring have the potential for significant time-saving in the planning process, being estimated in a range from 23 to 41 percent of the whole treatment planning. Several algorithms have being implemented for radiotherapy contouring including: gradient based, threshold based, atlas based, semi-automated (with human interaction), etc. There is no closed-form solution for the segmentation problem in general, so human expert inspection and correction is paramount. Today, automated contouring is an active field of research in Radiotherapy and major improvements are expected for the near future.

Learning objectives:

Identify the most common methods of automated contouring used in radiotherapy planning systems.

Indicate the accuracy and reliability of each method.

Propose methods for interactive contour correction.

MPS07 - RADIATION THERAPY

MPS07.1 - Image-Guided Radiotherapy, Including QC and Imaging Dose; Adaptative Radiotherapy Author(s): <u>Daniel Venencia</u>

Fisica Medica, Instituto de Radioterapia - Fundacion Marie Curie, Cordoba/ARGENTINA

Learning objectives

1. Understand the principles and challenges for image guidance radiation therapy (IGRT)

2. Understand issue related to IGRT commissioning, implementation in the routine clinical practice as well as quality assurance

3. Understand existing IGRT systems, specially room mounted kV x-ray systems

Delivery of conformal radiation dose to the target volume with conformal avoidance of critical structures requires a precise knowledge of the relationship between the patient's anatomy and treatment isocenter. Precise Radiotherapy allows us to reduce complications and improve the quality and likelihood of successful treatment. Uncertainties in Radiotherapy are associated with patient setup variation, internal organ movement and anatomical deformation. Image Guidance Radiotherapy (IGRT) gives us the possibility to reduce radiotherapy uncertainties improving the ability to setup patients on a daily basis and gives tools to detect anatomical changes which could require re-planning, Adaptive Radiation Therapy (ART). IGRT has become today, routine part of the modern Radiotherapy.

IGRT systems currently available allow us to get projection or volumetric imaging. Projection imaging used setup based on surrogates and includes conventional port films (films or CR), MV electronic portal imaging device (EPID), room mounted kV x-ray (ExacTrac, Cyberknife), ultrasound (BAT, Clarity) and active fiducial with GPS (Calypso). Volumetric imaging used setup based on GTV and includes CT/MRI on rail in the treatment room, MV spiral CT (Tomotherapy), kV CBCT (Elekta, Varian, BrainLAB) or MV CBCT (Siemens). IGRT systems use direct alignment (visualization of the target volume) or indirect alignment (bone and fiducial active or passive structures). The alignment method can be manual, automatic or point matching. IGRT strategies may involve an adjustment of the treatment parameters at the time of treatment (On-line) or the correction based on the accumulation of information (Off-line). Depending on the characteristics of IGRT system, its use would involve not deliver an additional dose to the patient, a low dose (< 1mSv) or medium (> 2mSv).

The use of IGRT requires a specific knowledge of the system and specific training for therapists, dosimetrists, radiation oncologists and medical physicists. IGRT systems require strict QC process. Problems associated with the system can lead to a global generation of systematic errors in the positioning. The coincidence between the treatment isocenter and reconstructed image isocenter is one of the most critical points. The image quality is related to clinical intervention.

This presentation will give an overview through all existing IGRT systems emphasizing on kV projection systems with radio opaque implanted fiducials. ART concept will be analyzed showing practical examples of application in head and neck IMRT.

MPS08 - MEDICAL PHYSICS EDUCATION AND PROFESSIONAL ISSUES

MPS08.1 - Curriculum Design: How to Train the Next Generation of Physicists? Author(s): Maria-Ester Brandan Instituto De Física, Universidad Nacional Autónoma de México, Mexico Clty/MEXICO

Learning objectives:

1. Understand current recommendations for education + training of medical physicists.

2. Learn the situation of education + training of medical physicists in Latin America.

3. Be informed about the main difficulties faced by program organizers in Latin America to comply with recommendations, and strategies to cope with them.

Abstract:

Current recommendations for the formation of medical physicists describe the process as a "3-act" play. The first act is university education at the undergraduate level, in physics, engineering or another career with a strong content of physics. The second act is graduate-level education, typically a master degree in medical physics, aimed at teaching basic principles behind the main applications of physics in medicine. The last act is a formal clinical training. After these 3 steps, the interested individual has received the education and acquired the skills that make him/her a medical physicist qualified to work independently in the clinic.

This play is not easy to stage. In the last 15 years, Latin America has witnessed the creation of a relativelely large number of university master programs --with different degrees of success-- and the number of graduated medical physicsts increases steadily. However, clinical residencies are still missing in most of our countries.

The talk will present statistical information about programs and residencies, description of the academic curricula, identification of the problems faced to run programs and residencies, and general strategies devised to cope with local limitations and lack of resources.

MPS09 - RADIATION THERAPY

MPS09.1 - Peripheral Neutron and Photon Doses

Author(s): <u>Francisco Sanchez-Doblado</u>¹, José A. Terrón¹, Leticia Irazola¹, Beatriz Sánchez-Nieto² ¹Servicio De Radiofísica, Hospital Universitario Virgen Macarena, SEVILLA/SPAIN, ²Instituto De Física, Pontificia Universidad Católica de Chile, Santiago/CHILE

Learning objectives:

- Importance of peripheral dose in radiotherapy patients
- Dosimetrical problems for neutron and dose estimation

- Necessity of the introduction of a new parameter SCP (Second Cancer Probability), in addition to the TCP and NTCP, for a better clinical decision of the best treatment planning

Abstract

The comprehensive study in radiotherapy, of the dose estimation outside the target, is usually restricted to closely surrounding volumes. The dose affecting the rest of the body, currently known as peripheral dose, has rarely been considered in the clinical routine. This approach is mainly based on the argument of the risk-benefit ratio, applied to a patient with a "fatal" disease, such as cancer. However, in the last years, there has been a fast-growing concern about this unnecessary radiation dose. There are three main reasons that make this situation clear: a) the large size of the affected population; b) the great success rate, which guarantees a high life expectancy, allowing the appearance of long term side effects, including second cancer; and finally c) the new radiotherapy techniques, which increase the long time survival, but at the cost of larger volumes irradiated to low dose [1-2].

Figure 1. Experimental setup for patient organ neutron dose estimation in the treatment room. Detector location is marked in red.

Peripheral dose in conventional radiotherapy has two main components: leakage and scattered photons and neutron contamination. Photon dosimetry is well stablished whereas the neutron contribution to the peripheral dose is complex to determine. Our group has developed [3-8] photon and neutron peripheral dose models which are being implemented on a TPS. The equivalent dose to peripheral organs should be taken into consideration during planning selection and/or optimization.

Figure 2. Anthropomorphic phantom used to generate the equivalent neutron and photon dose estimation models.

The classical consideration of tumor control and normal tissue complication probabilities functions (TCP and NTCP) should be extended, as an extra complication term, which considers the secondary cancer probability (SCP) [9].

Therefore, an efficient use of MU is mandatory throughout the balance of potential long term benefits and side effects (organ toxicity and second cancer), together with the clinical judgment on illness prognosis and, consequently, life expectancy [10-12].

MPS10 - RADIATION THERAPY

MPS10.1 - The Modern Physicist Tool Box: How to Choose Between Current Dosimeters

Author(s): Faustino Gómez¹, Luis G. Brualla², Diego Miguel Gonzalez-Castaño¹

¹Riaidt, Radiation Physics Laboratory, Santiago de Compostela/ SPAIN, ²Medical Physics, ERESA, Valencia/SPAIN

Current radiotherapy dosimetry toolbox for the medical physicist involves different technological embodiments of radiation detectors. This toolbox comprises old and new instruments such as:

1. Passive systems: film, alanine, TLD and gel dosimetry 2. Active systems:

2.1. Point detectors: air filled ionization chambers, diode, diamond, scintillator detectors

2.2. Multidetector systems: air and liquid filled ionization and silicon diode arrays

2.3. Electronic portal imaging devices (EPID)

On the other hand, the development of radiotherapy modalities is growing steadily including nowadays those as IMRT, VMAT, FFF linacs, Radiosurgery, Gating, etc. The medical physicist is confronted with an increasing space and time modulation of the radiation fluence and high dose gradients to deal with the clinical goal of a better conformation of the dose distribution to the target volume.

Thus, the medical physicist must decide what dosimeters to use in the different phases of the clinical dosimetry process: modelling, commissioning, verification and quality assurance. It is very important in each situation to be conscious about the idoneity and limitations of the different dosimeters available: tissue equivalence, energy and dose rate dependence, detector size and volume averaging effect, sampling rate, repeatibility, etc.

Some of the passive dosimetry tools, like radiochromic film exhibit excellent tissue equivalence and high resolution, although the dose uncertainty can be significant in some cases depending on the methodology and instrumentation employed.

