IFrom the results it is evident that the way the equipment is maintained directly affects its performance, lifespan and quality of care to patients and the need for capacity of staff handling the equipment need not be overemphasised.

The paper recommends a comprehensive assessment be carried out in the entire country and should cover entire hospital.

SP042.7 - Mathematical Model for Reliable Maintenance of Medical Equipment

Author(s): <u>Abdelbaset Khalaf</u> Clinical Engineering, Tshwane University of Technology, Pretoria/ SOUTH AFRICA

This paper proposes a mathematical maintenance model that analyses the effect of maintenance on the survival probability of medical equipment based on maintenance history and age of the equipment. The proposed model is simulated in Scilab using real data extracted from maintenance history of Anaesthesia Machine from Draeger. The analysis using survival approach reveals that conducting preventive maintenance (PM) on the selected medical equipment had a positive impact on survival of equipment. The model is then used to analyse the cost of maintenance scenarios and an appropriate scenario is proposed for Anaesthesia machine. A new failure-cost model is developed which may be used to calculate the number of failures of equipment and the annual maintenance cost. The proposed models may be used as a planning tool for selecting maintenance strategies for various medical equipment.

SP043 - Women in BioMedical Engineering

TRACK 18: GENDER, SCIENCE AND TECHNOLOGY

SP043.1 - One thousand years of women in science Author(s): Monique Frize

Systems And Computer Engineering, Carleton University, Ottawa/ CANADA

Since the beginning of documented history, in every epoch, women have made significant contributions in science and technology. The challenge, since historians have mainly concentrated on men's work, is to find these women and discover what they have done. A few examples will be presented in this paper, but interested persons can find many books and websites with biographies of women in science and medicine. A few books and websites include women in engineering and technology.

In the 4th century, Hypatia of Alexandria (c.355-415) is said to be the world's leading mathematician and astronomer of her time. She was a popular lecturer on philosophical topics, attracting many students and large audiences. In the middle ages, women became involved in alchemy, herbal medicine, midwifery, and science in its fullest meaning. For example, Hildegard von Bingen (1098-1179) mentioned heliocentricity nearly 400 years before Copernicus and speculated about universal gravitation 500 years before Newton, composed music, and wrote on medicine and natural history. The renaissance counts many women astronomers that include Sophia Brahe (1556-1643), Maria Cunitz (1610-1664), Maria Winkelmann (1670-1720) and Margaret Cavendish (1623-1673) who published extensively on natural philosophy and early modern science, including over a dozen original works. With revised works, this brings her total number of publications to twenty one. Women were also patrons and correspondents of men like Queen Christina of Sweden and Elizabeth von der Platz. The 18th and 19th centuries count numerous women involved in serious science and mathematics such as Laura Bassi, Maria Gaetana Agnesi, Émile du Châtelet, Christina Roccati, Mary Somerville and many others. Only in Bologna and Padua were women granted doctoral degrees in the 18th and early 19th centuries, before women in general were admitted to University starting from the 1870s.

The presentation is meant to stimulate interest in the discovery of women who came before us and especially to demonstrate the importance of collecting papers and archives on women, their life, and their work. The active participation of women in science activities in all epochs, in spite of important obstacles they faced, is a model for girls and women today, since it is much easier now to follow this path than it has been in all past eras. We should be truly inspired by these stories and dream in our own way about the road we wish to follow.

SP043.2 - Creating the Memories and Celebrating the Legacy of Women in Science and Engineering Author(s): <u>Ruby Heap</u>¹, Monique Frize²

¹History, University of Ottawa, Ottawa/ON/CANADA, ²Systems And Computer Engineering, Carleton University, Ottawa/CANADA

For centuries, women around the world have actively participated in science and engineering, both formally and informally. Unfortunately, their contributions as innovators and producers of knowledge in these fields remain, to a large extent, unknown or understated. The history of women scientists and engineers is still in its infancy in a large number of countries. One major reason is their invisibility in traditional and established archives, which collected male records and tended to privilege the life and work of men; but another key obstacle has been these women's inclination to underestimate their own accomplishments, with the result that most did not seek to preserve their papers, and neither did their family, friends, and colleagues. At a time when the call for more women in science and engineering careers resonates strongly within governmental, economic and academic circles, and when there is a strong consensus regarding the benefits of gender equity and increased diversity in these fields, there is a pressing need to provide current and future women scientists with an accurate and inspiring understanding of their past, to learn about the lives and contributions of those who came before them.

This session will discuss an ongoing Canadian initiative which aims to research, recover, and celebrate the lives of women through the creation of an Archives of Women Scientists and Engineers in Canada. Sponsored by the INWES-ERI (International Network of Women Engineers and Scientists-Education and Research Institute), this initiative was launched at a workshop held in September 2014 at the University of Ottawa. Close to 50 participants -engineers, scientists, archivists, librarians, historians, policy makers- discussed the Archives project, along with partners such as the University of Ottawa, IBM Canada, The Canadian Commission for UNESCO, the US Society of Women Engineers (SWE) and a grant from the Social Sciences and Humanities Research Council (SSHRC). An action plan was adopted by the participants and a multidisciplinary Task Force was established to help proceed with its implementation. The main features of the action plan will be discussed in this session: the first steps include building an inventory of existing archives in major local, regional, and national repositories, and in major professional associations and organizations in science and engineering; with the assistance of SWE, we also intend to produce a Best Practices Guide to the discovery, recovery, and preservation of archives (manuscript, printed, audio-visual, digital) on women scientists and engineers.

In this interactive session, participants are invited to exchange with the speakers on approaches, programs and projects that might be developed to document the lives and careers of members of their organisations, document public conferences and exhibitions, books, brochures, oral testimonies, and the preservation of records of scientists and engineers.

SP043.3 - Women In Bio-Medical Engineering In Kenya Author(s): Salome W. Mwaura

Bio-medical Engineering, MBAGATHI DISTRICT HOSPITAL, NAI-ROBI/KENYA

Women are often referred to as the weaker sex and in most communities in Kenya, they are regarded as children. It takes a lot of time for male Managers of health facilities to accept them in decision making.

As a primary school going girl, we took my brother to the local district hospital but the Doctors could not fully diagnose his condition due to some equipment in the laboratory and X-ray department

malfunctioning. In my mind, I was wondering what could have been wrong with the equipment and I decided that when I grow up, I must study the course for repair of equipment in hospitals.

After my "O" levels, I got three carrier opportunities in Medical Laboratory, Nursing and Medical Engineering. With my little knowledge about medical engineering, and remembering the incident in hospital earlier, I chose to pursue Medical engineering.

In 1993, I was admitted for a three year Diploma course in medical engineering at Mombasa polytechnic. I joined the civil service in 1997 and I have worked in various hospitals including Kisumu and Nyeri level V and Mbagathi level IV. In 2006, I enrolled for a 2 Year Higher National Diploma course in medical engineering at the Kenya Medical Training College, Nairobi.

In 2006, I was appointed HOD of Bio-medical engineering Department at Mbagathi District hospital heading a team of 8 bio-meds of whom 6 were male. It was an uphill task but today, I can proudly say that my work relation with everybody is very good. I am always involved in decision making as concerns medical engineering in the hospital by the hospital management.

I have attended several trainings. GAME, an American NGO organised one on theatre and ICU equipment in Kisumu, another one by JICA in Nairobi and another in South Africa by SAFHE/CEASA. I have also been to DITEC, USA for an advanced course in X-ray and Imaging.

I am a Member of AMEK which I have served in several capacities, and currently am the Treasurer. I have attended several conferences organised by the International Federation of Hospital Engineering (IFHE). I attend all annual conferences/events organised by AMEK and biennial East African conferences organised by the East African Country associations on rotational basis, the most recent one was in Kigali, Rwanda in December 2014.

Challenges

Biomedical engineering in Kenya is male dominated. Hence, fighting for recognition and appreciation by bosses is a major challenge in the field.

When it comes to factory training, most opportunities are given to men in the ratio of one out of ten.

Working with bosses who come from communities that do not recognise women plays a major role in demotivating women in their day to day operations.

Conclusion

There is need to support these ladies who are doing everything possible to give quality work in medical engineering and give them a chance as they have the capability.

They also need to be empowered academically in order to shine better in the field.

SP043.4 - Physics is a waste of your intelligence

Author(s): Shada Wadi-Ramahi

Biomedical Physics, King Faisal Specialist Hospital and Research Center, Riyadh/SAUDI ARABIA

Going to physics was not an easy road. It was unheard of that students who score high in the Jordanian SAT go to science. My parents were outraged. Graduating first in class in 3.5 years, still did not convince them. I was wasting my time and college was a waste of their money. Fast forward to 2003, I graduate with a PhD in Medical physics from the US. Time to go home. I land a position in the country's leading cancer center, joining a team of 7 physicists. It was not easy to be the only one with a higher degree in physics, most of the problems though did not come from fellow physicists, but from the chairman who could not handle having a "doctor" female staff. In official communications I was always referred to as "Ms." instead of "Dr.". The excuse was "you are like my daughter". Later the attitude escalated. In one of my earlier meetings with linac vendors in 2004, I challenged the representative of a company on one of his claims. The chairman annoyed that I spoke up, yelled "Hey girl stop this"! It took a good year before attitudes changed to formal behavior At least on paper.

The policies of the institution prevented discrimination, and later I became the head of medical physics. However, harassment came in many forms; it was encouraging male physicists (my subordinates) to side step me and report to the chairman directly, it was over-rid-ing the staff work schedule often after I distribute it (something that never happened to the chief technician ... a male), it was ridiculing my expertise even after I obtained ABR certification, It was stopping warning letters addressed to staff members who yelled at their supervisor (me). Harassment took many forms and shapes. Did I think about leaving? Yes, I wanted to go "back" to the US.

I loved my profession and I was determined not to let a male-dominated culture sway me off track. I am in my country contributing greatly to the treatment of cancer patients, and if I am not part of the force of change then I am a quitter. I endured.

Eleven years later in 2014, when I announced I am leaving to a position in another highly competitive institution in the region, my chairman gave me a counter offer and tried hard to convince me to stay. The offer was generous, and the emotions were real. It was a moment of vindication, my dedication to work and perseverance paid off. Alas, it was time to move on.

Women in science world-wide are a minority, in the Middle East they are a rarity. Women in science in the Middle East who assumes higher positions in par to their male colleagues are a species of their own.

I am proud of my achievements ... I am proud to call myself a medical physicist ... I am proud to call myself an Arab, but above all I am proud to be a woman.

SP043.5 - Medical physics – or how a change in career path becomes a passion

Author(s): Loredana G. Marcu

School Of Chemistry And Physics, University of Adelaide, Adelaide/ SA/AUSTRALIA

I was trained as a physicist in a country under transition after half a century of communism. I enjoyed being a student at the University of Timisoara (Romania) where I studied physics for six years under the guidance of some highly respected professors. After graduation, I was lucky enough to get a teaching position in my hometown at the University of Oradea, where, for the first time, I stood on the other side of the desk. While it was a great teaching experience, I felt that I needed something more for a fulfilled scientific life.

That was the moment of a life-changing decision: moving to Australia. In Adelaide, South Australia, I have been able to continue my scientific education in a specialised branch of physics that I fell in love with. I had the good fortune to be offered a scholarship to attain my PhD in Medical Physics. I got to work with an extraordinary group of people at the Royal Adelaide Hospital where I continued my career for nearly a decade. The people, the facilities and the working conditions all put together offered an optimal learning environment and a great source of inspiration. Radiobiology became my new passion, a field that I am continuously learning and which never ceases to amaze me.

In life circumstances and priorities change, so after ten years of learning, working and teaching in Adelaide, it was time to give something back to the country where I was raised and educated. I am now back on home soil where I have helped the Physics Department of the Science Faculty within the University of Oradea set up a Medical Physics training programme at both undergraduate and postgraduate levels. It is a wonderful feeling to pass on your own experience and teach students that have the same thirst for knowledge that I had at the beginning of my academic career. Medical Physics is a developing field in Romania and we need enthusiastic and welltrained specialists to raise this branch of science to European standards. The love and passion for this field should start from studenthood, and as the first woman medical physicist has once said "We must have perseverance and above all confidence in ourselves. We must believe that we are gifted for something" (Marie Curie).

SP044 - Bio-Impedance and Imaging (Other)

TRACK 01: IMAGING

SP044.1 - Personal Time-Varying Magnetic Fields Evaluation During Activities in MRI Sites

Author(s): <u>Giuseppe Acri</u>, Barbara Testagrossa, Giuseppe Vermiglio Dept. Of Sastas, University of Messina, Messina/ITALY

A person moving in and around the MRI site may experience strong time-varying magnetic fields. The physical consequence of the time variation of the magnetic flux density is the induction of currents in body parts. In this paper the time-varying gradient exposure associated with the magnetic flux densities is evaluated and measured. The acquired data, obtained from a personal magnetic dosimeter, represent the magnetic flux density function, B = B(t), related to the operator movement inside the MRI site. Such data have been processed to evaluate the corresponding dB/dt curves, that were estimated by calculating the time derivative. All the measurements were conducted on a 3.0 T MRI site, dedicated to research procedures, in two different conditions: at first during routine patient positioning, and secondly, simulating an emergency. In both the measurement conditions, two dosimeters, with different acquisition times, were simultaneously used. They were positioned the first time on the operator's torso and the second one on his head. The analysis conducted, simulating both normal and emergency conditions, demonstrated that the dB/dt peak values strictly depended on human motion through strong static magnetic fields, and, sometimes, exceeded the recommended limit. This consequence highlighted the necessity of drawing up, as in case of ionizing radiation, behavioural rules to be followed by workers and patients. Therefore it will be necessary to assess risk conditions in a proper manner.

SP044.2 - ECG Imaging of Ventricular Extrasystoles

Author(s): <u>Olaf Doessel</u>¹, Walther H.W. Schulze¹, Danila Potyagaylo¹, Rainer Schimpf², Martin Borggrefe²

¹Institute Of Biomedical Engineering, Karlsruhe Institute of Technology (KIT), Karlsruhe/GERMANY, ²First Department Of Medicine - Cardiology, University Medical Centre Mannheim, Mannheim/ GERMANY

Objectives: Frequent ventricular extrasystoles can lead to ventricular tachycardia and ventricular fibrillation and are therefore life threatening. They can be treated with RF ablation, provided the focus of the extrasystole is precisely known. Invasive ablation procedures can be accelerated significantly if the focus of the extrasystole is known beforehand from non-invasive measurements. This project aims at the localization of ventricular extrasystoles from Body Surface Potential Maps (BSPM).

Methods: 9 patients with frequent extrasystoles were selected. BSPM datasets and MRI images were acquired. The MRI data contained an enddiastolic dataset of the heart and a thorax scan. Heart, lungs, liver, spleen, stomach, kidneys and aorta were segmented. Tetrahedral meshes of typically 3000 nodes in the heart and 350000 nodes in the thorax were created for FEM calculations. A thorough localization and registration procedure for the electrodes was implemented. During the invasive procedure stimuli were given at various positions and the BSPM were measured. Finally the foci of the extrasystoles were ablated. Various algorithms of reconstruction of electrophysiological sources in the heart from BSPMs have been implemented and tested, e.g. Tikhonov (with and without bounds), activation times, model based optimization and Maximuma-Posteriori (MAP) estimates. Thorough validation was carried out by comparing the reconstructed foci with the ones found during the invasive ablation procedure.

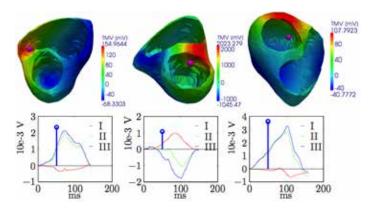

Figure 1: Three examples of reconstructed transmembrane voltages together with the true location of the extrasystole (pink bullet). **Method:** Tikhonov 2nd order. Blue bar indicates the time of reconstruction in the ECG (extracted from the BSPM).

Results: Figure 1 shows three examples. A median error of 20mm was achieved. This is somewhat disappointing but agrees with other publications with thorough validation of ECG imaging. The various reconstruction methods tested in this project deliver good results in one patient and worse results in another – no algorithm is the clear winner for all patients. The model based optimization performs slightly better as compared to the other methods.

Discussion: Despite the fact, that all the reconstruction algorithms mentioned above show very good results in computer simulations, the strict clinical validation uncovers some deficiencies. The results support the hypothesis, that the model assumptions that underlay all reconstruction algorithms are not yet perfect.

SP044.3 - Experimental Study on Amplitude Frequency of Acoustic Signal Excited by Coupling Magneto-Acoustic Field Author(s): Ren Ma, Shunqi Zhang, Tao Yin, <u>Zhipeng Liu</u> Institute Of Biomedical Engineering, Chinese Academy of Medical Sciences, Tianjin/CHINA

Object To study the relationship between exciting source characteristic and magneto-acoustic signal, also explore the frequency corresponding relationship between exciting signal and acoustic signal applied on the experimental sample. Methods A practical system has been established to detect magneto-acoustic signal. While single period sine pulse current with different amplitude and frequency were loaded in the sample of straight copper wire, acoustic signal was detected synchronously. Amplitude and frequency of exciting current and acoustic signal were analyzed by using time-frequency method, which was adopted by short time Fourier transform STFT and shifted smoothing rectangle window. Then, comparative study was conducted basing on the processed data. Result Giving the current same frequency as well as different amplitude, linear relationship is obtained between the output amplitude of acoustic signal and current amplitude. However, giving the current same amplitude as well as different frequency, the corresponding frequency spectrum of acoustic signal show different variation law, and thus, there is great difference among the system functions. Conclusion Detecting system is highly sensitive to frequency. In order to acquire more information in the magneto-acoustic signal, both of detecting circuit SNR and acoustic transducer bandwidth should be promoted.

SP044.4 - In vivo electric conductivity values of cervical cancer patients reconstructed with a 3T MR system for improved SAR determination

Author(s): Edmond Balidemaj¹, Peter De Boer¹, Henny P. Kok¹, Gerben Schooneveldt¹, R.F. Remis², C.A.T. Van Den Berg³, A.J. Nederveen¹, L.J. Stalpers¹, Johannes Crezee¹ ¹Radiotherapy, Academic Medical Center, Amsterdam/NETHER-LANDS, ²Technical University Delft, Delft/NETHERLANDS, ³University Medical Center Utrecht, Utrecht/NETHERLANDS

Introduction: Reliable tissue electrical conductivity (σ) values are required to determine the RF energy absorption for Hyperthermia Treatment Planning (HTP) or for Magnetic Resonance Imaging (MRI) for safety purposes. Currently used σ -values are mostly based on ex vivo measurements, and tumor σ is mostly unknown. Our aim is to acquire in vivo pelvic tissue conductivity for muscle, bladder and cervical tumor using 3T MRI.

Methods: Conductivity values were reconstructed using Electric Properties Tomography (EPT) which is based on the measurable B1⁺ field. Earlier we have validated this method for the pelvic region using phantom experiments and in vivo simulations. In this study, MR measurements of 12 cervical (squamous cell) carcinoma patients and one uterine adenocarcinoma patient were used to reconstruct σ -values in tumor, muscle and bladder. For a reliable σ -reconstruction the composition of a particular tissue should be relatively homogenous and sufficiently large (>3cm). Thus the σ of 9 tumors and 7 bladder fillings could be reconstructed. Results were compared to literature data.

Results: The reconstructed σ -values of muscle tissue were up to 35% elevated compared to literature values (Figure 1a). Moreover, the reconstructed σ -values of the bladder were up to 10 times higher than values currently used in human models for HTP (Figure 1b). Finally, for 75% of the squamous cell carcinomas the σ -values were 5-12% higher than the σ of muscle tissue found in this study. The reconstructed σ of the adenocarcinoma was 22% higher compared to muscle tissue.

Discussion & Conclusions: This study demonstrated the feasibility to measure the σ of healthy tissue and tumors in vivo. The measured conductivities were higher than reported in literature, which could probably be explained by the higher blood and water content during in vivo conditions. A decrease of σ after death has been reported for (human) liver, (animal) brain and (animal) muscle tissue. The present study showed that the commonly unknown tumor σ is 5-12% higher compared to the σ of muscle. The σ -value reported in the literature for bladder corresponds to bladder wall tissue, the volume percentage of which is lower than that of urine. However, this study shows that urine σ is much higher and shows a large inter-subject variation. Future studies will determine to which extent the reliability of HTP improves when using these patient-specific σ -values. These results are further interesting for applications such as MR safety and RF coil design for MR systems.

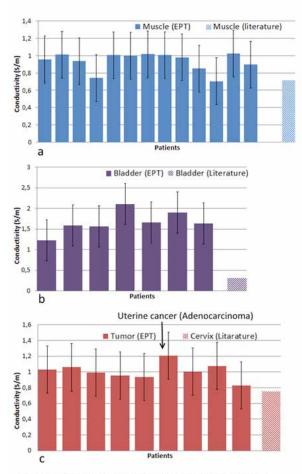

Figure 1. Reconstructed and literature conductivity values of muscle (a), bladder (b) and cervical tumor tissue (c).

SP044.5 - Focus Tunable Gel Lens Using Annular Dielectric Elastomer Actuator

Author(s): Thanh Giang La, Gih Keong Lau

School Of Mechanical & Aerospace Engineering, Nanyang Technological University, Singapore/SINGAPORE

Liquid lens, which is basically a soft capsule of oil or water, has recently been demonstrated capable of adaptive tunable focus. Its curvature changes can be activated by various means, mechanical, thermal, electrochemical or electrical. In mechanical or pneumatically activated liquid lens, change of liquid pressure or membrane stress can induce the curvature changes and thus the variable focus. Such variable focus liquid lens has a compact and lightweight design with integrated actuator, simpler than hard lenses'. However, it does not have as good shape stability as hard lens. The liquid capsule may sag under gravity if its size is larger than 1cm. In addition, the liquid lens may deform in response to vibration, causing image distortion. In contrary, human crystalline lens, which is made of gel, generally can function robustly despite orientation change and last for a long life time (>40 years).

Inspired by the human crystalline lens, we make use of solid-state silicone gel (Dow Corning Dielectric Gel Kit 3-4170) to build a tunable focus lens, which is electrically activated by an annular dielectric elastomer actuator. The annular dielectric elastomer actuator acts like ciliary muscles that control the eye's lens accommodation. Initially when the actuator is idle, the gel lens is flattened under the membrane pre-tension. Upon activation by the annular actuator that elongates, the gel lens bulges. Our experiment showed that this gel lens can vary focus on the objects between 2.5cm and 30cm when activated under voltages in range of 0-3kV at very small dc current of <20 µA. As such, the gel lens consumes low electric power of <60mW to work robustly more than 10,000 cycles. Furthermore, miniaturization of the dielectric elastomer actuators in term of membrane thickness could help reduce the driving voltage requirement. This gel lens showed good potential to be commercially adopted due to its enhanced shape stability.

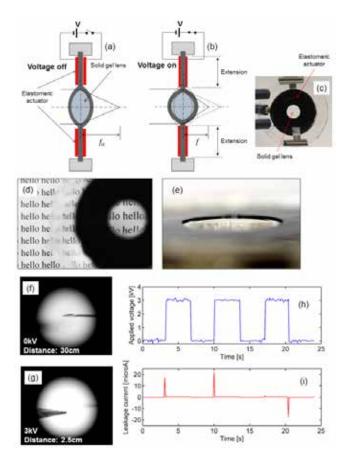

Figure 1. (a) Gel lens is configured with elastomeric actuator (unactivation). (b) The lens is activated by voltage V. (c) The device consists of a gel lens and an actuator. (d) Magnification of the convex gel lens is showed. (e) Photograph of the lens is in angle view. (f) At un-activated state, the lens focused on a far object (a needle) at 30cm-distance from its position. (g) Under 3kV, the lens focused on a near object (pencil) at 2.5cm. (h) External voltage is applied in onoff testing. (i) Dc current through actuator is <20microAmp.

SP044.6 - Ultra-low-field MRI for improving spatial accuracy of bioelectric source imaging

Author(s): Koos C.J. Zevenhoven

Department Of Neuroscience And Biomedical Engineering, Aalto University, Aalto/Espoo/FINLAND

In magnetoencephalography (MEG), one measures the extremely weak magnetic fields generated by electrical brain activity using an array of highly sensitive, typically superconducting magnetic-field sensors around the head. As a functional brain imaging modality, MEG surpasses functional magnetic resonance imaging (fMRI) in terms of temporal resolution and has a spatial accuracy superior to electroencephalography (EEG). However, the spatial accuracy is limited by coregistration, the procedure of aligning a structural image of the head with the MEG coordinate system. Typically, this is done manually by digitizing anatomical landmarks on the head in the MEG session and separately localizing corresponding points in a structural head MRI. Besides errors in identifying and digitizing the anatomical landmarks in both modalities, manual coregistration contains errors produced by a number of factors, such as the head-position measurement in MEG, distortions in high-field MRI, skin movements, and small differences between supine and seated positions regarding the geometry of the soft brain and cerebrospinal fluid.

The spatial coregistration accuracy is important not only for the alignment of electrical sources with the anatomy, but also for the reconstruction of the spatial origin of the signals, which depends on the geometry of the head and the changes in electrical conductivity across different tissues. As models for source localization become more detailed, their sensitivity to inaccuracies in geometry and conductivity values increases. The volume currents being particularly important in EEG, an accurate model of the conductivity structure is required especially for full benefit of the complementary information of simultaneous EEG and MEG. A hybrid MEG-MRI system provides natural approaches to addressing these issues.

At Aalto University, Finland, we have built a hybrid MEG-MRI system based on an array of sensors based on Superconducting QUantum Interference Devices (SQUIDs). The MRI is implemented at ultralow field (ULF), around 50 μ T, and measured inside a magnetically shielded room. The SQUID sensors tailored for ULF MRI can also be used for MEG. Together with the common sensor array, high-precision ULF-MRI electronics, and a stable coil structure, our novel algorithms can transform the largely manual coregistration problem to a fully automatic calibration, thereby eliminating human error and achieving sub-millimeter accuracy.

We describe the current state of our system and present obtained images. We further discuss the unique possibilities, shown recently, of ULF MRI in current-density imaging (CDI), potentially allowing also the imaging of electrical conductivity using the same hybrid device. We describe our methods, computations, and experimental setups for implementing the methods in our hybrid MEG-MRI device, along with preliminary results. If successful, conductivity imaging combined with sub-millimeter automatic coregistration will provide significant improvements to MEG and EEG source localization.

SP045 - Molecular Imaging PET/SPECT: Part 1

TRACK 01: IMAGING

SP045.1 - Quantitative accuracy of SPECT imaging with a dedicated cardiac camera: Physical phantom experiments Author(s): <u>Amir Pourmoghaddas</u>, R Glenn Wells Physics, Carleton University, ottawa/CANADA

Introduction

Recently, there has been increased interest in dedicated cardiac SPECT scanners with multi-pinhole designs and improved detector technology due to their improved count sensitivity and resolution over traditional parallel-hole cameras. However, the pinhole-collimator design introduces position-dependent attenuation, sensitivity and resolution variations. Differences in attenuation patterns and energy-spectrum responses compared to conventional SPECT scanners can also inhibit accurate measurement of activity distributions. Simple correction methods for these effects are easily implemented however their level of accuracy is unclear. In this study, we assess the quantitative accuracy and reproducibility of absolute activity measurements made using easily implemented correction techniques applied to controlled physical phantom experiments.

Materials and Methods

Activity in the cardiac compartment of an Anthropomorphic Torso phantom (Data Spectrum Corporation) was measured through multiple 99mTc-SPECT acquisitions (n=10). The ratio of activity concentrations in organ compartments resembled a clinical 99mTcsestamibi scan and was kept consistent across all experiments (6:1 heart to background, 1:1 heart to liver, 6:4 heart to lung ratio). To assess the effect of activity spill-in and increase scatter into the myocardium compartment, experiments were repeated with- and without activity in the soft-tissue torso compartment. The true net activity in each compartment was measured with a dose calibrator (CRC-25R, Capintec Inc). A ten minute SPECT image was acquired using a dedicated multi-pinhole cardiac camera with cadmiumzinc-telluride (CZT) detectors (Discovery NM530c, GE Healthcare), followed by a CT scan for attenuation correction (AC). Data were reconstructed with no corrections (NC), AC and AC with dual energy window (DEW) scatter correction (ACSC), using reconstruction with resolution recovery.

Results

T-tests comparing hot- and cold torso datasets (Table 1) showed no significant mean difference for all three reconstruction methods (NC, AC, ACSC: hot vs cold torso) (p>0.08). AC and ACSC significantly reduced the mean error over NC (p<0.001). The mean AC and ACSC errors were significantly different for the hot torso (p=0.04) but not for the cold torso (p=0.09), highlighting the effectiveness of DEW-SC in reducing errors introduced by photon scatter. While DEW-SC seemed to increase measurement uncertainty compared to AC in both cases, the increase was not significant (p \ge 0.2). Both AC and ACSC significantly increased uncertainty over NC for the cold torso phantom (p<0.03), but not for the hot-torso case (p>0.1).

Conclusions

CT-AC and an easily implemented DEW scatter correction significantly improve quantitative measurement of $^{99m}\text{Tc-SPECT}$ myocardial activity with a dedicated cardiac camera producing an error of <=2.2 +/- 6.5 %.

Table 1. Mean and standard deviation of errors between activity measured using reconstructed images vs true activity inserted into the cardiac compartment of the phantom. † indicates p<0.05 vs NC.

a) -		Measurement error			
		NC	AC	ACSC	
Hot Torso	Mean (%)	-77.5	5.5	-0.8	
(n=5)	SD (%)	2.0	4.6	5.0	
Cold Torso	Mean (%)	-76.4	1.6	-2.2	
(n=5)	SD (%)	0.9	3.21	6.5†	

SP045.2 - The Impact of time of flight algorithm and PSF modeling on standard uptake value in clinical PET/CT imaging Author(s): Mahnaz Shekari¹, Pardis Ghafarian², Mehrdad Bakhshayeshkaram², <u>Mohammad Reza Ay</u>¹

¹Tehran University Of Medical Sciences, Research Center for Molecular and Cellular Imaging, tehran/IRAN, ²Pet/ct And Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, tehran/IRAN

Introduction: Time Of Flight (TOF) and Point Spread Function (PSF) modeling are the most advanced reconstruction algorithms in PET/CT which dramatically improve the image quality. The aim of this study was to evaluate the impact of TOF and PSF modeling on Standard Uptake Value which is commonly used by physicians for staging of metastasis and monitoring response to therapy.

Materials and Methods: In this study, a whole-body ¹⁸F-FDG PET/ CT scan performed on 9 patients (BMI=25.4±1.21, 5.02±0.07 MBq per kg) using GE Discovery 690 PET/CT. The scanner was capable to reconstruct images with TOF, and also PSF modeling which is commercially named SharpIR algorithm. All PET data were reconstructed with HD+SharpIR (use for clinical report in this center), TOF, and TOF+SharpIR algorithms. 40 Focal points (short axis diameter of 1.1±0.38cm) were identified, and a semi-quantitative analysis was done by using SUVmean for normal lung tissue, SUVmax, and SUV50 for metastases. Furthermore, impact of lesion size, and location on SUV variation were assessed. We also evaluated noise in liver to analyze quality of clinical PET images.

Results: Our semi-quantitative analysis verify using TOF, and/or SharpIR algorithms significantly enhance SUVmax (15.95±3.38% for TOF, 33.01±3.1% for TOF+SharpIR), and SUV50 (16.37±3.43 for TOF, 34.4±3.23% for TOF+SharpIR) in compare with the image reconstructed using HD+SharpIR. The statistical analysis showed that for smaller lesions, TOF, and TOF+SharpIR lead to more robust changes in SUVmax, and SUV50(P-value<0.05). Figure.1 shows weak correlation between lesion location and SUV enhancement for both TOF, and TOF+SharpIR algorithms (R²=0.11, R²=0.03 respectively, P-value<0.5). Despite lesions, SUVlung wasn't affected by reconstruction algorithms. Image noise for TOF+SharpIR algorithm was similar to HD+SharpIR, but noise for images reconstructed with TOF algorithm were superior (p-value<0.001).

Conclusion: This study showed that SUVs of metastases are highly affected by reconstruction applied method. Based on our results, it can be concluded that it's vital to consider effects of TOF, and SharpIR algorithms on accuracy of SUV.

SP045.3 - Can Pacemaker and ICD degrade CT-Based Attenuation Corrected cardiac SPECT images?

Author(s): Zahra Etemadi¹, Ahmad Bitaran Rajabi², Hadi Malek³, Pardis Ghafarian⁴, Navid Zeraatkar¹, <u>Mohammad Reza Ay</u>⁵ ¹Research Center For Molecular And Cellular Imaging, Tehran University of Medical Sciences, Tehran/IRAN, ²Department Of Nuclear Medicine, Rajaei Cardiovascular, Medical & Research Center, Iran University Of Medical Sciences, Iran, assist.prof, tehran/IRAN, ³Cardiovascular Interventional Research Center, Department of Nuclear Medicine, Rajaei Cardiovascular, Medical, and Research Center, Iran University of Medical Sciences, Tehran, Iran., tehran/IRAN, ⁴Chronic Respiratory Diseases Research Center, National Research Institute Of Tuberculosis And Lung Diseases (nritld), Shahid Beheshti University of Medical Sciences, tehran/IRAN, ⁵Department Of Medical Physics & Biomedical Engineering, Tehran University of Medical Sciences, Tehran/IRAN

Introduction: Quantitative processing of myocardial perfusion is a questionable issue in the SPECT imaging due to the some artifacts such as attenuation. Although it has been demonstrated that CT-based attenuation correction (CTAC) technique can significantly improve the diagnostic accuracy of SPECT imaging, the presence of cardiac Pacemaker and ICD leads in CT imaging will impact the reconstructed myocardial perfusion SPECT image during the CTAC procedure. In this study we investigated and quantified the degradation magnitude of the metallic artifacts due to pacemaker and ICD leads on the CT-based attenuation corrected SPECT images using phantom studies.

Materials and Methods: A cardiac phantom with capability of including pacemaker and ICD leads was scanned in SPECT/CT scanner. Attenuation correction of the SPECT data was performed using the artefactual (metal artifact) CT images (Figure 1). Quantitative evaluation was performed between the actual activity and the measured activity concentration in the myocardial perfusion SPECT images without and with attenuation correction using the volume of interest (VOI)-based analysis on 17 myocardial segments.

Results: Quantitative analysis shows an overestimation of about 9% and 15% and an underestimation of about 6% and 11% in CT-based attenuation corrected SPECT images with pacemaker and ICD leads, respectively.

Conclusion: Since photoelectric interactions are more significant at CT energies and are dependent on atomic number, the metallic composition of pacemaker and ICD leads, especially ICD lead, can induce considerable artifacts on CT images. Despite the influence of cardiac lead-induced artefacts on inaccurate quantification of some segments of the myocardial perfusion SPECT images when using the CT-based attenuation correction process, however it does not induce erroneous clinical interpretation of the SPECT images corrected for attenuation using artifactual CT images. It can be concluded that implementation of down sampling and smoothing on the artifactual CT images for generation of attenuation map reduce the impact of metallic artifact during the CTAC of SPECT data.

SP045.4 - Impact of Point spread function modeling on tumor quantification in clinical PET/CT imaging

Author(s): Sahar Ahangari¹, Pardis Ghafarian², Mehrdad Bakhshayeshkaram², Mohammad Reza Ay¹

¹Department Of Medical Physics And Biomedical Engineering, Tehran University of Medical Sciences, tehran/IRAN, ²Pet/ct And Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, tehran/IRAN

Introduction: Quantitative assessment of PET images is increasingly used in cancer staging and therapy monitoring. In PET, partial-volume effects and point-spread function cause inaccuracy in estimation of lesion size and uptake. By regarding PSF-modeling during reconstruction procedure, the spatial resolution of PET images improves and as consequence the partial volume effect reduces. The aim of the present study was to evaluate the impact of PSF reconstruction (HD+SharpIR) compared with conventional OSEM reconstruction (HD) in non TOF PET imaging on quantitative accuracy of the lesions with respect to the lesion contrast.

Materials and Methods: In this study 17 patients (BMI:25.1±0.84) with 100 lesions were scanned using Discovery 690 PET/CT scanner. The patients were scanned 60 minutes after intravenous injection of 370 MBq of FDG (5.25±0.11MBq/kg). Emission data were acquired at 2 min/bed. All images were reconstructed using HD and HD+SharpIR algorithms with 3 iterations, 18 subsets, and 6.4 mm FWHM of post-smoothing filter. Image quality was evaluated by calculating COV (coefficient of variance) for a 3 cm spherical region in liver. The quantitative analysis was performed by measuring relative changes of standardized uptake values (SUV) and lesion size based on lesions location, and contrast with and without PSF-modeling. Contrast was defined as max activity concentration at lesion to mean activity concentration in background.

Results: Average of liver COV for HD and HD+SharpIR were 9.14 ± 0.36 and $7.38\%\pm0.33$ respectively. PSF modeling increased SUVmax by 12% compared with HD algorithm. The regression analysis showed that relative differences for SUVmax significantly increased with increasing lesion contrast (figure1, R²=0.41,p<0.001) and lesion distance from the central axis (R²=0.24,p<0.001). For lesions with contrast less than 3, SharpIR algorithm reduced the size of lesion to 4.36%, and for high-contrast lesions (contrast higher than 3) the size decreased up to 17.81%.

Conclusion: Image quality was improved by using of SharpIR algorithm. SharpIR performance was better in lesions with smaller size, further distance from the central axis and higher contrast. So the effectiveness of the algorithm is more in high contrast lesions.

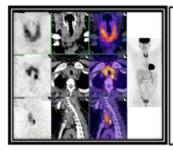

SP045.5 - Incidental Thyroid Cancer Identified on 18FDG- PET/ CT for Ovarian Cancer Evaluation-Case Study.