In the case of point detectors for absolute and relative dosimetry, the family of air ionization chambers and silicon diodes has been enlarged recently with the new CVD diamond and organic scintillating detectors that provide tissue-equivalent composition and geometries adequate for small field and high dose-gradient dosimetry.

On the other hand the use of two dimensional dose distribution measuring arrays has become very common, because they offer a higher verification efficiency, since they can be used for a large number of immediate dose measurements in a single irradiation procedure. Current state-of-the-art detectors are also including 2D and 3D array measuring systems or assemblies of 2D systems that provide a 3D verification methodology. The dose fidelity of these detectors will be analized in terms of their response function and repeatibility characteristics.

The use of point detectors require the choice of the adequate chamber geometry, materials and size. Their position in the radiation field has to be studied in order to provide a sufficiently homogeneous dose distribution to ensure measurement accuracy. Phantom selection in terms of geometry and materials is also a key factor for the adequate dosimetric verification. Eventually the use of EPID for dosimetry verification and treatment quality assurance is an complementary tool for the medical physicist.

This course is oriented to the description of the physical properties and main characteristics of current dosimeters to provide the necessary insight for their application. The talk will focus in the following learning objectives:

i) Radiation transport: physical constraints on dosimetry.

ii) Characterization of the different technologies of active and passive dosimetry systems.

iii) Implications of the use of array systems. Advantages and drawbacks.

iv) Application of the dosimeter choice to the different dose verification situations.

All this concepts will be explained in a typical medical physics environment showing how to travel from theory to practice.

MPS11 - RADIATION THERAPY

MPS11.1 - Dosimetry Under Non-Reference Conditions

Author(s): Faustino Gómez¹, Araceli A. Gago², Juan Pardo Montero³ ¹Fisica De Particulas, Facultad de Fisica, Universidad de Santiago, Santiago de Compostela/SPAIN, ²Instituto De Física, Pontificia Universidad Católica de Chile, Santiago de Chile/CHILE, ³Grupo De Imaxe Molecular, Instituto de Investigación Sanitaria (IDIS), Santiago de Compostela/SPAIN

Dosimetry under non-reference conditions

This course is oriented to the description of the problems arised from the use of small and composite fields in the clinical treatments and the need of reliable standard dosimetry procedures for their verification. The main learning objectives of the course are:

Explanation of the physical problems on small static field and composite dosimetry: energy response of the detector, beam hardening, charged particle equilibrium, field size definition and beam quality description.

New code of practice for standard non-reference conditions. Introduction and explanation of the new formalism: machine specific reference field (MSRF), plan class specific reference field (PSRF) and clinical fields.

The new CoP applied to the small static field dosimetry: factors to be considered and their determination and use.

The development of the standards of absorbed dose to water has lead to Codes of Practice for dosimetry in reference conditions such as IAEA TRS398 or AAPM TG-51. The use of reference conditions was intended for the calibration of a broad beam in a close to charged particle equilibrium situation for conventional radiotherapy or clinical reference dosimetry. The development of new radiotherapy techniques has lead to more frequent use of small and composite fields, such as those involved in Stereotactic Radiotherapy (SRT), Stereotactic Radiosurgery (SRS) or Intensity Modulated Radiation Therapy (IMRT). The proliferation of these narrow and composite fields has been boosted through the use of different multi-leaf collimator systems and new treatment delivery techniques. These developments have increased the complexity of clinical dosimetry and compromised the traceability to reference dosimetry based on conventional reference dosimetry protocols. There are two main reasons that affect the accuracy of dosimetric measurement in several of the new radiotherapy modalities:

CoP reference conditions can not be achieved in some of the new treatment machines.

In general terms, procedures for absorbed dose to water measurement in small and composite fields are not standardized.

Related to the first limitation in the realization of reference conditions, the new CoP approach is the definition of a reference field for each specific machine as close as possible to the standard conventional reference conditions. The correction factors for each chamber and specific reference field are tabulated in order to provide a standard dosimetric procedure. On the other hand, the determination of the beam quality has to be modified according to the achievable measurement conditions. The use of flatenning filter free linacs imply the need of an extra correction factor to account for the difference in the beam quality correction respect to linacs that use a flatenning filter. Additionally the ionization chamber volume-averaging effect may be taken into account with a proper convolution methodology. On the other hand, the new approach on composite field dosimetry imply the definition of PSRF (Planclass Specific Reference Field) with the purpose of reproducing the delivery features similar to those of clinical treatments. In this case a geometrically simple volume will

receive a homogeneous dose distribution. Different realizations of these PSRF have been already proposed in the literature for various treatment modalities. Substantial progress has been achieved in the last years, although this topic is still an important evolving subject for the international medical physics community.

MPS12 - IMAGING

MPS12.1 - PET State-of-the Art and Current Research Topics (Including CT-PET and CT-MRI)

Author(s): Josep M. Martí-Climent

Radiofísica Y Protección Radiológica, Clínica Universidad de Navarra, Pamplona/SPAIN

Learning objectives:

 \cdot To understand the factors affecting the image quality and quantitation in PET

• To gain knowledge about the impact of the new PET developments in the quality of image.

• To understand the changes introduced in the PET detector technology due to the development of PET/MRI scanners.

Abstract:

Inorganic scintillator crystals are the detectors used with photomultiplier tubes (PMT) in positron emission tomography (PET). Bismuth germanate (BGO) has been widely used as scintillator. With the introduction of lutetium-oryorthosilicate (LSO) as scintillator, time-offlight (TOF) information (allowing for the positron annihilation point to be localized accurately) has been incorporated to improve the image reconstruction. The development of the digital silicon photomultipliers (SiPMs), connecting each scintillator crystal to a single detector pixel, has improved the PET scanner performance.

Scanners without septa have allowed the use of a 3D acquisition, gaining sensitivity. The introduction of the iterative reconstruction methods, incorporating corrections such as scatter an attenuation in the modelling, instead of a direct correction of the projections or sinograms, have improved the image quality. Finally, with the point spread function (PSF) reconstruction algorithm, near-uniform spatial resolution can be achieved throughout the field of view.

PET image quality and quantitation are dependent of the reconstruction algorithms, including parameters used, and the corrections applied.

The disposition of a computer tomography (CT) scanner in tandem or in line with a PET scanner has led to the PET/CT scanner, providing accurately aligned of anatomical and functional images. CT images are used for attenuation correction of the PET data, eliminating the need of rotating radioactive ⁶⁸Ge sources around the patient and detection of the attenuated transmission signals. Conventional bed motion is stop and go, with overlapping bed positions due to the decrease in the axial sensitivity at the end of the field of view. The development of the continuous bed motion has improved protocols from bed planning protocols to organ specific examination protocols.

The combination of a magnetic resonance imaging (MRI) scanner with a PET scanner into a PET/MRI device has involved major modifications, especially in the PET detector technology. Different approaches have been proposed for the scanner configuration, including the two scanners mounted back-to-back to each other, similar to a PET/CT, a PET system within the MRI, and the two scanners mounted apart in the same or in a different room. Since the use of PMT in the magnetic field is excluded, scintillator detectors are coupled to position-sensitive avalanche photodiodes (APD) based detectors. In a PET/MRI scanner, tissue attenuation correction necessary for PET image reconstruction needs to be based on MR images. With that aim, different methods for attenuation correction have been developed.

MPS12.2 - 4D Imaging

Author(s): Manuel Llorente Manso

Medical Physics, Centro Oncológico MD Anderson España, Madrid/ SPAIN

Learning objectives:

Present image modalities with 4D techniques.

Explain different methods of acquisition and basic applications.

Discuss artifacts affecting 4D images and ways to improve them.

Abstract:

Several medial image modalities are capable of producing three dimensional reconstructions. In the study of moving organs, such as heart and lung, 4D image modalities, that is, incorporating time as fourth dimension, have been developed in the recent years.

One example of the use of 4D medical images are the cardiac ultrasound (US) studies. Last generation US devices can create 3D images with a rate of 25 Hz, allowing a real time 4D vision, having a great impact on cardiac and hemodynamic studies.

Also 4D magnetic resonance imaging (MRI) has application on cardiac studies. MR can create planar images with a good spatial resolution in a very short time, that is, less than a heart beat. Several heart beats should be necessary to generate 3D reconstructions. Planes should be acquired in the same cardiac phase. Acquisition can be synchronized with ECG prospective or retrospectively. In the first case, point R in the ECG works as a trigger for image acquisition and resulting images correspond to the same point in the cardiac cycle. In the latter, images are acquired continuously along with the ECG curve and sorted after wards. Result is a series of 3D images covering all the cycle.

Respiratory motion artifacts can be reduced by synchronizing acquisition with breathing cycle also. A respiration curve can be obtained using abdominal movement as a surrogate. Images are to be acquired only during a certain part of the respiratory cycle. Breathing phase can also be estimated using a navigator sequence: a fast sagital sequence where diaphragm is easily found. System detects automatically diaphragm position and uses it as a trigger.