Author(s): Farid Y. Risheq¹, <u>Shuaa J. Al-Sadoon²</u>, Mohd Ziad F. Risheq¹, Dina Q. Zaqqa³, Ayman A. Qwarik²

¹Nuclear Medicine, FARID RISHEQ NUCLEAR MEDICINE PET/CT & BONE DENSITY CENTER, AMMAN/JORDAN, ²Physics In Nuclear Medicine, FARID RISHEQ NUCLEAR MEDICINE PET/CT & BONE DENSITY CENTER, AMMAN/JORDAN, ³Medicine, PRIVATE PRAC-TICE ENDOCRINOLOGY & DIABETES, AMMAN/JORDAN

Objective: This study presents the clinical significance of focal increased ¹⁸FDG uptake in the thyroid as incidentally identified on PET/CT for ovarian cancer evaluation. Ovarian cancer is known to metastases to the thyroid resulting in clinical hypothyroidism.

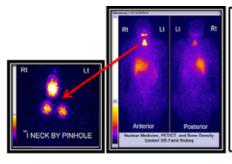

Clinical History and Results: A 54 year-old female with papillary adenocarcinoma of the ovary, underwent ¹⁸FDG-PET/CT post-surgery evaluation. ¹⁸FDG PET/CT was performed 1hr post IV ¹⁸FDG of 370MBq, (Fig. 1). A focal hyper metabolic lymph node lesion was visible in the left lower posterior deep cervical region with volume=12.4cm³, SUVmax=12.6. Thyroid was enlarged, focal nodular with irregular hyper metabolic ¹⁸FDG uptake in both lobes. The left and right lobes' nodule volume=(2.05; 2.4)cm³, and SUV-max=(9.58; 9.88) respectfully. The rest of the body showed normal and physiological ¹⁸FDG metabolism. Thyroid Function Test was advised.

(Fig. 1) Incidentally thyroid lesions identified on ¹¹FDG PET/CT; Coronal; Transverse; and Sagittal Planes. All views ¹¹FDG; CT without contrast; Fused PET/CT and MIP modality showed positive results. A focal hyper metabolic LN lesion in the left lower posterior deep cervical region with V=12.4cm³, SUV_{RM}=12.6. The thyroid was enlarged, focal-nodular with irregular increase in ¹¹FDG metabolism in both lobs; left lobe nodule with V=2.05cm³, SUV_{RM}=9.58 and right lobe nodule with V=2.4cm³, SUV_{RM}=9.88.

Results of TSH=7.9 IU/L, Tg=18.9 ng/ml, suggesting diagnosis of lymphocytic thyroiditis or differentiated thyroid cancer. The histopathology of US-guided FNAB samples showed: papillary carcinoma and Hashimoto thyroiditis; classical type. Tumor location: in both lobes with largest diameter: 3.5 cm. Lymph vessel invasion: present.

The patient underwent total thyroidectomy followed by ¹³¹I ablation dose of 3700 MBq. Post therapy ¹³¹IWBS and neck by pinhole showed three focal areas (3x2; 2x2; 2x1.8 cm²) of residual tissue in both sides of neck, (Fig.2).

(Fig. 2) ¹¹¹IWBS and neck by pinhole collimator performed 10 days post ¹³¹I ablation dose (after near thyroidectomy) showed faree focal uptake areas (residual tissue) on both sides of neck, (3x2; 2x2; 2x1.8) cm² of residual tissue.

Conclusions: Incidentally found hyper metabolism of ¹⁸FGD PET/CT in thyroid was due to papillary carcinoma, most probably metastases from ovarian cancer. Elevated serum levels of TSH hypothyroid and Tg were significant with incidental finding of focal increased uptake.

We recommend that for patients with ovarian cancer; metastatic disease to thyroid should be considered, especially when PET/CT scan showed focal hyper metabolic lesion in the thyroid or elevated TSH. Further work is needed aiming at assigning a threshold level of SUVmax in thyroid to differentiate benign from malignancy.

SP045.6 - Zinc material filter for scatter correction in Tc-99m myocardial SPECT imaging: Heart thorax phantom study Author(s): Nazifah Abdullah¹, Syed Inayatullah Shah¹, Ahmad Za-karia², Abdul Rahim Md Shahrir³

¹Allied Health Science, INTERNATIONAL ISLAMIC UNIVERSITY MALAYSIA, KUANTAN, PAHANG/MALAYSIA, ²Health Science, UNIVERSITI SAINS MALAYSIA, KUBANG KERIAN, KELANTAN/ MALAYSIA, ³Radiology, INTERNATIONAL ISLAMIC UNIVERSITY MALAYSIA, KUANTAN/MALAYSIA

SPECT is one of the techniques which provide the high diagnostic accuracy for the assessment of myocardial perfusion. However, the limitation in the diagnostic accuracy in the presence of Compton scattered photons in the image data. And the procedure is more complex in heart thorax phantom compared to homogenous volume.

Thus, this work focuses on the investigations into the effect of Zinc (0.1mm and 0.198mm) material filter on image quality. The anthropomorphic torso phantom was used to perform the experiments. Data acquisition was obtained with the dual head gamma camera (Infinia GE Hawkeye II), equipped with low energy high resolution (LEHR) collimators. The gantry performed a 90° rotation, thus covering 180º (dual-head) with thirty six projections using step and shoot acquisition and with total 2400 kcount. Matrix size 128 x 128 was used with window widths of the energy 20% by using a Tc99m source at 140 keV. The data was reconstructed by a filtered back projection method of Butterworth filter of order 10 and cut off frequency 0.4 cycles/cm was applied. The value of Chang's attenuation correction method was applied by selecting 0.164/cm linear attenuation coefficient. Image quality was analyzed by measuring contrast of lateral, anterior and septal defect using system software Xeleris 2.0. Images tomogram in Short Axis (SA), Vertical Long Axis (VLA) and Horizontal Long Axis (HLA) were also analyzed visually using MATLAB software with and without material filter. Results show that the contrast of the defect-to-healthy myocardium for lateral defect decreased with implantation of material filter compared to without filter, but for anterior defect the results were vice versa. For the septal defect there were slight decrease and increase for Zn 0.1mm and Zn 0.198mm compared to without filter, respectively. For the signal to noise ratio, with usage of Zn 0.1mm, the results show progression for lateral, anterior and septal defect compared to without the filter but is shown decrease for Zn 0.198mm. There was an insignificant decrease for left-ventricle-(LV) to-healthy myocardium contrast with implementation of material filter compared to without a filter. Qualitative analysis shown enhancement image guality for image obtains from Zn filter compared to without a material filter. So the application of the material filter in SPECT imaging has the potential to enhance the quality of the images, so it can increase the accuracy in the interpretation.

SP046 - Assessment of Radiotherapy Response

TRACK 04: RADIATION ONCOLOGY

SP046.1 - Early prediction of lung cancer recurrence after stereotactic radiotherapy using texture analysis of automatic graph cuts segmentations

Author(s): <u>Sarah A. Mattonen</u>¹, David A. Palma², Cornelis J.A. Haasbeek³, Suresh Senan³, Aaron D. Ward¹

¹Department Of Medical Biophysics, The University of Western Ontario, London/CANADA, ²Division Of Radiation Oncology, London Regional Cancer Program, London/CANADA, ³Department Of Radiation Oncology, VU University Medical Center, Amsterdam/ NETHERLANDS

Purpose: Stereotactic ablative radiotherapy (SABR) is becoming a standard treatment option for patients with early-stage lung cancer, and can achieve local control rates comparable to surgery. However, following SABR benign radiation induced lung injury (RILI) appears as radiographic changes on computed tomography (CT) imaging. These changes can be tumour-mimicking, making it difficult to distinguish recurrence from benign RILI. Current approaches do not reliably detect recurrence within a year post-SABR. Our previous work has shown the ability of CT texture features calculated within manually delineated regions of interest to predict recurrence post-SABR. The purpose of this study was to evaluate the accuracy CT texture features extracted within automatically derived regions of interest for prediction of eventual tumour recurrence.

Methods: We analyzed 22 patients with 24 lesions (11 recurrence, 13 RILI). Two regions of common post-SABR changes were manually delineated: consolidative and ground-glass opacity (GGO), shown in red and green respectively in Figure 1. The consolidative regions were also automatically delineated using a *OneCut* graph cuts algorithm with the only operator input being the single line segment measuring tumour diameter, normally taken during the clinical workflow. Surrogate GGO regions were approximated by automatic expansion of the consolidative regions. Within the GGO regions, second-order texture features from grey-level co-occurrence matrices were calculated. Classification was performed using a linear Bayes normal classifier and evaluated using cross-validation (CV).

Results: Leave-one-out CV on images taken 2–5 months post-SABR showed robustness of the entropy texture measure, with classification error of 26% and area under the receiver operating characteristic curve (AUC) of 0.77 using the automatic segmentation; the results using a fully manual segmentation were 19% and 0.80 respectively. Using our fully automated approach, AUCs for this feature increased to 0.82 and 0.93 at 8–14 months and 14–20 months post SABR, respectively, suggesting even better performance nearer to the date of clinical diagnosis of recurrence.

Conclusions: Texture features calculated within GGO delineated from a fully automated algorithm using only an input diameter measurement have shown the potential to predict recurrence in individual patients within 6 months of SABR, eliminating the need for any manual delineations. Based on our ongoing validation on a larger sample, we aim to develop a computer-aided diagnosis system which can be integrated into a physician's workstation to improve their assessment of response post-SABR. This could allow for earlier salvage for patients with recurrence, and result in fewer investigations of benign RILI.

(A) Recurrence

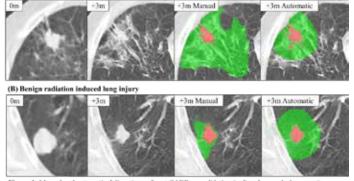

Figure 1: Manual and automatic delineations of post-SABR consolidative (red) and ground-glass opacity (green) findings at 3 months follow-up for a patient with recurrence (A) and radiation-induced lung injury (B). The zero-month (0m) time point indicates the pre-treatment lesion.

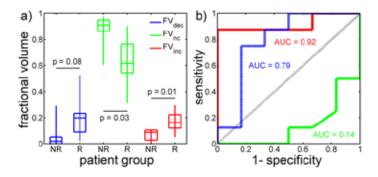

SP046.2 - Can parametric response maps predict voxel-wise treatment response? Implications for locally adaptive radiotherapy.

Author(s): <u>Anthony Lausch</u>¹, Timothy P.C. Yeung¹, Enrico Fainardi², Ting Yim Lee¹, Jeff Chen¹, Eugene Wong¹

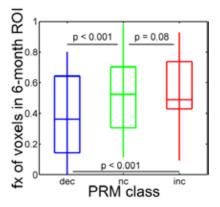

¹Medical Biophysics, The University of Western Ontario, London/ CANADA, ²Neuroradiology Unit, Department Of Neuroscience And Rehabilitation, Azienda Ospedaliero-Universitaria, Ferrara/ITALY

Parametric response map (PRM) analysis is a voxel-based image analysis method for predicting treatment response which shows promise as a means for guiding locally adaptive radiotherapy (RT) (e.g. sub-volume boosts). However to date, PRM predictive utility has been primarily verified with respect to global outcomes such as overall survival (OS). Here we investigated whether voxel-wise treatment response information can be inferred from a PRM analysis that has been correlated with OS.

PRMs were generated from rigidly registered MRI-derived apparent diffusion coefficient (ADC) maps (1 and 3 months post-RT) for n = 14 patients treated for high-grade glioblastoma. PRMs indicated whether each tumour voxel had undergone a significant increase, decrease, or no significant change in ADC. The fraction of the tumour volume (fractional volume) classified by the PRM as significantly increasing in ADC (FVinc) was the only PRM measure found to be significantly correlated with OS ($\rho = 0.63$, p = 0.02, Spearman rank test). FVinc values were then used to classify responding patients (R; OS > 18 months) in a receiver-operating characteristic analysis which produced an area under the curve of 0.92 (Fig. 1).

To investigate voxel-wise treatment response, the fraction of voxels in each PRM class that remained within the tumor boundary at 6 months post-RT was computed for each patient (Fig. 2). Despite the positive correlation with OS, significantly increasing ADC voxels (red) were found to be more likely to remain within the 6-month tumour volume compared to significantly decreasing voxels (blue) within the patient group.

In summary, the PRM showed potential for predicting both global and voxel-wise treatment response, however, the relationship between the two could not be directly inferred suggesting that rigorous validation for each target demographic is needed if the PRM is to be used to guide locally adaptive RT.

SP046.3 - Using Magnetic Resonance Imaging Radiomics to Personalize Brain Metastases Treatment

Author(s): <u>Sarah A. Mattonen</u>¹, Timothy Pok Chi Yeung¹, George Rodrigues², Andrew Warner¹, Carol Johnson¹, Frank Lagerwaard³, Miguel Palacios³, Omar Bohoudi³, Aaron D. Ward¹ ¹London Regional Cancer Program, London/CANADA, ²Department Of Oncology, The University of Western Ontario, London/CANA-DA, ³Radiation Oncology, VU University Medical Center, Amsterdam/NETHERLANDS

Purpose: For patients with brain metastases, early and accurate treatment selection is critical to maximizing quality of life and potentially extension to life. Prediction of response to stereotactic radio-surgery (SRS) informs personalized treatment selection. The classification of brain metastases as "homogeneous", "heterogeneous", and "ring-enhancing" has been shown to be predictive of overall survival (OS) after SRS [1], but is subject to inter-observer variability. Our objective was to improve OS prediction by developing and testing a radiomics software platform for quantitative assessment of brain metastases appearance.

Methods: Thirty-one brain metastasis patients (44 lesions) underwent routine gadolinium-enhanced T1 weighted magnetic resonance (MR) imaging prior to SRS. Each lesion was manually contoured and classified as "homogeneous", "heterogeneous", or "ring-enhancing" [1]. Image intensities were normalized using the brain ventricles as a statistical reference. Image features including the first-order image statistics, size and shape-based features, and gray-level co-occurrence (GLCM) textures averaged over 13 three-dimensional offsets were measured. Image features between the three contrast-enhancement groups were measured using the Kruskal-Wallis test followed by the Mann-Whitney *U* test. Correlations between image features and OS were evaluated using the Spearman correlation.

Results: The median time to compute 335 image features was 0.6 minutes/patient (range: 0.3 - 4.6) using a non-parallel and unoptimized MATLAB implementation. The three contrast-enhancement patterns showed significantly different first-order statistics (*P* < 0.0025) (Figure 1). Size and shape-based features and GLCM-based textures were not significantly different amongst the contrast-enhancement groups. Using the largest lesion in each patient as the index lesion, first-order energy showed a significant correlation with OS (*rho* = -0.61, *P* < 0.001). Range, 90th percentile, 99th percentile, surface area, normalized radial length entropy, correlation, and cluster prominence showed marginal correlations with OS (*P* < 0.05).

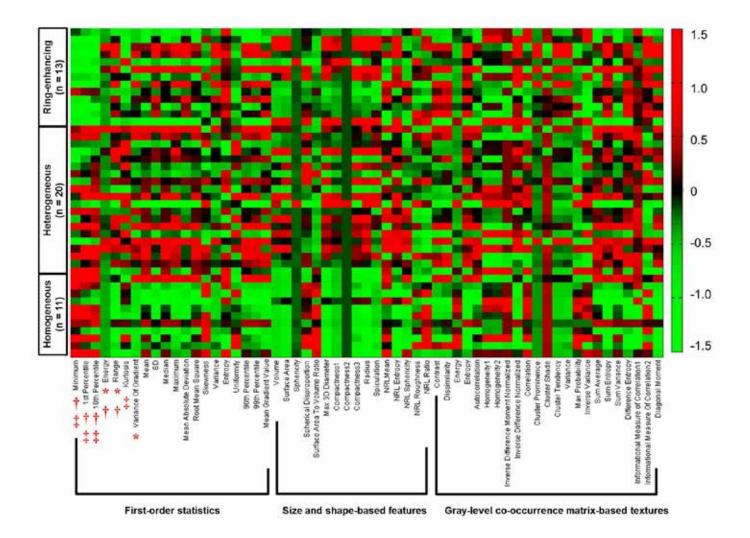

Figure 1. A heat map showing image features (columns) for each lesion (rows). Red and green indicate higher and lower standardized scores, respectively. (*), (†), and (‡) represent significant differences between homogeneous vs. heterogeneous lesions, homogeneous vs. ring-enhancing lesions, and heterogeneous vs. ring-enhancing lesions, respectively. A Bonferroni-corrected P < 0.0025 was considered significant.

Conclusion: First-order image statistics calculated by our radiomics platform correlated with expert qualitative classification of contrast-enhancement patterns, and first-order energy correlated with OS. Future work includes optimizing the calculation of GLCM-based textures and determining a combination of image features that can accurately predict OS for individual patients.

SP046.4 - Raman spectroscopy for assessment of radiation therapy response: Pre-clinical animal study results for lung cancer

Author(s): <u>Suneetha Devpura</u>¹, Ken Barton¹, Stephen Brown¹, Yingshu Zhang¹, Seema Sethi², Michael D. Klein³, Farzan Siddiqui¹, Indrin J. Chetty¹

¹Radiation Oncology, Henry Ford Health System, Detroit/MI/UNITED STATES OF AMERICA, ²Pathology, Wayne State University, Detroit/ MI/UNITED STATES OF AMERICA, ³Pediatric Surgery, Children's Hospital of Michigan, Detroit/MI/UNITED STATES OF AMERICA

The purpose of this study is to explore whether Raman spectroscopy is able to assess the response of lung tumors and healthy lung tissue in mice following radiation therapy. 4T1 mouse breast cancer cells injected intramuscularly metastasize to the lungs at day 14. These, 4T1 cancer cells were injected subcutaneously into the flanks of 18 Balb/C female mice. Five additional mice were used as "normal lung" controls. After 14 days, cohorts of mice bearing tumors received 6, 12 or 18 Gy to the left lung with 6MV photons. Five mice were treated as "unirradiated tumor" controls. After 24-48 hours, lungs were excised and the specimens were sectioned for Raman measurements and pathologic evaluation using a cryostatmicrotome. A total of 775 Raman spectra were collected; 107 from unirradiated normal lung tissues, 126 from unirradiated tumors, and 318 from tumors irradiated with 6, 12 or 18 Gy. Raman spectra were also collected from normal lung tissues of mice with unirradiated tumors (29) as well as irradiated (6, 12 or 18 Gy) tumors (195). Principal component analysis (PCA) and discriminant function analysis (DFA) were performed to analyze and interpret the results. Normal lung tissues and tumors were identified 100% of the time relative to pathologic scoring. Raman spectral data showed prominent results between unirradiated tumor and tumors receiving 12 or 18 Gy. Thus, in a model consisting of unirradiated and irradiated tumors (12 or 18 Gy) classification accuracies were 97.6%, 79.6%, and 80.8%, respectively, relative to pathologic assessment (see Fig.). Overall, 85.4% distinguishability was observed for unirradiated and irradiated (6, 12 or 18 Gy) normal lung tissues. Preliminary results demonstrate the promise for Raman spectroscopy in the prediction of normal vs. lung tumors as well as in the assessment of response of tumor and normal lung tissues following radiation therapy.

DFA plot for unirradiated tumors and irradiated lung tumors with 12 Gy and 18 Gy

SP046.5 - Serial 4DCT sand 4DPET imaging to monitor response for locally-advanced non-small cell lung cancer patients undergoing combined chemotherapy and radiotherapy Author(s): Jean-Pierre Bissonnette¹, Andrea Bezjak², Nathan Becker¹, Claudia Leavens¹, Doug Vines¹, Thomas G. Purdie¹, David Jaffray¹, Alexander Sun²

¹Radiation Physics, Princess Margaret Cancer Centre, Toronto/ CANADA, ²Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/CANADA

Background

Recent research comparing serial PET imaging acquired pre-, post-, and during RT has demonstrated that not only the maximal uptake of 18F-fluoro-2-deoxy-glucose (FDG) within the tumor, but also the heterogeneous patterns of FDG uptake correlate with treatment outcome. We propose to utilize 4DCT with FDG 4DPET scans to monitor the response of patients treated for locally-advanced non-small cell lung cancer (LA-NSCLC) and correlate the observed changes with clinically-relevant endpoints and to point out which patients might require adaptation to improve their chances of successful therapy.

Materials and Methods

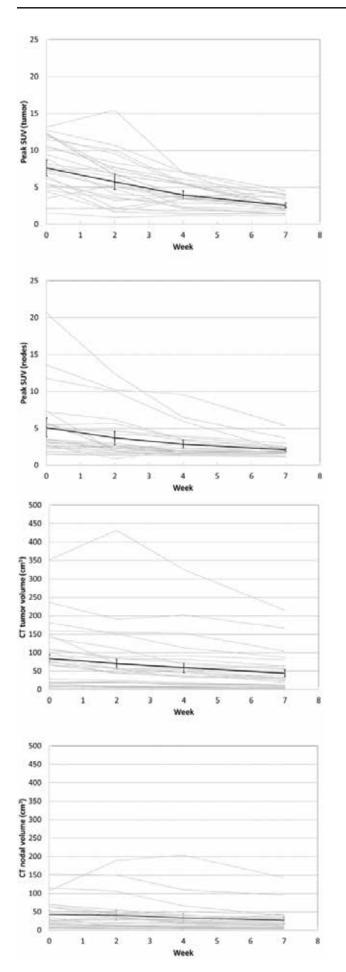

In this ethics-approved prospective study, we enrolled patients with LA-NSCLC receiving curative intent therapy. 4DCT and 4DPET images were acquired prior to (week 0) and during (weeks 2, 4, and 7) therapy. The gross tumor volume was contoured, for both the primary tumor (GTV-T) and for nodal disease (GTV-N) by experienced radiation oncologists on 4DCT datasets. PET image features derived from intensity volume histograms (i.e., SUVpeak, VSUV>3, V50% SUVmax) limited to the internal target volume were derived from matched PET images to identify tumoral (GTVPET-T) and nodal disease (GTVPET-N). Clinical outcomes at two years after treatment were recorded for all patients. All image features and the derivative of these features were tracked as a function of time point.

Results

32 patients were recruited, 27 completing all scans. On average, the GTV-T and GTV-N were reduced, at week 7 to 55±19% and 63±18% of their volume at week 0. Larger reductions were observed for all studied PET image features: on average, the GTVPET-T and GTV-PET-N were reduced, at week 7 to 17±8% and 7±3% of their volume at week 0, and the SUVpeak was reduced by $33\pm4\%$ and $41\pm8\%$ for tumoral and nodal disease, respectively. On average, the maximum rate of change occurred early in the treatment for all image metrics considered in this study.

Conclusions

In a homogeneous LA-NSCLC population, we have shown, using serial 4DCT and 4DPET images acquired during chemo-radiotherapy, that tumor anatomy and physiology change at different rate, and that the maximal rate of change in image features occurs early into treatment. These results may help determine the optimal time for adaptation of therapy. Correlation of image features and their respective rates of change with clinical outcomes is ongoing.

SP046.6 - Evaluation and Visualization of Radiogenomic Modeling Frameworks for the Prediction of Normal Tissue Toxicities Author(s): James Coates¹, Asha K. Jeyaseelan¹, Norma Ybarra¹, Jessie Tao¹, Marc David², Sergio Faria², Luis Souhami², Marie Duclos², <u>Issam El Naqa¹</u>, Fabio Cury² ¹Medical Physics Unit, Department Of Oncology, McGill University,

Montreal/QC/CANADA, ²Division Of Radiation Oncology, McGill University, Montreal/QC/CANADA

We explore techniques for the evaluation and visualization of radiogenomic data-driven models in an effort to investigate the integration of genetic variations (single nucleotide polymorphisms [SNPs] and copy number variations [CNVs]) with dosimetric and clinical variables in modeling radiation-induced rectal bleeding (RB).

One hundred and twelve (N=112) patients who underwent curative hypofractionated radiotherapy (66 Gy in 22 fractions) between 2002-2010 were retrospectively genotyped for SNPs and CNVs in six genes: XRCC1, XRCC3, VEGFa, TGF β 1, ERCC2 and SOD2. A logistic regression modeling approach was used to assess the risk of severe RB (Grade≥3) using dosimetric, clinical and biological variables. Statistical resampling based on cross-validation was used to evaluate model predictive power and generalizability to unseen data. Principle component analysis (PCA) and vector biplots were used to visualize the quality of model fit.

Biological variable XRCC1 CNV showed good overall fit to RB outcome data (p<0.001). When added to the logistic regression modeling, XRCC1 CNV improved classification performance over standard dosimetric models by 33.5%. No clinical variables were found to adequately fit the data.

As a proof-of-concept, we demonstrated that the combination of genetic and dosimetric variables could provide significant improvement in NTCP prediction using data-driven approaches. Moreover, we have shown that visualization techniques could aid in interpreting multivariate model predictions.

SP047 - Dose Calculation: Part 2

TRACK 04: RADIATION ONCOLOGY

SP047.1 - Non-Standard IOERT Dose Distributions Scenarios by Monte Carlo Studies

Author(s): <u>Alessandro Esposito</u>¹, Taxiarchis Sakellaris¹, Patricia Limede¹, Filipa Costa², Luís T. Cunha³, Anabela G. Dìas³, Joana Lencart³, Sandra Sarmento³, Carla C. Rosa¹ ¹INESC TEC, Porto/PORTUGAL, ²Medical Physics, Radiobiology and Radiation Protection Group, Research Centre, Portuguese Institute of Oncology, Porto/PORTUGAL, ³Medical Physics Department, Portuguese Institute of Oncology, Porto/PORTUGAL

In Intra-Operative Electron Radiation Therapy (IOERT) electron beams of high energy are used during surgical interventions, due to their short range and low penetration. This technique allows the direct irradiation of the treatment area, minimizing the dose in adjacent tissues. Due to the complexity of the abdominal and pelvic region sometimes the radiation field includes sensitive and/or uneven tissues.

To study the influence on dose distributions of several factors, such as shielding and irradiation of non-flat surfaces, the Monte Carlo simulation codes BEAMnrc and EGS++ were used to model a Varian Clinac 2100 CD linear accelerator, its hard docking system, IOERT applicators, and water phantom. The simulation model is validated under reference conditions (i.e. dose distributions in a homogeneous water phantom), using the gamma function, with a 2% difference dose and 2mm distance to agreement (DTA) as validation criteria, resulting in 98.3% of concordance between measured and simulated data.

A measurement with a 1cm radiotherapy bolus slab, placed over 16 parallel solid water plaques with gafchromic film in the middle, was also used as validation criterion for a non-standard condition (figure 1), where good agreement was achieved, allowing to use the model for further studies. In figure 2 the dose distribution deformation effect of an irregular surface with respect to the flat condition, is reported, showing a dominant central area of increased absolute dose, linked to distortion of lateral equilibrium. Further studies have been conducted on the effect of shape, dimensions and shielding material, particularly focusing on the case of pelvic region, using a geometrical model of the sacrum bone curvature.

The results obtained will allow a better understanding of dose distributions in pelvic IOERT, which is fundamental both to improve the technique and assess its efficacy, as well as to interpret results from in vivo dose measurements.

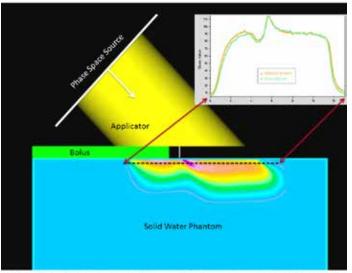

Figure 1 - Non-standard validation condition - dose distribution on tissue equivalent volume, with 1cm thickness of bolus material and 45° beveled applicator of 8cm diameter for a 9MeV beam energy.

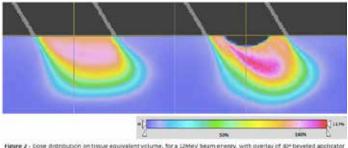

Figure 2 - Cose distribution on tissue equivalent volume, for a 12MeV beam energy, with overlay of 30^o beveled applicator of 6cm diameter: flat (left) and curved (right) surface.

SP047.2 - Validation of a Commercial GPU-Based Monte Carlo Dose Calculation Algorithm for use with an Elekta MRI-Linear Accelerator

Author(s): <u>Moti R. Paudel</u>¹, Anthony Kim², Syed Ahmad³, Arman Sarfehnia¹, Stephanie Lim-Reinders⁴, Sami Hissoiny⁵, Michel Moreau⁵, Arjun Sahgal¹, Brian Keller⁶

¹Department Of Radiation Oncology, University of Toronto, Toronto/ ON/CANADA, ²Department Of Medical Physics, Sunnybrook Health Sciences Centre, Toronto/ON/CANADA, ³Sunnybrook Research Institute, Toronto/CANADA, ⁴Department Of Physics, University of Toronto, Toronto/ON/CANADA, ⁵Elekta, Maryland Heights/MO/UNITED STATES OF AMERICA, ⁶Institute Of Medical Science, University of Toronto, Toronto/ON/CANADA

Purpose: A treatment planning algorithm from the commercial vendor Elekta[™] has been developed to be used with a future MRI-linear accelerator (MRI-LINAC). This is a GPU-based Monte Carlo dose calculation algorithm (GPUMCD) that is capable of modelling the magnetic field (B-field) associated with the MRI-LINAC. The purpose of this work is two-fold 1) to validate the algorithm without the presence of the Bfield as this algorithm can also be used to model a standard linac, and 2) to validate this algorithm, with the B-field activated, against an independent Monte Carlo algorithm (Geant4), as will be the case with the MRI-LINAC.

Methods: The research version of the Monaco TPS version 5.09.05 was used. This version contains the GPUMCD algorithm in addition to the XVMC algorithm that is in current clinical use. For the initial validation of the TPS for a standard linac, a beam model was created for an Elekta Agility linac for 6 MV. A heterogeneous phantom, simulating either bone-in-tissue, lung, tumour-in-lung, or steel-in-tissue, was designed and built to compare radiochromic film

measurements with the ability of the TPS system to model the dose. We compared film measurements with the Monaco GPUMCD and XVMC algorithms and with the Pinnacle collapsed cone algorithm (CCC). In terms of Bfield validation, an independent MC algorithm, Geant4 version 4.10, is being used to compare against Monaco.

Results: For the standard validation (no B-field), film measurements were done in the heterogeneous phantom for field sizes ranging from 1x1 to 10x10 cm², where a tumour in a lung was simulated, and these were compared with Monaco (1x1x1 mm³ dose grid resolution and 0.5% statistical uncertainty) and with Pinnacle. Our preliminary results indicate that Monaco GPUMCD algorithm shows good agreement with measurements for the comparisons done thus far. The largest differences were seen for the 1x1cm² field size, where the measured dose, in the lung region, was higher by 3.5% (compared to GPUMCD), 10% (compared to XVMC) and 14% (compared to CCC). Doses were relative to the depth of dose maximum and uncertainties will be discussed. There was negligible difference between the Monaco GPUMCD and XVMC algorithms for the other field sizes. The results for the B-field modeling are currently being generated and will be presented.

Conclusions: The Monaco GPUMCD algorithm showed good agreement with measurements. The agreement for this algorithm appears better at the small field sizes compared to Monaco XVMC and Pinnacle CCC algorithms.

SP047.3 - A Dosimetric Evaluation of Interface Effects Using Two Commercial Electron Treatment Planning Algorithms Author(s): Benjamin Catt, <u>Mark Yudelev</u>

Radiation Oncology, McLaren - Macomb, Mt. Clemens/UNITED STATES OF AMERICA

Purpose: In this work, we investigate the accuracy of two commercial Monte Carlo algorithms used for electron treatment planning. In particular, the dose distribution near an interface in a heterogeneous phantom is compared with results obtained from measurements and calculations using EGSnrc.

Methods: Phantoms were constructed and modeled in Eclipse 10.0 (Varian) and Monaco 5.0 (Elekta) treatment planning systems. Slabs of aluminum and bone equivalent material were inserted one at a time into a stack of solid water and situated at 2.9 cm depth, equivalent to dmax for a 12 MeV electron beam. This setup was chosen as an exaggeration of any clinically relevant inconsistencies which may be seen near interfaces. Plans were run on these phantoms and central axis depth doses were compared with results obtained using similar phantoms within EGSnrc. The measurements were performed in a 12 MeV electron beam from a Varian 21 iX linear accelerator using an Exradin A10 parallel plate chamber.

Results: General agreement was observed between calculated and measured dose distributions along the beam's central axis in the regions away from the heterogeneity; however, Varian's eMC algorithm could not properly account for backscatter from higher density materi-als, instead predicting a decrease in dose just before the interface. This leads to an underestimation of dose by up to 12% near the interface with an aluminum heterogeneity, when compared with ion chamber measurements. Elekta's VMC++ algorithm was able to more accurately account for the presence of the backscatter material, demonstrating an agreement within 1.3% of ion chamber measurements in the region before the interface.

Conclusions: Although Monte Carlo algorithms are widely regarded as the gold standard for accuracy, care must still be taken when using implementations which have been optimized for calculation efficiency, especially within regions lacking electronic equilibrium such as those found near interfaces with bone.

Backscatter factors*					
	Aluminum	Bone			
EGSnrc	1.076	1.029			
Monaco	1.080	1.055			
eMC	0.975	0.988			
Measured	1.095	1.042

SP047.4 - 4D Monte Carlo simulation for verification of delivered dose to deforming anatomy

Author(s): Sara Gholampourkashi¹, Miro Vujicic², Raanan Marants¹, Jason Belec², Joanna Cygler³, Emily Heath¹

¹Physics, Carleton University, Ottawa/ON/CANADA, ²Medical Physics, Ottawa Hospital Cancer Center, Ottawa/ON/CANADA, ³Radiation Medicine Program, The Ottawa Hospital Cancer Centre, Ottawa/CANADA

Objective: To develop a dose calculation method using 4D Monte Carlo (MC) simulations that accurately reconstructs and verifies the dose delivered to a moving anatomy during radiotherapy treatments. The method is to be used for accurate dose calculations of dynamic radiation therapy treatment plans such as VMAT (Volumetric Modulated Arc Therapy) and IMRT (Intensity Modulated Radiation Therapy).

Methods: Quasar respiratory motion programmable phantom was used for measurements with an Elekta Agility linac. A square beam of size 4x4 cm² was chosen to cover the tumor (1.5 cm radius) inside the lung insert of the phantom and the source to axis distance (SAD) was 100 cm. The beam was delivered to the phantom in static (no motion) and moving (1.8 cm respiratory amplitude) states. Doses were measured using calibrated EBT3 film and RADPOS 4D dosimetry system.

Treatment planning was performed with XiO Treatment Planning System (TPS). Dose calculated by XiO was compared against results from measurements and MC calculations.

The EGSnrc user code BEAMnrc was used for simulating photon beams from the Elekta Agility linac. The DOSXYZnrc and def-DOSXYZnrc user codes were used, respectively, for static and deforming anatomy dose calculations on the phantom file created from 4D CT-scans of the Quasar phantom, using the same beam configurations as in measurements. Dose calculation voxels were 0.25x0.25x0.6 cm³. Varian's Velocity software was used to perform the deformable image registration of the tumor in different respiratory phases to the tumor in the static anatomy. Deformation vectors were then extracted and input to the defDOSXYZnrc code to model the phantom motion during the dose calculation. **Results:** Table 1 shows the calculated and measured tumor doses and their uncertainties.

Table 1. Calculated and measured tumor doses and their uncertainties										
	Dose (cGy)			%Diff						
Phantom	TPS	мс	Measured		мс/					Film/
			Film	RADPOS	TPS	Film/TPS	RADPOS/TPS	Film/MC		RAD- POS
Static	120.7 ± 1	121.1 ± 0.6	118.9 ± 2.4	116.9 ± 2.4	0.3%	-1.5%	-3.1%	-1.8%	-3.5%	1.7%
Dynamic	-	110.9 ± 0.7	108.5 ± 2.2	112.7 ± 2.3	-	-	-	-2.2%	1.6%	-3.7%

Conclusions: Our work demonstrates that 4D Monte Carlo calculations using the defDOSXYZnrc code is an accurate method to calculate dose delivered in a moving anatomy.

This work was supported by OCAIRO grant.

SP047.5 - Clinical implementation of an EPID-based in vivo dose verification system for SBRT-VMAT delivery; catching errors

Author(s): <u>Peter Mccowan</u>¹, Eric Vanuytven², Timothy Van Beek², Ganiyu Asuni², Boyd Mccurdy¹

¹Physics And Astronomy, University of Manitoba, Winnipeg/CANA-DA, ²Medical Physics, CancerCare Manitoba, Winnipeg/CANADA

Introduction: Most linear accelerators (linacs) used for radiotherapy are equipped with a mega-voltage electronic portal imaging device (EPID). Literature has determined the EPID to be a reliable dosimetric device. The portal dosimetry research group at CancerCare Manitoba has developed a set of physics-based tools which utilize measured EPID data acquired during treatment in order to reconstruct the 3D in vivo dose delivered to the patient. Our model can also predict the in vivo dose similar to a treatment planning system (TPS). Due to the hypofractionated regimen of stereotactic body radiation therapy (SBRT) treatments, a verification of the inter-fractional dose could provide additional safety for the patient because any error in delivery, when compared to conventional treatments, would have a greater radiobiological impact on the patient. In this study, the results of a one year clinical implementation test of our dose verification system will be presented for lung and spine SBRT-VMAT treatments.

Methods: Our *in vivo* model employs an inverse dose reconstruction method which combines a back-projected measured EPID focal fluence and a predicted linac-head extra-focal fluence. The primary *in vivo* patient dose is calculated by taking the total incident fluence on the patient, converting it to TERMA, and performing a collapsed cone convolution with Monte Carlo derived point-based dose deposition kernels. *In vivo* patient scatter dose is calculated through convolutions of the incident fluence with a library of Monte Carlo derived patient scatter kernels. Heterogeneities are accounted for through radiological scaling of the dose deposition and scatter kernels via electron densities from CT data.

Overall, 43 lung and 13 spine patients were treated over roughly a one year period using a Varian 2300ix model linac operated in 6MV SRS-mode. Continuous EPID images were acquired every 1.25-2.50 seconds. Fractions sizes were between 1 and 8 while doses were in the range of 6 to 24Gy. All per-fraction data were compared to the Eclipse TPS dose calculation. Mean percentage dose differences and 3%/3mm gamma analyses were performed to compare the low dose voxel (LDV) regions (containing 20% of prescribed dose) and the high dose voxel (HDV) regions (containing 80% of prescribed dose).

Results: Three of the lung patients had significant errors in all fractions: mean HDV percentage differences and gamma pass rates were 10-20% and 50% respectively. A review of these three and seven other patient treatment histories (with less significan differences) revealed errors due to anatomical changes, patient setup, planning, as well as disruptions in EPID image acquisition. An average gamma pass rate of 90.6±8.3% and mean percentage dose difference of 4.8±1.9% were determined in the HDV region for the 'other' 40 lung patients. Due to the greater complexity and heterogeneity of the spine treatments slightly less agreeable results were determined.

Conclusion: A robust, EPID-based *in vivo* dose verification system has been employed clinically to test its feasibility in capturing inter-fractional SBRT-VMAT delivery errors. Significant errors were found which should encourage a full clinical implementation.

SP047.6 - pGPUMCD, a GPU-based Monte Carlo proton transport code

Author(s): <u>Daniel Maneval</u>¹, Benoît Ozell², Philippe Després¹ ¹Département De Physique, De Génie Physique Et D'optique, Université Laval, Québec/QC/CANADA, ²Département Génie Informatique Et Génie Logiciel, École polytechnique de Montréal, Montréal/ QC/CANADA

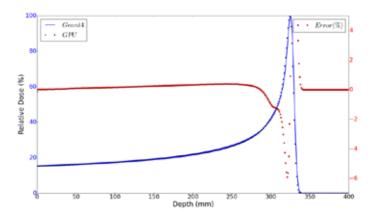

Purpose : The most accurate dose calculations in proton therapy result from Monte Carlo algorithms. However their clinical implementation remains problematic due to long computation times. To accelerate these simulations, a GPU-based Monte Carlo transport code was developed. pGPUMCD is an adaptation for protons of GPUMCD, a validated GPU-based Monte Carlo code for photons and electrons. Implementation strategies and validation results are presented in this work.

Methods : In pGPUMCD, protons are transported in a voxelized geometry by a class II condensed history approach with a continuous slowing down approximation. Energy straggling is considered as well as multiple scattering. Ionizations are modelled and secondary electrons are not transported. Moreover, elastic and non-elastic nuclear interactions in water are considered based on an empirical model. pGPUMCD was benchmarked against Geant4. Simulations consisted in a mono-energetic, mono-directional circular proton beam of radius 1 cm impinging normally homogeneous or heterogeneous phantoms. Relative statistical uncertainties were derived from a history by history scheme and were below 1% in 1 mm³ cubic voxels containing 50% of the maximal dose. A Geforce GTX Titan was used in pGPUMCD while Geant4 simulations were done on a

Xenon-based CPU cluster. The evaluation of GPU/CPU acceleration was carried out without computation of statistical uncertainties and with a single 3.3 GHz Intel Core i3-3220 CPU.

Results : Considering only electromagnetic processes, proton transport with pGPUMCD yielded results within 6% of Geant4 values, with the largest errors in the Bragg peak for a speed-up factor of at least 300 compared to a single-core CPU execution. The transportation of one million protons of 230 MeV took 50 seconds with pGPUMCD and eight hours with Geant4. A complete dose validation is under evaluation with Bragg peaks, dose profiles and gamma studies for several materials and different energies.

Conclusion : GPUMCD now allows proton transport with pG-PUMCD. Preliminary results suggest good agreement with Geant4 and significant savings in terms of computation times. Nuclear reactions in water were implemented in pGPUMCD and the validation is under investigation as well as the improvement of efficiency and computation time.

SP048 - Dosimetry of Protons and Heavy lons

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP048.1 - An Attempt to Predict the Proton Relative Biological Effectiveness using Radical Recombination Author(s): <u>Kiyofumi Haneda</u>

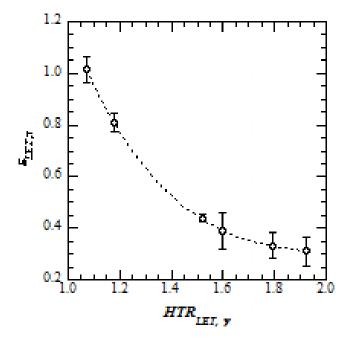

Hiroshima international university, Higashihiroshima/JAPAN

Most proton treatment facilities have adopted a relative biological effectiveness (RBE) of 1.1 for proton therapy. However, most of the in vitro and in vivo studies indicate that the RBE of the spread-out Bragg peak (SOBP) protons increases with depth. The increase in RBE of proton beams on the SOBP is a well-known phenomenon that is difficult to quantify accurately in vivo studies. The reason for this explains that the RBE increases as linear energy transfer (LET) increases within the SOBP. The fact that intra-track radical recombination can indicate to produce fully competent lesions in room. The purpose of this study was to analyze an impact on radical recombination for the RBE in the SOBP proton beams. First, a depth-dose curve for the 210 MeV proton beam measured using a gel dosimeter and an ionization chamber. Second, the spatial distribution of the physical dose was calculated by Monte Carlo code system PHITS; the role of nuclear interaction was taken into account and the geometry of the apparatus was faithfully reproduced. The simulation results were compared with measured the depth-dose distribution and very good agreement was found, and the spatial distribution of an LET- weighted dose with threshold LET value (4.9 keV/µm) was calculated by the same code. Then, the relative distribution of the radical-recombination was calculated from the physical dose and LET-weighted dose. The relative distribution of the radical-recombination was calculated at each depth as the quotient of relative dose obtained using physical and LET- weighted dose. The agreement between the relative distributions of radical-recombination and RBE was good at the SOBP.

SP048.2 - A correction method for absorbed dose estimation using TEP-TLSD/SR1 in therapeutic carbon beam

Author(s): Weishan Chang¹, Yusuke Koba², Shigekazu Fukuda², Genichiro Wakabayashi³, Hidetoshi Saitoh¹, Kiyomitsu Shinsho¹ ¹Radiological Sciences, Tokyo Metropolitan University, Tokyo/ JAPAN, ²National Institute of Radiological Sciences, Chiba/JA-PAN, ³Kinki University, Osaka/JAPAN

Introduction: TEP-TLSD/SR1, a slab type tissue-equivalent thermoluminescence dosimeter, has the advantage of acquiring 3D dose distribution in a single irradiation. This property is favorable to be a QA tool for radiotherapy. One of the difficulties by means of TLDs in heavy ion dosimetry is the LET dependence of thermoluminescent (TL) efficiency. It has been reported that LET dependence of TEP-TLSD/SR1 can be observed in not only the TL efficiency but also glow curve. The high temperature ratio (HTR) estimated using glow curve is a function of LET. Therefore it is possible to correct TL efficiency without information of LET for therapeutic carbon beam dosimetry. Purpose: The relation between HTR and TL efficiency is clarified and the feasibility of TEP-TLSD/SR1 for carbon beam dosimetry is evaluated. Methods: An in house TL readout system was used to obtain the glow curve with high accuracy and low uncertainty. Each TLD chip was calibrated individually by absorbed dose to water in $^{60}\text{Co}\,\gamma\text{-rays}.$ The TLD chips were irradiated by a 290 MeV carbon beam to clarify the relationships of HTR vs. LET (HTR-LET) and TL efficiency vs. LET (ELET). HTRLET and ELET at 60Co y-ray were normalized to 1. The normalized TL efficiency (ELET, Y) as a function of HTR (HTRLET, Y) was obtained from two relationships HTRLET and ε LET. The feasibility of HTR correction for the TEP-TLSD/SR1 was evaluated using a carbon beam. **Results:** The HTR increased with LET, and TL efficiency showed exponential decrease with increasing LET. Dose difference at SOBP region reduced from 20-30% to 10-20% after HTR correction. **Conclusion:** A correction method for determination of absorbed dose in therapeutic carbon beam using TEP-TLSD/SR1 was developed.

The normalized TL efficiency as a function of HTR.

SP048.3 - Biologically-weighted dosimetric quantities based on a multiscale approach

Author(s): <u>Heidi Nettelbeck</u>¹, Hans Rabus¹, Hugo Palmans², Marion Bug¹, Massimo Pinto³, Carmen Villagrasa⁴, Marta Bueno⁴, Sylvain Meylan⁴, Pedro Teles⁵

¹Fundamentals Of Dosimetry, Physikalisch-Technische Bundesanstalt (PTB), Braunschweig/GERMANY, ²Radiation Dosimetry, National Physical Laboratory, London/UNITED KINGDOM, ³Istituto Nazionale di Metrologia delle Radiazioni Ioniszanti (ENEA-INMRI), Santa Maria di Galeria/ITALY, ⁴Institut de Radioprotection et de Sûreté Nucléaire (IRSN), Fontenay-aux-Roses/FRANCE, ⁵Instituto Superior Técnico, Campus Tecnológico e Nuclear (IST-CTN), Sacavém/PORTUGAL

Particle therapy with protons and ions has gained increasing interest and its use has grown worldwide. Due to the different biological dose response of these types of radiation compared to high-energy photon beams, the current approach of treatment prescription is based on the product of the absorbed dose to water and a biological weighting factor. This method, however, is insufficient for quantifying the biological outcome of radiation, hence the need to define new dosimetric quantities that allow a separation of physics and biological processes.

"Biologically-weighted quantities in radiotherapy" (BioQuaRT) [1], a joint research project funded within the European Metrology Research Programme, uses a multiscale approach to lay the foundation for such new dosimetric quantities. This approach involves simulation and experimental techniques to determine the physical properties of ionising particle tracks on different length scales from a few nanometres (diameter of DNA) to micrometres (size of cell nucleus), which are then correlated with biological effects of radiation.

The present work focuses on the simulation aspect of the project – the development of a comprehensive multiscale simulation tool [2] that incorporates radiation interaction cross sections with DNA and production rates of radical species. This simulation tool is used to relate track structure characteristics at the nano- and micrometre level to biological consequences of radiation interaction, such as DNA strand breaks. This work has led to the development of existing Monte Carlo simulation codes dedicated to radiobiology, in particular PTra [3] and Geant4-DNA [4], which is used as a base for the simulation tool. The incorporation of interaction cross sections of DNA-substitute materials (rather than the conventional use of water) as well as fragmentation cross sections used to derive DNA strand break probabilities are among the improvements.

This multiscale approach has the potential to underpin the definition of new biologically-weighted dosimetric quantities relating track structure to relative biological effectiveness in proton and ion beam therapy.

SP048.4 - Studies of Helium and Carbon Ion Fragmentation processes in Water and in PMMA, using versatile Semiconductor Detectors

Author(s): <u>Giulia Arico</u>¹, Jan Jakubek², S Pospisil², Naruhiro Matsufuji³, Oliver Jäkel⁴, Maria Martisikova¹

¹Heidelberg University Hospital, Heidelberg/GERMANY, ²Institute of Experimental Applied Physics (IEAP), Prague/CZECH REPUB-LIC, ³National Institute of Radiological Sciences, Chiba/JAPAN, ⁴Heidelberg Ion-Beam Therapy Center (HIT), Heidelberg/GERMANY

Background/Purpose:

Heavy ion radiotherapy enables a more conformed dose distribution to the target than conventional radiotherapy. Moreover, helium and carbon ions have additional advantages when compared to protons, such as a narrower penumbra. However, ions heavier than protons may undergo nuclear fragmentation processes within the patient. The consequence is a spectrum of lighter fragments which affect the delivered biological dose distribution. Currently there is a lack of knowledge regarding ion nuclear fragmentation processes. Our research aims to provide some of the relevant data. The information gained in this study might be used to benchmark Monte Carlo codes and to improve the accuracy of the treatment planning systems.

Materials and Methods:

We use a single particle registration technique to compare the fragments arising from ion beams crossing water and polymethyl methacrylate (PMMA), for different target thicknesses. Solid PMMA is often used in dosimetric measurements to replace water phantoms. The used Timepix detectors [Llopart et al. NIM A 581, 2007], developed by the Medipix collaboration, have a sensitive area of 1.4 cm² (256x256 pixels, 55x55 um pitch) and 300 um or 500 um

thick silicon sensors. The fragmentation processes in water and in PMMA targets are compared, using ion beams with initial energies of 150 MeV/u (helium) and 290 MeV/u (carbon). The detectors are simultaneously placed in front (for beam monitoring) and behind the target. They enable to detect single particles and to measure particle position, arrival time and energy loss in the detector. The characteristics of the registered signal depend on the particle type and energy. Therefore, the signal features are exploited to differentiate between the particle species [Hartmann B. (2013), PhD Thesis, Univ. Heidelberg]. Moreover, particle tracks are reconstructed using several detector layers.

Results:

With the presented experimental setup, we analyse: 1) the percentage of primary ions which undergo fragmentation processes; 2) the number and kind of fragments arising from single primary ions; 3) the relative number of created fragments, for each fragment species; 4) the lateral particle distributions. Comparing the results obtained in water and PMMA targets with same water equivalent thickness, good agreement is achieved in thin targets, while greater differences are obtained above 100 mmw-eq of thickness. Monte Carlo simulations are also performed, for comparison.

Conclusions:

Timepix detectors are small and highly flexible devices, which enable to study fragmentation processes very close to the target. The presented comparison of ion fragmentation processes occurring in water and PMMA phantoms shows some limits in the equivalence of these two materials. The differences become higher with increasing the target thickness and should be carefully taken into account when PMMA is used in place of water for dosimetric purposes.

Acknowledgments:

Measurements are performed at the HIMAC and HIT facilities. This research is funded by the Deutsche Krebshilfe (project 110296) and by the JSPS (project PE14770). This work is carried out as research project 14H339 at NIRS-HIMAC, and in frame of the Medipix collaboration.

SP048.5 - Monte Carlo study of secondary neutron dose for multipurpose nozzle in proton therapy

Author(s): <u>Sungkoo Cho</u>¹, Jin Sung Kim¹, Dae-Hyun Kim¹, Eun Hyuk Shin¹, Youngyih Han¹, Sang Hoon Jung¹, Yoonsun Chung¹, Jungho Kim², Hyeonser Park²

¹Department Of Radiation Oncology, Samsung Medical Center, Seoul/KOREA, ²Center For Ionizing Radiation, Korea Research Institute of Standards and Science, Daejeon/KOREA

Two full rotating gantry with different nozzles (Multipurpose nozzle and Scanning Dedicated nozzle) with conventional cyclotron system is installed and under commissioning for various proton treatment options at Samsung Medical Center in Korea. Currently, an issue in proton therapy is to evaluate the influence of the secondary neutrons produced by nuclear interactions with the modules of nozzle and proton beam. In our proton facility, the multipurpose nozzle was composed of many modules such as scatterer, ridge filter, multileaf collimator (MLC), compensator, and aperture. Therefore, the purpose of this study is to investigate neutron dose in multipurpose nozzle for proton beam with Monte Carlo simulation.

A Monte Carlo studies with the Geant4 toolkit were performed based on multipurpose nozzle's geometry (MLC, compensator, aperture, ridge filter, scatterer and etc) given by Sumitomo Heavy Industry and secondary neutron dose was simulated with 230 MeV proton beams and 5 cm SOBP using a 10 x 10 cm² brass aperture

in a $40 \times 30 \times 30$ cm³ water phantom. At first, we calculated the neutron energy spectrum at water phantom surface. Next, we calculated neutron dose at isocenter, 20, 40, 60, 80, 100 cm distance from isocenter and compared with other research groups.

We used the phase space option of Geant4 toolkit to reduce the simulation time for repeated calculations and calculated neutron energy spectrum binned in 30 keV intervals on water phantom surface for wobbling beam at multipurpose nozzle. The portion of neutrons in the total neutron energy spectrum with energies less than 1 MeV and greater than 165 MeV were 53.5% and 43.8%, respectively.

Next, we calculated neutron dose at isocenter, 20, 40, 60, 80, 100 cm from isocenter and 2 different depths (surface and mid-SOBP) for the proton beam with and without water phantom. At a distance of 20 cm from isocenter, the neutron dose rapidly decreased because of the relatively small magnitude of the dose after lateral profile of the proton beam. In the water phantom, low energy neutrons were captured by an absorbing material (water) and high energy neutrons lost energy by inelastic collisions.

Neutron dose to water phantom for multipurpose nozzle under proton treatment conditions was simulated. The results of this showed comparable results with measured or simulated neutron dose of other proton therapy center. In future studies, we plan to investigate experimental measurement of neutron dose and validation of simulation data for treatment beam with additional neutron dose reduction method.

SP048.6 - Investigation of the uncertainties involved in the low energy proton interaction in different MC-codes for proton therapy application

Author(s): Lalageh Mirzakhanian¹, Valerio Giusti², Shirin A. Enger¹ ¹Medical Physics Unit, McGill University, Montreal/CANADA, ²Dept. Of Civil And Industrial Engineering, University of Pisa, Pisa/ITALY

Background: High precision external radiation therapy can be delivered by protons with a strongly increasing energy deposition that creates a narrow peak of dose, called the Bragg peak at the end of the particle's range and with sharp lateral dose fall-off, allowing to tailor the dose distribution to the target volume. The Monte Carlo (MC) method is an accurate and rigorous tool to simulate radiation transport and score energy deposition in heterogeneous media such as the human body. MC techniques have been implemented clinically for dose calculations in radiotherapy. The electromagnetic processes are well validated in different MC-codes, however there are discrepancies in nuclear models for low energy protons and therefore production of secondary particles such as neutrons. Neutrons contribute to out of field dose and in the long term may cause secondary cancers especially in children and young adults.

Aim: To Implement more accurate physics models and cross section for low energy proton interactions to be able to study secondary cancer induction related to primary protons in a clinical set up.

Method: Depth dose measurements were performed in the Svedberg Laboratory (TSL) proton therapy center at Uppsala University, Sweden, for a Gaussian shaped, mono-energetic beam with a energy of 178.25 ± 0.2 MeV using Scanditronix p-Si diode. The TSL beam setup was modelled and simulated with MC-codes Geant4.10.00 and MCNP6. Calculations were performed with the standard available models and cross section libraries of each code as well as importing new sets of cross sections for proton transport below 200 MeV from the TENDL-2012 library. The primary (proton) and secondary particle fluence (proton, neutron and gamma), proton depth dose and neutron equivalent dose were scored. The secondary particle fluence was filtered by several physics processes to find the process that causes the largest difference.

Results and discussion: The depth dose from protons is in agreement for both codes and measurements. However, there is a significant difference between both versions of Geant4 and MCNP6 in production of secondary particles despite of the use of same cross section library. The default version of Geant4 underestimates the production of secondary neutrons and overestimates the production of gammas compared with the modified version. The main difference between the default and modified version of Geant4 is due to proton inelastic process. The difference between the codes needs further investigation. The calculated neutron fluence must be verified with measurements.

Conclusion: The accuracy of models and cross sections implemented in different MC codes affects the accuracy of the dose calculation for proton beams and estimation of secondary dose calculation.

SP049 - Nanotechnology in Radiation Therapy and Imaging: Part 1

TRACK 06: NEW TECHNOLOGIES IN CANCER RESEARCH AND TREATMENT

SP049.1 - A plasma electrochemistry reactor enabling the rapid, efficient, automatic and on-site synthesis of radioactive gold nanoparticles for brachytherapy treatments Author(s): <u>Mathieu Bouchard</u>, Stéphane Turgeon, Marc-André Fortin

Centre de recherche du CHU de Québec, Quebec City/CANADA

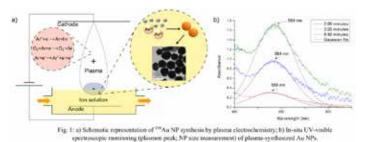

Gold nanoparticles (Au NPs) are increasingly considered for use as radioactive sources (198Au) for prostate brachytherapy procedures [1], [2]. The range of the ¹⁹⁸Au β-particle (0.96 MeV, ~ 11 mm in soft tissue, ~ 1100 cell diameters) is sufficiently long to provide crossfire effects of a radiation dose delivered to cells within the prostate gland, and short enough to minimize the dose to healthy peripheral tissues. The integration of ¹⁹⁸Au NPs into brachytherapy procedures requires the development of more efficient, safer, and more compact Au NP synthesis methods. Indeed, because of their relatively short half-life (2.7 days), ¹⁹⁸Au NPs should ideally be synthesized on site (directly in hospitals) and upon request. However, the current NP colloidal synthesis methods invariably rely on the expertise of skilled chemists. The preparation of NPs with current techniques comes with several manipulation steps (ligand exchange, solvent exchange, purification procedures), which represent critical radioprotection challenges. Therefore, novel bench-top technologies must be developed to facilitate the automated production of ¹⁹⁸Au NPs. Here we report on the development of a plasma reactor used to synthesize Au NPs based on plasma-liquid electrochemistry (Fig. 1a) [3]. In this reactor, an argon plasma is generated at the surface of an aqueous solution containing gold salts (AuCl4-) and surfactant molecules. This method yields a continuous production of stable Au NP suspensions directly in water. Within only 45 minutes, a 50 mL solution containing 1 mM of AuCl4⁻ can be reduced into NPs with a reduction yield of 99.3 \pm 0.7 %. Thus-synthesized Au NPs are readily capped with dextran, a biocompatible molecule widely used in vascular injection media. The diameter of Au NPs can be tuned by varying the initial concentration of dextran in the solution. Finally, an integrated UV-visible spectrometer is used to monitor the Au NPs growth kinetics and their final size (Fig. 1b; plasmon peak: 531 ± 3 nm for 5 nm diameter NPs, 570 ± 4 nm for 120 nm diameter NPs), which is necessary for quality control. Overall, plasma electrochemistry could enable the efficient, on-site and upon request production of ¹⁹⁸Au NPs for a next generation of brachytherapy procedures.

SP049.2 - Dose Enhancement in Radiotherapy by Novel Application Of Gadolinium Based MRI Contrast Agent Nanomagnetic Particles in Gel Dosimetry

Author(s): Mahsa Amirrashedi Bonab¹, <u>Nader Riyahi Alam</u>¹, Ahmad Mostaar², Soheila Haghgoo³, Ensiyeh Gorji³, Ramin Jaberi⁴ ¹Medical Physics, tehran university of medical sciences, tehran/ IRAN, ²Medical Physics, shahid beheshti university of medical sciences, tehran/IRAN, ³Food And Drug Organization, Pharmaceutical Department, tehran/IRAN, ⁴Cancer Institute, Imam Khomeini hospital, tehran/IRAN

The primary goal of radiotherapy is increasing dose in tumor cells and sparing normal tissues. One of the novel ways to achieve this goal is enhancing tumor dose by high atomic number (z) materials. Using high-z radiosensitizers in tumor cells could increase the effect of radiotherapy treatments through increasing photoelectric cross section and number of auger electrons. Advancements in nanotechnology made it possible to use nanoparticles in cancer imaging and treatments. Although many studies have been done on radiosensitization by different materials, most of them have focused on the dose response in the presence of gold nanoparticles. Of our knowledge there is not any experimental study on the radiosensitizing by gadolinium oxide (Gd2O3) nanomagnetic particles in brachytherapy and megavoltage beam radiotherapy. In this study we evaluate dose enhancement properties of gadolinium nanoparticle which is an MRI contrast agent in complex form. Because of increasing relaxation time and high atomic number (z=64), Gd2O3 can be used in imageguided radiotherapy. In recent studies there was a great interest on MRI guided radiotherapy, so it could be efficient to use an MRI contrast agent simultaneously as radiosensitizer in radiotherapy. Herein, dose enhancement in the presence of gadolinium oxide nanoparticles with 0.1mM concentration in a gel filled phantom was investigated. The results show maximum dose enhancement about 15%±0.01 up to 22%±0.02 in brachytherapy by Iridium-192, however this value is about 3.8%±0.002 in external beam radiotherapy with 6 MV photons. Our study approved radiosensitization property of gadolinium oxide nanoparticles in brachytherapy and external beam radiotherapy.

SP049.3 - Monte Carlo simulation of the radiosensitizing effect by gold nanoparticles: comparison between proton and X-ray irradiation

Author(s): <u>Jihun Kwon</u>, Kenneth Sutherland, Takayuki Hashimoto, Hiroyuki Date

Hokkaido University, Sapporo/JAPAN

Purpose

Radiosensitizer gold nanoparticles (GNPs) have recently drawn attention. GNPs target tumor cells by functionalizing proteins. When GNPs are irradiated, electrons are ejected, causing a dose enhancement effect. Although this effect is usually discussed in the context of X-rays, we have investigated the effectiveness under proton beam irradiation and shown that the dose enhancement occurs in both depth and lateral directions around the GNPs. In this study we compare the characteristics of dose enhancement between protons

and photons.

Methods

The dose distribution around a 20 nm diameter GNP was calculated with the Geant4 Monte Carlo simulation toolkit for a 0.7 MeV proton beam and 6 MV X-rays. For the proton simulation, a GNP was exposed unidirectionally at 0.5 µm depth in a water box (10 µm × 1 µm × 1 µm) so that the Bragg Peak was formed at the approximate location of the GNP. In the X-ray simulation, two steps were used: (i) 6 MV photons were shot into a water cube (30 cm on a side) and the energy spectra was tallied by 1 nm diameter water spheres at 4 depths, (ii) a GNP inside a water box (10 µm × 1 µm × 1 µm) was irradiated by four X-ray beams with different spectra. For both types of beams, the incident number of particles was 10⁶. Five nm width water slabs were positioned at a variety of depths behind the GNP in order to obtain the dose distribution of secondary electrons.

Results

In both proton and X-ray simulations it was confirmed that the dose enhancement effect occurred in both the depth and lateral directions. The effective area in the X-ray beam was shown to be much larger than that in the proton beam. However, the dose enhancement by protons was more intense near the GNP compared to that by X-rays. The results suggest that if GNPs are absorbed into cells or cell nuclei in high concentration, proton beams benefit by higher radiosensitizing effects than X-rays.

Conclusion

The dose enhancement effects of a GNP exposed to proton and X-ray beams was investigated in order to show the difference of dose distributions. A larger effective area was formed by X-rays while a higher enhancement in the vicinity of the GNP was observed in the proton irradiation. The results in this study suggest that the appropriate GNP concentration should be chosen depending on the type of radiation in order to obtain the maximum radiosensitizing effect.

SP049.4 - Colloidal quantum dots: radiation resistant nano-scintillators for radiation-based applications

Author(s): <u>Marie-Ève Delage</u>¹, Marie-Ève Lecavalier², Dominic Larivière², Claudine N. Allen³, Luc Beaulieu⁴

¹Département De Physique, Génie Physique Et D'optique, Et Centre De Recherche Sur Le Cancer, Université Laval, Québec/CANA-DA, ²Département De Chimie, Université Laval, Québec/CANA-DA, ³Département De Physique, Génie Physique Et D'optique, Et Centre D'optique Photonique Et Laser, Université Laval, Québec/ CANADA, ⁴Radio-oncologie Et Axe Oncologie Du Centre De Recherche Du Chu De Québec, CHU de Québec, Québec/CANADA

Purpose : CdSe quantum dots (QDs) optical properties have been investigated for many years. Their tunable luminescence emission peak, sweeping the visible range, has fed interest in these nanocrystals. Emission wavelengths are directly determined by the size of the QDs, which is well controlled during the nanocrystals synthesis. The choice of the scintillation light color provides flexibility for different applications and allows a predictable match to the best sensitivity range of photodetectors. In this work, we compare a novel CdSe colloidal quantum dots (cQDs) system with multiple layers to an existing CdSe/ZnS commercial sample. This study presents a radio-resistant scintillating quantum-dots formulation for multiple applications in different medical physics fields like dosimetry, imaging as well as other possible applications in nanotheranostics.

Methods: CdSe/CdS/Cd0.5Zn0.5S/ZnS multi-shell cQDs were grown through the successive ionic layer adsorption and reaction (SILAR) synthesis. The nanocrystals, in powder form, were incorporated to a fiber optic-based detector: the cQDs were placed at one extremity of a non-scintillating plastic collecting fiber, with the other extremity free to be coupled to a photodetector. A similar detector

was prepared with commercial CdSe/ZnS (Ocean NanoTech) QDs. Luminescence signal of the QDs was collected with a CCD camera (Apogee U2000C) to measure the integrated signal. Two devices were used to irradiate the QDs: an Xstrahl 200 orthovoltage unit for kV energies (120, 180 and 220 kVp) and a Varian Clinax iX for 6 and 23 MV.

Results: For all beam energies, scintillation intensity decreases as a function of dose cumulated. Damage caused by radiation creates trap states that enhance the proportion of charge carriers experiencing non-radiative recombination, hence decreasing their contribution to the scintillation light. This trend was already reported in the literature but here cQDs demonstrated a better resistance to radiation. For a 220 kVp beam energy, the multi-shell cQDs signal drop of 1.6% per kGy (38% decreases with 23.5 kGy of accumulated dose) compared to a 5% signal loss per kGy measured for the commercial monolayer QDs sample. Literature predicts larger signal drop at MV photon energies, between 500-700%/kGy for monolayer QDs. The commercial CdSe/ZnS QDs shows a similar behavior with a significant drop of 30%/kGy for a 6 MV beam energy, an effect not observed for our cQDs.

Conclusion: Loss of scintillation light production from initial measurement of our cQDs was found to be small and negligible for standard irradiation found in radiation therapy and medical imaging. Therefore, our multi-shell cQDs showed much better resistance to radiation than other commonly used CdSe/ZnS QDs. One could take advantage of this durability in making cQDs part of applications requiring a scintillating material, keeping in mind their particular property of size-tunable emission wavelength.

SP049.5 - Use of gold nanoparticles and pHLIP (pH Low Insertion Peptide) to increase radiation effectiveness in cancer cells. Gold nanoparticles have been shown to increase the effectiveness of radiation on cancer. Increased radiation effectiveness would allow for smaller radiation doses to be used on patients, reducing side effects; alternatively, more cancer killing can be achieved using the radiation doses currently in use.

Gold nanoparticles increase radiation effectiveness because they have a higher absorption rate than human tissue at photon energies around 100 keV, and because they release Auger electrons upon irradiation. The effect of these Auger electrons is very localized, which means that proper placement of the gold nanoparticles is crucial in optimizing the effect. In our recent experimental work, we used the cancer-targeting molecule pH Low Insertion Peptide (pHLIP) to target the gold nanoparticles to tumors. pHLIP has been shown to target tumors using the property that tumors are more acidic than normal human tissue.

Our experimental results show that the use of pHLIP with gold nanoparticles causes a statistically significant increase in gold up-

take by cancer cells, and that the gold nanoparticles locate mostly to the cell membrane. In a clonogenic experiment, cells exposed to gold and pHLIP survived less well than control cells as well as cells exposed to gold nanoparticles alone, by a statistically significant amount.

These results suggest that the use of pHLIP significantly improves the impact of gold nanoparticles on improving the effectiveness of radiation. In vivo studies are in preparation. Previous work by members of our research collaboration has shown that pHLIP is capable of significantly increasing the amount of gold that locates to a tumor in a mouse model. Thus, it appears likely that pHLIP will also increase the impact of gold nanoparticles on radiation effectiveness in mice.

SP049.6 - The use of nanoparticles to improve hadrontherapy

Author(s): <u>Marta Bolsa-Ferruz</u>¹, Erika Porcel¹, Noriko Usami², Katsumi Kobayashi², Olivier Tillement³, Hynd Remita⁴, Ryoichi Hirayama⁵, Yoshiya Furusawa⁵, Vladimir Ivosev¹, Daniela Salado¹, Lenka Stefancikova¹, Sandrine Lacombe¹

Radiotherapy, one of the main treatments in cancer, can be improved by the use of heavy atoms, as radiation enhancers. Many investigations are conducted in this area. The challenge is to increase the radiation damage on tumor whilst preserving healthy tissue by improving targeting. Recent developments in nanotechnology brought new perspectives by using nanoparticles, which can be specifically functionalized. We have shown recently that platinum nanoparticles enhance even more than platinum complexes the DNA damage induced as well by fast carbon ions [1], as by gamma rays [2]. This effect is not due to the nature of the incoming radiation but explained by the auto-amplification of electron cascades into the nanoparticles. This result finds strong interest for developing medical protocols such as hadrontherapy and nanomedecine.

Similar results were found with gadolinium based nanoparticles (GBN) which give the possibility to associate RMN imaging to radiotherapy. Furthermore, a decrease of mammalian cell survival was also observed when GBN are associated to ions radiation [3].

This last result allows us to measure how the use of heavy nanoparticles could improve treatments by enhancing efficiency and targeting of radiations into the tumor. The treatment could be simultaneously followed by MRI.

SP050 - Time-Frequency Analysis

TRACK 09: BIOSIGNAL PROCESSING

SP050.1 - Frontiers of Neuroengineering

Neuroengineering field is seeing an explosive growth thanks to the major brain initiatives worldwide, and the belief that technologies that can push the scientific and clinical frontiers in brain sciences as well as diagnosis and treatment of the nervous system diseases and disorders. Technology is playing a key role from discoveries at cellular to whole brain level. Examples include nano and microprobes are used for recording from neurons, nerves and from many brain regions, and various imaging modalities using high resolution optical neuronal imaging to whole brain functional imaging. Neurotechnology is also playing a key role in diagnostic and therapeutic domains. Among the exciting frontiers are neural interfaces to restore function (limbs and visceral organs), treating brain disorders, neuroprosthetics, and brain machine interfaces. This talk will overview the emerging technologies and key applications and successes driving the field of Neuroengineering as well as lay out several problems and challenges.

SP050.2 - Neural responses to hearing own names comparing with repeated/non-repeated unfamiliar stimuli

Author(s): <u>Kaori Tamura</u>, Toshiki Matsuo, Keiji Iramina Graduate School Of Systems Life Sciences, Kyushu University, Fukuoka City/JAPAN

Neural responses to self-related stimuli have been investigated to reveal the function of self-recognition. Subject's own name (SON) is the word which closely related to self-recognition process. The present study focused on this own name stimulus and examined neuronal responses to hearing SON by measuring and analyzing electroencephalography (EEG), comparing with hearing unknown names.

Our experimental sequence consisted of calling SON and unfamiliar names (UN) those have no relationship with each participant. However, the habituation caused from stimulus repetition in the experimental design would affect the difference between UNs and SON. Taking this repetition effect into account when we investigate the cognitive function of self-related tasks, we used two kinds of unknown name stimuli conditions. In the one of the conditions, only one UN was selected and presented several times as the same numbers as SON (repeated UN: rUN). In another condition, several types of UNs were presented only at once during an experiment (single presented UN: sUN). By this experimental sequence, we performed EEG measurements and analyzed the collected EEG data by wavelet transform. Then we obtained event-related (de-)synchronization (ERD/ERS) in each condition from wavelet coefficients.

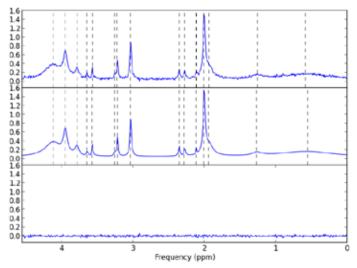

In SON, we found significant beta ERD, while sUN showed beta ERS at the same latency. The mean value of beta power in rUN was midway between those of SON and sUN. This linearity of beta power changes seemed to be related with familiarity levels. SON was the most familiar stimulus among the all stimuli, and stimuli of sUN were completely not because they were presented only once. The familiarity of rUN could be increased by repetition during an experiment, though it was not familiar one before the measurement. Considering these results, we suggest that beta power changes related with the familiarity levels. SP050.3 - MRS data deconvolution through KBDM with multiple signal truncation and clustering: circumventing noise effects Author(s): Danilo M.D.D. Da Silva¹, Yule Vaz², Fernando F. Paiva¹ ¹Departamento De Fisica E Ciencia Interdisciplinar, Instituto de Fisica de Sao Carlos, Universidade de Sao Paulo, Sao Carlos/ BRAZIL, ²Departamento De Ciencias De Computacao, Instituto de Ciencias Matematicas e de Computacao, Universidade de Sao Paulo, Sao Carlos/BRAZIL

The spectral analysis using Fourier Transform (FT) formalism shown to be very useful in a wide range of MRS applications. However, this technique can be tricky in some cases where peak superposition occurs, a common situation during in vivo data quantification process. This work describes an unsupervised deconvolution algorithm using Krylov Basis Diagonalization Method (KBDM) with multiple signal truncation and clustering. The KBDM is a fitting algorithm based on Lorentzian model functions and its mathematical approach is described at [1-4].

Basically, the output of the KBDM is a tuple (T2, frequency, amplitude and phase of each signal component) of M points obtained from a generalized eigenvalue equation of MxM matrices built using M points of the MRS signal. If only K Lorentzian components are present in the signal, the remaining M-K components will vanish for noiseless signal. When noise is present, it will be represented using Lorentzian components, which will lead to spurious components.

We exploited the fact that varying the number of points of the signal (M) used to construct the matrices aforementioned leads to different representations of noise components to minimize its effect in the estimation of each signal component. We applied the method multiple times with different values of M, clustering its results with a density-based algorithm and averaging the values of each cluster. The figure below shows the original noisy signal (top), the estimated signal using our method (middle) and the residual (bottom).

Our results show that using the proposed processing strategy, KBDM-estimated values are highly consistent with simulated values for different sets of spectra and noise level. The effects of the noise in the spectral quantification was not found to be critical, at least for simulated data with signal-to-noise ratio equivalent to that typically found in clinical MRS at 1.5T. In summary, KDBM is a promising tool that can provide complimentary information to the well-established Fourier techniques, especially when overlapping peaks are present. Further studies are in progress in order to validate the proposed method for *in vivo* data processing.

SP050.4 - Quantification of Wavelet Band Metrics for Assessing Heart Rate Variability

Author(s): Mark P. Wachowiak¹, Dean C. Hay², Michel J. Johnson³ ¹Computer Science And Mathematics, Nipissing University, North Bay/ON/CANADA, ²Physical And Health Education, Nipissing University, North Bay/ON/CANADA, ³École De Kinésiologie Et De Loisir, Université de Moncton, Moncton/CANADA

Because of its physiological and clinical importance, heart rate variability (HRV) has been investigated with many techniques, including time-frequency methods. In this study, time-varying frequency changes in the lower bands of continuous wavelet transforms directly computed from ECG signals are quantified with statistical and information-theoretic measures. These metrics are compared for resting and lower body negative pressure (LBNP) conditions, and with standard HRV metrics. Although the latter confirm the expected lower variability in the LBNP condition, metrics from the main frequency band in the wavelet transform corresponding to the observed range of heart rate (0.5–1.25 Hz) exhibit statistically significant higher variability than baseline conditions. It is proposed that a more complete HRV analysis can emerge when lower-band variability metrics of ECG in the time-frequency domain is used in conjunction with more traditional time and frequency domain approaches.