In 4D-CT cardiac studies, ECG is used as a external signal both in prospective and retrospective modes. In this kind of studies, acquisition time is short enough to be performed in one single breath hold, so breathing synchronization is not necessary.

4D-CT synchronized with breathing are of interest in Radiotherapy in the treatment of thoracic and abdominal tumors. In general, respiration curve is obtained from the abdomen movement and depending on the manufacturer images are acquired in prospective (ciné) or retrospective (helical) mode.

Cone beam CT images (CBCT) correlated with respiration are also of interest in Radiotherapy. Those images, taken on the treatment couch, help estimating tumor motion and position.

Also PET-CT images can be correlated with respiratory cycle, reducing motion artifacts. Such corrections can have an impact on patient diagnosis.

SPECIAL SESSIONS

SS06 - IOMP AWARDEES PRESENTATIONS

SS06.1 – IOMP Marie Sklodowska-Curie Award: A Brief History of X-Ray Therapy: Evolution, Convolution, and Revolution

Author(s): Colin G. Orton,

Ph.D., Professor Emeritus, Wayne State University, Detroit MI, USA

Evolution

X-ray therapy for the treatment of cancer evolved immediately after Roentgen's discovery of X rays in November, 1895: just two months later, Emil Grubbé treated a woman with breast cancer. It was not long after this, in 1899, that Stenbeck, in Sweden, delivered the 1st documented curative cancer treatment (basal cell carcinoma), using a grand total of 99 fractions! Why so many fractions? It was not because, as we learned much later, that treatments had to be fractionated in order to cure a cancer without exceeding normal tissue tolerance, but because outputs were so low and unpredictable. It was not until 1914, with the advent of the Coolidge hot-cathode X-ray tube, that high dose rates and controllable exposures became possible, and this sparked a debate on the need for fractionation, which was not resolved until 1932 when Coutard published his excellent results using fractionated radiotherapy. The Coolidge tube also sparked the evolution of X-ray machines of ever increasing energy in order to be able to treat deeper lesions, with energies rising to 1 MV by 1933. In the quest for even higher energies, new technologies were developed such as the Van de Graaff accelerator in 1937, the betatron in 1940, and the linear accelerator in 1953. The linear accelerator became the workhorse of radiotherapy by the end of the 1970s.

Convolution

Modern radiotherapy was sparked by three applications of computer technology in the 1980s and '90s: 3-D treatment planning, the use of computerized tomography in planning, and the advent of computer controlled linacs and multileaf collimators. Highly conformal radiotherapy became possible and this ultimately led to the development of IMRT, the CyberKnife, and Tomotherapy. At the same time, accurate targeting of treatments was evolving with real-time electronic portal, CT, PET and MRI imaging. The convolution of computerized delivery and sophisticated imaging is about to revolutionize radiotherapy.

Revolution

With the advent of flattening filter free linacs and the concomitant very high dose rates, combined with highly conformal treatments with tight margins and subsequent normal tissue sparing, the delivery of higher doses/fraction without excessive risk of complications is now possible. Such hypofractionation has been shown to be at least as effective as conventional fractionation for the treatment of several common cancers and, because it is so much more cost effective, it is likely to revolutionize radiotherapy within the next few years.

SS06.2 - IOMP Harold Johns Medal: The Importance of Teachers

Author(s): William Hendee

Distinguished Professor Emeritus of Radiology, Radiation Oncology, Biophysics, Community and Public Health, Medical College of Wisconsin, Milwaukee, WI USA

Receiving the Harold Johns medal from the International Organization of Medical Physics is a great honor that offers an opportunity to reflect on the importance of teachers in the our professional and personal lives. We are all the product of dedicated teachers who provided guidance in the molding of our professional careers and personal characters. Were it not for these teachers, we would not be the physicists or persons that we are, and our lives would be decidedly different, as would the contributions we make to our profession and our families.

We can all think of individuals who have been instrumental in molding our personal and professional lives, many of whom were unaware they were doing so. In the same manner, each of us is a teacher of others, especially young medical physicists and biomedical engineers entering the discipline. We teach not only by what we say in the classroom, but also how we interact in the clinic, at meetings and in personal encounters both inside and outside the hospital. Teaching is more than what we say, although what we say is important. It is also how we conduct ourselves as professionals and as persons, and how we project ourselves as role models to those younger than ourselves.

Health care is experiencing momentous change around the world, especially in developed societies impacted by technologies, information systems and services that drive healthcare costs to unprecedented costs. Medical physicists work at the "sharp end" where these technologies, information systems and services impact directly on patients. In this position, physicists can influence how these developments are used in an effective and cost-efficient manner. But to fulfill this responsibility, younger physicists need senior leaders to serve as exemplars. Never in the history of medical physics has the need for devoted teachers been greater.

SS07.2 - IUPESM AWARDEES PRESENTATIONS

SS07.2.01 - IUPESM Award of Merit (Medical Physics): Cost-Effective Provision of Medical Physics and Medical Engineering Services in Healthcare

Author(s): Peter H S Smith Aberdeen, UK

All healthcare services, in both developed and developing counties, are under increasing pressure. Growing use of technology is one the factors involved and medical physics and engineering services are one just more cost pressure and therefore it is essential that these services are provided in the most cost-effective way.

A number of factors will be examined including organizational aspects, staffing and research and development. The author's experience of providing integrated engineering and physics services on a regional basis will be used to illustrate some of the issues, including the advantages and disadvantages of horizontally organized and integrated medical physics and engineering service.

The correct provision and deployment of professional, technical, administrative and other staff is essential and can raise difficulties: cultural, perceived job roles, professional barriers, supply and training. Should clinical engineers and physicists be involved in research? If so, who funds and what links to academic institutions are essential?

Manufactures of medical devices are a major influence on the deployment and maintenance of technology in healthcare and medical physicists and engineers can help ensure that appropriate technology is procured in accordance with defined needs and maintained in a cost-effective manner.

The contribution that can be provided by national, regional and international professional, governmental and UN organisations, to finding solutions to these issues will also be considered.

SS07.2.02 - IUPESM Award of Merit (Biomedical Engineering): Improvement of Health Care Quality by Medical and Biological Engineering (MBE) with the collaboration of Academia, Industry, the Government and the People

Author(s): Fumihiko Kajiya, M.D., Ph.D

Special Appointed Professor, Kawasaki College of Allied Health Professions

The American Institute for Medical and Biological Engineering (AIM-BE) has highlighted nearly 30 medical technologies since the Hall of Fame began in 2005. In subsequent years new technologies were added as the key innovations of the 20th century until now. For example, artificial kidneys, X-ray, ECG, pacemakers, cardiopulmonary bypass, antibiotic production technology and defibrillatorsup to the 1960's, and since the 1990's genomic sequencing and micro-arrays,-PET, image-guided surgery and optical coherence tomography(see AIMBE home page). Virtually, every person has benefitted from these key technical innovations in receiving better health care. For instance, more than 2 million people have hemodialysis treatment in the world(3 hundred thousand in Japan). However, the development of each technology doesn't progress in a straightforward way. As for artificial kidneys, it is well known that many crucial technological developments, such as dialysis-circuits, pumps, vascular access, anticoagulant measures and high performance membranes have been achieved. These are a result of fusion technology from many disciplines. Personally, I have been engaged as a co-chair (2004-13) inthe Medical Engineering Technology and Industrial Technology (METIS) in Japan, i.e., Cooperative organization of academia, industry and government. The scope of METIS includes not only medical

devices but also science and engineering in health care. From my small experiences, lwould like to emphasize the possible improvement of health care quality by future contributions of MBE in the interdisciplinary fusion with the collaboration of academia,industry, the government and the people.

To promote President Obama's Precision Medicine Initiative, cohort study of genome together with MBE,IT and other fields with the participation of the majority of people is very important. For MBE to walk along with society worldwide will be effective route to our goal.

SS08 - THE FUTURE OF CLINICAL ENGINEERING EDUCATION

SS08.1 - Clinical Education at University of Connecticut Author(s): <u>Frank R. Painter</u>

Biomedical Engineering, University of Connecticut, Trumbull/UNIT-ED STATES OF AMERICA

The clinical engineering graduate educational program at the University of Connecticut is in its 41st year. Dr. Joseph Bronzino started the program in 1973 at Trinity College and the Hartford Graduate Center in Connecticut, USA. In 1995 the program moved to the University of Connecticut. Dr. Bronzino retired in 2000 and Frank Painter assumed responsibility for the program under the guidance of Dr. John Enderle.

The program provides students with a two year clinical engineering internship experience as well as seven academic courses which focus on various aspects of clinical engineering. A successful student will graduate from UCONN with an MS BME degree.

There are 20-24 students in the program in most years. Each year 30-50 students apply for the CE internship program. Normally there are ten to twelve openings each year in the 17 participating internship locations. A few more students are selected to interview than the number of openings available. These candidates are then invited to come to the Southern New England area and in a four day period, as a group, they interview at all hospitals who have internship openings. In the interview the hospital's CE director and several of their staff, including the current interns, interview each candidate. During the end of the interviews the CE directors are asked to select their five preferred candidates and the candidates their five preferred hospital locations. A meeting of the directors is then held to match the choices and the candidates are informed of the outcome.

Starting in late August, the interns spend two full academic years in the program. They are required to work in the hospital 20 hours per week and spend an additional 10-15 hours per week in the hospital working on their class projects, homework, clinical observations, research, reading and studying. Additionally the students take the following clinical engineering focused course work over the four semester program. Clinical Engineering Fundamentals focuses on how a CE department is managed, Engineering Problems in The Hospital focuses on utility systems in the hospital which support medical equipment, Human Error and Medical Device Accidents focuses on managing the risks of healthcare technology, Medical Instrumentation in the Hospital focuses on high end medical systems, including imaging and therapy, Clinical Systems Engineering focuses on medical device integration and interoperability and Clinical Rotations focuses on observing clinician-technology-patient interface in the clinical environment.

The program is the result of a partnership between the hospitals and the University. The clinical engineering directors greatly contribute to the program a success. Each hospital signs a contract with the university and pays a yearly fee to finance the graduate student stipend and program administrative fees. Every hospital in the program has hired a program graduate and many have hired several.

The majority of the second year students receive multiple clinical engineering job offers before graduation. Most of the program graduates end up in a career working directly for hospitals. All of the remaining students work for companies either providing services or products to the healthcare technology community.

SS08.2 - The Future of Clinical Engineering Education in the Western Hemisphere: USA and Peru

Author(s): <u>Thomas M. Judd</u>¹, Luis Vilcahuaman², Rossana Rivas³, Herbert F. Voigt⁴

¹Clinical Technology, Kaiser Permanente, Marietta/UNITED STATES OF AMERICA, ²Health Technopole CENGETS PUCP, Pontifical Catholic University of Peru, Lima/PERU, ³School Of Public Health, Universidad Peruana Cayetano Heredia, Lima/PERU, ⁴Biomedical Engineering, Boston University, Boston/MA/UNITED STATES OF AMERICA

It is undeniable that engineers have played an important role in the delivery of modern health care. The boots on the clinical floors have been filled with BMETs, clinical engineers (CEs) and biomedical engineers (BMEs), the mix of which has been uniquely formulated in thousands of clinical environments globally. It is interesting that although educational opportunities to train BMETs are common, training of CEs at the undergraduate and graduate level is virtually non-existent in the Western Hemisphere.

In fact, there are only a few CE MS programs (some with no internship opportunities) and no CE Ph.D. programs in the western hemisphere. There is an urgent need to provide highly qualified, certified CEs at all levels, BMET, BS, MS and Ph.D. level. Many Universities that provide biomedical engineering undergraduate education do not offer clinical engineering internships, local or international, that are so important for training CEs. In addition, the clinical environments in developed countries offer very different challenges than those in developing countries. For certification purposes, this is likely to result in different weighting of the factors important in the various environments. This session will address the need for new clinical engineering programs at various educational levels to serve the current and future health system needs.

The CE profession is changing in ways that significantly impacts US and global healthcare. In addition to the historic CE medical device lifecycle management function (called health technology management or HTM), there is (1) the emerging integration of medical devices into electronic health records (also called Health IT or CE-IT), and (2) other key topics in which CEs help drive changes in clinical workflows at health organizations: planning, policies, acquisition, management, strategies, investments, risk, design of clinical environments and others. This is accomplished through the interoperability of devices and EHRs so that care everywhere (inpatient, clinic-based and mobile health) profoundly allows redesign of care delivery.

The profession needs practitioners with new skillsets - both for emerging graduates and people at all stages of their careers. These requirements are outlined in a White Paper by Sloane, Welsh, and Judd: *New Opportunities for BME/CE Health IT Education,* May 2014, (http://ceitcollaboration.org/docs/NewOpportunitiesBME_CE_ Health_IT_Education.pdf). This session will address the pertinence and impacts of exploring more opportunities to grow Clinical Engineering Education in the U.S.A. and promote this specialty in developing countries and globally moving forward.

The Future of Clinical Engineering in the Western Hemisphere, which is a model for CE globally, will be addressed in oral presentations, followed by a Panel Discussion.

SS09 - INNOVATIVE BIOMEDICAL ENGINEERING RESEARCH IN ASIA

SS09.1 - Functionalized gold nanoparticles for point-of-care nucleic acid detection

Author(s): Thomas M.H. Lee

Interdisciplinary Division Of Biomedical Engineering, Hong Kong Polytechnic University, Kowloon/HONG KONG

Gold nanoparticles (AuNPs) have been extensively investigated for colorimetric detection of nucleic acid. This is enabled by the unique interparticle distance-dependent optical property of AuNPs. The solution color for monodispersed particles appears red (for widely used 13 nm AuNPs) but turns purple upon aggregation due to a red-shift in the surface plasmon resonance absorption band. Until now, all the reported platforms are not practical for point-of-care testing. To address this, our group developed a new platform by incorporating 11-mercaptoundecanoic acid-modified AuNPs (MUA-AuNPs) into loop-mediated isothermal amplification (LAMP). When added into the LAMP reaction mixture, MUA-AuNPs aggregated as a result of ion-templated chelation between the carboxyl groups and magnesium ion (Mg²⁺, which plays an indispensable role in LAMP reaction as an enzyme cofactor). The solution color changed from red to purple. In the presence of a specific target DNA sequence, the LAMP reaction occurred and pyrophosphate ion (P2O74-) was generated as a reaction by-product. The chelated Mg2+ was then extracted by P2O74-, leading to the deaggregation/redispersion of the MUA-AuNPs and the solution color turned red. This new platform possesses all the ideal features for point-of-care testing, including simple preparation and operation, low cost, high sensitivity, and worry-free carryover contamination control.

SS09.2 - Hemodynamic function of Fontan circulation mechanical assistance in Fontan circulation animal experimental model Author(s): <u>Akihiro Yamada</u>¹, Yasuyuki Shiraishi¹, Hidekazu Miura¹, Yusuke Tsuboko², Yasunori Taira², Masaaki Yamagishi³, Dai Homma⁴, Tomoyuki Yambe¹

¹Institute Of Development, Aging And Cancer, Tohoku University, Sendai/JAPAN, ²Graduate School Of Biomedical Engineering, Tohoku University, Sendai/JAPAN, ³Department Of Pediatric Cardiovascular Surgery,, Kyoto Prefectural University of Medicine, Kyoto/ JAPAN, ⁴Toki Corporation, Tokyo/JAPAN

Fontan procedure is selected the final palliative surgical operation in pediatric patients with serious congenital heart diseases. After Fontan procedure, there is non-pulsatile flow in the pulmonary circulation called Fontan circulation. We focused on the additional pulsatility in the Fontan circulation for the pulmonary flow assistance for congenital heart failure patients. In order to promote the pulsatility in the flow that infuses the lungs, we implemented an original mechanical contractile device which promotes flow pulsatility. Then we have been developing a circulatory support device with the function of peristaltic contraction for the promotion of an efficient assistance for Fontan circulation using shape memory alloy fibers. The structure of the device was a mechanically contraction from the outside of the extracardiac conduit. The device was consisted the 16 units of the shape memory alloy actuators in parallel arrangement. In this study, we developed the animal experimental model for in vivo examination of the Fontan circulation assist device for the pre-clinical research. And also, we examined the hemodynamics function in the device driving by the animal experimental model. The animal experimental model was constructed in four adult goats (45.8±15.6 kg). The right heart bypass of inferior vena cava (IVC) to pulmonary artery (PA) was constructed by using extracardiac conduit (Dacron, D = 18mm, Boston Scientic Corporation, USA). The vascular tape was indwelling in IVC and right atrium (RA) anastomosis for clamping. And the left ventricular assist device (LVAD, Gyro Pump C1E3, Kyocera

Medical Corporation, Japan) was connected to the apex to reduce the left ventricular load. Rotational speed of the LVAD was set to 1400rpm. The right heart bypass circulation could be created by the IVC-RA clamping. IVC and PA pressure rose to 15mmHg during clamping. The device could be mounted easily to the conduit in the thoracic cavity. The pulsatile flow could be generated in the pulmonary circulation by the device contraction. In the faster peristaltic contractile speed, the device could be generated larger pulsatile flow waveform. The animal experimental model could be constructed to reproduce the hemodynamic of Fontan circulation by using LVAD. In our model, it was represented to steady flow in the bypass circulation. In the pulmonary circulation of the experimental model, the flow fluctuation was included by heart beat and respiratory variation. For the further investigation to more effective assistance, it is considered to require the control method including synchronization with the heart beat or respiration. We examined the function of the device in the animal experimental model. And it was indicated that the pulsatility by the device could be generated pulsatile flow in device implantation.