SP050.5 - Effect of Coffee on EEG Spectral Asymmetry

Author(s): Madina Saifudinova, <u>Maie Bachmann</u>, Jaanus Lass, Hiie Hinrikus

Department Of Biomedical Engineering, Technomedicum, Tallinn University of Technology, Tallinn/ESTONIA

This study aims to evaluate the sensitivity of EEG spectral asymmetry index (SASI) for detection of the effect of coffee as a chemical stressor on human EEG. SASI, based on the balance of powers of EEG frequency bands in undisturbed brain, was previously proposed as a novel objective method for evaluation of depression. The experiments were performed on 17 young healthy subjects. The EEG time series were recorded using 9 channels: F3, Fz, F4, C3, C4, P3, P4, O1, O2 (common reference Cz). The coffee intake causes significant decrease of SASI in F3, Fz, F4, C3 and C4 channels. Maximal changes were detected in frontal area, while most significant alterations were observed in parietal brain area in previous depression studies. The results suppose that SASI is a promising measure for evaluating also the effect of chemical stressor on brain bioelectrical activity.

SP050.6 - Effects of Changing in the Neck Fluid Volume, Neck Circumference and Upper Airway during Sleep on Snoring Sound Characteristics

Author(s): Shumit Saha¹, Mahsa Taheri², <u>Zahra Moussavi¹</u>, Azadeh Yadollahi²

¹Biomedical Engineering, University of Manitoba, Winnipeg/CAN-ADA, ²Toronto Rehabilitation Institute-University Health Network, Toronto/ON/CANADA

Introduction: Rostral fluid shift during sleep can increase neck circumference (NC) and narrow the upper airway cross-sectional area (UA-XSA). Such narrowing in UA-XSA may increase turbulence of airflow passing through the upper airway; thus, induce snoring. The objective of this study was to investigate whether acoustic features of snoring change with the increases in NFV, NC and decreases in UA-XSA. We hypothesize that fluid accumulation in the neck changes the snoring sound features in time and frequency domains.

Method: Twelve men (age: 46±13 years, BMI: 26±3, AHI: 39±25) attended the sleep laboratory for a daytime sleep study. Subjects slept in supine position only, and their sleep was assessed by a regular polysomnography. NC and UA-XSA were measured before and after sleep using a measuring tape and acoustic pharyngometry, respectively. During sleep, snoring sounds were recorded with a microphone attached to the neck. Snoring segments were annotated manually by an expert. Snoring features such as duration and occurrence of snoring, average power for seven frequency sub-bands were extracted in various sleep stages as well as the entire sleep duration. Correlations between snoring features and changes in NC and UA-XSA were assessed by Pearson or Spearman's correlations.

Results: Increases in NC after sleep were found to be associated with an increase in average power of the snoring sounds in the frequency range of 100-4000 Hz (r = 0.76, P=0.011) and of 150-450 Hz (r = 0.73, P=0.017). Furthermore, reductions in UA-XSA increased snoring sounds' average power in the frequency range of 100-4000Hz (r = -0.70, P=0.025) and 150-450Hz (r = -0.64, P=0.044). Similar strong correlations between snoring sounds' average power and changes in NC (100-4000Hz: r = 0.72, P= 0.019; 150-450 Hz: r = 0.73, P= 0.016) and UA-XSA (100-4000Hz: r = -0.71, P= 0.022; 150-450 Hz: r = -0.79, P= 0.006) were achieved in non-REM stage 2 of sleep.

Conclusion: Our findings suggest that an increase in NC and narrowing in the UA-XSA could increase snoring sounds' power in various frequency ranges.

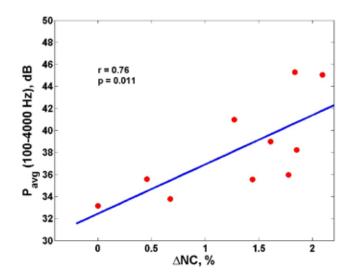

Figure 1. Relationship between percentage change in NC and average power of snoring sounds (calculated over the entire sleep duration) within 100 – 4000 Hz frequency range

SP051 - Rehabilitation Robotics

TRACK 10: REHABILITATION MEDICINE, SPORTS MEDICINE, REHABILITATION ENGINEERING AND PROSTHETICS

SP051.1 - Biomechanical Simulation of Upper Extremities Exoskeleton to Aid Stroke Patients

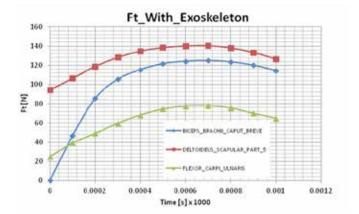

Author(s): Yahia M. Al-Smadi

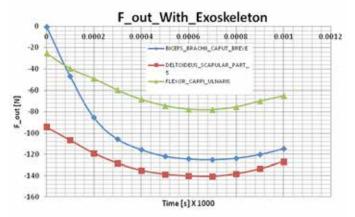

Mechanical Engineering, Texas A&M University - Kingsville, Kingsville/UNITED STATES OF AMERICA

Recently many efforts are carried out that can help people with restricted arm movement or rehabilitate injuries and disabilities. In this case exoskeleton is the most extensively used equipment to get rid of this restriction. Exoskeleton helps to boost strength and endurance as well as reduce the efforts required to perform various activities in day-to-day life.

In order to manipulate characteristic of the exoskeleton, we carried out two virtual experiments. Initially using Denavit–Hartenberg parameters, we patronized our model with number of degree of freedom. ADAMS and AnyBody simulations were carried out. We computed results of effects over human body with and without exoskeleton.

While studying exoskeleton effect on human arm, we studied several joints, muscles and bones reactions in different load conditions. We studied two different load conditions while concentrating on performance of the exoskeleton. The very first condition was constant load where as the second one is the variable load acting on the arm. In both the case we considered gravity force to get more precise result. Below shown graphs are some of the results which we have explained later.

While doing virtual experiments of an exoskeleton on human arm, we observed significant change in reaction of the muscles, bone and joints movement. We found some muscles reacts same with and without exoskeleton where as at the joints we recorded tremendous output of an exoskeleton and human arm fusion. selected muscles for our study are Caput breve a short head of biceps brachii muscles, deltoid muscles which responsible for arm movement in scapular plane and the flexor Carpi ulnaris (FCU) muscle which is located in forearm and responsible for flexion and adduction of the hand.

SP051.2 - Testing a mobile robot toy for children with disabilities Author(s): Adriana M. Rios Rincón, Daniel A. Quiroga Torres, Javier Castellanos, Maria F. Gómez Medina, Antonio Miguel Cruz, <u>William</u> <u>R. Rodríguez</u>

School Of Medicine And Health Sciences, Universidad del Rosario, Bogotá/COLOMBIA

Robots showed a potential to enhance engagement in free play of children with severe motor impairment, however, they are too expensive to be used in low-income settings. The objective of this study is to perform technical assessment of a prototype of a low cost car-like robot that can be operated by head movements for children with motor impairment. We designed a robot that and tested its technical features. We found that the robot power efficiency is low (47%), current peak for both motors were 474.4 mA (right) and 416 mA (left) both of them were below 2 Amp which is the maximum current limit threshold tolerated by the L293B component, as the robots get far away from the control the response time slightly increased. The reaching distance of the remote control was 20.7 meters which is enough for using in therapeutic activities. Regarding the functional features, the robot moved forward in a straight line 86.6% of the tested trials (26/30) and was able to turn 90 degrees left or right 93.3% of the trials (28/30). The robotic prototype met basic technical and functional requirements. Power efficiency, safety and apparel features should be improved for being used by children with using for children with motor impairments.

$\ensuremath{\mathsf{SP051.3}}$ - Pilot study of a soft metal hydride actuator for a wearable rehabilitation system

Author(s): <u>Minako Hosono</u>¹, Kouji Sakaki², Shuichi Ino² ¹Industrial Research Institute of Shizuoka Prefecture, Shizuoka/ JAPAN, ²National Institute of Advanced Industrial Science and Technology, Tsukuba/JAPAN

A prototype actuator for a wearable rehabilitation system was proposed in this study.

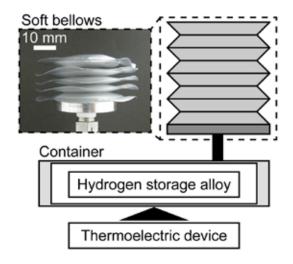

A wearable rehabilitation system has a potential to play an important role in remote rehabilitation to free patients from stressfull constraints. It is essential for such a rehabilitation system to be reliably safe, compact, and silent. To meet these needs, we have developed a soft metal hydride (MH) actuator utilizing the property of a hydrogen storage alloy for a part of the rehabilitation system.

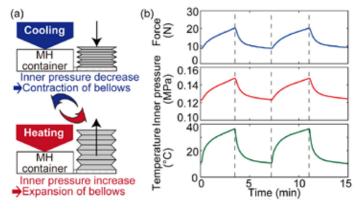

The soft MH actuator consists of a soft bellows made from laminated aluminum film (PE/AI/PET, 0.1 mm in thickness) as an end effector, a container of a hydrogen storage alloy as a source of bellows motion, and a thermoelectric device such as a Peltier device for temperature control (Figure 1). A hydrogen storage alloy can reversibly absorb and release a large amount of hydrogen gas by thermal control, i.e. cooling for absorption of hydrogen and heating for realsing hydrogen from the hydride (Figure 2(a)). By converting this reversible chemical reaction into bellows stroke due to the inner hydrogen pressure change, the soft MH actuator can generate high force by a compact device and realize silent operation and shock-absorbing function like a cushion¹. In this study, the soft MH actuator, which contained 1 g of alloy (Ti0.5Zr0.5Mn0.8V0.2Ni0.9 Al0.1)² and utilized a soft bellows with 50 mm of diameteras the end effector, achieved 20 N cyclic output by controlling the temperature between 284 K to 310 K (Figure 2(b)). From this result, we expect that the soft MH actuator works as a powerfull tool in a part of a wearable rehabilitation system.

This work was supported by JSPS KAKENHI Grant Numbers 25560281, 25242057.

SP051.4 - Robotic Spasticity Quantification: Velocity Dependent Component of Biomechanical Resistance

Author(s): <u>Nitin Seth</u>¹, Denise Johnson², Hussein A. Abdullah³ ¹School Of Engineering, University of Guelph, Guelph/CANA-DA, ²Acquired Brain Injury Program, Regional Rehabilitation Centre, Hamilton Health Sciences, Hamilton/ON/CANADA, ³School Of Engineering, University of Guelph, Guelph/ON/CANADA

Introduction: Spasticity, is commonly referred to as velocity dependent resistance to passive motion arising from upper motor neuron lesions. It is monitored closely and is important for determining stages of recovery. Doctors, physiotherapists and clinicians require more sensitive and quantitative method for spasticity assessment. The most commonly used method is the Modified Ashworth Scale. It has, however, had several studies test its applicability to spasticity assessment and has been deemed reliable for assessment of upper limb flexion/extension.

Methods: Using a robotic system, 5 controlled flexion/extension motions are employed at progressively faster speeds to collect biomechanical resistive force, position, and time data in real time. Motions are performed in the individual's sagittal plane similar to functional motions of raising an object to their head or face. A linearly separable model quantifies the velocity dependent component of resistance and statistical model demonstrates the effect MAS scores have on the new velocity dependent resistance metric. This study considered healthy controls (n = 44) and individuals with an acquired brain injury receiving treatment for spasticity (n = 39). To determine the best representation, the quantitative spasticity metric was calculated once with flexion data, once with extension data, and a final time with data from both motions.

Results: The MAS, while augmented with an additional value to indicate healthy controls, was found to be significantly effect the metric calculated from both flexion and extension motions. This was true for both MAS bicep and tricep scores. Table 1 lists fixed effects for each of the 4 models.

Effect	F	Р
MAS Bicep (Flexion/Extension)	16.25	<0.0001
MAS Tricep (Flexion/Extension)	11.55	<0.0001
Extension Only Data	1.99	0.0987
Flexion Only Data	5.19	0.0008

The metric can also distinguish between the high MAS scores (MAS 2, 3) and low MAS scores (healthy controls, MAS 0, 1) with values that were statistically significantly different.

Discussion/Conclusions: MAS bicep/ tricep scores demonstrated effects on the quantitative spasticity metric. The strongest relationship was determined for metrics calculated from both flexion and extension motions together. Flexion only calculations also found that MAS had a direct effect, whereas it approached significance with extension data. More studies and data is required to determine if a stronger relationship is achievable. The robot's controlled and varied speed motions allowed for a calculation of a velocity dependent effect to quantify spasticity. These values are determined only from biomechanical data directly relatable to the MAS scale. This data can potentially aid clinicians in making treatment decisions and measuring progress or changes in spasticity.

SP052 - Functional Neuroimaging and Neuronavigation

TRACK 11: NEUROENGINEERING, NEURAL SYSTEMS

SP052.1 - From human neuron to human brain: Neurosurgical contributions to understanding the brain

Author(s): Taufik Valiante

Director Of The Surgical Epilepsy Program, Krembil Neuroscience Center, Toronto/ON/CANADA

In this talk I will review neurosurgical contributions to understanding the human brain, particularly in the context of surgery for epilepsy and movement disorders. I will review early studies that have led to the understanding of localized cortical function, which formed the basis of initial attempts at understanding information processing within the brain. I will then describe ongoing work using electrocorticography and single unit recordings to elucidate fundamental human brain function including memory, attention, and language. The investigations that I will review will span many levels of investigations, from the activity of single human cortical neurons, to small cortical microcircuits, and then up to large scale integration – largely as a byproduct of the clinical care afforded to people with epilepsy. I will conclude by attempting to outline the limitations of current technologies to record from and control the human brain.

SP052.2 - Modulation of event-related desynchronization and synchronization during right finger flexion in patients with Amyotrophic Lateral Sclerosis

Author(s): Nataša Bizovičar

University Rehabilitation Institute of Republic of Slovenia, Ljubljana/ SLOVENIA

Introduction

Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disorder with signs of upper and lower motor neuron degeneration. Potential electroencephalographic (EEG) methods for studying upper motor neuron and other cortical motor functions during the preparation and execution of volitional movements are so-called event-related desynchronization (ERD) and synchronization (ERS) ERD is a relative EEG power decrease pre- and during motor activity and is described as an electrophysiological correlate of an activated cortical network. ERS is a relative EEG power increase after termination of the movement and is an electrophysiological correlate of cortical areas at rest. The brain has the capacity to change the architecture of the neural networks during learning or as a response to injury. Diseases that affect neuronal networks such as ALS could have an impact on the change in absolute and relative EEG spectral power, its topography and time course. Our aim was to study ERD/ ERS related to finger flexion in patients with ALS.

Methods

Twenty-one ALS patients (aged 54-74 years) and nineteen matched controls (aged 48-72 years) were assessed for their hand dexterity and strength, spasticity and functional rating scales. EEGs (10-20 system, 30 channels) were recorded while patients and controls performed self-paced fast right index finger flexion motor task. EEG time-frequency analysis was performed in the alpha (8–12 Hz) and beta (13–30 Hz) bands.

Results

Patients performed significantly worse on all hand function tests and had decreased hand muscle strength compared to control subjects. Latencies of the ERD beginning did not differ between the ALS patients and controls. Patients generated significantly smaller resting alpha spectral power density and lower beta ERD compared to controls. There was a larger difference in ERS between the contra- and ipsilateral brain hemispheres in the ALS group. No significant correlations between ERD/ERS and clinical measures were observed.

Conclusions

There are different morphological and functional changes in the brain of ALS patients described in the literature which could explain some of the changes in ERD and ERS. The reduction of beta ERD could result from the loss of pyramidal cortical neurons and asymmetry of ERS in patients with ALS compared to controls could be the result of interhemispheric corticomotor network degeneration in ALS.

SP052.3 - Functional connectivity patterns associated with swallowing of fluids with various viscosity

Author(s): Iva Jestrovic¹, James L. Coyle², <u>Ervin Sejdic¹</u> ¹Department Of Electrical And Computer Engineering, University of Pittsburgh, Pittsburgh/PA/UNITED STATES OF AMERICA, ²2department Of Communications Science And Disorders, University of Pittsburgh, Pittsburgh/PA/UNITED STATES OF AMERICA

Thickened dietary fluids are commonly deployed to prevent ordinary thin liquids from entering the airway of patients with certain swallowing disorders. Their mechanism of action has thus far been attributed to two possible explanations. First, rheological properties of the thicker fluids, may render them less likely to enter a small opening in the poorly-closed airway during swallowing. Alternately, the thicker liquids may adhere to the pharyngeal mucosa thereby reducing their rate of flow. However the possibility that thicker liquids cause perturbations in central sensorimotor processing has not been considered or investigated. Therefore, we investigated the influence of fluid viscosity on associated swallowing brain networks. EEG signals were collected from 55 healthy adults who performed five water, five nectar-thick, and five honey-thick liquid swallows. Standard preprocessing of EEG time-series was utilized and pre-processed signals were filtered in the frequency bands of interest. Brain networks were formed using the time-frequency based synchrony measure. Results showed that increasing fluid viscosity resulted in higher clustering coefficients in all frequency bands (p<0.04) (Figure 1.A), while the characteristic path length tended to be lower in the Delta, Theta, and Alpha frequency bands (p<0.03) (Figure 1.B). Brain networks formed during swallowing of thicker liquids had higher small-world parameters in the Delta, Theta, and Alpha frequency bands (p<0.05) (Figure 1.C). These results provide intriguing possibilities regarding the effects of peripheral manipulations on central processing of swallowing sensorimotor function. Further investigations of the neural basis of dysphagia are warranted to elucidate this and related possibilities.

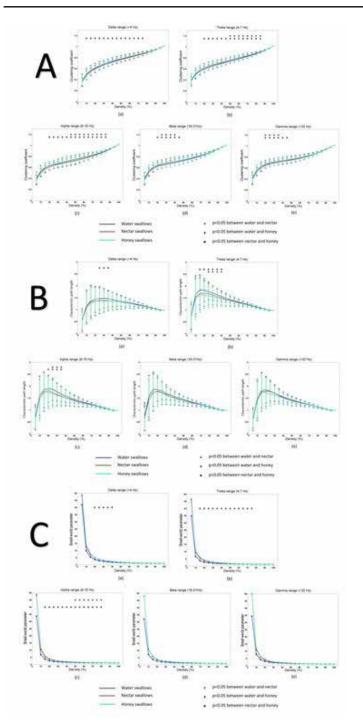

Figure 1: (A) Mean clustering coefficient for a different threshold percentage and for different frequency bands. (B) Mean characteristic path length for a different threshold percentage and for different frequency bands. (C) Small-world parameter for a different threshold percentage and for different frequency bands

SP052.4 - Distribution of F-Latency (DFL) - a new nerve conduction parameter for early detection of radiculo-myelopathy Author(s): <u>K Siddique Rabbani</u>

Biomedical Physics & Technology, University of Dhaka, Dhaka/BAN-GLADESH

Distribution of F-Latency (DFL) is a new nerve conduction parameter conceived and named by the author several years back and who has led many researchers over the period in improving the understanding of the parameter and its application in early detection of radiculo-myelopathy. The method has been found to work equally for the cervical and the lumbo-sacral regions, however bulk of the systematic work carried out so far is for the former, particularly using the median nerve. Described for the median nerve, DFL is basically a statistical distribution of latencies of F-responses obtained through electrical stimulation of the nerve at the wrist and recording of the evoked muscle responses from the Thenar muscle group at the base of the thumb. F-response is the secondary response occurring due to antidromic conduction of action potentials in the motor nerve fibres from the wrist to the spinal cord, and then through random backfiring in a few percent of cell bodies contributing to action potentials through these backfired nerve fibres. Because of random recruitment of nerve fibres with different conduction velocity values, the F-latencies due to multiple stimulations vary randomly and this has been used to advantage in DFL to get a picture of the distribution of Conduction velocity (DCV) of nerve fibres as an approximate mirror image of DFL, thus contributing to a practical method to measure DCV in a clinical setting, which was not possible earlier. It has been found by groups led by the author that for normal subjects DFL has a single sharp peak while for subjects with cervical radiculopathy (entrapment of the nerve roots near the spinal cord) or myelopathy (compression of the spinal cord due to a vertebral disc bulging or herniation) DFL has double peaks or broad peaks. Hypotheses have been put forward in explaining the causes of the observed patterns which have been verified to a great extent through MRI investigations on the same subjects. Some of the broad peaks are very close to a single peak and a special criterion has been set up, based on a learning process using MRI on the same subjects through a research carried out in Singapore, again led by the author, to identify these subtle broad peaks from single peaks. Recently improved detection has resulted from changing the bin starting values in calculating the statistical frequency distribution that result in the DFL and combining the outcomes of the two distributions. Further work has been carried out in order to assess the minimum number of F-responses needed to differentiate the patterns of DFL in radiculo-myelopathy. It has been found that about 15 F-responses are adequate to distinguish the DFL patterns in the above detection if the bin size is chosen as 2ms. Through the combined procedure, almost 80% correct prediction have been obtained through a double blind study, when evaluated using MRI. It is expected that this method of DFL would become a first line screening test in any peripheral neuropathy in the near future.

SP053 - Cardiovascular Instrumentation

TRACK 12: MEDICAL DEVICES

SP053.1 - A Microfluidic cell culture Instrument for individual testing of therapeutics.

Author(s): <u>Marie Keays</u>¹, Patrick A. Kiely², Tara Dalton¹ ¹Stokes Institute, University Of Limerick, Limerick/IRELAND, ²Department Of Life Sciences, And Materials And Surface Science Institute, University Of Limerick, Limerick/IRELAND

The realisation of personalised medicine has been the target of many multidisciplinary scientific teams. A system that can individualise point of care diagnostics has the potential to revolutionise medical treatment. Currently, drug discovery uses 2-dimensional cell culture techniques as a test to monitor the cells reactions to drugs these models have provided the platform for most toxicity and drug testing. However, the requirement of sample containers such as dishes or flasks are a limiting factor and do not lend themselves to automation. With a desire to understand and diagnose disease and infection at a patient specific and cellular level, there is a pressing need to modify procedures to facilitate multi-experimental approaches that are cost effective, automated and use small amounts of patient sample and reagents. This has encouraged us to develop a microfluidic droplet cell culture platform. The proposed system will create droplet cultures and facilitate incubation and imaging of the cultures on one platform. This system facilitates the establishment three-dimensional culture conditions that more accurately mimics natural cell conditions and cell-cell communication. The culture droplets are created in a nano-litre range and multiple unique bioreactor droplets can be prepared and analysed on one system making this a time and cost effective instrument. This system can benefit cancer diagnosis as multiple assays can be mixed with individual culture droplets. This lends itself to drug cocktail testing tested against a specific sample making this a powerful instrument in understanding cells.

SP053.2 - A Bioinspired Catheter Harnessing Gecko Adhesion and Inchworm-Like Locomotion for Targeted Drug Delivery Author(s): Jonathan Wolfe¹, Huan Qi², Paul J.L. Ong³, Tze Tec Chong⁴, Denis Fichou⁵, Claus D. Ohl⁵, Joo S. Chia⁶, Subbu Venkatraman², Swee H. Teoh⁷

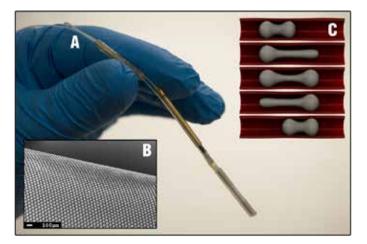

¹Interdisciplinary Graduate School, Nanyang Technological University, Singapore/SINGAPORE, ²Material Science And Engineering, Nanyang Technological University, Singapore/SINGAPORE, ³Cardiology Clinic, Tan Tock Seng Hospital, Singapore/SINGA-PORE, ⁴Vascular Surgery, Singapore General Hospital, Singapore/ SINGAPORE, ⁵School Of Physical And Mathematical Sciences, Nanyang Technological University, Singapore/SINGAPORE, ⁶Urology & Continence Clinic, Tan Tock Seng Hospital, Singapore/SINGA-PORE, ⁷School Of Chemical And Biological Engineering, Nanyang Technological University, Singapore/SINGAPORE

Invented more than 250 years ago, modern catheters have developed into a technological diagnostic/therapeutic medical instruments used in myriad applications such as catheterization, colonoscopy, ureteroscopy, dilating balloon and stenting. Some of the larger devices are capable of carrying sophisticated imaging and sensing modalities with robotic ultra-fine surgical instruments.

In recent years, smart-materials and advanced micro-manufacturing techniques have enabled the construction of millimeter-sized catheters capable of robotic bending and rotation, allowing catheters to maneuver deeper inside the patient's body. However, a fundamental drawback is that catheters are pushed from the outside by the surgeon. This works well for large diameter vessels but poses many challenging issues for small diameter vessels. As the artery diameter decreases, increasing forces between the catheter and the vessel inner wall causes the catheter to buckle rather than advance. Moreover, the high friction caused by pushing the catheter, especially at curvatures, may result in life-threatening vessel injuries.

To resolve this, we have developed an alternative principle for catheter locomotion, here named *SmartCat*, an inchworm-inspired μ -robotic catheter that is powered by saline pressure. This selfpulling catheter is 2.5 millimeters in diameter, and can autonomously navigate the vessel at a speed of 2 cm/sec. The robots are batchfabricated, and are thus suitable for mass production.

For safe implementation of the inchworm locomotion, hemocompatible gecko-inspired balloon clampers were developed. This gentle, reusable adhesive enables a dramatic reduction in the force required to achieve adequate vessel grip. In addition, these balloon clampers can also be used to form a close-off region for localized drug delivery.

(A) Prototype of an inchworm-robotic catheter prior to encapsulation within elastic silicone-gecko cloak, shown in (B). (C) Schematic of the inchworm locomotion principle.

SP053.3 - Covered stent with perforated membrane for treatment of peripheral atheroembolic disease

Author(s): Foad Kabinejadian¹, Mercedeh Kaabi Nezhadian², Fangsen Cui³, Pei Ho¹, Hwa Liang Leo²

¹Department Of Surgery, National University of Singapore, Singapore/SINGAPORE, ²Department Of Biomedical Engineering, National University of Singapore, Singapore/SINGAPORE, ³Engineering Mechanics, Institute of High Performance Computing, A*STAR, Singapore/SINGAPORE

We have recently developed a novel stent membrane design for covered stents that prevents emboli while preserving the side-branch flows. Our earlier in vitro studies in models of carotid arteries have shown that this novel design can maintain more than 83% of the original external carotid artery (ECA) branch flow and has the potential to considerably reduce the chance of emboli release as compared to bare metal stents. In the present study, the application of this novel stent membrane design in the treatment of atheroembolic disease in peripheral arteries is investigated. The novel stent design has been tested in a PDMS model of superficial femoral artery (SFA) and its performance has been evaluated in vitro under physiological pulsatile flow condition, utilizing flow visualization (dye injection), and particle image velocimetry (PIV) techniques. These evaluations include the assessment of emboli prevention capability, side-branch flow preservation, and influence on the branch flow pattern and velocity field. The novel covered stent demonstrated significant emboli prevention capability, and the flow in the side branches was smooth and uniform. This study demonstrated the potential of this novel covered stent design for the treatment of atheroembolic disease in peripheral arteries. However, further in vivo investigations of biological effects and mechanical performance of this covered stent design is warranted.

SP053.4 - Nanostructuring Carbon Fibre Probes for Use in Central Venous Catheters

Author(s): Jolene Mchugh¹, Meixian Li², Marco F. Cardosi³, James Davis¹

¹Nibec, School Of Engineering, University of Ulster, Newtownabbey/ UNITED KINGDOM, ²College Of Chemistry And Molecular Engineering, Peking University, Beijing/CHINA, ³Lifescan Scotland Ltd, Inverness/UNITED KINGDOM

Central venous catheters (CVCs) and peripherally inserted central catheters (PICC) are vital access lines through which to deliver life preserving agents whether nutritional or chemotherapeutic formulations or, as in haemodialysis, allow the removal of toxins that accumulate. It has been estimated that some 5 million central venous access devices are inserted in the US each year but, sadly, the occurrence of catheter-related blood stream infections (CRB-SIs) are known to present a considerable challenge for clinicians. This is a long standing problem with some 300,000 cases reported annually which incur considerable costs in terms of additional treatment through increasing the average hospital stay to 7-12 days. The severity of such conditions is highlighted by an unacceptably high mortality rate that can rise as high as 40% for infection by Candida species. The subsequent treatment regime is often complicated by the fact that bacteria associated with biofilm formation within the catheter lumen possess an increased resistance to conventional antimicrobial treatments and leads to a prolonged hospital admission which can often necessitate the complete removal of the line to prevent re-infection.

While there has been extensive research into the development of antimicrobial materials to minimise biofilm formation, there are no point of care diagnostics available to provide an early warning for the onset of infection. In most cases, infection is only detected once gross symptoms (typically fever and rigor) appear and has traditionally relied upon the expertise and vigilance of the healthcare staff. As most CVC lines are maintained by outpatients, there can be obvious ambiguity in ascribing a feeling of being unwell. When combined with a reluctance to present a false positive, the conditions can easily progress to the severe detriment of the patient. The present communication has sought to investigate the design of a probe that could, in principle, allow the condition of the line to be autonomously monitored and, ultimately, alert the patient or the healthcare staff to the onset of biofilm formation such more appropriate and effective remedial treatment could be employed that would enhance the lifetime of the line.

The carbon fiber probe described utilizes the oxidation of an endogenous biomarker (Uric Acid) to provide diagnostic information on the condition of intravascular access lines. The probe surface was modified through anodic oxidation to provide a high selectivity towards urate which was used as a redox probe through which the pH could be determined. The sensing rationale relates to the fact that bacterial colonisation and biofilm formation of the line will result in changes to the localised pH at the electrode and thus it could be envisaged that the probe would provide an early warning signal such that remedial treatment could be applied before the film takes hold. A Nerstian response (-60mV/pH) was obtained which was free from the interference of other redox species common to biofluids. The electroanalytical performance of the probe has been optimized and the applicability of the approach demonstrated through testing the responses in whole blood.

SP053.5 - Denoising RF defibrillator waveforms for intracardiac atrial substrate impedance characterisation using digital filtering techniques

Author(s): <u>Omar J. Escalona</u>¹, Philip R. Walsh¹, Ali S. Rababah¹, Vivek Kodoth², Ganesh Manoharan² ¹Engineering Research Institute, Ulster University, Newtownabbey/

UNITED KINGDOM, ²The Heart Centre, Royal Victoria Hospital, Belfast/UNITED KINGDOM

Introduction: Atrial fibrillation (AF) is the most common cardiac arrhythmias and accounts for 30% -40% of all cardiac arrhythmia related hospital admissions. It is also one of the leading causes of stroke. Treatment can be achieved using electrical internal cardioversion, which involves application of an electrical shock to the heart tissue by means of internal electrodes. Recently, novel low-tilt rectilinear waveforms generated by a radiofrequency defibrillator device have shown enhanced efficacy in the treatment of atrial fibrillation in comparison to conventional capacitor based shock waveforms. During defibrillation, intra-cardiac impedance (ICI) is one of the major determinants of success and has been identified as critical to understanding and optimization of therapies. In addition, accurate ICI measurements are thought to provide valuable information about tissue-electrode interface characteristics and may relate to other variables such as voltage amplitude, defibrillation energy threshold and outcome.

Methods: At Royal Victoria Hospital Belfast, voltage and current waveforms were digitally recorded at 250 kHz sampling frequency using a digital oscilloscope (Tektronix TDS 3014B) and a current probe (Fluke 80i-110s) during internal cardioversion of patients with persistent AF using a novel low-tilt rectilinear waveform (generated by a radiofrequency defibrillator device) following a step up energy protocol (50V to 300V in 50V steps). However, typically, the recorded signals are inherently corrupted by electrical noise. The objective of this work was to investigate if it was possible to develop an algorithm, using digital signal processing (DSP) in the MATLAB environment, to denoise the AF defibrillation voltage and current waveforms by applying spectral analysis and digital filtering techniques. Specifically, the MATLAB algorithm was developed to automatically handle the large data files recorded during defibrillation therapy. Patient number and case number were used to automate loading of the associated defibrillation voltage and current waveforms and deduce the sampling frequency; based on a-priori rectilinear pulse width (12ms). The algorithm is designed to then select the desired waveform segment (part of the rectilinear signal at time between 2ms and 10ms) and denoises, generates and plots the filtered waveforms. Finally, the algorithm calculates the dynamic resistance (ICI) and present associated parameters.

Results: Analysing the spectrum of the processed rectilinear waveform signals enabled finding the most appropriate normalized cutoff frequency estimation. The study results provided this being between 0.01 and 0.02 (normalised frequency), which corresponds to 1125Hz - 2250Hz. The evaluation results also indicated that Hanning windowing was more appropriate than Blackman windowing in the spectral analysis preservation of the rectilinear waveform signals. Furthermore, noise reduction of these signals using a 7th order Butterworth filter design was found to be more efficacious in denoising than a 200 order FIR digital filter.

Conclusion: The processing algorithm developed and applied to RF defibrillator waveforms was effective for denoising voltage and current signals. This provides a useful tool for studying large number of patient cases in the characterisation of intra-cardiac impedance and its potential relation to other factors such as the outcome of cardioversion treatment and defibrillation energy threshold.

SP054 - Women in Medical Physics: Current Status

TRACK 18: GENDER, SCIENCE AND TECHNOLOGY

SP054.1 - Experiences as a Women in the Biomedical Engineering Field

Author(s): Molly S. Shoichet

Chemical Engineering And Applied Chemistry, University of Toronto, Toronto/CANADA

Professor Molly Shoichet holds the Tier 1 Canada Research Chair in Tissue Engineering at the University of Toronto. She has published over 480 papers, patents and abstracts and has given over 310 lectures worldwide. She currently leads a laboratory of 25 and has graduated 134 researchers. She founded two spin-off companies, is actively engaged in translational research and science outreach. Dr. Shoichet is the recipient of many prestigious distinctions and the only person to be a Fellow of Canada's 3 National Academies: Canadian Academy of Sciences of the Royal Society of Canada, Canadian Academy of Engineering, and Canadian Academy of Health Sciences. Dr. Shoichet holds the Order of Ontario, Ontario's highest honour and is a Fellow of the American Association for the Advancement of Science. In 2013, her contributions to Canada's innovation agenda and the advancement of knowledge were recognized with the QEII Diamond Jubilee Award. In 2014, she was given the University of Toronto's highest distinction, University Professor, a distinction held by less than 2% of the faculty. Dr. Shoichet received her SB from the Massachusetts Institute of Technology (1987) and her PhD from the University of Massachusetts, Amherst in Polymer Science and Engineering (1992).

SP054.2 - The Historical Role of Women in Medical Physics Author(s): <u>Magdalena Stoeva</u>¹, Virginia Tsapakis², Simone Kodlulovich³

¹IOMP Medical Phisics World, York/UNITED KINGDOM, ²Konstantopoulio General Hospital, Athens/GREECE, ³Asociación Latinoamericana de Física Médica (ALFIM), Brazil/BRAZIL

Women have always played a key role in the development of science. The first recorded information for women scientists dates back to over 10-20 centuries BC. Leading women scientists and philosophers during the antiquity have contributed towards the development of various scientific branches - Enheduanna (Sumerian astronomer), Agamede (ancient Greek physician), Merit Ptah (Egyptian physician), Tapputi-Belatekallim (Babylon chemist).

Although for centuries the scientific world was dominated by men, there are many gifted women who made key discoveries, inventions or overall scientific contributions. Whilst discussing the role of women in science, this is indisputably dominated by Marie Skłodowska-Curie – the brilliant physicist and chemist, the first woman to win a Nobel Prize, the first person to win two Nobel Prizes and the only person to win Nobel Prizes in multiple scientific disciplines.

Many other brilliant women have made their contribution to science – some of them with a direct relation to Medical Physics - Irène Joliot-Curie, Goeppert-Mayer, Rosalyn S. Yallow, Harriet Brooks, Chien-Shiung Wu.

To mark the 50th Anniversary of the IOMP, national and regional medical physics organizations nominated medical physicists and other closely related professionals who have made outstanding contribution to the advancement of medical physics and healthcare through research, clinical developments, education and training activities, service development, and to professional matters over the last 50 years. Women medical physicists have been included in this Outstanding Contributions list as recognition for their devotion and contributions to Medical Physics - Penelope Allisy-Roberts, Carridad Borras, Maryellen L. Giger, Anchali Krisanachinda.

The trends in the contemporary scientific and working environment and women's dedication to science and practical application of Medical Physics lead to the formation of a number of women scientific and professional societies dedicated to the advancement of Medical Physics.

SP054.4 - Women in Medical Physics; current status in Australia and New Zealand. Author(s): Eva Bezak

Australasian College of Physical Scientists and Engineers in Medicine (ACPSEM)., Adelaide/AUSTRALIA

According to the recent data by Australian Institute of Physics, Australian schoolgirls still prefer life sciences to physical sciences with a 2:1 ratio. This worsens at university to about 4:1. The proportion of women in senior science positions is improving at just 1 per cent per annum, and even going backwards at lower levels.

In the specific case of medical physics, in Australia and New Zealand, there have been some positive developments in enrolment of women into medical physics training and females now account for 30% of trainee medical physicists. This is can be considered an achievement considering that 15-20 years ago many departments would not have any or only a few female medical physicists.

However, there is still underrepresentation of women at senior roles and consequently a potential lack of role models for women earlier in their career. There is also a lack of suitable part time positions (especially at senior levels) for women who would like to balance family and work commitments.

Additionally, while the public service is generally accommodating for working mothers, private practice centres can be a different story (long hours, lots of travel). As the ratio of private to public radiation oncology services increases it may result in a more difficult environment for women and there may also be a pronounced gender bias in recruitment.

In conclusion, more work needs to be done mentor and support young women into sustainable careers in the physical sciences and engineering, including medical physics and biomedical engineering. Strategies need to be developed that will allow women successfully balance their family and work commitments both in public and private sectors.