SS09.3 - Biomedical Engineering at the Nanoscale: the Inspiration We can Draw from Endogenous Systems Interactions to Design the Nano-Bio Interface

Author(s): James C.Y. Kah

Department Of Biomedical Engineering, National University of Singapore, singapore/SINGAPORE

Nanomedicine can be described as biomedical engineering on the nanoscale where we seek to apply intelligent design to tackle health challenges. The last decade has seen tremendous growth in this field as studies on the various applications of nanotechnology in medicine and biotechnology form a sizeable aspect of modern day research. Biomedical applications of these nanoparticles have been reported in four major areas, namely, drug delivery, disease diagnostics, imaging and therapeutic applications as an outcome of man's ingenious design on the nanoscale. Nature's intelligent design has also created a range of endogenous biomolecules that exist in the same size regime as nanoparticles. In biology, however, there are numerous examples of biomolecular systems that far surpass any man-made machine in terms of efficiency, precision, and complexity. Natural endogenous biomolecules such as DNA and proteins often self-assemble, or interact with other biomolecules in order to perform their naturally intended function. Most often, these interactions between biomolecules are useful, if not critical, to the survival of the organism. In a similar manner, nanoparticles also demonstrate a high propensity to interact with other biomolecules to form the nano-bio interface. Intelligent design of this nano-bio interface is therefore crucial to the functionality of nanoscale systems in biology. In this talk, I will show how we can draw inspiration from nature and design appropriate nano-bio interface formed from DNA, proteins and peptides to probe and control biology in at least four ways: (1) to enhance efficiency of protein translation in vitro; (2) tune cellular response; (3) to enable loading and trigger release of drugs; and (4) to develop a cost-effective and instantaneous biomolecular assay. I will also be sharing some of our current research that involves understanding and engineering the nano-bio interface in molecular and cell biology.

SS09.4 - High Frequency Ultrasound Elastography and its Biomedical Applications

Author(s): Chih-Chung Huang

Department Of Biomedical Engineering, National Cheng Kung University, Tainan/TAIWAN

It is well known that the mechanical properties of soft tissues, such as elasticity, viscosity, and mechanical impedance, change depending on the conditions of tissues, for instance disease and age, hence

the mechanical properties may give useful information in medical diagnosis. Several ultrasound elastographs have been proposed to measure the mechanical properties of tissue quantitatively, such as sonoelastographic image, shear wave image, and acoustic radiation force impulse image. However, the image resolutions of above elastographs are insufficient due to their operational ultrasound frequency. It remains difficult to estimate the mechanical properties of smaller organs and tissues using current elastographs. Therefore, the high frequency ultrasound elastographs based on acoustic radiation force impulse imaging and shear wave imaging were proposed in our Lab to assess the mechanical properties of some micro-structure tissues, such as cornea, plaque, and vessel wall. In cornea study, a 50 MHz high frequency acoustic radiation force impulse (ARFI) imaging system were built for mapping the hardness of cornea. A dual frequency ultrasonic transducer was designed for this objective. The outer 10 MHz element was used to push the fibers in cornea and the inner 50 MHz element was used to detect the displacement of cornea. The experiments were carried out using artificial porcine cornea and a new algorithm for high frequency ARFI imaging was established. In plague study, a 40 MHz shear wave imaging system was built for measuring the elastic properties of blood clots. Furthermore, we applied our high frequency ARFI imaging and shear wave systems into intravascular ultrasound (IVUS). A concept of combining the high frequency AFRI and shear wave technology on IVUS for assessing the mechanical properties of thrombus and vessel was proposed in present study.

SS10 - IFMBE AWARDEES PRESENTATIONS

SS10.1 - IFMBE Otto Schmidt Award: Neuro-engineering for navigation, intervention and implementation in neurosurgery

Author(s): Karin Wårdell

Department of Biomedical Engineering, Linköping University, Sweden

Neurosurgery and neuro-intensive care are clinical areas in which highly specialized interventional, navigational and monitoring techniques are imperative for patient care and improved health in the society. The overall aim of our research is to developed and evaluate new methods and techniques for radical improvement of navigation, intervention and monitoring in neurosurgery. Topics of special interest are deep brain stimulation (DBS), optical techniques for intraoperative neuronavigation, brain microcirculation as well as the integration and translation of the new tools and methods for clinical use. In the DBS research we have developed a patient-specific modelling and simulation concept for investigation of the electric field around active DBS-contacts. This allows for visualization of the relative electric field changes in relation to the patient's anatomy by using MRI together with superimposed atlas structures. The simulation method has proven useful for clinical evaluations of movement and speech in Parkinson's disease and is now also introduced for new DBS-indications and brain targets. During the talk examples of both optical application in neurosurgery as well as projects related to DBS will be presented.

SS10.2 - IFMBE Vladimir Zworykin Award: Microfluidic Technologies for Disease Diagnosis, Therapeutics and Personalized Medicine

Author(s): Chwee Teck Lim

Provost's Chair Professor, Dept of Biomedical Engineering & Mechanobiology Institute, National University of Singapore

Our blood comprises ~5 billion cells in one cubic milliliter with red blood cells (RBCs) accounting for >99% of all cellular components suspended in protein-rich plasma. Besides blood constituents, pathogenic microorganisms or diseased cells can also be present in bloodfor certain diseases, which can present possible routes for disease detection, diagnosis and therapy. However, the presence of the large number of RBCs complicates removal of pathogens in blood as well as makes disease diagnosis such as detection of rare circulating tumour cells (CTCs) in blood of cancer patients extremely challenging. Here, we address these issues and demonstrate that physical biomarkers such as the unique size and deformability of diseased cells can be effectively used for their detection and separation from blood by using microfluidics. We do this by leveraging on the many inherent advantages of microfluidics such as high sensitivity and spatial resolution, short processing time and low device cost. We developed a suite of microfluidic biochips that exploit the principles of cell size/deformabilitybased separation as well as inertial focusing toperform high throughput continuous detection and separation of diseased cells. These simple, efficient and costeffective microfluidic platforms will be imperative in realizing point-ofcare (POC) diagnostics and invaluable for many downstream clinical and biological applications as well as personalized treatment.

SS10.3 - IFMBE John A. Hopps Distinguished Service Award: Medical and Biological Engineering: Celebrating the Past, Envisioning the Future.

Author(s): Robert M. Nerem

Georgia Institute of Technology

Over the past half century engineers have made enormous contributions to both an increased understanding of biology and biological mechanisms and to improvements in clinical treatments. For these many contributions by engineers and physical scientists, there is much to celebrate. From the study of blood flow, to the role of hemodynamics in atherosclerosis and the role of the vascular endothelium, to the development of new medical devices, to regenerative medicine and stem cell technology, the contributions of the medical and biological engineering community have had a major impact. This includes everything from advances in pacemakers to continuing efforts to understand "the rules of life" that determine cell function. As one further envisions the future, although the application of engineering to the medical area will continue to be important, such new areas as energy, the environment, and food will be an expanded part of medical and biological engineering. Already we are seeing an industrialization of biology with the biomanufacturing of chemicals today becoming a significant element of the economy of the U.S. and there are efforts focused on creating biological machines, ones that might not even exist in nature. Over the past half century the International Federation of Medical and Biological Engineering (IFMBE) has had a major leadership role, and in the world of the future, IFMBE will have to evolve its role in order to provide the leadership necessary for the global community.

SS10.4 - IFMBE Laura M.C. Bassi Award: Machine learning in ultrasound imaging

Author(s): Professor Alison Noble OBE FREng,

Technikos Professor of Biomedical Engineering, Oxford University Department of Engineering Science, Director, Institute for Biomedical Engineering (IBME), President of the MICCAI Society

Machine learning approaches to biomedical image analysis are gaining popularity encouraged by successes in the sister field of computer vision and increasing availability of large clinical and biological image databases.

This talk will describe how we are applying machine learning in ultrasound image analysis, an area where quantification by traditional image analysis methods is very hard due to the wide range of data qualities met in real world applications.

A major application area of interest is "womb-to-cot" imaging – imaging in pregnancy and early life. I will describe progress towards developing machine learning based solutions for ultrasound-based biomarker estimation and quantification. These solutions are designed to be "accessible" – or easy to use – by a clinical end-user, and hence suitable for application in community care and to support healthcare delivery in the developing world.

SS11 - ICSU BIO-UNIONS CLUSTER SESSION

SS11.1 - The Role of IUPESM in the ICSU Bio-Unions Cluster Author(s): <u>Herbert F. Voigt</u>

Biomedical Engineering, Boston University, Boston/UNITED STATES OF AMERICA

The Bio-Unions Cluster of the International Council for Science (ICSU) consists of 11 of the 32 International Scientific Unions that are Union-members of ICSU, of which the IUPESM (the International Union for Physical and Engineering Sciences in Medicine) www. iupesm.org/ is one. "The principal objective of IUPESM is to contribute to the advancement of physical and engineering sciences in medicine for the benefit and well-being of humanity."

ICSU's website states, "The International Council for Science (ICSU) is a non-governmental organisation with a global membership of national scientific bodies (121 Members, representing 141 countries) and International Scientific Unions (32 Members). ICSU's mission is to strengthen international science for the benefit of society. To do this, ICSU mobilizes the knowledge and resources of the international science community to:

Identify and address major issues of importance to science and society.

Facilitate interaction amongst scientists across all disciplines and from all countries.

Promote the participation of all scientists—regardless of race, citizenship, language, political stance, or gender—in the international scientific endeavour.

Provide independent, authoritative advice to stimulate constructive dialogue between the scientific community and governments, civil society, and the private sector."

The ICSU member unions fall into four clusters, one of which is the Bio-Unions Cluster. Since 2010, the Bio-Unions Cluster has been meeting among themselves to plan interdisciplinary activities, including:

a presence at each other's congresses,

the joint sponsorship of meetings, and

joint sponsorship of teaching activities.

In 2013, the Bio-Unions Cluster met in Paris a day before the ISCU Unions meeting. At that meeting additional decisions were made. They decided:

1) To meet at least once a year.

2) To create a school that meets in conference facilities on a Greek island.

3) To consider supporting satellite conferences in conjunction with a World Congress of one of the ICSU members.

4) To organize a session(s) at one of the Bio-Union Cluster's World Congress

5) To build into the Unions' budget money to support the Bio-Union Cluster's activities. (\$5,000 - \$10,000/year)

Our activities here today at IUPESM's WC 2015 demonstrate a continuing commitment made by the Unions in the Bio-Unions Cluster to uphold these activities. But there are additional opportunities related to long-term programs that involve ISCU. Two of ICSU's relatively new, long-term programs are: 1) Health and Wellbeing in the Urban Environment and 2) Future Earth (Global sustainability). IUPESM has resources and capacity to be helpful in both of these programs. For example, Future Earth, is a 10-year international research initiative "sponsored by the Science and Technology Alliance for Global Sustainability comprising the International Council for Science (ICSU), the International Social Science Council (ISSC), the Belmont Forum of funding agencies, the United Nations Educational, Scientific, and Cultural Organization (UNES-CO), the United Nations Environment Programme (UNEP), the United Nations University (UNU), and the World Meteorological Organization" (Future Earth Website). Biology is essential to Future Earth and therefore the Bio-Unions Cluster must establish a role for itself in this complex activity.

SS11.2 - The International Council for Science (ICSU) Bio-Unions Cluster

Author(s): <u>Nils Chr. Stenseth</u>¹, Herbert F. Voigt² ¹Université Paris Sud Xi, IUBS, Orsay/FRANCE, ²Health Technopole CENGETS PUCP, Pontifical Catholic University of Peru, Lima/PERU

The Bio-Unions Cluster of the International Council for Science (ICSU) consists of 11 of the 32 International Scientific Unions that are Union members of ICSU. This session will be an introduction to some of the ICSU Unions making up the Bio-Unions Cluster. It will include speakers, primarily Officers, from several of the Unions within the Bio-Unions Cluster, who will address their Unions' Mission and their interactions with ICSU and other Unions within the Bio-Unions Cluster. The Session Chair is Nils Stenseth, Chair of ICSU Bio-Union Cluster and President, International Union of Biological Sciences (IUBS). Other speakers are: K.Y. Cheung, President-Elect, International Union for Physical and Engineering Sciences in Medicine (IUPESM); Elaine Faustman, Secretary General, International Union of Toxicology (IUTOX); Pingfan Rao, Past-President, International Union of Food Science and Technology (IUFoST); Walter Boron, Secretary General, International Union of Physiological Sciences (IUPS) and Herbert Voigt, President, International Union for Physical and Engineering Sciences in Medicine (IUPESM). The session will end with an open discussion regarding the future activities of the ICSU Bio-Unions Cluster.

Bio-Unions Cluster/ICSU

ICSU's website states, "The International Council for Science (ICSU) is a non-governmental organisation with a global membership of national scientific bodies (121 Members, representing 141 countries) and International Scientific Unions (32 Members). SS16 - ADDRESSING GLOBAL CHALLENGES

SS16.1 - Bioengineering in the 21st Century Author(s): Robert M. Nerem Mechanical Engineering, Georgia Institute of Technology, Atlanta/ GA/UNITED STATES OF AMERICA

Bioengineering in the 21st Century

Robert M. Nerem

Georgia Institute of Technology

In the last half century the field of bioengineering has evolved from its beginnings with the medical device industry to one that is much broader today and will be even broader as we move further into the 21st century. In this span of more than 50 years, there has been a technological revolution in healthcare and also an educational revolution. In the 1950s as the medical device industry began to develop, engineers at universities in the traditional fields began to apply their expertise to problems in medicine. With the advent of the biological revolution, however, what subsequently emerged is an engineering discipline based on the science of biology, i.e. bioengineering. As this new discipline has evolved, the medical device industry has expanded and continues to be important; however, there are major trends in public health that are influencing and will continue to influence the development of bioengineering. These include a shift from acute to chronic disease, an aging population, the disparities in healthcare, emerging and re-emerging diseases, and the escalation in healthcare costs. In this there will be a transformation of medicine and there will be a need for the development of new innovative technologies. These are technologies that reduce healthcare costs, also ones that allow for imaging at the molecular level, and in addition technologies that will drive science just as science drives technology. There also will continue to be a focus at the cell and molecular level and the application areas of regenerative medicine and stem cell technology. Here engineers can take the lead in developing new, innovative enabling technologies. This includes high-throughput screening techniques, improved culture and differentiation systems, and in vitro models engineered to be more physiologic. The last of these include organ-on-a-chip models and engineered in vitro tumor models that can lead to a better understanding of cancer. Finally, for cell-based biomanufacturing there is a need for further advances in scaleup, techniques for real-time monitoring, and for process automation. It is clear that the engineering approach with its quantitative, systems-based thinking can contribute much more to advancing medicine than it has to date. Engineering analysis can be used to identify the components of highly complex biological systems and provide an understanding of how these components work together. Furthermore, computational models will be increasingly important in our efforts to achieve a better understanding of complex biological systems. For all of these areas it is the bioengineers that will create the reality of the 21st century age of biotechnology.

SS16.2 - ICT for Prevention of Non-Communicable Diseases Author(s): <u>Niilo Saranummi</u>

Health, VTT Technical Research Centre of Finland, Tampere/FINLAND

Non-communicable diseases (NCDs) – such as heart disease and stroke, cancer, diabetes, and chronic lung disease kill more people globally than infectious diseases and are responsible for about two-thirds of deaths worldwide. Six out of the seven most important risk factors for premature death (high blood pressure, high cholesterol, high Body Mass Index, inadequate fruit and vegetable intake, physical inactivity, and excessive alcohol consumption, smoking excluded) are related to diet and physical activity.

Our lifestyle choices combined with our social, built, and economic

environments influence the way our genes express in our dynamic phenotype and interactively contribute to health or disease. NCDs can to a large extent be prevented by following current health guidelines on diet, alcohol, physical activity, and smoking. Therefore, NCDs are often called lifestyle diseases.

Current thinking still views much of health promotion and prevention as relying on public health awareness campaigns to increase health literacy, education, feedback and support, as well policy and regulatory activities to decrease unhealthy behavior (e.g., regarding smoking, intoxicants, package labeling, and urban planning). Health statistics, however, show that the prevalence of NCDs is increasing around the world and that these efforts are only modestly effective in preventing disease and reducing the overall disease burden and health expenditure.

We need novel solutions to prevent disease and promote health, as well as to better manage NCDs while they occur. What is needed is an approach that *engages individuals* to manage their everyday health-related behaviors. Empowering people to manage their health and wellness and, if present, chronic diseases requires that two challenges are met.

The first is a disruption in the way health services are delivered and incentivized. The current illness-centered healthcare model needs to be replaced with a proactive health and wellness-centered model where people together with healthcare professionals manage their health and illness.

The second is to engage people to manage their health with innovative services and tools that people want to use and that provide them with the ability to respond wisely in health related situations. The new approach might be achieved with the following steps:

• Harness emerging mobile and ubiquitous digital technologies (sensors, mHealth apps, Internet of things (IoT), etc.) to collect comprehensive datasets on personal behavior in context while maintaining the required level of personal privacy and security;

• Liberate existing data; not just health or illness data but also data that are being already collected for various business purposes, such as loyalty cards in shopping for food and other items, credit cards telling a lot of our behavior, mobile phone use and location data etc.;

 Use data mining and systems modeling to build predictive models of personal behavior;

• Deploy these models combined with knowledge from systems medicine and behavior science to predict and anticipate personal behavior; and

• Provide users with personalized feedback at opportune moments that engages them to manage their health related behaviors.