SP055 - Cellular & Molecular Mechanics

TRACK 03: BIOMECHANICS AND ARTIFICIAL ORGANS

SP055.1 - Neurite outgrowth induced by shock waves

Author(s): <u>Youn Kihwan</u>¹, Akira Tsukamoto², Akihumi Furuichi¹, Keiichi Nakagawa³, Takegiro Ando¹, Etsuko Kobayashi¹, Takashi Ushida⁴, Ichiro Sakuma¹

¹Precision Engineering, The University of Tokyo, Tokyo/JAPAN, ²Department Of Applied Physics, National Defense Academy of Japan, Yokosuka/JAPAN, ³Department Of Chemistry, The University of Tokyo, Tokyo/JAPAN, ⁴Department Of Mechanical Engineering, The University of Tokyo, Tokyo/JAPAN

Neurite outgrowth is one of important factors to restore neurodegenerative diseases, such as Parkinson's disease and Alzheimer's disease. One way to stimulate the neurite outgrowth is mechanical stimulation. For example, mechanical stretches were demonstrated to stimulate the neurite outgrowth [1]. Although mechanical stimulations are expected to be superior in treatment targeting, minimally invasive way of mechanical stimulation is required for realizing medical applications. Shock wave is one of the noninvasive ways to introduce mechanical stimulations. In addition with Extracorporeal Shock Wave Therapy (ESWT), recent studies demonstrated that shock wave could stimulate revascularization noninvasively [2]. In this research, we hypothesized that shock wave irradiation could stimulate neurite outgrowth. To verify the hypothesis, PC12 cells, a cell line of pheochromocytoma, were irradiated with shock waves. Before shock wave irradiations, PC12 cells were cultured with DMEM supplemented with 10% FBS, 5% HS, 1% L-glutamine and 30ng/ml NGF for 2days. After that, shock waves were irradiated 10 times/day for 6 days. Peak pressure of shock waves was 3MPa and irradiation frequency was 1Hz. Neurite outgrowth was quantified with NeuronJ (ImageJ add-on software) by measuring the length of selected neurites which were longer than cell bodies. As a result, neurite outgrowth was stimulated with shock wave irradiations on PC12 cells (Fig. 1(a), Fig.1(b)). With the shock wave stimulation, average length of neurites reached 268µm±95µm compared to 213µm±88µm in control cells without shock wave irradiations (Fig. 1(c), ***p<0.001). Through this result, we knew that neurite extension can be promoted by shockwave. Although it was revealed that shock wave could stimulate neurite outgrowth in PC12 cells, further study is required to clarify the mechanical and biological mechanisms by which shock waves promote neurite outgrowth.

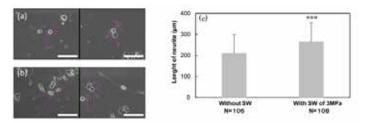

Fig.1 Images of PC12cells after exposure of NGF without and with Shock Wave (SW) for 6days. Scale bar = 300µm. (a) Without SW. (b) With SW of 3Mpa. (c) The length of neurite after exposure of NGF without and with SW for 6days. A comparison between with and without SW of 3MPa is shown with ***p<0.001. 106 neurites without SW and 108 neurites with SW were measured.

SP055.2 - Investigating mechanical behavior and structural response to strain of bovine tendon collagen fibrils using atomic force microscopy

Author(s): <u>Andrew S. Quigley</u>¹, Samuel P. Veres², Laurent Kreplak¹ ¹Physics, Dalhousie University, Halifax/NS/CANADA, ²Saint Mary's University, Halifax/CANADA

To fully understand the structure-function properties of tendons and ligaments, it is necessary to understand the mechanical response of their primary load-bearing elements: nanoscale collagen fibrils. The goal of this study is to investigate the mechanical and morphological properties of collagen fibrils as a function of applied strain, and understand the changes in fibril structure caused by tensile load and rupture. Using collagen fibrils extracted from a bovine digital extensor tendon, we developed a technique for mechanically stretching and then quantitatively imaging single, isolated fibrils using an atomic force microscope (AFM). Fibrils were extracted, deposited onto a glass substrate, and then divided into mechanically isolated 50-micron-long segments via evenly spaced epoxy droplets. Using a stiff AFM cantilever, a strain between 0 and 18% (or rupture) was applied to each segment while submerged in phosphate buffered saline (PBS) by displacing the segment's centre laterally at a rate of 1 µm/s. The force required to achieve the target strain for each segment was measured with the AFM, and increased with strain. Following the mechanical interventions, each fibril segment was imaged in PBS using the PeakForce Quantitative Nanomechanical Mapping mode of operation to characterize the high-velocity radial modulus, fibril height, and fibril morphology. The high velocity radial modulus is a measurement of molecular density within a fibril, and generally decreased with maximum applied strain. Figure 1 shows the decrease in modulus of a fibril strained to 12.0 \pm 0.5% compared to an unpulled, control segment. Consistent with this modulus trend, the change in height of the fibril generally increased with maximum strain. Fibril swelling is likely associated with water absorption, which would decrease density and high velocity radial modulus. Since the modulus and height of the fibrils changed in regions both with and without evidence of local plastic deformation, we conclude that tensile loading can cause both plastic and non-plastic structural rearrangements within tendon collagen fibrils.

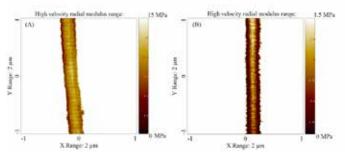

Figure 1 – High velocity radial modulus images of an unloaded control fibril segment (A) compared to a segment loaded in tension to $12.0 \pm 0.5\%$ strain (B). The radial modulus of the loaded segment is lower by an order of magnitude compared to the unpulled control segment.

SP055.3 - Collagen fibrils from overloaded tendons show sites of discrete plasticity and overall perturbation in molecular packing Author(s): Samuel Baldwin¹, Laurent Kreplak², J. Michael Lee³ ¹Physics And Atmospheric Science, Dalhousie University, halifax/NS/CANADA, ²Physics And Atmospheric Science, Dalhousie University, Halifax/NS/CANADA, ³School Of Biomedical Engineering, Dalhousie University, Halifax/NS/CANADA

Tendons show the ability to resist rupture and to retain partial mechanical function after overload, characteristics which may have evolutionary importance. Understanding the origins of such intrinsic structural toughness, and the mechanisms of cellular response to damage, may provide important insights into tendon trauma and its treatment. Probing the nanoscopic structure of overloaded tendon has revealed an intriguing candidate mechanism. This process, termed discrete plasticity, was revealed by scanning electron microscopy to involve periodic kink deformations along individual collagen fibrils within overloaded tendon [1]. The influence of discrete plasticity on thermal stability of collagen, its enzymatic susceptibility, and its cellular response have been studied; however, the localized, nanoscale mechanical properties of the kinked structure remain unknown [2,3].

Previous work with atomic force microscopy on hydrated collagen fibrils has demonstrated the ability of peak force quantitative nanomechanical mapping as a probe of molecular density, mapping lateral packing variations along individual collagen fibrils by measuring compression modulus at tip velocities above 100µm/s [4]. Applying this methodology to fibrils displaying discrete plasticity resulted in high resolution maps of the localized molecular density of kinked structures formed along overloaded collagen fibrils (Figure 1,A). The resulting data demonstrated that the topologically discrete kinks are coupled with a decrease in molecular density along the entire fibril. This decrease can be attributed to an increased uptake of water when compared to control fibrils. High resolution maps of the same fibrils in a dehydrated state clearly demonstrate retention of D-banding axial packing structure throughout the kinked fibril with the exception of periodic fault lines at kink locations (Figure 1, B). This suggests that the axial register of collagen molecules, characteristic of collagen fibrils, is retained in regions spanning the kinked structures of the discrete plasticity phenomenon in collagen.

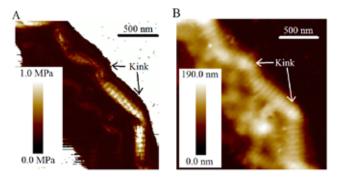

Figure 1: High resolution maps of the same kinked fibril representing (A) its compression modulus in the hydrated state and (B) its height in the dehydrated state.

SP055.4 - Mechanobiology of Hepatic Cells and Engineered Construction of Liver Author(s): <u>Mian Long</u>

Center For Biomechanics And Bioengineering, Institute of Mechanics, Chinese Academy of Sciences, Beijing/CHINA

Liver microcirculation is unique due to its complicated structure of sinusoidal nodes, in which multiple types of hepatic and/or hemapoietic cells interact with each other under blood flow in a three-dimensional (3D) environment. Adhesion of flowing leukocytes to liver sinusoidal endothelial cells (LSECs) or Kupffer cells (KCs) is crucial in liver immune responses. While it is known that two b2 integrins LFA-1 and Mac-1 play distinct roles in the most of organ-specific microcirculations, Mac-1 seems to be predominant in neutrophil (PMN) adhesion and crawling in localized inflammation while the role of LFA-1 is controversial in liver. We first compared the binding kinetics of LFA-1 and Mac-1 to ICAM-1s on mouse LSECs or KCs and found that the binding kinetics between these two integrin molecules is different when ICAM-1s were expressed on distinct cells, supporting that Mac-1 predominantly mediates the adhesion between leukocytes and LSECs and KCs. Next, we tested the flow-induced crawling of mouse PMNs on LSEC monolayer and observed that PMNs tend to migrate along the direction of shear flow and yield high crawling velocity and moving displacement than those under static condition, mainly mediated by LFA-1. Then, we also quantified the impact of substrate stiffness and microtopography on hepatic differentiation of stem cells using 3D in vitro sinusoidal model and engineered liver bioreactor, in which physiologically-mimicking microenvironment is critical for implementing hepatic functions. This work provides an insight for quantifying the intrinsic binding kinetics and the blood flow-induced crawling features of hepatic cells and proposes a novel 3D supporting system for liver function, from a viewpoint of mechanobiology.

This work was supported by National Natural Science Foundation of China grants 31230027 and 31110103918, and Strategic Priority Research Program of Chinese Academy of Sciences grant XDA01030102.

SP055.5 - Modelling and Understanding Normal Pressure Hydrocephalus

Author(s): <u>Christine Goffin</u>¹, Anne Holterhoff¹, Steffen Leonhardt², Klaus Radermacher¹

¹Chair Of Medical Engineering, RWTH Aachen University, Aachen/ GERMANY, ²Chair Of Medical Information Technology, RWTH Aachen University, Aachen/GERMANY

Up to 10% of all dementia patients may actually suffer from Normal Pressure Hydrocephalus (NPH), a disease whose pathogenesis is not yet understood. The ventricles enlarge in this particular form of hydrocephalus, although the mean intracranial pressure (ICP) is not elevated. In this paper, the two main biomechanical hypotheses for the formation of NPH are examined by critically reviewing biomechanical models investigating the onset of NPH: 1) A transmantle pressure gradient between ventricles and subarachnoid space (SAS) widens the ventricular space mechanically, stresses the ventricular walls and causes edema leading to tissue damage. 2) Disturbed dynamics caused either by reduced compliance, vascular disease, malabsorption or obstructions of cerebrospinal fluid (CSF) pathways cause tissue damage. The different models are analyzed and contrasted with clinical findings in order to summon what could be gained by biomechanical model based analysis. It is the goal of this article to identify open questions that can be answered by biomechanical models.

SP055.6 - Osteolytic tumour involvement modifies characteristics of Collagen-I within the vertebral bone matrix impacting mechanical behaviour

Author(s): <u>Mikhail V. Burke</u>, Cari Whyne, Thomas Willett University of Toronto, Toronto/CANADA

Vertebral mechanical integrity is diminished in the presence of metastatic disease. Modelling of the biomechanical behaviour of metastatically involved (MI) bones, however, has to date focused on structural changes alone, without accounting for the potential impact of alterations in bone quality (tissue level changes). More specifically, changes in the organic components of the bone matrix. This study aims to characterize vertebral structure, modifications in primary organic constituent of bone: Collagen-I and mechanical consequences due to the presence of osteolytic metastasis.

Osteolytic (n=8) vertebral metastases were generated in an athymic rat model via intracardiac injection of HeLa cancer cells. μ CT imaging was used to quantify the stereologic distribution of mineralized tissue. Transmission electron microscopy (TEM) and high power liquid chromatography (HPLC) were used to assess the organic phase of bone. And finally, mechanical testing of spinal motion segments was conducted through stepwise loading (axial compression) in combination with time-lapsed μ CT imaging.

Osteolytic tumour involvement (TI) caused an increase in trabecular spacing; and a decrease in trabecular number, spacing and tissue & bone mineral density compared to healthy controls. This indicates that osteolytic involvement reduced both the amount of trabecular bone and the mineral density of the remaining bone.

TEM revealed fibril misorientation in osteolytic specimens and a decrease in the fibril diameter of the collagen fibril matrix on the surface of bone adjacent to tumour lesions. HPLC analysis showed no impact of osteolytic disease on the collagen content in bone, but revealed a decrease in specific enzymatic crosslinks (deoxy-pyrid-inoline) and an increase in non-enzymatic crosslinks (pentosidine) indicative of the operation of reactive oxygen species produced by tumour presence and the resulting oxidative stress.

Osteolytic motion segments when loaded to failure also showed reduced peak failure loads and stiffness with bone failure being focal in nature and not causing major deformation throughout the entire structure with continued loading.

Osteolytic tumour involvement both reduced bone mineral density and caused changes within the organic phase of bone, negatively impacting the mechanical behaviour of bone. Identifying changes in the material phase of (MI) bone and establishing correlations between such changes and the material & mechanical properties/behaviour is critical for the establishment of a fundamental knowledge base needed for modelling and evaluating fracture risk and guiding future treatment options.

SP056 - Image Guided RT: Part 2

TRACK 04: RADIATION ONCOLOGY

SP056.1 - Imaging Dose and Dose Pattern in Image-guided Radiotherapy of Cancers

Author(s): Li Zhou¹, Sen Bai¹, Yibao Zhang², Xin Ming³, Ying Zhang³, Jun Deng⁴

¹Center For Radiation Physics And Technology, Cancer Center, West China Hospital, Sichuan University, Chengdu/CHINA, ²Key Laboratory Of Carcinogenesis And Translational Research (ministry Of Education), Department Of Radiotherapy, Peking University Cancer Hospital & Institute, Beijing/CHINA, ³Department Of Biomedical Engineering, Tianjin University, Tianjin/CHINA, ⁴Department Of Therapeutic Radiology, Yale University, New Haven/CT/UNITED STATES OF AMERICA

Purpose: To systematically evaluate cumulative doses to organs-atrisk from various radiological imaging procedures in image-guided radiotherapy (IGRT) and corresponding dose patterns in a large cohort of cancer patients treated at one institution in past four-andhalf years.

Methods and Materials: With IRB approval, 4832 cancer patients treated at our institution during past four-and-half years were collected with their gender, age, circumference as well as all the radiological imaging procedures performed, which may include computed tomography (CT), kilo-voltage portal imaging (kVPI), megavoltage portal imaging (MVPI) and kilovoltage cone-beam computed tomography (kVCBCT). Correlations between patient's size and organ dose were first established via Monte Carlo dose calculations in patient anatomy, and then used for patient-specific organ dose estimation. BEIR VII models were employed for radiation-induced relative risk estimation based on one's gender, age and radiation dose.

Results: There were a total of 5298, 24173, 30605, 35110, 37509 and 9322 procedures performed on 202, 938, 1056, 1117, 1165 and 354 patients in 2009, 2010, 2011, 2012, 2013 and 2014, respectively. Among them, 3.6%, 14.2%, 23.8 and 58.4% were from CT, kVCBCT, MVPI and kVPI, respectively. In total, 92.8%, 90.3% and 68.5% of patients received 30 cGy or less doses to brain, lungs and RBM, respectively. Yet, 80 cGy or more doses were deposited to brain, lungs and RBM in 273 small-sized patients (maximum 136, 278 and 267 cGy, respectively), due largely to repetitive procedures and nonpersonalized imaging settings.

Conclusions: The cumulative imaging doses and associated cancer risks from multi-imaging procedures were highly patient-specific and lesion-dependent, with much higher doses and risks in pediatric patients. With personalized dose estimation, the impact of radiological imaging procedures can be accounted for effectively for clinical treatment planning and decision-making. This study indicated a pressing need for personalized imaging to maximize its clinical benefits while reducing associated cancer risks.

SP056.2 - Residual errors and dosimetric consequences related to the spinal cord in head and neck radiotherapy Author(s): Jinkoo Kim, Chang Liu, Akila Kumarasiri, Robert Rusnac, Correen Fraser, Indrin J. Chetty, Farzan Siddiqui Radiation Oncology, Henry Ford Health System, Detroit/MI/UNITED STATES OF AMERICA

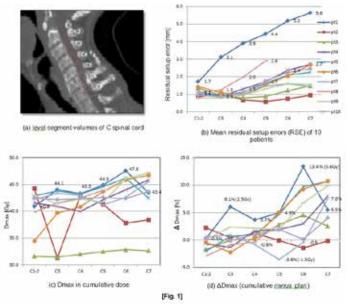

Purpose: To estimate daily setup errors related to the cervical spinal cord and associated dosimetric consequences during head and neck radiotherapy.

Methods and Materials: Ten oropharyngeal cancer patients (stage IV, squamous cell carcinoma) were retrospectively selected. All patients were treated with volumetric modulated arc therapy (VMAT) with two full gantry rotations. A total dose of 60-70 *Gy* was delivered in 30-35 fractions. The spinal cord dose was constrained to be less than 45 *Gy* using an expansion margin of 5 mm (PRV). Cone-beam CT (CBCT) imaging was used for daily patient setup, and patients were immobilized with a thermoplastic mask.

In order to measure quantities at each spinal cord level, the spinal cord contours were split into "*level*" segments (Fig 1a). For the calculation of cumulative dose to cords, 1) dose distributions were calculated on all CBCT images using the original treatment plan, and 2) transferred and accumulated in the corresponding planning CT space using a deformable image registration algorithm. The maximum doses (*Dmax*) in the segmented cord volumes were reported. In addition, the residual setup errors (RSE) were calculated by averaging the deformation vectors in the *level* segments.

Results: The mean RSE for 10 patients are shown in Fig 1b. A minimum error of approximately 1 *mm* occurred between C3 and C4 and increased for C5-C7. The largest error was observed on Pt #1 (5.6 *mm* at C7), which was in part due to in-plane rotations, not compensated for during treatment. The estimated cumulative *Dmax* and their relative increase from plan (Δ Dmax) are presented in Fig 1c and Fig 1d respectively. For five patients, the delivered*Dmax* exceeded 45 Gy with a maximum of 47.6 Gy (Fig 1c). The largest increase of 13.4% (5.6Gy) was observed in Pt #1 due to the largest RSE.

Discussions and summary: In regard to the cumulative dose, 5 of 10 patients had the *Dmax* between 45 and 50 Gy, which exceeded the dose constraint of 45 Gy. Structures beyond the C spine were not included in this study due to the limited length of CBCT images. These results indicate that caution must be exercised during daily positioning of patients with head and neck cancers. Proper PRV margins must be developed to ensure that the maximum cord doses from setup errors, such as flexion, are within the maximum dose constraint over the entire course of treatment. Further research in this area is warranted.

SP056.3 - An automatic dosimetric and geometric tracking system for head and neck adaptive radiotherapy Author(s): Chang Liu¹, Akila Kumarasiri¹, Mona Kamal¹, Mikhail Chetvertkov², J. James Gordon¹, Hualiang Zhong¹, Farzan Siddiqui¹,

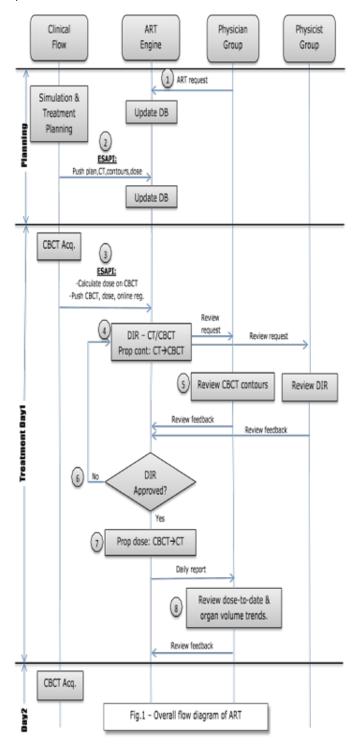

Indrin J. Chetty¹, <u>Jinkoo Kim</u>¹ ¹Radiation Oncology, Henry Ford Health System, Detroit/MI/UNITED STATES OF AMERICA, ²Medical Physics, Wayne State University, Detroit/MI/UNITED STATES OF AMERICA

Purpose: The ability to track geometric and dosimetric changes in tumors and organs at risk, over the course of fractionated radio-therapy is essential for proper adaptive radiation therapy (ART). To that end, we have developed an ART engine that integrates clinical processes and groups (Fig1).

Methods: The ART engine is fully autonomous and consists of several modules; data import/export, automatic dose calculation, deformable image registration (DIR), interactive DIR/report review, and messaging. 1) The data import/export module transfers data between the Varian Eclipse TPS and the ART database, implemented via the Varian DICOM DB daemon and the Eclipse Scripting API (ESAPI). 2) The automatic dose calculation module calculates the dose of the day (DoD) on CBCT images. 3) The calculated DoD is then warped via the DIR module to the planning CT for cumula-

tive dose calculation. At the same time, the planning contours are warped to daily CBCT images. 4) The DIR review module allows users to review the quality of registrations in a graphical user interface, and the report review module provides plots of dosimetric/geometric trends, which assists the clinician in evaluating the ongoing treatment quality. Finally, 5) the messaging module notifies clinicians via email for various events.

Results/Discussion: The system has been successfully used for various research projects and is currently being thoroughly tested as part of our institutional software valdiation and quality assurance process. We have evaluated our DIR algorithm against four commercial DIR algorithms for H&N RT. The estimated accuracy was equivalent or better.

SP056.4 - Morphological Analysis of Tumor Regression and Its Impact on Deformable Image Registration for Adaptive Radiotherapy of Lung Cancer Patients

Author(s): <u>Hualiang Zhong</u>, Jinkoo Kim, James J. Gordon, Stephen Brown, Benjamin Movsas, Indrin J. Chetty Radiation Oncology, Henry Ford Health System, Detroit/UNITED STATES OF AMERICA

Deformational and mass changes associated with regression of the visible tumor during the course of fractionated radiotherapy have confounded the ability to perform accurate deformable image registration, subsequently limiting the clinical implementation of adaptive radiotherapy. This study sought to investigate the impact of tumor regression on the accuracy of deformable image registrations (DIR) and then to find a solution to improve the performance of DIR for treatment of lung cancer patients. Specifically, daily cone-beam computed tomography (CBCT) images were acquired from three locally advanced NSCLC patients. DIRs were performed from fractions 1, 10, and 20 to fraction 25 using a B-Spline-based algorithm implemented within the VelocityAl platform. To improve the accuracy of the B-Spline-based registrations in the region of regressing tumors, a hybrid finite element method (FEM) was developed with a mesh defined in a bounding box surrounding the tumor in the target image. The constraints of the FEM model were derived from the displacements generated by the B-Spline registrations. Using the displacement vector fields (DVFs) of the B-Spline and hybrid registrations, the source images were warped to their targets. The accuracies of the two registration algorithms were evaluated, using landmark points identified on both the source and target images, as well as quantitative analysis of the generated DVFs. For the three patients, average tumor volumes were reduced by 53% between fraction 1 and fraction 25. Comparison of landmark points showed that the mean errors of the FEM-based hybrid registrations were 1.4, 1.6, and 1.7 mm for the three patients. The average displacement differences between the B-Spline and FEM-hybrid registrations for the three patients were 4.8, 6.2 and 3.9 mm with a maximum of 15 mm for patient 2. Lung tissue does not move consistently with the shrinking tumor. The more the tumor regresses, the larger the B-Spline registration error in the tumor region. The proposed hybrid method that consists of the intensity-based image registration and mechanics-based tissue modeling to correct geometric changes induced by anatomical deformation and tumor regression, respectively, may have the potential to improve the quality of adaptive radiation therapy for lung cancer patients.

SP056.5 - Assessment of a 4D-CBCT system for managing respiratory motion in Radiotherapy

Table 1: Results of evaluated parameters in the CIRS008A phantom

Introduction: Four-dimensional image guidance for correcting baseline shifts of tumors, affected by respiratory motion, has become available in the motion management option implemented inside the Elekta's Cone Beam Computed Tomography (CBCT) system. Using this 4D-CBCT is particularly relevant when the tumor is localized in thorax, allowing reduction of target margins. The aim of this study was to design and test a procedure for appraising the performance of a 4D-CBCT system, intended to improve accuracy in treatment delivery of Stereotactic Body Radiation Therapy (SBRT). Material and Methods: Volumetric reconstruction accuracy (VRA), target displacement accuracy (TDA) and patient positioning accuracy (PPA), resulting from the use of the studied 4D-CBCT system (Elekta XVI VolumeView SymmetryTM), was evaluated under different acquisition and reconstruction conditions. A CIR008Aâ Dynamic Thorax Phantom was employed, which allows simulation of a breathing human torso, including insertion of «tumors» of different sizes and shapes. Static and dynamic phantom scans were performed with the CBCT system in 3D and 4D (SymmetryTM) modes. Resource sparing settings were additionally tested, decreasing the number of reconstructed phases per breathing cycle (PPBC) increasing the gantry speed (GS) or reducing image resolution (IR). The impact on accuracy of these modifications was investigated. Results: The acquisition of 3D-CBCT with static phantom was used as baseline for some parameters, as VRA and PPA. The results obtained with the CIRS008A phantom (with 2 cm spherical tumor insert) are presented in table 1.

Using the default settings suggested by the manufacturer (No. 3 in table 1), the 4D-CBCT ensures an adequate VRA, compared with the conventional 3D-CBCT (±1mm). Reduction of PPBC from 10 to 5 significantly degraded the VRA, emphasized when the GS is increased. An IR increment does not produce substantial benefits in VRA. A preset "shark fin" waveform with known amplitude in the three main axis was used for analysis for the TDA, evidencing that setting 7 guarantees optimal TDA with faster data acquisition and processing and much less data storage requirement. **Conclusions:** The methodology implemented allowed to verify the capability of the*SymmetryTM* tool for optimizing target localization in dynamic conditions, including internal margin assessment, which is not considered in the XVI acceptance testing protocol. It could serve as comprehensive guidance for commissioning and optimizing 4D-CBCT systems intended for IGRT, in low resource environments.

SP057 - Quality Assurance: Part 2

TRACK 04: RADIATION ONCOLOGY

SP057.1 - Sensitivity of VMAT patient specific QC devices to linac calibration errors

Author(s): Eduard Gershkevitsh, Mihhail Gershkevitsh Radiotherapy, North Estonia Medical Centre, Tallinn/ESTONIA

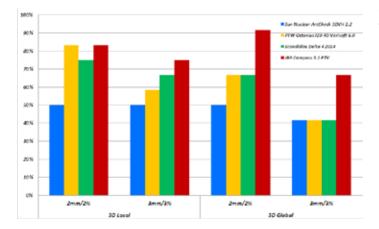

Purpose: The aim of this study was to investigate the impact of linear accelerator calibration (dose and MLC) errors on 3D gamma analyses performed by four different devices for VMAT patient specific QC.

Methods and Material: Different calibration errors were introduced to the Linac and fifteen different VMAT plans (5 prostate, 5 pelvic nodes, 5 head & neck) were measured. The errors include 1) addition of 1.6 mm MLC leaf gap to all leaves; 2) shift of both MLC banks by 1.6 mm in one direction; 3) increasing dose output by 3%, decreasing dose output by 3%. For all conditions the treatment plans were measured with ArcCheck (Sun Nuclear), Octavius 4D (PTW Freiburg), Delta 4 (Scandidos) and Compass (IBA Dosimetry) devices. 3D gamma evaluation using local and global settings were performed. The original measurement (without intentional errors) results were than compared to those with errors and the ability of devices and used metrics to detect the errors were analyzed. Student's T-test was used to evaluate the differences at 0.05 level.

Results: In total 300 measurements were made. The best results for the devices were achieved using 3D gamma index with 2% local dose difference and 2 mm distance to agreement criteria which identified most of the introduced errors (Figure 1). ArcCheck was able to detect 50% of the errors introduced in the present study using 3D gamma metrics while other detectors were able to do so for more than 70%. Compass was able to pick-up the most errors while performing 3D gamma evaluation only on PTV volumes. Octavius 4D was not able to detect the introduced gap to MLC for the pelvic nodes plans, whereas ArcCheck and Compass were not able to do so for the prostate plans.

Conclusion: 3D gamma analyses with 2%/2mm criteria identified more errors than 3%/3mm. Different devices can detect various errors and sensitivity to the introduced errors depends on the anatomical site/modulation complexity. Since not all errors were detected by the tested devices using 3D gamma index the alternative metrics would have to be employed to increase the sensitivity.

Figure 1. Percentage of detected errors with 3D gamma metrics

SP057.2 - Clinical implementation of a novel transmission detector for 3D quality assurance during radiation therapy Author(s): Gueorgui Gueorguiev¹, Fazal Khan¹, Christopher Cotter¹, Michael Young¹, Bruce Crawford¹, Julie Turcotte¹, Mufeed Mahd², <u>Greg Sharp¹</u>

¹Radiation Oncology, Massachusetts General Hospital, Boston/ UNITED STATES OF AMERICA, ²Electrical & Computer Engineering, University of Massachusetts Lowell, Lowell/UNITED STATES OF AMERICA

Purpose

To investigate the clinical implementation of a novel transmission detector 'Dolphin' for pre-treatment and intra-fractional quality assurance during radiation therapy, and to compare it's performance to that of an another detector - MatriXX.

Materials and Methods

Measurements were performed twice for 34 patients (12 IMRT, 10 VMAT, 1 XSRS and 12 SBRT plans) on Elekta linear accelerator using IBA's COMPASS system, once with MatriXX detector and once with transmission detector. The transmission detector consists of an ion chamber array that measures X-ray fluence, which is then used to reconstruct the 3D radiation dose in the patient image set. Raystation treatment planning system was used to plan all patients. For each measurement and treatment plan structure of interest three statistical parameters in COMPASS system were investigated including, average dose difference, absolute dose difference and 3D gamma test (3mm DTA and 3% dose difference were used as gamma test parameters). Three doses were analyzed, Raystation computed, COMPASS measured with Matrixx detector and COM-PASS measured with transmission detector.

Results

For all plans and structures statistical parameter average dose difference showed the biggest difference of an average 3% and maximum of 8% between the three doses investigated. For all plans and structures statistical parameters 3D gamma test and absolute dose difference showed an average of 0.8% and maximum of 3% difference between the three doses investigated. For all plans and structures the average dose difference between the doses acquired with MatriXX and with transmission detector was with an average of 2.5% and maximum of 6% difference. For the same two doses 3D gamma test and absolute dose difference had an average of 0.4% and maximum of 1.8% difference. Both detectors gave satisfactory results with SBRT and XSRS plans, even though the treatment target sizes were small.

Conclusion

IBA's transmission detector measured dose is in good agreement with the dose computed by Raystation and with the dose measured with MatriXX detector. It is a promising device which has the potential to improve the quality assurance process in radiation therapy by allowing to perform pre-treatment and intra-fractional measurements.

SP057.3 - Development of a Radiochromic Film Dosimetry Imaging System

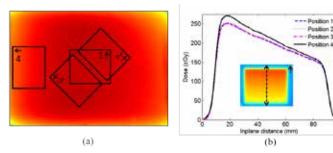

Author(s): Kevin M. Alexander¹, Ajay Rajaram², L John Schreiner² ¹Department Of Physics, Engineering Physics And Astronomy, Queen's University, Kingston/CANADA, ²Department Of Medical Physics, Cancer Centre of Southeastern Ontario, Kingston/ON/ CANADA

As radiation therapy treatment modalities advance, dose deliveries for cancer treatments have become more and more complex. Due to their advanced nature, these treatments call for increasingly high spatial resolution dosimetry techniques to verify that a prescribed dose is delivered accurately and precisely. Radiochromic film dosimetry has been adopted in the clinic as a convenient option for quality assurance because it provides high resolution, two-dimensional measurements, is essentially energy independent, and is near tissue equivalent. Unfortunately, it is not always easy to use due to imaging challenges with current readout systems.

Gafchromic EBT3 film (International Specialty Products, Wayne, NJ) is typically read out using an advanced flatbed scanner. However, difficulties overcoming imaging artifacts on these scanners, related to such factors as directional dependence of the dosimetry results with respect to film orientation and non-uniform sensitivity over the scanner area, have prompted the development of strict protocols for film readout and sophisticated image correction techniques. Even with strict protocols, reliable and reproducible dosimetry can be a challenge. To overcome these challenges, a simple readout technique based on components of the Vista optical CT scanner (Modus Medical Devices, London, Canada) was investigated.

In this work, a film readout system consisting of a digital camera and diffuse light box, interfaced with computer image acquisition software has been developed and characterized for the purpose of imaging film. The optical properties of the system, light field flatness and stability, and various calibration techniques were studied and optimized. Films are rapidly read out by averaging 100 images in 7 seconds, producing submillimetre digitized film data with a high signal-to-noise ratio. Single channel and triple channel film readout algorithms have been implemented and applied for dose processing. Validation tests examining simple irradiations as well as more complex dose deliveries (from IMRT, VMAT, and SBRT) showed that film imaging using our imaging system is orientation independent, and that good agreement (< 1.5% dose difference) is found using single channel dosimetry methods with red light illumination in the central region (15 x 20 cm²) of the light field (see Figure). However, when films are imaged near the perimeter of the light box, large dose discrepancies can be produced due to the non-uniformity of the light field (see Figure). Studies are currently underway to improve uniformity.

Overall, this simple imaging technique shows good promise to simplify and improve on existing film dosimetry readout. Further optimization of the system is underway.

(a) Various film imaging positions about the surface of the diffuse red light field.

(b) Dose profiles for the film irradiated with a 250 MU dynamic wedge, taken along the wedged direction of the dose delivery for each of the imaging positions/orientations shown in (a). The inset shows the dose distribution for the wedge film delivery, and the line along which the profile was measured. The small arrow in the top right corner indicates film orientation in (a). This jold shows that when films are read in the central flat light field area, agreement is better than 1.5% over the entire profile. This agreement fails if one reads a film outside of the central flat light field area, which in this case shows a dose discrepancy of ~8% for imaging at position 4.

SP057.4 - Implementation of MOSFET detectors for in-vivo radiotherapy dosimetry.

Author(s): <u>Yi Wah Eva Cheung</u> Medical Engineering & Physics, King's College London, London/ UNITED KINGDOM

Background: In vivo dosimetry is an essential part of radiotherapy (RT) and is recommended by national and international organisations. For patient undergoes radiotherapy for brain tumours or head and neck cancers, lens dose is concerned. Recently, ICRP review the dose to organs at risk (OARs) and reduced the lens dose limit to 50cGy. IAEA suggested that proper eye protection should be used for these patients. For patients undergo total skin electron beam therapy (TSEBT), in vivo dosimetry is important to verify the trunk dose, to ensure appropriate dose is given with sparing effect to the underneath organs. At Guy's and St. Thomas' hospital (GSTT), TLDs were employed for in vivo dosimetry, while It involves complicated pathway. MOSFET is handy and easy to use, it has been widely used in vivo dosimetry in recent years.

Methods. MOSFET characteristics including calibration factor, linearity, post irradiation stability, reproducibility, dose rate, beam angulation, beam energy, field size, temperature and attenuation effect were carried out. Phantom study was performed using MOSFET to measure the lens dose for brain tumour or head and neck cancer and trunk dose for TSEBT. Finally, clinical study was performed for lens dose measurements for two 3D conformal, two IMRT, two VMAT and three tomotherapy patients. Trunk dose measurement was performed for one TSEBT patient.

Results and Discussion. MOSFET sensitivity met the manufacturer's specifications for linearity post irradiation stability and reproducibility. Further study is needed to verify beam angulation and temperature dependence, as our setup used was different from that of the manufacturer's recommendations.

In phantom study, measurements by MOSFET exhibited less variation against treatment planning system (TPS) in both lens dose and trunk dose measurement (max. 2.84cGy and 5cGy respectively) compared to the TLDs (max 5.43cGy to 16.6cGy) respectively.

In real time in vivo lens dose measurement, MOSFET exhibited similar measured dose difference against TPS compared to TLD in most of the cases. It showed higher measured dose difference in a few cases, where technical or patients challenges may be encountered. The measured dose difference in lens dose between TLD and MOS-FET were within 4cGy in 78% of cases. For radiotherapy treatment for brain tumour or head and neck cancer, this would contribute no more than 120cGy dose difference over a standard course of 30fractions and is within the acceptance tolerance in GSTT, which is 200cGy dose difference over the whole course of treatment.

Conclusion. The use of MOSFET for in-vivo dosimetry has some advantages and disadvantages. It is physically small and provides accurate real time measurement with simple calibration procedure. Time required for pre and post processing is minimal compared to TLDs. It serves as a good alternative for lens dose measurement in radiotherapy for patients with brain tumour or head and neck cancer. However, practical issues may need to be resolved prior to the application of MOSFET in trunk dose measurement in TSEBT.

SP057.5 - 3D in vivo dose verification at The Netherlands Cancer Institute

Author(s): <u>Ben Mijnheer</u>, Patrick Gonzalez, Igor Olaciregui-Ruiz, Roel Rozendaal, Hanno Spreeuw, Rene Tielenburg, Ron Vijlbrief, Marcel Van Herk, Anton Mans

Department Of Radiation Oncology, The Netherlands Cancer Institute, Amsterdam/NETHERLANDS

Purpose: 1) To elucidate the clinical implementation of our *of-fline* 3D *in vivo* dosimetry method for daily patient-specific QA, and 2) to test a method for terminating treatment delivery if the *on-line* measured 3D dose distribution would result in a strong overdose in the patient.