SS19 - SOCIAL IMPLICATIONS OF TECHNOLOGY WORK-SHOP (IN HONOR OR OUR FRIEND & COLLEAGUE; DR LODEWIJK BOS)

SS19.1 - "Realizing and Preserving Privacy and Security for Self in Interoperable Global Healthcare Venues" Author(s): Robert Mathews

Office Of Scientifc Inquiry & Applications, University of Hawai'i, Honolulu & Hilo/HI/UNITED STATES OF AMERICA

Canadians and Americans have both been steadfast advocates for personal privacy since the birth of the two nations on the North-American Continent. However, in the 21st Century, the rate of digital technology proliferation, the widening range of technology adoption, and uses, all without a sufficiently broad and systematic construal, or comprehension, has produced a decay of long evolving frameworks for civil liberties, and the desecrations of more founded personal privileges. Nowhere has this decay been more conspicuously grand more recently than in the area of Healthcare practices within the United States. Will it be possible to arrest this decay? Are the 'loss of privacy' expansions reversible? How can Globally Interoperable Healthcare Services ever be a reality at all, where Patient's personal safety and security cannot be properly assured?

SS19.2 - Social Implications of Technology Author(s): Luis G. Kun

Private, Consultant, Vienna,/VA/UNITED STATES OF AMERICA

Wireless technologies and remote sensing when combined with social networks and geographical information systems are having a prominent role in the coordination, communication, planning, response and management to some of the most devastating disaster scenarios we have witnessed in the last few decades. On the other hand many issues we routinely experience with respect to solving health care or public health problems, such as medical errors, occur and are perpetuated because of our silos or stovepipes of information. The scientific community recognizes intimately that preparing for the provision of health care, and erecting our public health system of tomorrow, is not just a matter of converging heterogeneous technologies and science but of people and processes as well. As society prepares to shift the current systems into some where wellness and disease prevention will be the focus, society will face some major challenges. Many changes can affect positively medical and cost effective outcomes as well as the reduction and or elimination of medical errors and patient safety for example and yet privacy and security of personal medical information continue to be a major hurdle. Information Technology acting as a catalyst for change when combined with discovery and advances in research and development of new devices, and new drugs offers a multitude of avenues that were hard to imagine just a few decades ago. The convergence of science and technology open some doors of opportunity that may help diminish the polarization among the developed and underdeveloped nations. Society needs a systems approach and having a holistic view of the problem; to be able to see the whole and not just discrete pieces; and help determine, for example unintended consequences which are absent. Integration of multidisciplinary and interdisciplinary orientations and activities when trying to understand the problem and moving toward generating potential solutions are needed; yet present approaches are grossly insufficient in this respect. A new Global Health strategy where the public and private sectors work together will be presented as well as a wide range of opportunities that can start at the cellular, molecular and genetics levels and go as far as population health. A Global Economy that will be pushed to integrate surveillance and epidemiology for better protection against environmental threats and food borne diseases through the use of remote sensing data and a worldwide food enterprise architecture will also be discussed. The access to new

services such as home healthcare delivery and public health safety are generating a "new digital divide" discussion between those that have the means and those that don't. The current Internet Neutrality debate must incorporate these concepts in order to address new social challenges posed by the new technologies.

SS20 - EMBEDDED SENSOR SYSTEMS FOR HEALTH WORKSHOP

SS20.1 - Workshop on "Embedded Sensor systems for Health" Author(s): <u>Maria Lindén</u>, Magnus Otterskog, Mobyen Uddin Ahmed, Ivan Tomasic, Elaine Åstrand, Arash Ghareh Baghi, Mats Björkman Mälardalen University, Västerås/SWEDEN

Demographic changes, where the expected lifetime of people is increasing and many suffer from not one but several chronic diseases, are challenging our healthcare system. There is a clear need for wearable and distributed health monitoring systems, allowing people to continue their normal activities independent of location; at home, at work or in hospital. Monitoring of changes and trends in health status can facilitate early intervention and prevent severe conditions to develop, and new technology enables simultaneous monitoring of multiple physiological parameters. Hence, this can prevent suffering for patients and also means large savings for society. Moving the point-of-care from hospitals to homes is a trend that will increase in the future. The recent development of embedded sensor systems, the rapid development in wireless technology. and the ability to include intelligence in small, embedded sensor systems are all key enablers to achieve ambient monitoring of health conditions. To successfully address these issues, holistic system approaches are necessary, including not only sensor and hardware expertise, but also software expertise. The current workshop will bring together experts in these areas, and will address the need and potential in using embedded sensor systems for monitoring of health conditions in home environments, including the use of Internet, Wi-Fi, and smart phones. A keypoint addressed will be the starting point from clinical needs, thus the involvement of clinical experts is essential throughout the whole development process. Also the user-friendliness of the systems is essential. If not easy to use, there will be a large resistance against using the systems. Topics to be addressed in the workshop are sensor system applications, signal processing, intelligent decision support, and infrastructure. Further, decision support distributed in the system will be included, together with safe and secure transport and storage of physiological data, to ensure personal integrity of the persons being monitored.

SS22 - IUPESM-HTTG WORKSHOP ON INNOVATIONS IN THE USE OF MOBILE DEVICES IN HEALTHCARE

SS22.1 - IUPESM-HTTG Workshop on "Innovations in the Use of Mobile Devices in Healthcare"

Author(s): <u>Caridad Borrás</u>¹, <u>Kwan Hoong Ng</u>², <u>Yadin B. David</u>³, <u>K Siddique Rabbani</u>⁴, <u>Marlen Perez-Diaz</u>⁵, <u>Tobey Clark</u>⁶, <u>Colin G.</u> <u>Orton</u>⁷

¹Health Technology Task Group, IUPESM, Washington/DC/UNITED STATES OF AMERICA, ²Biomedical Imaging Department, University of Malaya, Kuala Lumpur/MALAYSIA, ³Technology Management, Biomedical Engineering Consultants, LLC, Houston/UNITED STATES OF AMERICA, ⁴Biomedical Physics & Technology, University of Dhaka, Dhaka/BANGLADESH, ⁶Study Center On Electronic And Information Technologies, Universidad Central "Marta Abreu"de las Villas, Santa Clara/CUBA, ⁶Instrumentation & Technical Services, University of Vermont, Burlington/VT/UNITED STATES OF AMERI-CA, ⁷Radiation Oncology, Wayne State University, Grosse Pointe/MI/ UNITED STATES OF AMERICA

Growing populations and shortages of healthcare workers paired with the explosive growth of mobile communications infrastructure over the last decade has sparked growing interest in the provision of health services through mobile and wireless technologies. This Workshop will address the use of mobile systems and devices such as smartphones, tablets, and laptops to address the unmet healthcare needs in rural/urban marginalized areas of the resourcelimited regions of the world, where health conditions and vital signs data acquired from geriatric, pediatric and infirm patients have to be communicated in a timely manner to adequately trained and gualified caregivers. The Workshop will bring together experts to assess the clinical needs to be fulfilled, to review some innovative solutions that are ready to be implemented and to identify benefits from implementation of such mobile systems by overcoming barriers and matching patient needs with solutions. These experts will address and demonstrate new devices (hardware and software) that provide improved healthcare at the point-of-care, will review communication aspects and telemedicine (sending data to and from remote experts for consultation, diagnosis and prescription), and will discuss how to assure continuum of care and remote support to improve the utilization and maintenance of existing equipment.

Specific topics to be addressed include: The state of TeleHealth, TeleMedicine, and mHealth; implementation, barriers and policy issues in industrialized and resource-limited regions; telecommunications, interoperability, regulatory and legal issues; telemedicine challenges and opportunities; development of new mobile-centric hardware to detect health conditions; development of healthcare applications using facilities and functions available in modern mobile devices; quality of service assessment; and evaluation of maintenance and sustainability issues. Following the formal presentations, there will be an open discussion between the audience and the Workshop participants, from which final conclusions and recommendations will be drawn.

SS25 - CHALLENGES AND BENEFITS OF CLINICAL ENGINEERING PEER REVIEW

SS25.1 - Challenges and Benefits of Clinical Engineering Peer Review.

Author(s): Jean Ngoie¹, Michael J. Capuano² ¹Biomedical Engineering, Niagara Health System, St. Catharines/ CANADA, ²Biomedical Technology, Hamilton Health Sciences, Hamilton/CANADA

Clinical engineering departments in Canada have the opportunity to be reviewed based on the CMBES Clinical Engineering Standards of Practice (CESOP). The process is designed to affirm well established programs, provide recognition of excellence in Clinical Engineering, and to provide programs with a baseline for improvement and knowledge exchange. The CMBES Peer Review Committee coordinates and approves all requests for review and assigns the reviewers (surveyors) to the requesting facility. Peer review requires the clinical engineering program to complete a pre-survey questionnaire and to provide information about the program including policies and procedures, organizational structure, explanation of processes, and demographics. A physical on-site visit is arranged lasting several days depending on the size of the organization and involves an equipment/work audit, interviews with staff and clients including senior management, tours of the facility, and review of department records. A summary report is provided after the review accompanied by a certificate of successful completion. This presentation will cover all of the above mentioned steps as well as past experiences and thoughts. Perspectives from the survey team and the reviewed will be presented including the benefits of Peer Review and the most challenging aspects of the process.

PLENARY SESSIONS

PL01 - WOMEN IN BIOMEDICAL ENGINEERING AND MEDICAL PHYSICS

PL01.1 - Engaging Women and Men for a Better Future Worldwide

Author(s): Monique Frize

Systems And Computer Engineering, Carleton University, Ottawa/ ON/CANADA

From the three approaches suggested by Londa Schiebinger to harness the power of gender analysis, this part of the presentation deals with the first two: "Fixing the number of women" and "fixing the institutions". Women and men can generate and participate in activities that lead to an increased participation of women in biomedical engineering and medical physics. Evidence also exists, demonstrating that there are economic benefits and more complete solutions created by gender balanced design teams and an increased number of women in decision-making bodies such as corporate boards, management teams in industry, government, and universities. It is critical to collect sex disaggregated data on undergraduate post-secondary enrolments and graduations in science and engineering, as well as to understand the gender participation in the workplace in these fields. Examining the issues that limit women's participation at all levels is a first step, which can then be followed by the development and implementation of strategies that help eliminate gender bias and provide the necessary support for women to have a successful career in these fields.

PL01.2 - Gendered Innovations in Health & Technology Author(s): Londa Schiebinger

Stanford University, Stanford/UNITED STATES OF AMERICA

How can we harness the power of gender analysis to discover new things? Schiebinger identified three major approaches to gender in science research, policy, and practice: 1) "Fix the Numbers of Women" focuses on increasing women's participation; 2) "Fix the Institutions" promotes gender equality in careers through structural change in research organizations; and 3) "Fix the Knowledge" or "gendered innovations" stimulates excellence in science and technology by integrating sex and gender analysis into research. This talk focuses on the third approach. Gendered Innovations: 1) develops state-of-the-art methods of sex and gender analysis for scientists and engineers; and 2) provides 24 case studies as concrete illustrations of how sex and gender analysis leads to new ideas and excellence in research. Several case studies will be discussed, including stem cells, assistive technologies for the elderly, and osteoporosis in men. All case studies can be found at: http://genderedinnovations.stanford.edu/. To match the global reach of science and technology, this project was developed through a collaboration of over sixty experts from across the United States, Europe, and Canada (and has now extended to Asia). Gendered Innovations was funded by the National Science Foundation, the European Commission, and Stanford University.

PL03 - URBAN HEALTH AND FUTURE EARTH / GLOBAL HEALTH CHALLENGES

PL03.1 - The Changing Urban Environment and Health in a Future Earth

Author(s): Gordon Mcbean Western University, London/ON/CANADA

Around our planet there have been increasing numbers of disasters due to floods, storms, earthquakes and other natural hazards. Although earthquakes are most horrific when they happen, climaterelated events cause about three-quarters of all disasters and as the climate warms, these hazards are increasing. There is also the migration to people to major cities, often on coasts of the oceans or major rivers. The result is the intersection of the effects of the major issues of climate change, disaster risk reduction and sustainable development. In all cases we need to look to the future and takes actions now to reduce losses in the future.

In 2015, nations will negotiate a revised framework on action on disaster risk reduction, a possible Paris-protocol on climate change and Sustainable Development Goals to be attained by all countries by 2030. The draft list of SDGs includes: end poverty and hunger; attain healthy life for all at all ages; secure water and sanitation; and build inclusive, safe and sustainable cities and human settlements. For the global science community, the challenge is providing the scientific basis for definitions and approaches, including how to achieve these goals and the criteria for measurement of progress.

This presentation will bring together these issues in the context of the new international research programs Future Earth: Research for Global Sustainability; Integrated Research on Disaster Risk; and Health and Wellbeing in the Changing Urban Environment: a Systems Analysis Approach; with a Canadian-funded project, Coastal Cities at Risk: Building Adaptive Capacity for Managing Climate Change in Coastal Megacities. The Future Earth program is adopting an approach to involve the stakeholder community in the research program from the beginning to co-design and co-produce the research based on the logic that this will make the research most directly relevant to societies needs to address these issues. The Coastal Cities research project is integrating across social-natural-economic-engineering and health sciences to develop a systems approach to quantifying urban resilience and then undertake "what if" experiments to identify the most effective approaches to improving resilience and reducing impacts, recognizing the complex interactions across these elements of society.

The International Council for Science is leading the Science and Technology Major Groups to input to these UN processes and will endeavour to bring these scientific principles to the negotiations. Working with UN agencies such as UNESCO, UNU and WMO, and non-governmental partners such as the Inter-Academy Medical Panel, the Council will continue in the coming decades to assert the importance of scientific bases for these international agreements and national actions. We need to have the full support of medical physicists and biomedical engineers engaged in supporting health care in diverse environments in order to achieve these societal objectives, consistent with the Council's Mission to strengthen international science for the benefit of society - all societies and all people.

PL03.2 - Global Health Challenges – Participating in the Health Revolution

Author(s): Mary Gospodarowicz

Professor of Radiation Oncology, University of Toronto/CANADA. Medical Director, Princess Margaret Cancer Centre, and Regional Vice President, Cancer Care Ontario

The last century witnessed staggering increase in life expectancy, massive population growth, and steady migration out of extreme poverty. With this came the epidemiologic migration from acute life limiting illnesses to chronic or episodic illness and disability. The global healthcare industry has struggled to keep up with this change.

Cancer is an escalating health problem with 15 million new cases each year and this number is projected to grow to 24 million in the next 15 years. Cancer control requires a robust healthcare system capable of implementing a comprehensive cancer control plan from prevention through early detection, accurate diagnosis, effective treatment, and optimal support.

Fortunately the 21st century offers great promise for healthcare. Increasingly health is seen as a human right and investment in health as an economic necessity. Universal access to healthcare and the universal health coverage are on the global agenda. Recent increase in investment in healthcare such as seen in GAVI, Global Fund, PEP-FAR, and other programs is producing results faster than expected in some aspects of healthcare but the same level of investment is still to be applied to cancer.

The complexity and cost of cancer care calls for massive innovation to reduce the expected deaths and suffering. Rapid introduction and dissemination of new technologies (information, imaging, robotics, etc.) has potential for a huge humanitarian and economic benefit.

PL04 - EVIDENCE AND HEALTH INFORMATICS

PL04.1 - Academic Biomedical Informatics: Synergies and Challenges at the Interface with Industry Author(s): Edward Shortliffe

College Of Health Solutions, Arizona State University, Phoenix/ UNITED STATES OF AMERICA

Academic biomedical informatics has achieved great successes through research contributions and education of professional informaticians over several decades, now reflected in a thriving commercial marketplace for electronic health records and other informatics tools. That very success, coupled with changes in the ability of governments to support research at past levels, is forcing a reconsideration of the directions and emphases for faculty members in informatics academic units. In this presentation Dr. Shortliffe will discuss those forces and propose areas of emphasis that will strengthen the academic discipline as it continues to evolve. He will distinguish the roles of academic informaticians as practitioners of informatics, as researchers, and as educators. He will also stress the necessary synergies between academic informatics and the health information technology industry, arguing that both will be strengthened by more fertile relationships and joint efforts.

PL04.2 - Cognitive Challenges for Safe Human Computer Interaction

Author(s): Vimla Patel

The New York Academy of Medicine and Columbia University, New York/UNITED STATES OF AMERICA

Given the complexities of modern medicine, delivery of safe and timely care is an ongoing and recognized challenge. Errors, misunderstandings, and inaccuracies-large and small-are routine occurrences in healthcare delivery. Health information technology (IT) has undoubtedly reduced the risk of serious injury for patients. However, its true potential for preventing medical errors remains only partially realized. Unfortunately, such systems may even give rise to hazards of their own. There is a growing recognition that many errors are attributable neither solely to lapses in human performance nor to flawed technology. Rather they develop as a product of the interaction between human beings and technology. In our view, errors are the product of cognitive activity in human adaptation to complex physical, social, and cultural environments. How well the design of health IT complements its intended setting and purpose is critically important for safe and effective performance. In this presentation, I will discuss the cognitive challenges we face in understanding human-computer interaction (HCI) that make the integration of computing and clinical practice a difficult task that, improperly addressed, can lead to threats to patient safety.