Methods: Automatic 3D in vivo dose verification has been implemented in our department using a-Si EPIDs in combination with a back-projection algorithm, and is applied for almost all IMRT/VMAT and palliative treatments. Comparison of the EPID-based reconstructed and planned 3D dose distribution is done offline. In our current clinical workflow we measure the 3D in vivo dose distribution during the first fractions of a treatment. When deviations are detected, alerts are raised automatically and actions scheduled. Furthermore, a software package for online dose reconstruction has been developed, which processes portal images in real time. Hot spots are then sought in which the average cumulative reconstructed dose exceeds the average total planned dose by at least 20% and 50 cGy. The complete processing of a single portal frame, including hot spot detection, takes about 220 ms, which is faster than the frame rate of about 2.5 frames/s of the portal imager. The software was tested by irradiating an Alderson phantom with two arcs from a head-and-neck VMAT treatment when various types of serious delivery errors were introduced.

Results: 5766 treatment plans were verified in 2013; alerts were raised in 1397 cases (24%). Non-optimal implementation of our method in the clinic, and limitations of the dose reconstruction algorithm are the main sources of alerts. About 50% of the alerts during lung treatments are caused by anatomy changes, while during breast treatments about 50% of the alerts result from patient setup variation. The *online* dose reconstruction tests with the Alderson phantom showed that it was possible to detect hot spots in real time before dose delivery was completed. This information was able to generate a trigger to halt the linac in case of gross errors (see figure). This method would be complemented by *offline* dose verification to detect more subtle errors.

Conclusions: Our automatic *offline* verification method enables large scale clinical implementation of 3D EPID-based *in vivo* dose verification. A prototype *online* 3D dose verification tool using portal images has been successfully tested for various kinds of gross de-livery errors, allowing to stop an irradiation in case of serious errors even before a full fraction is given.

SP057.6 - Dosimetric commissioning of high end features in Radiotherapy Treatment Planning Systems: a proposed update of the IAEA TECDOC-1583 guidelines

Author(s): <u>Rodolfo Alfonso</u>¹, Liset De La Fuente², Haydee M. Linares¹, Javier Cofre³, Alvaro Hermosilla³, <u>Yudy Ascencion</u>¹, Yelina Gonzalez⁴, Rogelio Diaz Moreno⁵, Eduardo Larrinaga⁵ ¹Nuclear Engineering, High Institute for Applyed Technologies and Sciences (InSTEC), Havana/CUBA, ²Radiotherapy, Institute of Oncology and Radiobiology, Havana/CUBA, ³Physics, Universidad de la Frontera, Temuco/CHILE, ⁴Radiotherapy, Hosp. Hnos. Ameijeiras, Havana/CUBA, ⁵Department Of Radiotherapy, Institute of Oncology and Radiobiology, Havana/CUBA

Introduction: The TECDOC-1583 (IAEA, Vienna 2008) proposed a set of test cases for commissioning of dosimetric calculations in Radiotherapy Treatment Planning Systems (RTPS), intended to preventing severe errors in the treatment planning process in a specific institution. This guideline, however, covered typical treatment techniques only. Linear accelerators with high end capabilities, such as IMRT, SRS, SBRT, IGRT and motion management have been installed in many radiotherapy facilities during recent years in Latin America. A new set of test cases, oriented to assess the accuracy of RTPS dosimetric calculations in such high end applications, not addressed in TECDOC 1583, is proposed.

Methods and Materials: Advanced test cases were conceived based on strategy proposed by TECDOC 1583, for assessing main sources of inaccuracy in dose calculations, provided the RTPS has successfully passed the conventional tests proposed by TECDOC 1583. A total of 6 test cases were designed and tested, employing three phantoms and implemented on two different RTPS.

Test case 1 (IMRT) has the purpose of verifying calculations with intensity modulated static fields. A *CIRS IMRT THORAX phantom, model 002LFC* was employed. Target and avoidance structures, beam arrangement and goals were adapted from the *"CShape (harder)"* test proposed in AAPM TG-119.

Test case 2 (highly conformed arc) is intended to verify calculations with dynamically conformed arcs. The target is a very irregular structure, which demands rapid changes of the dynamic MLC shape with the gantry angle. The same phantom as test case 1 is used.

Test case 3 (SRS-head): is used for checking calculations in small field conditions with stereotactic positioning devices and dynamically conformed arcs. A home-made skull phantom was used.

Test case 4 (SBRT-frame-based) verifies calculations with small fields in low density tissues, including positional accuracy using stereotactic body frames. The same phantom as test case 1 is used.

Test case 5 (SBRT-IGRT): similar to case 4, but using IGRT system.

Test case 6 (4D-SBRT) utilizes a dynamic thorax phantom (CIR-S008A) for evaluating dose calculation features under respiratory motion conditions.

Results and Discussion: Results of test cases are summarized in Table 1. Relative errors are compared with agreement criteria adapted from IAEA TRS-430 and TECDOC-1583, considering complexity of case analyzed.

Table 1. Discrepancies of calculated and measured dose
--

Test case	RTPS	Points of evaluation	Meas. Dose [cGy]	Calc. Dose [cGy]	Errora	Agreement Criterion
1001 0000					[%]	[%]
1. IMRT	XiO	Target	209.9	204.4	-2.62%	4
		OAR	70.99	53.97	-8.11%	5
2. Highly Conformed Arc	XiO	Target 218.8 224.0		2.38%	4	
		OAR	201.3	201.6	0.14%	5
3. SRS (head)	ERGO++	Target	206.0	200.0	-2.91%	4
4. SBRT (frame-based)	Precise- Plan	Target	288.0	292.0	1.39%	4
5. SBRT (IGRT-based)	XiO	Target	298.0	292.0	-2.01%	4
6. 4D-SBRT	XiO	Target	376.4	354.0	-5.95%	5

Error [%] =100(Dcal-Dmeas)/Dmeas,ref

Conclusions: Proposed test cases demonstrated being very useful not only for assessing RTPS dose calculation accuracy, but as comprehensive end-to-end verification of the overall process.

SP057.7 - Implementation of statistical tolerance for patient specific QA and independent monitor unit calculation Author(s): Frédéric Girard

Département De Radio-oncologie, Centre intégré de cancérologie de Laval, Laval/QC/CANADA

Purpose: Standard and arbitrary tolerance for patient specific QA and independent monitor unit calculation were replaced by statistical tolerance based on past clinical results. The implementation of these tolerances was evaluated over a period of two years.

Materials and Methods: Patient QA results were collected and analysed statistically. They included ionization chamber dose difference, ArcCHECK (Sun Nuclear Corporation, Melbourne, FL) gamma factor passing rate, and radiochromic film gamma factor passing rate. Gamma factors were calculated with 3% absolute dose and 3 mm distance thresholds. Results from the ionization chamber and the ArcCHECK were divided in different categories based on the treatment plan complexity: 3D conformal (including wedge field), forward planning step and shoot, inverse planning step and shoot and VMAT. Radiochromic film were only used in patient QA when the modulation of the treatment plan was estimated to be very high, therefore the results were not divided into categories. For electron treatment plan, the difference between the measured and calculated depth of the isodose of prescription was also included. In addition, treatment field monitor unit difference calculated by the treatment planification system and the independent system were also included in the analysis and divided into several categories: open, wedge, forward planning step and shoot, inverse planning step and shoot and VMAT. Outliers were removed from each distribution. If the distribution was normal, parametric statistics were used, otherwise non-parametric statistics were used. A first set of tolerances was define has the 95% confidence interval of the dataset (or the range for 95% of the observation for non-parametric dataset). A second set of tolerances was defined at 99%. Results that were beyond the first tolerances required an investigation but were still deemed acceptable whereas results beyond the second tolerances were unacceptable.

Results: These new tolerances were tested for a period of two years. In most cases, test results that fall beyond tolerances were caused by a preparation error and were easily corrected. In other cases, the errors encountered were real and significant. For example, ionization chamber measurement would sometime fall outside tolerances when a plan was highly modulated. This situation led to the improvement of our QA procedure by using a smaller chamber less prone to this error. In another situation, large differences in the depth of the prescription isodose led to the discovery of a calculation error in our independent monitor unit calculation system in some conditions. In some rare instances, small calibration errors of the linac were detected using these new tolerances. None of these errors would have been detected with the conventional arbitrary tolerance.

Conclusion: Building new tolerances based on clinic statistical results provides an increased sensitivity of the QA program to errors that may otherwise remain undetected using conventional tolerance.

SP058 - Characterization of Detector Systems for Therapy Dosimetry: Part 1

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP058.1 - Destructive backscatter-based readout of polymer gel dosimeters: proof of principle

Author(s): <u>Warren G. Campbell</u>¹, Derek M. Wells², Andrew Jirasek³ ¹Physics & Astronomy, University of Victoria, Victoria/BC/CANA-DA, ²Physics, British Columbia Cancer Agency - Vancouver Island Centre, Victoria/BC/CANADA, ³Physics, University of British Columbia - Okanagan, Kelowna/BC/CANADA

A new method is introduced for evaluating the radiation-induced polymer distributions in polymer gel dosimeters. Destructive backscatter-based readout (DBBR) involves the careful slicing and scanning of dosimeters using dual chromatic scans (e.g., red and blue). Spectral differences in scatter attenuation coefficients cause blue light to be more likely to be scattered by polymers than red light. Comparing the intensities of backscattered red and blue photons allows one to evaluate polymer density.

Two polymer gel dosimeters were irradiated, sliced and scanned using the DBBR method. Scans of central slices in two different irradiation patterns were acquired using a flatbed scanner, and ['blue channel' – 'red channel'] images were used to measure polymer distributions. DBBR scan results were then compared against dose distributions calculated by treatment planning software, and select regions of interest (ROIs) from each scan allowed for quantitative comparison between DBBR values and dose. For comparison, reconstructions were also obtained for the same dosimeters (prior to their destruction) using a fan-beam optical computed tomography (CT) scanner.

Results demonstrate that DBBR is a feasible method for polymer gel dosimeter readout. The new method shows great potential, especially in comparison to optical CT results. The following figures are provided for this short abstract. For more details and discussion, see the full paper abstract.

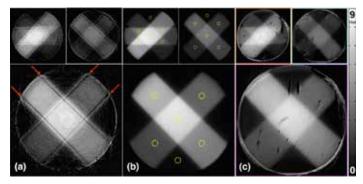

Fig. 1: Dose images for two irradiation patterns – a star pattern and two dosages of a cross pattern – are shown in (a) optical CT reconstructions, (b) TPS-calculated dose distributions, and (c) DBBR scans. Circular ROIs, 5 mm in diameter and indicated in (b), were used for DBBR-to-TPS comparisons and DBBR calibration.

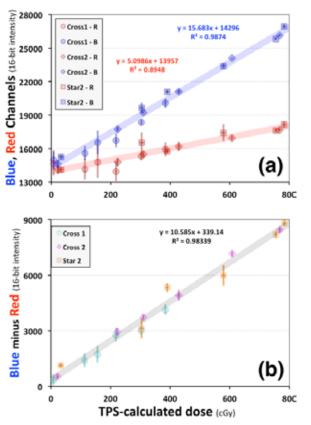

Fig. 2: Plots of ROI comparisons between DBBR and TPS images are shown for (a) blue and red channels, and (b) [blue – red]. Plot points are means and error bars indicate ± 1 standard deviation.

SP058.2 - New Detector Systems for the Dosimetry in Radiation Therapy

Author(s): <u>Viktor lakovenko</u>¹, Stephan Brons², M Campbell³, O Kovalchuk¹, Xavier Llopart³, Immaculada Martínez-Rovira⁴, S Pospisil⁵, V Pugatch¹, Yolanda Prezado⁴, Iurii Sorokin¹

¹High Energy Physics Department, Kiev Institute for Nuclear Research, Kiev/UKRAINE, ²Heidelberg Ion Beam Therapy Center (HIT), Heidelberg/GERMANY, ³CERN, Geneva/SWITZERLAND, ⁴Laboratoire D'imagerie Et Modélisation En Neurobiologie Et Cancérologie, Centre National de la Recherche Scientifique (CNRS), ORSAY/ FRANCE, ⁵Institute of Experimental Applied Physics (IEAP), Prague/ CZECH REPUBLIC

The main goal of radiotherapy is to deposit a high dose of ionizing radiation in a tumor while keeping the absorbed dose in the surrounding healthy tissue at a tolerant level. Current developments in radiation therapy require non-destructive beam profile monitoring devices providing dose distribution measurements and imaging in real time. For this purposes a Micro-strip Metal Detector (MMD) has been developed [1]. Physics and techniques of this detector for the dosimetry, measuring and imaging charged particles and synchrotron radiation beams are discussed. An extremely low thickness (~ 1 µm) of the MMD in combination with its high radiation tolerance (~ 100 MGy) introduces an opportunity to keep a device in the beam permanently [2]. MMD as well as metal-mode of micropixel detector TimePix have been successfully tested at the Minibeam Radiation Therapy (MBRT) setup (Bio-Medical Beamline ID17, ESRF) [3]. These detectors were explored also in recent studies at Heidelberg Heavy-Ion Therapy Center (HIT) devoted to the evaluation of the prospects of spatially fractioned hadron therapy. Hadron multibeam structures have been created by the collimators with different shape. Holes or slits were made in aluminum, brass or tungsten (50

mm thick) samples to arrange different multi-beam structure shape ("MATRIX" or "SLIT" structure). Measurements were carried out at HIT with protons (86.72 MeV, 150.95 MeV), carbon ions (100.07 MeV/u and 200.28 MeV/u) and oxygen ion beams (233 MeV/u). MMD and TimePix were applied for the beam intensity and overall beam profile monitoring. For spatially fractioned techniques the peakto-valley dose ratio (PVDR) is an essential value that defines the efficiency of the MBRT. Both detector types provided PVDR results in excellent agreement with the radiochromic films data.

MMD and TimePix have shown a reliable performance for online beam profile monitoring. Calibrated detector could be used for dose monitoring in real time. The results of our studies suggest the possibility of MMD application in clinical practice. Their implementation will improve beam delivery to tumor tissue, fast imaging and evaluation of data, optimization of treatment regimes.

SP058.3 - Dose response evaluation of lung equivalent gel dosimeters by use of a new fitting algorithm

Author(s): Farideh Pak¹, <u>Hassan Ali Nedaie²</u>, Abbas Takavar¹, Hamid Saligheh Rad³, Vahid Vaezzadeh⁴

¹Medical Physics And Biomedical Engineering, Tehran University of Medical Sciences, Tehran/IRAN, ²Radiotherapy Oncology Department, Cancer Research Centre, Cancer Institute, Tehran University of Medical Sciences, Tehran/IRAN, ³Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran/ IRAN, ⁴Radiotherapy Oncology Department, Cancer Research Centre, Cancer Institute,Tehran University of Medical Sciences, Tehran/IRAN

Low signal to noise ratio (SNR) images of lung equivalent gel dosimeters compare to unit density gels, necessitate use of a different fitting for data analysis. In this study a new fitting method (SQEXP) based on noise correction was introduced and its' feasibility for quantifying absorbed dose in lung equivalent gels was investigated. The effect of new method was studied in term of dose sensitivity, linearity and correlation of calibration curve for both unit and low density gel dosimeter. The results were compared to conventional (Truncation) and a newly introduced method (VAREC).

Dose response of low density gel dosimeter showed wider detectable dose rang (up to 20 Gy) against unit density gel dosimeter (10 Gy). it seems that reaction of excess amount of anti oxidant with hidden oxygen inside of styrofoam beads is responsible for this difference between low and unit density gel dosimeters. Relatively more sensitive calibration curve was obtained by SQEXP method in bothtype of gel dosimeters. Effect of signal denoising was more significant in low density gel dosimeters when high doses ≥10 Gy were absorbed by the gel. Detectable dynamic dose range of low density did not change by different fitting algorithms but in unit density gel dosimeters it was reduced by VAREC method. Dose sensitivity of low and unit dosimeters was reduced by use of VAREC method.

The SQEXP method seems to be more effective method than conventional algorithms for analysis of low density gel dosimeters especially where steep dose gradients exist such as in intensity-modulated radiation therapy (IMRT) and stereotactic radiosurgery (SRS).

SP058.4 - Photoluminescence response of pure LiF crystals to clinical proton and carbon ions: a preliminary assessment for dose to water evaluations

Author(s): Jose E. Villarreal-Barajas¹, Massimo Piccinini², Mario Ciocca³, Alfredo Mirandola³, Maria Aurora Vincenti², Francesca Bonfigli², Rao Khan⁴, Rosa Maria Montereali²

¹Physics And Astronomy, University of Calgary, Calgary/AB/CANA-DA, ²Photonics, ENEA C.R., Frascati (RM)/ITALY, ³Medical Physics, CNAO, Pavia (PV)/ITALY, ⁴Oncology, University of Calgary, Calgary/ CANADA

Visible photoluminescence (PL) of pure LiF crystals irradiated with clinical proton and carbon ion beams has been investigated. The PL response was defined as the PL peak intensity measured at 670 nm when the irradiated pure LiF crystals were excited using the 458 nm line from an Argon laser operated in continuous mode at 25 mW. The emission band centered at 678 nm is due to the formation of F2 colour centres, stable at room temperature. Sets of three commercially available LiF crystals (5x5x0.5 mm³) were simultaneously irradiated. A custom- designed PMMA holder, diameter 30 mm, containing the LiF crystals, was positioned at 2 cm depth (dose plateau) in a PTW horizontal type water tank. The PL vs. dose (absorbed dose to water) was assessed for the intermediate energies of 148 MeV and 278 MeV/u for the proton and carbon ion irradiations, respectively. All irradiations were performed using a scanning beam covering a 6x6 cm² field size. The PL vs. dose in the 2-20 Gy range exhibited a fairly linear behavior for both the proton and carbon ions irradiations, as shown in figure 1. In an independent set of irradiations, a test dose of 5 Gy was given to six sets of three LiF crystals at 62, 148 and 197 MeV for protons and 115, 278 and 380 MeV/u for carbon ions, in order to evaluate the PL signal dependence with beam energy. The response to the 5 Gy test dose for protons was within 3%, while the carbon ions response decreased systematically with increasing beam energy. The PL intensity observed at 115 MeV/u was 30% higher than the one observed at 380 MeV/u. In order to test the dosimetric capabilities of the LiF-PL system, two spread out bragg peaks (SOBP) irradiations were performed at 15 cm depth using beams in the 129-163 MeV and 248-316 MeV/u range for protons and carbon ions, respectively. The proton SOBP dose evaluation was correctly predicted by applying the proton calibration derived at 148 MeV, while the SOBP dose for the carbon ions was overestimated by 7% when using the 278 MeV/u calibration. The PL of LiF can be used for the accurate dose evaluation of clinical proton beams, while a more comprehensive investigation is required to effectively apply the PL of pure LiF crystals to the dose evaluation of clinical carbon ions.

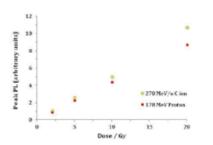

Figure 1. Pure LiF crystals PL peak intensity (measured at 670 nm) for carbon and proton beam irradiations. The carbon irradiations at 278 MeV/u consistently showed a higher PL peak signal of about 20% respect the corresponding proton irradiations at 178 MeV.

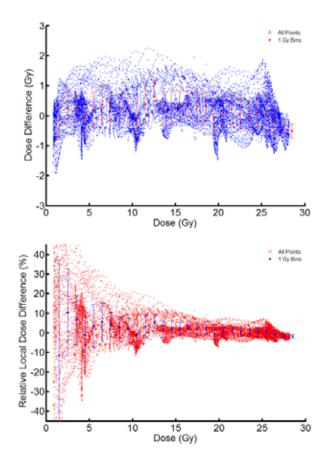

SP058.5 - Evaluation of Accuracy and Precision in X-ray Computed Tomography Polymer Gel Dosimetry.

Author(s): Evan Maynard¹, Andrew Jirasek², Michelle Hilts³, Emily Heath⁴

¹Physics And Astronomy, University of Victoria, Victoria/BC/CANA-DA, ²Physics, University of British Columbia - Okanagan, Kelowna/ BC/CANADA, ³Medical Physics, BC Cancer Agency - Southern Interior, Kelowna/BC/CANADA, ⁴Physics, Carleton University, Ottawa/ ON/CANADA

Purpose: To evaluate the accuracy and precision of an x-ray computed tomography (CT) polymer gel dosimetry system.

Methods: A high %T (19.5%T, 23%C) N-isopropylacrylamide (NIPAM) based gel formulation optimized for x-ray CT gel dosimetry was utilized and the results over six different batches of gels were analyzed. All gels were irradiated with three 6 MV beams in a calibration pattern. Post irradiation CT images of the gels were processed using background subtraction, image averaging, adaptive mean filtering and remnant artifact removal. The gel dose distributions were calibrated using a Monte Carlo calculated dose distribution of the calibration pattern and the self-calibrated gel dose was compared to Monte Carlo and a commercial treatment planning system (AAA, Varian, Palo Alto, CA).

Results: Over all gels, the mean local dose difference, which is the difference relative to the dose at the point of interest, was found to be 4.1%. The mean global dose difference, which is the difference relative to the maximum dose, was found to be 1.6%. For these calculations a 10% dose threshold was used and areas of high dose gradient were removed. Results in the higher dose regions produced significantly better local dose difference results than in the low dose regions as can be seen in Table 1. The results in Table 1 also suggest that there is fixed absolute dose accuracy which is not relative dose differences in lower dose regions. This can also be

seen in Figure 1, where the relative dose error decreases as a function of dose delivered.

Table 1: Me	an dose d	ifferences	for six gels	in differen	t dose rang	jes.
Dose Range (Gy)	0-5	5-10	10-15	15-20	20-25	25-30
Mean Dose Differ- ence (σ)	Dose 0.40 Gy 0 Differ- (0.04) 0		0.47 Gy (0.06)	0.55 Gy (0.08)	0.36 Gy (0.02)	0.55 Gy (0.05)
Mean Global Relative Dose Differ- ence (ơ)	1.42% (0.14)	1.16% (0.11)	1.67% (0.22)	1.96% (0.28)	1.27% (0.06)	1.96% (0.19)
Mean Local Relative Dose Differ- ence (σ)	an cal ative 9.92% 4.19% se (1.00) (0.40) fer-		4.05% (0.53)	2.99% (0.43)	1.61% (0.08)	2.08% (0.20)

Conclusion: The establishment of an overall accuracy and precision of this system provides a framework for potential areas of application such as high dose SABR treatments.

SP059 - Drug Delivery and Control Release

TRACK 08: BIOSENSOR, NANOTECHNOLOGY, BIOMEMS AND BIOPHOTONICS

SP059.1 - Nanotechnology applied in drug delivery

Author(s): Gabriela Barbosa¹, Pedro Augusto F.D. Silva¹, Glécia V.D.S. Luz², <u>Lourdes M. Brasil³</u>

¹Unb At Gama, University of Brasília, Gama/BRAZIL, ²Pos. Engenharia Biomedica, UNIVERSIDADE DE BRASILIA, Brasilia/BRAZIL, ³Fga, UnB, Brasília/BRAZIL

Nanotechnology is a multidisciplinary field that deals with the study, manipulation or rearrangement of particles at the nanoscale, which is equivalent to a billionth of meter, the material at this scale shows unlike physical, chemical and biological proprieties. This area has impacted a lot in the development of new products in various sectors and has been widely studied for offering effective solutions to several problems, such as pollution, energy rationing and cure of various diseases. What makes the field so promising is that the elements behave differently at the nanoscale, when compared to the macroscale. In this article it will be described how this field can be applied in the biomedical field, especially in controlled drug delivery systems using nanoparticles, nanobots and organometallic compounds, for greater effectiveness in the treatment of diseases. Nanoparticles (NPs) are nanosized particles (3-200 nm), devices or systems that can be made using a variety of materials including polymers, lipids, viruses, and even organometallic compounds. The uses of NP with drug delivery systems have made a remarkable difference in site-specific release of drugs, owing to their physical and chemical characteristics and biological attributes. Various researches in this exciting area have been conducted and several formulations were released in the market and are now routinely used in clinics. In this review will be found a few nanoparticles more used in the medical area, as Solid Lipids Nanoparticles (SLN), Magnetic Nanoparticles, for instance. Nanobots or nanorobots is based on the creation of tiny machines that can do the functions of today's machines, but more exactly, to develop projects that bring benefits in medicine, industry, and others areas. An ideal nanotechnologybased drug delivery system is a pharmacyte a self-powered, computer-controlled medical nanorobot system capable of digitally precise transport, timing, and targeted delivery of pharmaceutical agents to specific cellular and intracellular destinations within the human body. Some advances with these devices will be described in the review. Organometallic compounds are usually described as components having at least one metal-carbon bond. They also are considered nanoparticles. In the following review, will be discussed the application of Graphene and Carbon Nanotubes in drug delivery systems. Although some researches were not evaluated in vivo, there is a high expectation on this field. It is necessary study more about the behavior of nanoparticles at the organism, as well as figure manners to use these devices so that they do not exhibit toxicity to the body.

SP059.2 - Controlled electrochemical dissolution of iron alginate for smart drug release in micro devices Author(s): <u>Ashleigh Anderson</u>, James Davis

Computing And Engineering, University of Ulster, Newtownabbey/ UNITED KINGDOM

Smart devices that can routinely monitor patient's health with little or no involvement from clinical staff have slowly begun to emerge over recent years and have arisen from significant developments in sensing and communication technologies. In cases where a rapid response may be required, a much more effective substitute would be the development of a truly smart system that could autonomously act on the information received from the sensing component and, where appropriate, deliver a therapeutic agent in a controlled manner. This presentation details the result of an investigation in to the development of electrochemically initiated transitions of redox gels. The hydrogel structure can be held together through chemical or physical bonds and it is within the resulting network that drugs can be entrapped.

The approach to delivery is highlighted in Figure 1 where there is an electronically controlled layer that separates the drug reservoir from the skin. The core methodology employed in this project will involve electrochemical control to influence the porosity of a redox hydrogel, typically sodium alginate.

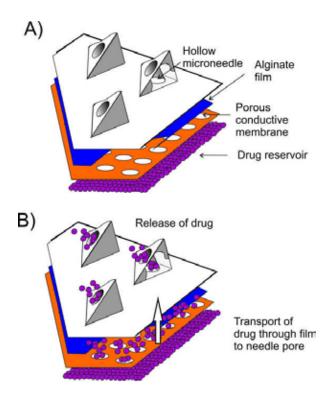

Figure 1. Microneedle patch with alginate release film. A) before release (-1.1V) and B) after release (+0.5V)

The use of the iron as the binding agent is of prime interest in the present context as, in contrast to the other metal ions, it can be electrochemically cycled (Fe^{3+}/Fe^{2+}). The formation of the film and its dissolution are both controllable through electrochemical means. The oxidation of the Fe^{2+} to Fe^{3+} in the presence of the alginate will activate the crosslinking process and enable site specific deposition at the electrode. While this is similar to the polypyrrole and polythiophene films, there is a crucial difference. The electrochemical reduction of the coordinated Fe^{3+} to Fe^{2+} will result not only in a simple swelling of the film but rather its dissolution. Ordinarily this would be expected to cause significant issues, especially for a film in contact with biofluids, but the alginate-iron system is inherently biocompatible (the alginate is readily hydrolysed under normal physiological conditions) and this may be a critical advantage in the future use of redox films.

SP059.3 - Next generation transdermal drug delivery – An electrochemical approach to pH manipulation for controlled release within smart patch technologies Author(s): <u>Ashleigh Anderson</u>, James Davis Computing And Engineering, University of Ulster, Newtownabbey/ UNITED KINGDOM

The majority of conventional controlled release technologies tend to be based around encapsulant systems in which a polymeric binder or gel typically responds to changes in the local environment in which the delivery device has been placed. The contents are typically released when the particle, capsule, film or droplet is exposed to the appropriate physico-chemical trigger (typically a change in pH) with the time-release-dose delivery characteristics controlled through manipulation of the encapsulant formulation. In this communication, the adaptation of this core strategy for use in the next generation of transdermal microdevice or smart patch is explored. A key feature of the approach is the ability to electronically trigger the release of the drug on demand.

The strategy relies on the electrochemical properties of a carbon composite film in which micro-nanoscale pores are created through controlled laser ablation. The porous carbon layer is then combined with the cellulose ester barrier film to complete the prototype patch as indicated in Figure 1 Under normal conditions the enteric coating remains intact with no diffusion of the drug to the bulk of the solution. Upon imposing a reducing potential on the carbon film top layer however, the local pH within the pores is dramatically increased such that hydrolysis of the ester occurs with dissolution of the protective barrier releasing the drug.

The presentation covers three aspects: the design of an innovative microprobe necessary for monitoring the changes in pH within the pores, the structural and electrochemical characterisation of the carbon film and the proof of concept demonstration of a model drug release.

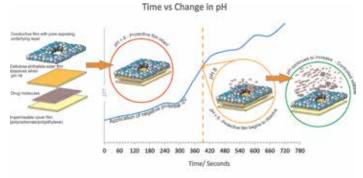

Figure 1. Design of transformal patch and detail of how drug release is achieved as a result of pH change

SP059.4 - Protein nanocages for stabilization of bio-inspired emulsions/gel systems and cutaneous drug delivery Author(s): <u>Sierin Lim</u>, Sathya Moorthy Bhaskar, Mridul Sarker School Of Chemical And Biomedical Engineering, Nanyang Technological University, Singapore/SINGAPORE

Self-assembling protein nanocages forming hollow structures are explored as potential carriers in various nanotechnology applications. The fact that proteins are integral parts of a biological system makes them promising for use as carriers for drug delivery, cosmetics and food emulsifiers. E2 Protein from pyruvate dehydrogenase multienzyme complex of *Geobacillus stearothermophilus* have the capability to self-assemble into a hollow dodecahedral cage of a unique size about 25 nm. The nanocages are extremely thermostable and porous with 12 openings of 5nm each. These inimitable characteristics of E2 protein nanocage are suitable to encapsulate and carry foreign molecules inside its cavity. E2 protein nanocages are engineered genetically or chemically, to shuttle drugs into the skin cells such as melanocytes (Figure-1) and keratinocytes (Figure-2, protein conjugated to Alex fluor-green, nucleus stain-blue) for the treatment of pigmentary disorders. The existence of both hydrophilic and hydrophobic patches on the surface of E2 protein nanocages molds it to be a surface active bionanoparticle. Our preliminary results show the deposition of E2 protein nanocages at liquid-liquid interface under TIRF microscope (Figure 3). Thus the E2 protein nanocages can also be used as a potential stabilizer of bioinspired emulsion and gel system. This study can be very functional in designing emulsion-and gel-based pharmaceutical products for topical application, skin care products and food products.

SP059.5 - Image-Guided Predictions of Nanoparticle Transport in Solid Tumors

Author(s): <u>Shawn Stapleton</u>¹, Michael Milosevic¹, Christine Allen², Ian F. Tannock³, David Jaffray⁴

¹Radiation Medicine Program, University Health Network, Toronto/ON/CANADA, ²Leslie Dan Faculty Of Pharmacy, University of Toronto, Toronto/ON/CANADA, ³Medical Biophysics, University of Toronto, Toronto/ON/CANADA, ⁴Techna Institute, University Health Network, Toronto/ON/CANADA

Due to the ability to preferentially accumulate and deliver drug payloads to solid tumours, nanomedicine, including liposomes, has emerged as an exciting therapeutic strategy for cancer therapy. Unfortunately, negligible increases in patient survival following liposome therapy have been observed in the clinical setting. This is due in part to the heterogeneous intra-tumoural transport of cytotoxic drugs, caused by chaotic tumour microcirculation and elevated interstitial fluid pressure (IFP). Here we explored the relationship between tumour microcirculation, IFP, and the intra-tumoural accumulation of liposomes using a combination of quantitative imaging and mathematical modeling. The combination of quantitative imaging and mathematical modeling presents a novel framework to guide nanoparticle drug-delivery in the clinical setting. A biophysical mathematical transport model, termed the intra-tumoural transport model (ITTM), was developed and used in combination with non-invasive imaging methods to predict liposome transport in solid tumours. The ITTM was validated using in vivo measurements of accumulation of a computed tomography (CT) liposome contrast agent made in three different tumour models. The ITTM attributed inter-tumoural heterogeneity of liposome accumulation to variations in IFP; however, several limitations were noted, including limitations in the accuracy of intra-tumoural liposome accumulation predictions based solely on IFP. These limitations were mitigated by developing a novel imaging method, termed Volume Fraction Imaging (VFI), to accurately measure additional key transport parameters, including microvascular permeability, perfusion, plasma volume and interstitial volume. VFI is based on the sequential injection of a nanoparticle and freely diffusible CAs. Simulations demonstrated that the VFI method substantially improves the accuracy and precision of plasma and interstitial volume, blood flow, and capillary permeability compared to standard pharmacokinetic modeling. In vivoexperiments demonstrated that VFI substantially improves quantification of healthy and malignant tissue treated with Sorafenib, radiation, and mild hyperthermia. Using VFI we established that tumour perfusion and plasma volume are also key mediators of the intra-tumoural heterogeneity in liposome accumulation in several tumour models. We probed the relationship between tumour microcirculation using VFI, IFP using a novel image-guided robotic needle positioning

system, and the intra-tumoural distribution of liposomes using volumetric micro-CT imaging where performed. A strong relationship between the radial distribution of IFP, metrics of tumour perfusion, and the intra-tumoural accumulation of liposomes was observed. Therefore, both tumour perfusion and elevated IFP play an integral role in mediating the intra-tumoural accumulation of liposomes, and strengthen the need to account for intra-tumoural heterogeneity in transport properties for guiding the use of nanomedicine in the clinical setting. This work provides a pivotal piece of the image-guided drug delivery schema whereby quantitative imaging can derive patient specific information on drug pharmacokinetics, biodistribution, intra-tumoural transport, biological targets, and mechanisms of resistance. Integrating image-derived information with an established mathematical framework based on the ITTM can conceivably predict drug-transport and treatment response. This represents a major leap forward compared to the convectional chemotherapeutic strategies whereby optimal dosing and scheduling strategies can be prescribed and adapted on a based on validated mathematical models of drug delivery that are informed by quantitative imaging methods.

SP060 - SPECIAL SESSION: UNESCO International Year of Light

TRACK 12: MEDICAL DEVICES

SP060.2 - Design of Wireless Implantable Optogenetics System for Animal Studies

Author(s): <u>Fu-Yu Chen</u>¹, Peter S. Freestone², Simon Malpas¹, Daniel Mccormick¹, David Budgett¹

¹Auckland Bioengineering Institute, Auckland/NEW ZEALAND, ²Centre for Brain Research, Auckland/NEW ZEALAND

Optogenetics uses light to manipulate neural activity which has several advantages over conventional electrical stimulation approach including specific cell-type targeting with precise temporal precision, simultaneous stimulation using different wavelengths of light and relatively harmless to targeted tissue. In optogenetics experiments, targeted neurons are transfected with photo-sensitive proteins (opsins) for subsequent exciting or silencing neurons with pulses of visible light.

Optogenetic stimulation offers the prospect of treating lifetime conditions; however, current optogenetics available commercially are mainly connected with wires coming out of head of the animal head which brings a risk of infection and is vulnerable to damage from chewing or scratching. Also, current light stimulation systems are generally not suitable for chronic use due to the risk of infection associated with components located outside the brain. This study aims to investigate the technical feasibility of implementing a fully implantable optogenetics system supporting long-term light stimulation as well as for feasibility of wireless transmission of recorded signals outwards.

A miniature LED die with dimensions of 280µm by 280µm has been sourced with an output wavelength of 470nm which is suitable for exciting the opsin ChR2. The power needed is about 6.4mW to deliver the required optical power for opsin excitation. This is an exciting proof-of-principle outcome showing adequate light from a small package of components consuming a manageable amount of electrical power.

In the experimental setup, the LED die coupled to a 200µm optical fibre is feasible and sufficient to activate ChR2 (>32µW). With 80% of the light transmitted with a bend radius of 2mm, the fibre can be tracked from the brain to the wirelessly powered telemeter located in the abdomen to form a fully implanted optogenetics system. Our results show that LED-fibre optic system is able to generate a cellular response in a ChR2-expressed cell with a short pulse (4ms) of light. The cellular response generated can also be sustained by long duration light stimulation (500ms). The amplitudes of the cellular response can be controlled by changing the light intensity emitted on the targeted cell. This can be achieved by modulating DC voltage supply using Pulse-Width Modulation (PWM) technique. This technique is favorable for implantable device because it is easy to implement using a microcontroller and does not increase the size of the circuit. This experiment motivates the use of the custom-made LED-fibre optic system in vivo chronic rodent studies in the future.

Critical questions for technical feasibility include size, optical power, heat generated and physical delivery of the light to the region requiring illumination have been considered.

The proposed module has been validated to measure individual cellular response to optical stimulation of photosensitive rat brain slices performed. This experiment motivates the use of the custom-made LED-fibre optic system for future *in vivo* chronic rat studies including animal behavior as well as wireless transmission of recorded brain potentials during various treatment schemes. The implantable wireless optogenetics would have great potential to enhance basic neuroscience research and help develop interventions for various neurological disorders, such as Parkinson's disease.

SP060.3 - A method to determine the variation of irradiance in bilirubin lamps as function of the time of use

Author(s): <u>Graciela M. Salum</u>¹, Di Teodoro Cotua², J Salerno³, E Marino³, R D. Piacentini⁴

¹Yachay Tech, Yachay City Of Knowledge, School of Physics Science and Nanotechnology, Urcuqui/ECUADOR, ²School Of Mathematics, Yachay Tech, Yachay City of Knowledge, Urcuqui/ ECUADOR, ³Facultad Regional Rosario, Universidad Tecnológica Nacional, Rosario/ARGENTINA, ⁴Imae, Fac. De Cs Exactas, Ing Y Agrim/unrosario, Laboratorio de Eficiencia Energética, Sustentabilidad Cambio climático, Rosario/ARGENTINA

Hyperbilirubinemia is a pathologic process consisting of the abnormal increase of the amount of bilirubin in the circulating blood, which can cause jaundice. A common treatment is expose the premature newborn to the phototherapy treatment, with lamps that emit in a specific region of the electromagnetic spectrum (mainly 410-550 nm). In the present work we describe one irradiance analysis method to this type of bilirubin lamps (in the case a Phillips TL20W/52), based on the determination of the intensity variation as a mathematical function depends on time (hours) with which we can simulate this behavior. We used the Exhaustive Approximation method combined with the Distinguish region-curve method for the determination of the corresponding function.

Also, we compare the spectral irradiance of the lamp, with the solar spectral irradiance measured with a high quality double monocromator Optronic 756 spectrorradiometer, the day October 26 of 2012, at 12:49 local hour, in Rosario, Argentina. As a consequence, it was observed that the lamp intensity is very small compared with the solar one, which means that a careful analysis of the solar radiation incident on a given place needs to be made, if a treatment with natural radiation would be used for bilirubin reduction.

SP060.4 - Study of the sensibility of induced heat effects in edible oil measured by interferometric techniques

Author(s): <u>Joel Espinosa-Barrios</u>¹, Francisco Corella-Jimenez¹, Alejandra Guillen-Peralta², Amy Avila², Gerardo S. Romo-Cardenas¹, Andres Piña-Barrera²

¹School Of Engineering, Montemorelos University, Montemorelos/ MEXICO, ²School Of Health Sciences, Montemorelos University, Montemorelos/MEXICO

Currently the use of edible fats and oils in the preparation of fried products has increased, it is known that excessive consumption of foods containing fats, can have a deleterious effect on the health of people, forcing increasingly strict control of oils and fats in fried foods to maintain quality of fried foods and ensure their safety, lack of laboratory facilities in fried food preparation establishments, limit the compliance of existing quality standards requiring new simple alternative methods to be used by the user.[1] Optical interferometers are instruments that can make very precise measurements of objects using the pattern of interference of two waves of light. These devices have been used to characterize materials and study their properties. This paper propose a new prototype of this application in order to reach a characterization protocol of fluids with low differentiation of components. Results in oil samples indicate that it is possible to make characterization using interferometric techniques.

SP060.5 - Design and study of Infrared-Guard

Author(s): Shanmugam Senthilkumar

Dept. Of Radiotherapy, Govt. Rajaji Hospital & Madurai Medical College, Madurai/INDIA

Introduction: Gantry - couch collision is a serious concern for cancer patient treatment planning of the radiotherapy machine. The radiotherapy machines moving parts may cause collision between the treatment couch and the treatment head, which affects the accuracy of the machine and sometimes a replacement of parts. If a patient interferes, it results in severe injuries. In this work we have developed Infrared Guard (IRG) to prevent gantry - couch collision in the Radiation Therapy machine.

Material and Methods: The Infrared Guard consists of a distance measuring sensor unit, composed of an integrated combination of PSD (position sensitive detector), infrared sensor and signal processing circuit. The infrared sensor is made up of the emitter (infrared LED) and detector (photodiode). The emitter emits IR light pulse and the receiver detects the corresponding light pulse. The infrared intensity of the emitter influences the detection range. On the IR receiver side, the desired output voltage depends on the detection distance. This output voltage signal connected to an analog amplifier, comparator, or Schmitt-Trigger, to control various functions. IRG device placed in the treatment machine gantry, which is inner side of the gantry and above to the gantry angle indicator. IRG device monitors the region between the collimator face and the treatment table (or) patient. The IRG provides an infrared invisible sensing shield, which covers the entire collimator face. The IRG device sensing area or protection zone distance can be varied according to the requirement with adequate clearance. If the potential collision is detected by the IRG device in the protection zone, the radiotherapy machine will stop the movement and the red LED will glow and also buzzer will produces sound. We have also provided the IRG OFF key in the machine. If you want to override or turn off to the power to the IRG device a blue light will glow and illuminating words Infrared Guard OFF will appear.

Results and Discussion: We have studied this IRG device to monitor the accuracy in the radiotherapy machine using phantoms and patients. Our method correctly confirmed clearance between the patient/treatment table and the gantry. This device is easy to handle, inexpensive and stops the machine movement when the gantry and the couch come nearer to each other. Infrared Guard provides an additional level of safety to automated radiotherapy machine operation. IRG monitors the closeness of the patient treatment couch to the treatment head during remote movements and restrain or stops machine movements prior to a potential collision. IRG provides an additional "set of eye" to monitor and minimize risk. IRG does not require physical contact to detect potential collision. IRG anti-collision device improves the performance of the machine and most importantly reduces the chance of collision.

SP061 - Improvement of Diagnosis and Therapies

TRACK 12: MEDICAL DEVICES

SP061.1 - Development of heart sparing device for Left Breast Radiotherapy with deep breath-holding

Author(s): <u>Shanmugam Senthilkumar</u> Dept. Of Radiotherapy, Govt. Rajaji Hospital & Madurai Medical College, Madurai/INDIA

Introduction

Breast radiotherapy is now part of the routine care of patients with early breast cancer. Adjuvant radiotherapy for post-mastectomy breast cancer patients consists of a pair of tangential photon beams treating the breast tumor bed. In addition, internal mammary chain (IMC) and supraclavicular (SCV) beams are also employed to treat the corresponding lymphatic nodes within the region. Radiotherapy has been shown to reduce recurrence and improve the survival rate for post-mastectomy breast cancer patients. However, the benefits of adjuvant radiotherapy is compromised by the secondary cardiac mortality that occurs 15 to 20 years after the therapy has completed. Therefore, it is critical to develop radiation techniques that retain the benefits but reduce late toxicity to the heart and other organs at risk. Patients with left-sided breast cancer who receive chest wall radiation have increased risk of treatment related cardiovascular morbidity. To reduce the dose to the heart, it has been suggested that electrons be used in the IMC beam. Another strategy to reduce cardiac dose is to employ breathing adapted radiotherapy, including the deep inspiration breath-hold (DIBH) technique. It has been demonstrated that employing the DIBH technique in tangential beams appreciably reduces cardiac dose. However, there has been no study on the effect of utilizing the DIBH technique in IMC electron beams. The aim of this study was to evaluate the effect of decreasing the irradiated cardiac volume in breast-conserving therapy (BCT) with indigenously developed deep inspiration breath-hold device(DIBHD) using breath-adapted radiation therapy (BART).

Materials and Methods

We have developed indigenously deep inspiration breath-hold device(DIBHD), which consist of laser sensor, in-house software, video goggles, a breath hold signal device, alarm and visual indicator. The sensor is used to display the breath-hold position of the chest wall in the computer monitor as graphical signal as well as digital. Patients can able to see their breath hold position while using the video goggles and maintain the uniform level without reducing the lung volume. Once the threshold level reduces, patient starts to exhale the radiation will be stopped, simultaneously alarm will produce sound and visual indicator glows.

Results

DIBHD has been used for the left sided breast cancer patients during the radiotherapy in deep inspiration breath-hold. The tangential fields were planned for each respiratory-gated CT image. The dose-volume histograms (DVHs) of the heart, lung, and breast of each respiratory phase were compared. Patient's position during each breath hold was carefully monitored and make sure the heart is positioned away from the chest wall. Radiation was delivered during these repeated breath holds. A deep breath pulls the diaphragm and heart down and out of the radiation beam path. Delivering radiation treatment during these deep breath holds protects the heart from radiation. We concluded that radiotherapy using DIBHD facilitates a reduction of the irradiated heart volume which enables more complete cardiac sparing without any compromise of PTV coverage.

SP061.2 - HTA for Medical Devices: Multiple-Criteria Decision Making as an Outcome Evaluation Tool

Author(s): Ivana Jurickova¹, Jozef Rosina¹, Vladimir Rogalewicz¹, Ilya Ivlev¹, Gleb Donin², Jakub Vacek¹, Radka Otawova¹, Peter Kneppo¹ ¹Department Of Biomedical Technology, Czech Technical University in Prague, Faculty of Biomedical Engineering, Kladno/CZECH RE-PUBLIC, ²Department Of Biomedical Technology, Czech technical university in Prague, Kladno/CZECH REPUBLIC

Health Technology Assessment (HTA), although having been routinely applied in drugs and surgery for a long time, is still quite challenging in medical devices. The reason is that the main objective of HTA studies for devices is not optimization of the cost-effectiveness ratio, but rather decisions about procurement and/or incorporation of the apparatus. The clinical benefit is not expressed in terms of quality of life, but in the rate of diagnostic yield, comfort of the clinician, or the extent to which the technology makes the therapy shorter and/or more patient-friendly. Utilization of multiple-criteria decision-making methods for evaluation of the aggregated clinical, technical and user's effect (outcome) is recommended as the input to cost-effectiveness analyses. Different methods are derived for strategic and/or operational assessment of new technology.

SP061.3 - Developing Smart Bandage Materials for the Management of Chronic Wounds in Diabetic Patients Author(s): Jolene Mchugh, Karl Mccreadie, James Davis Nibec, School Of Engineering, University of Ulster, Newtownabbey/ UNITED KINGDOM

Bacterial contamination of chronic wounds has long been a major concern for those involved in the management of diabetic foot disease (DFD). The latter is an increasingly common complication of diabetes whose treatment has a profound impact on both patient and healthcare resources. In 2013, global healthcare expenditure for diabetes totalled \$548 billion. With the ever increasing population of people with diabetes expected to increase by 55% in 2035, we can expect expenditure to reach \$627 billion and upwards. A study has estimated that a population with diabetes costs three to four times greater than a population without. The majority of these costs are due to the complications that arise from diabetes such as neuropathy, infection and ulceration. It has been estimated that approximately 25% of all diabetes related hospital admissions in the US and the UK are due to such complications and consequent limb threatening infections. Approximately 15% of patients with diabetes will suffer from foot problems and around 7% have a foot ulcer at any given time. Around 56% of foot ulcers become infected, making patients 30 times more likely to have an amputation compared to the general population making it the most common cause of lower limb amputation.

While there has been considerable activity in the development of wound dressings that aim to minimise bacterial contamination and aid the healing process, the majority are passive and possess little or no diagnostic capability. The present communication details the results of an investigation into the use of a smart bandage which can permit electrochemical interrogation of the wound environment and therein proffer the possibility of more timely and effective interventions in the management of the wound.

Carbon loaded polyethylene films were selected as the base substrate for a mechanically flexible and conductive sensing material for use in wound monitoring technologies. The films were processed using laser ablation of the surface to increase the effective surface area of the electrode and were then subject to an oxidative electrochemical etch to improve the electron transfer kinetics. The surface morphology of the resulting film was analyzed and the electrode performance in relation to monitoring uric acid, a key wound biomarker, was optimized. A prototype smart bandage interfaced with a miniaturized potentiostat capable of monitoring the wound condition was developed and the response to urate harnessed to measure both the wound pH and wound severity. The viability of using urate for use in complex fluids was assessed using whole blood and other potential interferences. The mechanical flexibility of the polyethylene film is ideal for incorporation within existing dressing materials and could be produced in bulk at relatively low cost, a pre-requisite given the frequency with which dressings need to be replaced.

SP061.4 - A CdZnTe-based automated Blood Counter for Quantitative Molecular Imaging

Author(s): <u>Romain Espagnet</u>¹, Jean-Pierre Martin², Louis-André Hamel², Philippe Després¹

¹Département De Physique, De Génie Physique Et D'optique, Université Laval, Québec/QC/CANADA, ²Département De Physique, Université de Montréal, Montréal/QC/CANADA

Positron Emission Tomography (PET) and Single-Photon Emission Computed Tomography (SPECT) are well established molecular imaging modalities used in many fields of the biomedical sciences. They allow in vivoinvestigations of biological processes at the molecular level, and provide valuable information on the onset and progression of diseases. The images obtained are based on a measurable number of nuclear disintegrations and, as such, are inherently quantitative. However, the quantitative nature of these modalities is usually dismissed, largely because tools and methods dedicated to quantitative imaging are lacking. Accurate quantification in PET and SPECT typically requires frequent assessments of blood activity through indirect image-based estimations or direct sampling and measurements in a well-counter to obtain a time-activity curve that will feed pharmacokinetic models. These methods however can be inaccurate and error-prone. A new automated tool for the determination of blood activity as a function of time is presented. The device relies on a peristaltic pump for continuous blood withdrawal and can package blood samples in evacuated tubes at specific times for further analysis. The device uses a 20×20×15 mm3 Cadmium Zinc Telluride (CZT) detector, read by a custom-made preamplifier and a FPGA-based signal processing unit. A Graphical User Interface (GUI) offers a user-friendly interface with preselected parameters to perform an acquisition. This paper presents the overall design of the tool as well as preliminary results related to detector performance in terms of linearity, stability and sensitivity. The sensitivity is estimated at 0.9 cps/Bq/µL

SP061.5 - A Portable Free-Hand 3D SPECT System Author(s): Jonathon Irish¹, <u>Harley Chan</u>², David Jaffray³ ¹Surgical Oncology, University Health Network, Toronto/CANA-DA, ²Radiation Medicine Program, Princess Margaret Cancer Centre / University Health Network, Toronto/CANADA, ³Dept Radiation Oncology, University of Toronto, Toronto/ON/CANADA

We have developed a system that can produce 3-dimensional single photon emission computed tomography (SPECT) images from a handheld gamma camera that can be moved freely by a surgeon around a patient. This system is called FreeSPECT, will better localize lymph nodes for sentinel lymph node biopsies (SNLB). With 3-dimensional image-guidance that can be linked to high-resolution anatomical images from CT or MR, surgeons will be able to more accurately remove lymph nodes and plan around sensitive tissues. The FreeSPECT system we have developed is based upon a lightweight gamma detector (MRG15, Cubresa, Winnipeg, Manitoba) which is small in size and MR compatible. Figure 1 shows the system including the electronics cabinet, gamma detector, and user interface. The silicon photomultiplier (SiPM) detector head has 16 pixels in a square 4x4 pattern, with a 5 mm thick CsI(TI) scintillator. The detector efficiency is 149.7cps/MBq at 50 mm source distance, and signal multiplexing allows sampling of each pixel every 4 µs. In-house developed navigation platform "GTxEyes" provide gamma image acquisition, real-time tracking, navigation, visualization, and reality augmentation. This platform is developed based on open-source toolkits and libraries including VTK, ITK, IGSTK, and OpenCV, as well as our own proprietary image reconstruction and co-registration algorithms. Additional capabilities of this platform include critical organ monitoring with visual/audio alerts and image overlay of multi-modality images. Fast deformable Demon image registration algorithm is also available to register pre-operative images (and/or contours) to intra-operative images such as the proposed Free-Hand SPECT image. The prototype FreeSPECT system has integrated optical tracking technology (Spectra, Polaris, NDI), a reference tool affixed to the camera's body for identifying the position and orientation of the gamma camera images in 3D. To precisely locate the gamma camera images in space, the spatial relationship between the tracking tool and camera space is first calibrated. In the localization process, the clinician uses the handheld gamma camera to scan above and around the region of interest. The software records the 6D position and orientation of the camera simultaneously with the gamma image acquisition at every instant. In the prototype system, this recorded information is saved in ASCII text format for subsequent tomographic image reconstruction. The SPECT image reconstruction is based on the ordered subset expectation maximization algorithm as implemented in the NiftyRec open source tomography toolbox. Preliminary results from the FreeSPECT prototype system are shown in Figure 2.

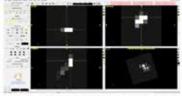

Figure 1: The FreeSPECT prototype system integrates compact gamma camera, optical tracker, and in-house GTxEves software platform

Figure 2: Illustration showing a preliminary result of the FreeSPECT prototype system.

SP061.6 - Probing the Biomechanical Properties of Cells using High-Frequency Ultrasound and Acoustic Levitation Author(s): Natalie Sullivan¹, Brian D. Patchett², Timothy E. Doyle² ¹Chemisty, Utah Valley University, Orem/UT/UNITED STATES OF AMERICA, ²Physics, Utah Valley University, Orem/UT/UNITED STATES OF AMERICA

Alterations in the biomechanical properties of cells are important in many pathologies including cancer, neurodegenerative diseases, and autoimmune disorders. For example, the more aggressive molecular subtypes of breast cancer may express different biomechanical phenotypes due to subtype-specific mutations which code for proteins that regulate the cytoskeleton. Microtubule destabilization and other cytoskeletal dysfunctions play a pivotal role in neurodegenerative disorders such as Alzheimer's disease. In autoimmune diseases, cytoskeletal changes in T cells are key to signaling, immune recognition, and activation. Our research at Utah Valley University is currently exploring the capabilities of high-frequency ultrasound for detecting variations in the biomechanical properties of cells. To date, high-frequency (10-100 MHz) ultrasonic spectra have been found to be sensitive to breast cancer cell types and chemical modification of the cytoskeleton in cell cultures. The cells are noninvasively probed using a pulse-echo measurement. Time-domain signals acquired from cells are converted into frequency spectra and analyzed for spectral features that correlate to biomechanical properties. Ultrasonic scattering models, experimental data, and data analysis methods such as principal component analysis have confirmed that high-frequency ultrasound can detect changes in the cytoskeleton. However, a critical problem with the current approach is the strong ultrasonic reflection from the well bottom of the cell culture plate, which interferes with the weak ultrasonic signals from the cells adhering to the bottom. The objectives of this study were to develop an approach to eliminate the well-bottom interference from the cell signals, and to provide a capability for probing cells in liquid suspension (thereby expanding application to cells extracted from tissue and blood). The approach uses acoustic levitation to induce free-floating cells into forming a thin, suspended, planar layer which can then be probed by high-frequency ultrasound. Acoustic levitation is accomplished by establishing an acoustic standing wave in the media using a low-frequency ultrasonic transducer. A significant challenge in the acoustic levitation of cells is the random motion of the cells about the node position of the standing wave. This paper reports on a new method for damping cell motion during acoustic levitation. The method uses harmonic modulation of the standing wave to create nodal regions of greater stability and cell localization as compared to a single-frequency standing wave. Numerical simulations indicate that such "acoustic wells" can be created using a multifrequency layered piezoelectric transducer to modulate the standing wave with an optimized set of harmonic frequencies. Breast cancer cells having distinct spectral signatures will be tested to validate the approach. The acoustic levitation system will consist of a 30-MHz function generator, an RF amplifier, and a multifrequency (0.1-1.0 MHz) layered piezoelectric transducer. The high-frequency ultrasound system will consist of a 50-MHz immersion transducer, a high-frequency square-wave pulser/receiver, and a 1-GHz digital storage oscilloscope. Our research group has developed a new method for stabilizing cell motion during acoustic levitation using numerical simulations. This new method promises to not only expand the capabilities of high-frequency ultrasonic testing of the biomechanical properties of cells, but also has applications as a 3D patterning approach in tissue engineering.

SP062 - Clinical Process Analysis, Optimization, Productivity and Benchmarking

TRACK 16: CLINICAL ENGINEERING, CLINICAL PHYSICS, AND PATIENT SAFETY

SP062.1 - Guaranteeing the quality of rigid endoscopes with the ScopeControl

Author(s): <u>Herke Jan Noordmans</u>¹, Rens Wientjes² ¹Fb Medical Technology And Clinical Physics, UMC Utrecht, Utrecht/NETHERLANDS, ²Fb Medical Technology And Clinical Pysicist, UMC Utrecht, Utrecht/NETHERLANDS

As rigid endoscopes are re-used after minimal invasive surgery, they degrade over time. To guarantee the optical quality of a rigid endoscope for the next surgery, the ScopeControl has been developed to measure key optical parameters such as light transmission, color correctness, focus, fiber transmission, viewing angle and field of view. The ScopeControl is placed in the reprocessing cycle right after cleaning, before wrapping and sterilizing the endoscope. After a measurement has been performed, all parameter buttons/indicators should turn green. When, however, a parameter button/indicator turns red, its value falls below a pre-defined threshold (acceptation criterion) and the endoscope should be rejected for further processing.

In 2013 a pre-commercial version of the ScopeControl has been tested in six hospitals in the Netherlands. It proves to be stable, and able to measure optical parameters with sufficient precision that it can discriminate between good and bad endoscopes [1]. Since April 2014, the commercial version of the ScopeControl has been in use at the sterilization department of the UMC Utrecht (about 4000 minimally invasive surgeries a year). In this project we want to address several issues when introducing the ScopeControl in the clinical process:

 What kind of training people of the sterilization department should get in handling and interpreting the results of the ScopeControl.
 What kind of tracking is needed for endoscopes. Conventional basket tracking systems are often not sufficient as endoscopes are easily swapped between baskets. The ultimate goal is to track on endoscope level (e.g. using a data matrix or RFID).
 What should be agreed between the departments of sterilization, OR and medical technology about rejecting/accepting endoscopes when reprocessing them or sending them in for repair or replacement. What can be said about the rejection/acceptation levels? Generally a repaired or new endoscope should have a higher quality than an endoscope that is still good enough for surgery. There should be some bandwidth where endoscopes may deteriorate slowly.

4. What kind of reports can be derived from such a system and how can these results be coupled to information from other electronic registration systems in the hospital like basket tracking and OR management systems.

5. Which steps in the reprocessing cycle may damage endoscopes and can we get an idea of their impact? Think of handling, transport, cleaning, disinfection and sterilization.

These issues are illustrated in two examples: The replacement of a large number of rigid endoscopes in a public tendering, and the large fall-out of large number of cystoscopes for children. We look forward to a live discussion to see whether these problems are recognized in other hospitals and which approaches other people have found to address these problems.

SP062.2 - Low-entry level CT exam times and availability in worldwide markets

Author(s): <u>Renan M. Almeida</u>¹, Fernando C. Coelli², Andrei L. Pires³, Renan M. Almeida⁴, Wagner C. Pereira⁴ ¹CEFET "CSF" RJ, Itaguaí/BRAZIL, ²Cefet "CSF" RJ, Itaguaí/BRA-ZIL, ³UFRJ, Rio de Janeiro/BRAZIL, ⁴Peb/coppe, UFRJ, Rio de Janeiro/BRAZIL

Context and background: Computerized Tomography (CT) is widely used for disease diagnosis, treatment planning, and follow-up. Currently, its state-of-the-art is a 320-slice equipment, but machines with one, two, four and 16 slices are still used in many countries. Exam speed (and, thus, number of exams per period of time) may change among models, but the smallest slice thickness is usually about 1mm regardless of the number of detector rows. However, most of the basic models already had their production discontinued, a situation that makes CT entry level more expensive, and, therefore, decreases its adoption in less developed countries.

Objective: To study the differences in productivity (exams/unit of time under real working conditions) between 1, 2, 4 and 16 slices CTs.

Methods: Four CTs (with one, two, four and 16-slices) were studied relatively to their performance in patient exam time, divided as: *i*) patient arrival; *ii*) patient initial preparation; *iii*) patient positioning in the equipment; *iv*) data scan; *v*) examination time and *vi*) time for patient departure. Times were measured in minutes and seconds by two researchers with an Android Tablet and a timer application. Equipments were located in Rio de Janeiro city or nearby cities in Brazil, 2013-2014. Additionally, an Internet search was performed among equipment producers trying to identify the supplier of the simpler models in the Asian, European and USA markets.

Results: A total of 85 exams were followed, and three had to be discarded, one due to equipment failure at the moment of the exam and two due to patient arrival delays. Average times for the arrival / preparation / positioning / scanning / departure stages did no differ markedly. As for the "scan" stage, the average time for the single slice case was 8'38", as opposed to respectively 2'05"/ 2'31"/ 2'41" for the remaining models.

Concerning model availability, the Internet search identified that few older model options are still available, with the number of slices beginning at "sixteen" among USA and European manufacturers.

Conclusion: Despite their wide variations in technology, average time differences among the studied models were small for the "non-examination" stages, indicating that the general (including ergonomic) characteristics of the equipments did not change markedly. Regarding the "scan" stage, however, 2-16 slices models had a similar and clearly better performance relatively to the single-slice model, and, thus, a similar productivity could be achieved with the former models. This is an important consideration, given that productivity is important both for the public health sector (allowing for attending a larger patient population) and for the private sector. Therefore, these models, if still available, could satisfy the demand of many less developed countries, but the Internet search identified that entry level now refers to 16 slices and over. An alternative for keeping low cost models in production would be the development of "upgradeable platforms" by manufacturers, allowing for the acquisition of more simple alternatives that could be adequately upgraded along time.

SP062.3 - The critical evaluation of AV control features in modern pacemakers and cardioverters Author(s): Kazimierz Peczalski, <u>Tadeusz Palko</u> Warsaw University of Technology, Warsaw/POLAND

The modern prostheses of different vital systems of human body are equipped in many control features related to the physiological behavior of replaced systems. The critical evaluation of some algorithms for the synchronization of the heart conductive systems that are implemented in modern pacemakers and cardioverters is goal of our evaluation. We describe our clinical evidence that the algorithms should be customized to individual patients. Two of the most important pacing parameters: default atrioventricular interval (AVI) and AVI adapted to heart rate (HR) were evaluated by the authors. The criterion for enrolment to the both study groups was the 80% pacing recorded by the pacemaker holter systems and 100% pacing during the duration of the test.

The goal of the studies was to assess the differences between SV for optimal AVI and SVs for default AVI values proposed by two of the biggest word pacemaker companies and the impact of varying HR on the optimal AVI in two groups of 20 paced patients: first (mean age 74.0 years +/- 7,0 years) consists of 4 females (mean age 75.3+/- 6.1) and 16 males (mean age 74.3+/-4.1) and second treated by DDDR were enrolled the in the study.

The mean value of SV for optimal AVI achieved in the first clinical study is pretty close to SV for default AVI' (150 ms) and differ from SV for the second default AVI" (170 ms). Significant changes (p≤0.05) were found for SV vs SV". The high SD level of optimal AVI's (mean 148.50 msec., SD 41.07 msec.) shows wide range of its variations assessed for some patients. The estimated default AVI" may be based on a different population of patients for instant North American. All of the facts listed above prove the assumption that the default AVI values preset by companies can lead for nonoptimal settings for some patients. Such wrong settings can be especially important in group of patients with poor condition of cardiac muscle which limits the physiological adaptation of the heart to an intense exercise. The results of the second study of reaction of AVI to increase or decrease of HR lead to similar conclusion. The normal relationships between shorter AVI for faster HR and longer AVI for slower HR simply do not work for some, pretty significant in presented study, number of paced patients with impaired systole by atrophy of heart muscles geometry and non physiological systole of paced ventricles (the impulse is propagated from the apex of the heart in opposition to physiological direction of impulse propagation).

Conclusion: The presence of non physiological behavior of the heart conductive system should be taken under consideration during adjustment of parameters of pacing treatment.

SP062.4 - Assisted Reproductive Technology Center Design with Quality Function Deployment Approach

Author(s): <u>Alessio Luschi</u>¹, Massimiliano Monti², Ernesto Iadanza³ ¹Information Engineering, University of Florence, FIRENZE/ITA-LY, ²ESTAV Centro, FIRENZE/ITALY, ³Department Of Information Engineering, University of Florence, Florence/ITALY

Assisted Reproductive Technology (ART) is the technology used to achieve pregnancy in procedures such as fertility medication, artificial insemination, in-vitro fertilization and surrogacy. The paper shows an application of Quality Function Deployment method to Careggi Hospital ART Laboratory of Florence in order to give a prioritization order for ameliorative interventions.

SP062.5 - Study of the Sensitivity on the Measurement of the Prevalence of Total Cholesterol in Blood Serum by Interferometric Techniques

Author(s): <u>Bettsy Hernandez-Zacarias</u>¹, Gerardo S. Romo-Cardenas¹, Alejandra Guillen-Peralta², Alex Muñoz-Arpaiz¹, Juan Alvarez-Arana², Ismael Chable²

¹School Of Engineering, Montemorelos University, Montemorelos/ MEXICO, ²School Of Health Sciences, Montemorelos University, Montemorelos/MEXICO

Current blood testing techniques require the use of sensitive equipment and a constant consumption of specific chemical compounds in order to analyze fluid composition and concentration. It is known that optical interferometers are instruments that can make precise measurements of objects using the interference pattern of two light waves. These devices have been used to characterize materials and to study their properties. Interferometric studies results, prove that by this type of optical arrangements combined with image processing, enables a method that applies for fluid characterization. Being this is a non-destructive protocol that could be used for different applications in engineering. This study, propose the use of optical interferometry to analyze blood serum in order to explore the possibility of developing an alternative method for blood sample analysis. The methodology consists of analyzing different blood serum samples previously quantized to determine the effect of the variability of its components in the acquired interferograms. The results show an unexpected behavior of the acquired interferograms in relation of the amount of total cholesterol included in the samples, this in relation with the information generally considered from the medical practice.

The scope of this paper seeks to apply technology and optical engineering also consider the effect of the prevalence of lipid components in blood serum in order to develop a standardized technique that allows the study of concentration information from acquired interferograms and thus validate the option as an alternative to the quantization of such compounds. Helping to complement the knowledge of the biochemistry of the blood and develop novel methods for quantization and analysis of its components by non-destructive techniques and less expensive methods known on the market.

SP062.6 - Critical role of sustaining technology and utilities in healthcare institutions facing disaster through development of an international center for information and training of health technology managers on disaster preparedness

Author(s): <u>Yadin B. David</u>¹, Caridad Borrás², Fred Hosea³, Douglas Drepps⁴

¹Biomedical Engineering Consultnats, LLC, Houston/UNITED STATES OF AMERICA, ²IUPESM, Washington DC/UNITED STATES OF AMERICA, ³Clinical Technology, Kaiser Permanente, San Francisco/CA/UNITED STATES OF AMERICA, ⁴Clinical Engineering, Mercy System, St. Luis/MO/UNITED STATES OF AMERICA

Study/Objective

Promote awareness of critical role of sustaining technology and utilities in healthcare institutions facing disaster by exploring development and establishment of international center for information and training of health technology managers on disaster preparedness and situation-awareness methodologies.

Background

Review of disasters that affected healthcare institutions suggests a need to make technological systems more robust and better trained users about disaster preparedness. The burden is magnified due to ever growing critical dependency on technology, i.e. central oxygen, vacuum, nuclear, radiological equipment, communication systems.

Methods

The need for a training center based on a case study of the impact

on several hospitals: a flood from tropical storm affected several hospitals and their technological systems in Houston, Texas, 2001. The problems caused by rising water, the immediate response, the recovery efforts and the financial losses will be analyzed. This will also include the transfer of learned lessons to environment of resource-poor countries.

Results

Water caused shutdown of electrical, air, vacuum systems and submerged areas containing radiological equipment. Patients had to be evacuated, unfortunately four patients died, research animals, and years of investigation data lost. The case shows lack of technology-focused plans for triaging healthcare systems and of training programs. There was lack of understanding of systems (including networks) and devices' vulnerability, especially when multiple systems crushed. The possibility of unique hazards like those from radiation-emitting devices and radioactive materials, other biomedical equipment such as mechanical ventilators were considered last. Prioritization of backup and strengthening resilience of technology prior to disaster and during disaster were a last minute approach. The recovery focused on commissioning technologies critical to life. Had the facility been better prepared, lives and financial losses would have been minimized.

Conclusion

Disaster preparedness plans in healthcare institutions must include knowledge of the vulnerabilities they may face and plans to mitigate risk of operations disruption due to technology and utility issues.

SP063 - Accreditation, Certification and Licensure Issues

TRACK 17: EDUCATIONAL AND PROFESSIONAL ACTIVITIES

SP063.1 - The Current State of Clinical Engineering Education and Career

Author(s): Yadin David

Health Technology Management, Biomedical Engineering Consultants, LLC, Houston/UNITED STATES OF AMERICA

Today's practice of healthcare has grown to depend on the deployment and integration of technological tools for the delivery of its services like never before. Furthermore, these technological tools are being integrated into systems requiring competencies and expertise that challenges conventional training. It is critical, for the practice of safe and effective healthcare services, that these systems and their integrated technological tools are well planned, managed and safely serviced throughout their complete life cycle. Not only the dependence on these systems has grown but even more so, the quality and the volume of the intelligence embedded within these technological tools. Intelligence that guides the management of patients' conditions. As example, the emergence of the utilization of electronic medical records, of health informatics, surgical robots, 3-D medical imaging, smart infusion pumps, bedside telecommunications, wireless accessibility and mobile devices. It is clear, therefore, that clinical engineers for successfully managing their hospital's clinical technology program require new knowledge and additional competencies.

In reviewing the academic preparation of engineers for career in the clinical environment, the clinical engineers, it seems obvious that most if not all are based in the biomedical engineering academic programs. While there are some joint sciences, the training of clinical engineer is different from training of biomedical engineer. The curriculum and the format of the clinical engineering programs must anticipate and train for the specific body-of-knowledge needed for practicing as clinical engineering professional. Therefore, helping its graduate to become successful practitioners that will pursue, after graduation, further professional development and certification supported by lifelong clinically related continuing education. This presentation will provide a review of the healthcare technological tools and their integration into systems. It will further identify how these changes influence the body-of-knowledge that clinical engineers must have. It will summarize some suggestions on how to improve clinical engineering education programs so that their graduates will be successful in their career, happy as professional practitioners, and contributors to best possible care outcomes.

Objectives

1. To describe the relationship between changing healthcare and clinical engineers practice

2. To identify why changes in practice of clinical engineers impact their education and preparation

3. To link specific knowledge that must be part of future clinical engineering education and their career

SP063.2 - The Pursuit of Regulated Health Profession Status for Medical Physicists in Alberta

Author(s): <u>Charles J. Kirkby</u>¹, Joel St. Aubin², Alana Hudson³, Brad Warkentin², Lesley Baldwin², Matthew Larocque², Atiyah Yahya², G. Colin Field²

¹Medical Physics, Jack Ady Cancer Centre, Lethbridge/CANA-DA, ²Medical Physics, Cross Cancer Institute, Edmonton/CANA-DA, ³Medical Physics, Tom Baker Cancer Centre, Calgary/CANADA

The purpose of this presentation is to report on the progress towards Medical Physics becoming a regulated health profession in Alberta.

Medical Physicists in Canada have a nationally recognized certification system through membership with the Canadian College of Physicists in Medicine (CCPM). While most Medical Physicist employers desire this membership or its equivalent, it is enforced only voluntarily by hiring institutions and managers. There is no legal requirement for membership with the CCPM to work as a Medical Physicist. Many of the clinical activities performed by Medical Physicists that can have direct clinical consequences for patients in terms of detecting and treating disease can be legally performed by anyone. This lies in contrast with many of our professional peers (physicians, radiation therapists, nurses, etc.), where provincial colleges independently define a scope of clinical practice, regulate those who may conduct that practice, and restrict the practice of certain activities to those registered with the college.

By defining a scope of practice and requiring members of a profession to meet and maintain minimum standards of competence, professional regulation ensures both patient safety and a minimum standard of care. Root cause analysis commonly identifies lack of Medical Physicist involvement, training, or qualifications as a significant contributor to major radiation therapy accidents and near miss situations. This suggests a key link between quality and safety and the regulation of Medical Physics.

In Alberta there are approximately 40 qualified medical physicists. For over five years the Association of Medical Physicists in Alberta (AMPA) has pursued professional regulation under Alberta's Health Professions Act. In 2011, AMPA submitted an application for professional regulation to the Government of Alberta. Government feedback identified small physicist numbers as a primary barrier to regulation: the administrative workload of operating a professional college, and the cost of potential investigations and disciplinary committee hearings (involving legal council) were deemed prohibitive. However, subsequent feedback suggested the potential viability of a joint application with the Alberta Association of Clinical Laboratory Doctoral Scientists (AACLDS), an organization also seeking regulation, but limited by similar membership numbers. AACLDS represents professions including clinical chemists, microbiologists, geneticists, and toxicologists who share several professional similarities with medical physicists. Its members complete PhDs, then do two years of clinical training before writing a national certification exam. In the newly proposed model, Medical Physicists and the professions represented by AACLDS would join and be administrated by the College of Physicians and Surgeons of Alberta. The CPSA is a natural choice because (i) this college is the provincial accreditation body for ionizing radiation devices below energies of 1 MeV and (ii) our groups share common professional ground with physicians and surgeons, including a balance of clinical and academic responsibilities, and the extensive training involved in our professions.

At the time of this abstract submission, AMPA and AACLDS are in the process of submitting this joint application to the Government of Alberta. If successful, Alberta would become the first province in Canada designating Medical Physicists as a regulated health profession.

SP063.3 - The International Medical Physics Certification Board

Author(s): <u>Colin G. Orton</u>¹, Tomas Kron², Raymond K. Wu³ ¹Radiation Oncology, Wayne State University, Grosse Pointe/ UNITED STATES OF AMERICA, ²Radiation Oncology, Peter MacCallum Cancer Centre, Melburone/AUSTRALIA, ³Radiation Oncology & Cyberknife Department, University of Arizona Cancer Center, PHOE-NIX/UNITED STATES OF AMERICA

This talk will present an overview of the objectives of the International Medical Physics Certification Board (IMPCB), progress made since its formation, and the results of recent discussions to assure that the IOMP will play a major role in IMPCB governance in the future. The IMPCB was established in 2010 with the assistance of the Certification Task Group of the IOMP Professional Relations Committee, with the goal of improving the quality of clinical medical physicists and the profession. To achieve this objective, the IMPCB will accredit existing national/regional Medical Physics Certification Boards and encourage and assist those countries/regions that currently have no certification programs to develop them. It also works towards conducting certification examinations for medical physicists practicing where local certification is not currently available. The first tasks of the IMPCB were to develop a model certification program (published in 2011), write the By-Laws (adopted in 2012), and elect the 1st Board of Directors (took office in January, 2014). An Accreditation Committee was established with the initial task of development of the requirements for certification and accreditation (completed in November, 2014). These include requirements for general education (a minimum of a Masters degree), medical physics education (general and specialty), and clinical training. These requirements adhere closely to those published in IOMP Policy Statement No. 2: Basic Requirements for Education and Training of Medical Physicists, and several IAEA documents. Medical physics certification examinations might be in three parts: Part I (a written exam on general medical physics to be taken by all candidates), Part II (a written exam for each specialty), and Part III (an oral exam for each specialty). But the IMPCB recognizes that there are national/ regional variations to certification in medical physics based on differences in national/regional legislation and educational traditions, so it gives to national and regional certification bodies considerable freedom to decide on the manner in which a given organization seeking IMPCB accreditation conducts the certification process. The Board decided to initially restrict accreditation of Boards and IMPCB certification examinations for only the three specialties Radiation Oncology Medical Physics, Diagnostic and Interventional Radiological Physics, and Nuclear Medicine Physics, and begin accepting applications for accreditation of national or regional medical physics certification boards in January, 2015. The Board also approved collaboration with the IAEA to work on certification of experienced medical physicists working in countries which currently have no certification Board. For the latter, a Question Bank has been developed for Parts I and II of the IMPCB certification examination.

SP063.4 - Radiation protection continued training program evaluation: return on a 7-year experience

Author(s): <u>Nadia Octave</u>, Janelle Morrier, Mario Chrétien Radiation Oncology, CHU de Québec - Hôtel-Dieu de Québec, Québec/QC/CANADA

Introduction: As healthcare professionals working with ionizing radiations, radiation safety is of paramount importance. In Canadian regulations (Nuclear Safety and Control Act, NSCA), requirements regarding workers radiation protection (RP) training and training programs are highlighted at different times. We aim to present: (1) our experience of RP training program (RPTP) since its inception in 2007; (2) our RPTP evaluation and (3) how it complies with Canadian regulations.

Materials and Methods: The RPTP implemented is based on 6 educational modalities: (1) oral classroom presentations on general topics, (2) bimonthly bulletin publication distributed both electronically and on paper form, (3) computer-based training, basically interactive modules, with questions and answer to ensure and assess understanding of the notions developed, (4) posters display, (5) practical training on routine tasks and, (6) simulations of emergency situations in working environment. A registration methodology is used to verify the level of knowledge and competence of each worker to safely perform their job. After 5 years of the RPTP implementation, an internal audit was conducted with a 10-question survey designed with Survey Monkey to measure the training effectiveness and perception among users.

Results: Readership of our informative bulletin alone is equal or higher than 70% for the past 4 years with highest rates among technologists. 73 people answered to the satisfaction survey, among them 74% were technologists, 11% were physicists, 11% were physicians and 2.7% and 1.3%, service techs and oncology residents respectively. The preferred educational supports were the interactive modules and the bulletin respectively, while posters are majorly disregarded. Interestingly enough, people are highly attached to classroom format and were very interested in emergency situations simulations. Respondents majorly stated to read the bulletins "always" for 68.5 % and "often" for 13.7%, independently of workers category. The answers are more divergent by work categories when asked about bulletin frequency appropriateness. Technologists are majorly satisfied with the actual bi-monthly rate while radiation oncologists are heavenly distributed between status quo and frequency reduction. Contrariwise, for a majority of the physicists, frequency should be reduced. When asked about perception level of RP knowledge with regards to routine tasks, all physicists and physicians answered "adequate". Answers were more mitigated among technologists where 68.5% answered "adequate", 29.6% "basic" and 1.9% "thorough". Interestingly, the commune highest confidence knowledge in all workers categories was found in RP specific to treatment machines, and the lesser in RP in non-medical related areas. Annual completion of electronic module was majorly accepted.

Conclusion: As stated in the NSCA and other regulations, it is the licensee direct responsibility to ensure that workers receive appropriate training related to their specific jobs. Since its inception, the RPTP was well received and closely monitored. Users' compliance and feedback helped to better meet their needs while continuously developing a radiation protection culture as proposed by the IRPA. It is possible to conclude that overall department stakeholders feel they have sufficient RP knowledge for their daily duties.

SP063.5 - Where to find biomedical engineers worldwide? Mapping biomedical engineers around the world

Author(s): Daniela Rodriguez Rodriguez, <u>Adriana Velazquez Beru-</u> men, Megan M. Smith, Ricardo X. Martinez

His/emp/pau/medical Devices, World Health Organization Headquarters, Geneva/SWITZERLAND

Background

Within health systems around the world trained and qualified biomedical engineering (BME) professionals are required to design, evaluate, regulate, acquire, maintain, manage and train on the safe use of the medical healthcare technologies. Nevertheless the profession is often left out from the health workforce in various countries, and biomedical engineers' recognition and classification by the International Labour Organization (ILO) is still pending due to lack of statistical information of the current number of biomedical engineers around the world.

Therefore with the intention of: a) promoting the role of biomedical engineering and related disciplines in healthcare, b) disseminating

information about BME educational programmes and societies; and c) acquiring recognition of the profession at country/international level (e.g. International Standard Classification of Occupations (ISCO) by ILO) WHO started efforts to track biomedical engineers' presence worldwide since 2009 and in four different stages: 1-2009: in collaboration with the University of Campinas, work coordinated by professor S. Calil.

2-2010: C. Long and R. Magjarevik

3- 2013-2014: D. Desai, J. Barragan, S. Mullally and N. Jimenez 4- 2015: on-going

On January 2015 WHO launched an extensive survey that aims to map biomedical engineers' presence at a country level. Additionally information on existing professional societies, educational institutions in the field of BME and women's role within the profession is being collected.

<u>Methodology</u>

2015 survey was sent to over 3200 contacts using WHO medical devices listserv tool. The survey was divided in four parts: country profile, educational institutions, professional societies and international organizations. Each part aimed to collect specific information on the topic and was aimed to be completed by the professionals holding section-specific information.

Additionally a question regarding female presence within the profession was added in each section in order to measure the proportion of women actively working (in different sectors) or recently graduated in BME or related field.

All collected information (including the four stages) is expected to be published in WHO Global Health Observatory (GHO), the World Health Statistics 2015 and ideally in ISCO-18.

Results

Research is ongoing but anticipates disclosing the presence of biomedical engineers by country (country profile), the number of educational institutions per country and the percentage of women actively present in the field. Additionally the presence of biomedical engineers in international organizations (e.g. UN agencies, Red Cross, development agencies, NGOs) and international professional societies is expected to be unveiled.

Conclusion

New information regarding the presence of biomedical engineers is now being collected and is aimed to be publicly available by June 2015. The dissemination and promotion of this information aims to strengthen biomedical engineering recognition in order to improve health care delivery.

SP063.6 - Oh dear medical physicist and biomedical engineer, why is it difficult to pioneer your specialist career? Author(s): <u>Mario Medvedec</u>

Department Of Nuclear Medicine And Radiation Protection, University Hospital Centre Zagreb, Zagreb/CROATIA

By the end of 2013 Croatia's health care sector had a permanent work force of about 74,500, around 13,750 medical doctors among whom approximately 9,700 specialists, and about 750 university degree health associates including clinical medical physicists and biomedical engineers. The objective of this paper is to present one national example of medical specialists grandfathering in favor of improved regulation of medical doctor profession, but all in wider context of global efforts towards better perception and regulation of clinical medical physics and biomedical engineering profession worldwide. Equal opportunities of continuing professional education and training, as well as career advancement (internship, residency, subspecialization, postgraduate specialist programs, etc.) should be facilitated and provided to all clinical scientists. Grandfathering is certainly a usual step to give initial momentum, but grandfathering under the same criteria for all health professionals. For the maximal benefit of the patients, health professionals, health institutions and national health system, it appears that there is an urgent need in Croatia to make decisive actions towards much better perceiving and regulating the status of clinical scientists with background in natural, technical, biotechnical and social sciences.

SP063.7 - Biomedical Engineering Education and Training and Accreditation of Bachelor-degree Biomedical Engineering Programmes

Author(s): Min Wang

Department Of Mechanical Engineering And The Medical Engineering Programme, The University of Hong Kong, Hong Kong/HONG KONG

Hong Kong, like other advanced economies in the Asia-Pacific region, has an aging population and hence high-quality healthcare is required for its citizens. There is therefore an increasing demand for well-educated and well-trained biomedical engineers in Hong Kong. Hong Kong has a well-established system for tertiary education and professional training of engineers. In 2012 in Hong Kong, the British style 3-year university education was changed to the North-American 4-year one, giving local universities various opportunities for reforming their curricula, enhancing teaching and learning, improving student exchange programmes, etc. Biomedical engineering (BME) is a constantly expanding and intrinsically interdisciplinary field. The US and Western Europe as pioneers in the field have provided exemplary BME educational programmes. How to learn from these programmes and then set up their own programmes with distinct features for local students is not an easy task for BME educators in other countries. Hong Kong joined the legion of BME education providers and started BME educational programmes in the mid-1990s. Currently, four universities in Hong Kong provide bachelor-degree level BME education: The Hong Kong Polytechnic University (PolyU), The University of Hong Kong (HKU), The Chinese University of Hong Kong (CUHK), and City University of Hong Kong (CityU). The 3-year curriculum BME programmes (which started in different universities at different times and will all end in 2015) in PolyU, HKU and CUHK have been fully accredited by the Hong Kong Institution of Engineers (HKIE) which is a signatory of the Washington Accord. The accreditation in Hong Kong of 4-year curriculum BME programmes was started in 2013, and in 2014 HKU's 4-year curriculum Medical Engineering Programme became the first BME programme to gain HKIE's provisional accreditation. (A BSc or BEng engineering programme can only gain provisional accreditation, not full accreditation, before it produces its first cohort of graduates.) Another university's BME programme is currently going through the accreditation exercise. All 4-year curriculum engineering programmes put forward for HKIE's accreditation must use the outcome-based approaches in student learning and hence the programme's preparation for accreditation and the accreditation itself (criteria, documentation and presentation, process, etc.) are different for those used in the 3-year curriculum accreditation exercises. With these programmes as the foundation, a three-tier BME education is now in place in Hong Kong: the bachelor-degree level education (BSc or BEng), the taught-master degree (MSc), and research degrees (MPhil or PhD). Beyond the university education at these three levels, professional training in BME can be obtained in different organizations in Hong Kong. Government departments and the private sector alike contribute to BME engineer training. This presentation will give an overview of BME education and training in Hong Kong and briefly compare the BME programmes. It will also discuss various aspects of BME programme accreditation, drawing the author's experience as the Programme Director to lead the HKU BME programme through its accreditation and also as the Visiting Team member for HKIE's accreditation of a BME programme in another university.

SP063.8 - IOMP initiative for Validation and Accreditation of MSc courses

Author(s): Slavik Tabakov¹, John Damilakis²

¹Medical Engineering And Physics, King's College London, London/ UNITED KINGDOM, ²Medical Physics, University of Crete, Iraklion/ GREECE

The Education and Training Committee (ETC) of the IOMP guides and supports a number of educational courses, workshops and projects around the world. One of these projects developed a Model Curriculum for post-graduate (MSc level) courses on Medical Physics. It also presented guidance on the organisation of such courses. The next stage of this activity is the initiative of international Validation and Accreditation of MSc courses in Medical Physics. These were briefly described in the book with educational experience from 26 countries (Medical Physics and Engineering Education and Training, available free from: http://www.emerald2.eu/mep/e-book11/ ETC_BOOK_2011_ebook_s.pdf).

The Validation and Accreditation of MSc courses will be performed by the IOMP ETC. It will include assessment of the curriculum; assessment of the teaching methods; assessment of the examination process and assessment of the research activities (MSc project). The IOMP Model Curriculum will be used for the purpose and a number of expert medical physicists will be attracted to the validation process. The initial phase of the project will be guided in English and will be based on assessment of an English translation of the MSc Curriculum.

This IOMP activity will allow for a small country with limited expertise to set-up a post-graduate course in Medical Physics. This will boost the profession in many developing countries. The Validation and Accreditation of MSc courses will be used also for supporting step of the future Professional Certification of professionals. It is expected the first MSc courses to be accredited during 2015-16. The paper will present the application form and will discuss the application of the process.

SP064 - Biomechanics and Artificial Organs

PRESIDENTS CALL

SP064.1 - Biomechanical Analysis of Optimal Orientation and Stress Shielding for Short and Long Stem Hip Implants Author(s): Peter Goshulak¹, Saeid Samiezadeh², Mina S.R. Aziz¹, Habiba Bougherara², Radovan Zdero¹, Emil H. Schemitsch¹ ¹Martin Orthopaedic Biomechanics Lab, St. Michael's Hospital, Toronto/CANADA, ²Mechanical & Industrial Engineering, Ryerson University, Toronto/CANADA

Introduction: Short stem hip implants are increasingly common because they conserve bone for future surgeries. They also improve load distribution in the proximal femur. Stress shielding is a problematic effect caused by poor stress distribution, where the bone is understressed and beins to atrophy. The decreased bone density could cause implant loosening and ultimately fracture. The aim of this study was to compare short vs. long stem implants to protect against stress shielding, and to determine if implant orientation has a significant influence.

Methods: Twelve artificial femurs received a short stem modular neck implant or long stem monolithic implant in either neutral or anteverted orientations. Modular neck options - standard, anteverted, and retroverted - were assessed in each short stem. Three additional femurs remained intact as controls. Femurs were mounted in cement blocks in 7 deg adduction and underwent quasistatic axial loading in flexion, neutral, and extension phases of the gait cycle. Strains were collected from surface-mounted strain gauges. A finite element (FE) model employed laser scanned implants and a previously validated femur model. Experimental strains were used to validate the FE model. After validation, the full range of implant types and physiologically possible orientations (i.e. varying anteversion and anterior-posterior offset) were simulated (i.e. n=25 orientations for each implant) under clinical-level loads. Stress was computed in the calcar region and was compared between implants and across each implant's range of orientations. Stress shielding was the overall stress change vs. an intact femur.

Results: FE model strains vs. experimental strains linear graphs showed an excellent fit for no implant (slope=0.898, R=0.943), short stem (slope=0.731, R=0.948) and long stem (slope=0.743, R=0.859). Altering implant orientation had no significant advantage (α =.05, p>.05). Stress shielding existed for short and long stem implants (p<.001), but was higher in the long stem implant (i.e. 63% change from intact femur, p<.001) vs. short stem implants with any of the 3 modular necks (i.e. 39%, 31%, 30% change from intact femur for standard, anteverted, and retroverted necks; p<.001 for difference between all stems except anteverted and retroverted). Long stems showed more distal-dominant stress transfer vs. short stems (p<.001), whilst peak stress was concentrated at the tip of the stem.

Discussion: Implant orientation via anteversion or anterior-posterior offset does not alter stress shielding if the implant is properly inserted into the femoral canal. Short-stem implants reduce stress shielding vs. long-stem implants. Anteverted and retroverted necks further reduce stress shielding. Results indicate some stress shielding in correctly implanted hip stems in patients with realistic activity levels. Implants with shorter stems and longer necks have a greater chance of maintaining calcar bone strength, but these parameters may reduce short-term stability because of increased proximal loading.

SP064.2 - Biomechanical Analysis of Acute Total Hip

Replacements after Acetabular Fracture: Plate vs Cable Repair Author(s): <u>Mina S.R. Aziz</u>¹, Saeid Samiezadeh², Omar Dessouki³, Habiba Bougherara², Emil H. Schemitsch⁴, Radovan Zdero¹ ¹Martin Orthopaedic Biomechanics Lab, St. Michael's Hospital, Toronto/CANADA, ²Mechanical & Industrial Engineering, Ryerson University, Toronto/CANADA, ³Department Of Surgery, University of Toronto, Toronto/CANADA,⁴Institute Of Biomaterials & Biomedical Engineering, University of Toronto, Toronto/CANADA

Introduction

Many techniques widely employed in repairing "complex" type acetabular fractures are not biomechanically validated. This paper analyzed the biomechanical aspects of two main types of repair methods, namely the traditional "plate and screws" method vs a newly introduced "cable" method. for treating complex acetabular fractures in the elderly in the presence of a primary Total Hip Arthroplasty (THA).

Methods

In Phase I, non-destructive experimental and computational analyses were performed on 6 artificial hemipelvis groups, which replicated various repair methods for an acetabular column plus posterior hemitransverse (AHT) acetabular fracture. One group was the intact control, while the other 5 groups were: intact hemipelvis with an acetabular cup of a THA; fractured hemipelvis with an acetabular cup fixed with a posterior column plate and anterior column lag screw; fractured hemipelvis with an acetabular cup fixed with the Mears and Shirahama cable technique; fractured hemipelvis with an acetabular cup fixed with the Kang and Min cable technique; and fractured hemipelvis with an acetabular cup fixed with the Mouhsine et al. cable technique. The groups were experimentally and computationally mounted to rigid supports at the sacro-iliac and symphysis pubis regions. Specimens were subjected to an acetabular non-destructive compressive force of 200 N. Computational model stress maps were directly validated against experimental results from surface strain gage measurements. The computational model was then reanalyzed using a clinical-level load of 2207 N, i.e. 3 x body weight for a 75 kg person. Stress maps were examined using a "highest stiffness" and "lowest peak bone stress" criterion to determine the most biomechanically stable cable fixation method. In Phase II, the plate/screw method (which is a traditional "gold standard" approach) was directly compared to the optimal cable technique from Phase I using experimental destructive loads to obtain stiffness, failure displacement, failure force, failure energy, fracture "sliding", and fracture "gapping". Clinical failure was defined as 5 mm displacement in the direction of the loading vector, whilst mechanical failure was defined as the peak force event needed for catastrophic failure of the specimen.

Results

From Phase I, among cable groups the Mouhsine technique provided the best biomechanical stability, yielding the lowest peak bone stress of 181 MPa at 3 x body weight for a 75 kg person. From Phase II, data showed the Plate method's superiority over the Mouhsine method for 2 outcome measurements (i.e. stiffness and failure force at clinical failure), its inferiority for 2 outcomes (i.e. failure displacement and gapping for posterior markers at mechanical failure), and statistical equivalence for the remaining parameters.

Conclusion

This is the first biomechanical investigation on the stability of the conventional Plate technique vs. 3 cable methods for fixing complex acetabular fractures in the presence of a THA. The Plate method was superior for the 2 critical outcomes of stiffness and failure force at clinical failure. However, the Mouhsine cable method is a reasonably effective alternative to the Plate group for repairing complex acetabular fractures in the elderly, as also clinically reported previously in the literature.

SP064.3 - Biomechanical Validation of the Radiographic Union Score for Tibial fractures (RUST) as a Predictor for Fracture Healing

Author(s): <u>Sandra Fiset</u>¹, Shuai Shi², Radovan Zdero³, Emil H. Schemitsch³

¹Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/ON/CANADA, ²Institute Of Biomaterials & Biomedical Engineering, University of Toronto, Toronto/CANADA, ³Martin Orthopaedic Biomechanics Lab, St. Michael's Hospital, Toronto/ CANADA

There is currently no objective parameter to define bone fracture union. This makes it difficult for orthopedic care providers to properly treat fractures in areas that are prone to complications such as the tibial shaft. Additionally, the lack of an objective scale for fracture union complicates the comparison of the endpoints of various clinical studies on novel fracture treatments. The Radiographic Union Score for Tibial fractures (RUST) is gaining popularity as a standard for assessing fracture healing progress via simple orthogonal x-ray images, but it has yet to be biomechanically validated as a predictor of fracture healing.

This study aims to validate RUST as a predictor of biomechanical properties of a fractured bone at different stages during healing using a rat model. A group of 45 male rats will undergo standardized osteotomy of the left tibia and the insertion of an unlocked and unreamed intramedullary nail. Orthogonal radiographs will be taken of the rat's tibia on a weekly basis and each rat will be assigned a RUST score. The first 9 rats to reach RUST scores of 8, 9, 10, 11 and 12 respectfully will be sacrificed and the left tibia will be dissected. A μ -CT scan and bone densitometry will be performed on both the bones. Subsequently, the intramedullary nail will be removed from the left tibia which will undergo biomechanical testing under torsion.

The imaging and mechanical testing results will be compared with the rats' RUST score and a score will be identified as a point when a bone can clinically be considered healed. This will allow for the standardization of an objective parameter to be used in clinical practice and studies.

SP064.4 - Patient-specific multi-scaling simulation of blood flow and fractional flow reserve in a coronary artery Author(s): Kyung E. Lee, Gook T. Kim, Eun B. Shim Mechanical And Biomedical Engineering, Kangwon National University, Kangwondo/KOREA

Fractional flow reserve(FFR) is a well-known gold-standard for stenting decision in a coronary artery. Aim of this study is to present the influences of stenosis on pulsatile flow in multi-scale coronary modelling with virtual narrowing. A further purpose is to better understand the co-relation between fractional flow reserve and biomechanical factors for improving the decision- making strategy of stenting. In the present study, we present a patient-specific 3D coronary arterial modeling by coupled with lumped parameter coronary vascular bed outlet models. The computations of pulsatile flows in coronary artery were performed using a high-speed Navier-Stokes solver based on a finite element method. In this study, we analyse the haemodynamics in terms of various mechanical facotrs (velocity, pressure, wall shear stress, etc.) with FFR and some other Index. Hybrid FFR-biomechanical factors could play a positive role on decision-making strategy for better diagnosis and prognosis.

SP064.5 - A Modified PID Algorithm with Fuzzy Control for Closed-loop Artificial Pancreas

Author(s): Jin Hao Yu¹, Yao X. Huang² ¹Department Of Medical Devices, Guangdong Food and Drug Vocational College, Guangzhou/CHINA, ²Department Of Biomedical Engieering, Jinan University, Guangzhou/CHINA

Objective: Now, one of the main goals of diabetes treatment research is to develop a set of artificial pancreas incorporating continuous glucose sensors, control algoritm and insulin pumps. The system can completely replace the patient's disability of pancreas, automatically infuse insulin according to the human body blood glucose fluctuations to control blood changes. We intends to study a novel closed-loop control algorithm for insulin infusion system based on the technologies of continuous glucose monitoring system and accurately insulin infusion of insulin pump. The control algorithm can adjust insulin pump dosage instantly, microscale, dynamically, according to the real-time continuous glucose monitoring data of human body.

Methods: We studied the feasibility of a modified proportional-integral-derivative (PID) algorithm which main calculation parameters were optimized in real time by fuzzy control method.

Results: We used the American food and drug administration-approved type 1 diabetes mellitus simulator to evaluate and optimize the modified proportional-integral-derivative controller. The academic version of the simulator includs 10 adults, 10 adolescents and 10 children of virtual type 1 diabees patients. The control results of 10 adults and 10 adolescents are perfect that the fluctuation range of blood glucose were 100% in the target range. But the results of 10 children were not ideal that the flutuation range of blood glucose were 60% in the target range.

Conclusion: For adults and adolescents this algorithm can greatly reduce the fluctuation range of blood glucose, control blood glucose level in the target range, greatly improve the accuracy and effectiveness of insulin infusion, make blood glucose levels of diabetic patients close to a normal person. Neverthless the control effect is not ideal for children, one of the possible reasons maybe more growth hormone in children that lead to larger fuluctuation range of blood glucose than adults and adolescents. Although there are lots of work to do, this algorithm can provide better glucose control for adults and adolescnets and has very important clinical value.

SP065 - Conebeam CT

TRACK 01: IMAGING

SP065.1 - Towards Functional C-arm CT Imaging in the Interventional Suite: Progress and challenges Author(s): Rebecca Fahrig

Radiology, Stanford University, Stanford/CA/UNITED STATES OF AMERICA

When C-arm CT entered the interventional suite in the late 1990's, the reaction from interventional radiologists ranged from 'we don't need it - we can easily create 3D images in our heads' to 'wow! that's the first time I've been able to see that vessel clearly!' Now, 3D C-arm CT imaging is done routinely during neuro- body- and even cardiac-interventional procedures. Technical advances in system components (faster rotation speeds, digital flat panel detectors with readout rates of 80 frames/s, variable trajectories) have enabled a progression from simple, high-contrast vessel imaging to detection of low-contrast soft-tissue lesions. It is now appropriate to explore what further advances are possible given the rapid evolution of the imaging hardware and software, and what these changes would bring to the interventional suite. We will examine these issues with the goal of providing functional information for intra-procedure and endpoint evaluation.

As a first step towards functional information, significant effort has been expended to improve the quantitative accuracy of C-arm CT reconstructions. The challenge is to improve image quality while providing very short turnaround between data acquisition and volume/data visualization. Corrections for x-ray scatter, view aliasing and patient motion that require no more than 2 iterations keep processing time short while reducing artifact. Additional challenges include detector non-linearity/saturation and restricted field of view.

Fast, multi-sweep acquisitions can be used to image blood flow in the brain and liver, permit assessment of left ventricular function, and visualization of radiofrequency lesions created to treat arrhythmias. Workflows for each imaging goal have been developed and validated against gold standard clinical CT or histology. The challenges, opportunities and limitations of the new functional imaging techniques will be discussed.

SP065.2 - 2D/3D Registration for Motion Compensated **Reconstruction in Cone-Beam CT of Knees Under** Weight-Bearing Condition

Author(s): Martin Berger¹, Kerstin Mueller², Jang-Hwan Choi², Andre Aichert¹, Andreas Maier³, Rebecca Fahrig²

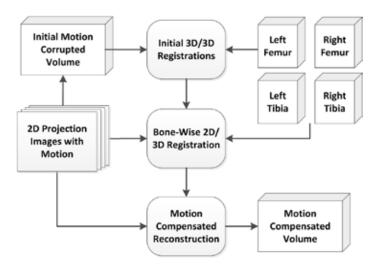

¹Pattern Recognition Lab, Department Of Computer Science, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen/GER-MANY, ²Radiological Sciences Lab, Stanford University, Stanford/ UNITED STATES OF AMERICA, 3Research Training Group 1773 "Heterogeneous Image Systems", Erlangen/GERMANY

Introduction: Over the last decade, increased effort has been made to acquire three dimensional images of knee joints under weightbearing condition. Cone-beam CT systems are popular because of their high flexibility with respect to patient position and scan trajectory. However, scans in a standing or squatting patient position are affected by involuntary patient motion during the acquisition, which results in streaking and blurring artifacts in the reconstructed volumes.

Previous work suggested the use of fiducial markers to estimate and

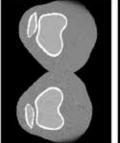

compensate for motion artifacts. However, marker placement on the skin might not accurately reflect the motion at the center of the joint.

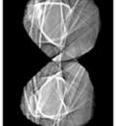

Method: We propose a marker-free, data-driven motion compensation method that is based on 2D/3D rigid registrations of segmented bones from a prior, motion-free scan.

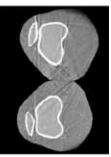

The Figure above gives an overview of the pipeline of our method. The segmentations are roughly aligned in 3D with respect to an initial motion corrupted reconstruction. Motion parameters are estimated by 2D/3D registration of each bone to each projection image. After combining the individual bone motions to a global deformation, we can generate a corrected reconstruction.

Results and Discussion: To verify our approach we used a simulated dataset from previous work [1]. Our numeric phantom is based on segmentations of real anatomical structures. Real motion of healthy volunteers was incorporated into the phantom using an optical tracking system.

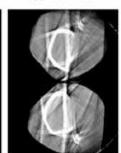

(b) With Motion

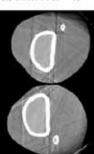

(c) Corrected ($\sigma = 1$)

(a) Reference

(d) Reference

(f) Corrected ($\sigma = 1$)

Our results show great improvement over images without correction. In particular the bones' outlines are accurately restored. This is important because most relevant structures in the knee joint are located close to the bones, e.g., the cartilage. Incorporating smooth-

(e) With Motion

ness constraints into the registration cost-function further improved the results.

[1] Choi, J.-H. et al.. (2013). Fiducial marker-based correction for involuntary motion in weight-bearing C-arm CT scanning of knees. Part I. Numerical model-based optimization. Medical Physics, 40(9), 091905

SP065.3 - Direct Scatter Estimation and Separation for Cone-beam CT Images Utilizing Monte Carlo Simulation Author(s): <u>Yu Wang</u>, Chaobin Chen, Ruifen Cao, Liqin Hu University of Science and Technology of China, Hefei/CHINA

Objective: The scatter radiation degrades the reconstructed Cone-beam CT(CBCT) images quality, which limits the application of CBCT images into the re-optimization of treatment plans for Adaptive Radiotherapy (ART). This paper estimated the scatter distribution in the CBCT projections directly utilizing the Monte Carlo simulation. In addition, the scatter separation was taken into account to determine the corresponding scatter fraction introduced by different parts of the system.

Methods and Materials: Using EGSnrc Monte Carlo program, the ELEKTA XVI CBCT system was modeled including the x-ray tube, water phantom with different thickness and flat-panel detector. The LATCH option was adopted to record the particles information, including the fluence, energy, weight, weather a secondary particle and which modules it had interacted with. The model was validated by percentage depth dose (PDD) and lateral profiles measurements. A program based on Visual C++ was developed to extract the primary particles and calculate the total scatter radiation at the scoring plane. At last, the corresponding scatter fractions introduced by different parts of the system were separated.

Results: The calculated PDD and lateral dose profiles were compared against the dose measurements under 1cm water. The dose difference of PDD was better than 1% within the depth of 10cm. More than 85% points of lateral dose profiles was within 2%. For CBCT system, the phantom produced the larger part of the scatter radiation, almost 50% with water thickness of more than 25cm.

Conclusions: The CBCT system has been fully modeled including x-ray tube, phantom and flat-panel detector and the model was validated by the PDD and lateral profiles measurements. The scatter fractions introduced by the phantom with thickness of more than 25cm should be corrected to improve the images quality. This study is expected to be applied to the scatter radiation correction for improving CBCT images quality and optimizing the CBCT modules design.

SP065.4 - Automatic Motion Estimation and Compensation Framework for Weight-bearing C-arm CT scans using Fiducial Markers

Author(s): <u>Kerstin Mueller</u>¹, Martin Berger², Jang-Hwan Choi¹, Andreas Maier², Rebecca Fahrig¹

¹Radiological Sciences Lab, Stanford University, Stanford/CA/UNIT-ED STATES OF AMERICA, ²Research Training Group 1773 "Heterogeneous Image Systems", Erlangen/GERMANY

Cone-beam CT systems are widely used because of their high flexibility with respect to patient position and scan trajectory. In the last years, C-arm CT systems have been used to acquire images in weight-bearing conditions in order to expose, e.g. the knee joint under realistic loads. Straight standing or squatting patient positions lead to involuntary patient motion during the acquisition. In this paper, a fully-automatic motion estimation and compensation framework to mitigate knee-joint motion during weight-bearing C-arm scans is presented. Our framework consists of three major steps: marker detection with outlier removal, motion estimation and correction, and marker removal. The marker detection is based on an initial estimate of the marker position extracted from the motionblurred filtered backprojection (FDK) reconstruction and on the fast radial symmetry transformed (FRST) 2-D projection images. The motion is estimated by the alignment of the forward projected 3-D initial marker positions with the actual detected 2-D marker positions. The motion is then corrected in the filtered backprojection step. Finally, the detected markers are removed in the 2-D projection images by simple interpolation. The framework was evaluated on three C-arm CT datasets from one volunteer in a straight standing, moderate squatted and deep squatted position. All 3-D reconstructions show a large improvement in image quality compared to the non-corrected 3-D reconstructions.

SP065.5 - Evaluation of two-pass view aliasing artifact suppression algorithm using clinical data

Author(s): Meng Wu¹, <u>Kerstin Mueller</u>¹, Michael P. Marks², Rebecca Fahrig¹

¹Department Of Radiology, Stanford University, Stanford/UNITED STATES OF AMERICA, ²Department Of Radiology And Neurosurgery, Stanford University, Stanford/UNITED STATES OF AMERICA

Purpose: In brain perfusion CT imaging, state-of-the-art C-arm CT systems can rotate up to 100 degrees / second, which permits CT imaging with high temporal resolution. However, the read-out rate of the flat panel detector often limits the number of projections acquired in the fast scan and causes view aliasing artifacts in the reconstruction. We propose to suppress aliasing artifacts in decomposed projections through feature preserving interpolation.

Methods: The high frequency structures that cause streak artifacts are hidden within the total line integral. Thus, the interpolation-based method for angular up-sampling often fails to correct for these high frequency structures. We propose an FBP-based algorithm using multi-resolution reconstruction to identify the structures in projection space that may cause the artifacts. The adaptive multi-resolution FDK reconstruction adaptively selects the bandwidth of the ramp filter in the FDK method to reconstruct regions of the image at maximal frequency without view aliasing artifacts. A feature preserving interpolation in projection space is used to increase the angular sampling rate. The restored high frequency structures are then added back to the view aliasing-free reconstruction. The proposed method's performance is assessed using real patient C-arm (Artis zee biplane system, Siemens AG, Germany) head scan data. Only 124 out of 248 projections are used for the reconstruction to mimic the sparse-view data in the fast scan. Our results are compared to those with and without linear interpolation method.

Results: As shown in Figure 1, the proposed method can effectively reduce the view aliasing streak artifacts. The structural similarity (SSIM) indices of the brain tissue region using the FDK, linear interpolation, and proposed methods comparing to the ground truth are 0.7428, 0.7686 and 0.8060, respectively. The proposed method also reduces the standard deviation of the brain tissue without contrast (which is assumed to be uniform) from 56.2 HU to 35.7 HU while the linear interpolation method has a standard deviation of 42.5 HU. The proposed method is compatible with a projection-based motion compensation technique to further improve the image quality.

Conclusion: Distinct from other blurring-based and iterative reconstruction methods, our method maximally preserves image spatial resolution with only two iterations. Future investigations will incorporate the technique for noise reduction and compare to sparse view iterative reconstruction.

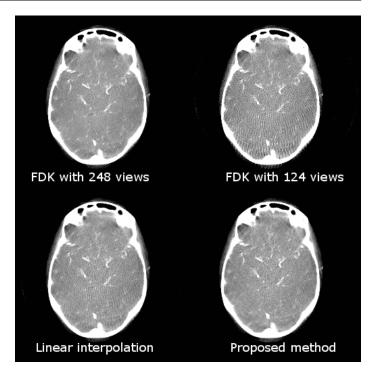

Figure 1, reconstruction results using FDK, linear interpolation and the proposed method. The display window is [-500 500] HU.

SP065.6 - A simple algorithm to remove metal artifacts in frame based radiosurgical treatments

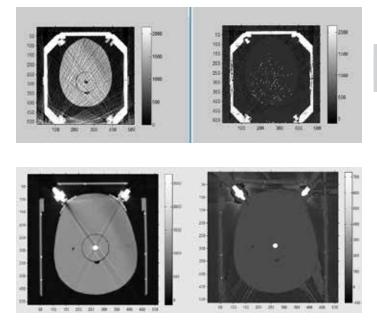

Author(s): Gopishankar Natanasabapathi Gamma Knife Unit, All India Institute of Medical Sciences, New Delhi/INDIA

Purpose: To show a simple method to remove metal artifacts generated during imaging for treatment planning purpose. Materials and

Methods: A human head shaped phantom made from acrylic material was fixed to stereotactic Leksell frame for artifact simulation purpose. Four metal screws aided in holding the metal frame to the phantom with carbon fixation posts. An ion chamber positioned in the middle portion of the phantom determines point dose measurement. In this study same ion chamber setup generated artifacts at the phantom center which required artifact removal. CT scans of the phantom were acquired using following scanning parameters: Tube voltage-110 kV, Slice thickness-1 mm and FOV-240 mm. Image slices with severe artifacts were selected for image processing using in-house developed matlab codes. Pixels in the phantom image affected by noise were isolated and digitally post processed by applying threshold value to the hounsfield units (HU).

Results: The images showed more than 95 % improvisation after implementing correction algorithm. Before image correction the HU present in the phantom image due to metal frame and pins was found to be more than 3000 HU. After applying correction algorithm, HU of ion chamber region, metal frame and pin region were restored.

Conclusion: The TPS system of Gamma Knife (GK) performs convolution algorithm based calculation on CT images with HU values range between -1000 to +1024. Any HU values beyond these values are automatically ignored by the TPS during calculation. It means that the TPS ignores the artifact affected region for calculation irrespective of where it is present. This is one of the major limitations of convolution algorithm based planning in GK. The artifact removal method shown in this study is a simple, effective technique which overcomes these limitations and is a valuable tool for GK.

SP066 - Human Movement

TRACK 03: BIOMECHANICS AND ARTIFICIAL ORGANS

SP066.1 - Fingertip touch adjust postural orientation during perturbed stance

Author(s): <u>Aizreena Azaman</u>, Shin-Ichiroh Yamamoto Department Of Bioscience And Engineeering, Shibaura Institute of Technology, Saitama City/JAPAN

Additional sensory information; especially from touch, was suggested to improve stability by reducing body sway. However, it is less known about the effect of touch on the body's joint movement during perturbed standing; which is commonly experienced by public transport users. In this study, subjects were asked to try to maintain their standing position with their fingertips on a rigid surface, while surface perturbation was applied at four different perturbation frequencies (0.2, 0.4, 0.6, and 0.6 Hz) and different vision input. Motion of joint (ankle, hip and head) and relative centre of mass (COM) were recorded and analysed. The results show that fingertip pressure was higher without vision. Furthermore, different fingertip moment directions were recorded between with vision and with no vision. This possibly indicates a preferred fingertip position that can provide better sensory information to replace sensory loss; especially vision. The range of motion of joints also decreased with fingertip touch - except for head motion. Furthermore, even though there were no significant differences observed between with touch and without touch, the relative COM displacement was less with touch. Thus, even with a very light touch, subjects were able to reduce body sway even in a perturbed stance. Further investigation is needed to determine the changes in centre of pressure (COP) and significant position of fingertip, which can enhance stability.

SP066.2 - Design and Evaluation of a Prosthetic Knee Joint based on Automatic Stance-Phase Lock (ASPL) Technology for Children with Transfemoral Amputations Author(s): <u>Calvin Ngan</u>, Jan Andrysek

Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto/ON/CANADA

Introduction: Lower extremity amputation strongly affects an individual's mobility and quality of life, as well as creating a socioeconomic burden for society. Studies have shown that amputations in children have a particularly significant impact on their physical and psychological developments. Therefore, it is important to provide child amputees with a well-functioning prosthetic knee joint to restore their mobility function and enable them to partake in physical activities with peers and family.

<u>Problem</u>: Many paediatric prosthetic knee joints in the market incorporate four- or six-bar linkage mechanisms that offer good stance phase control, but their added size and weight make them unsuitable for very small children. Furthermore, to accommodate these size constraints, many designs exclude swing phase control and extension assist mechanisms, negatively impacting user's gait characteristics such as energy expenditure and gait speed.Therefore, the objective of this project is to design and evaluate an original paediatric prosthetic knee that will provide good stance phase stability by incorporating the novel, patented Automatic Stance Phase Lock (ASPL) mechanisms developed in Holland Bloorview Kids Rehabilitation Hospital, and integrating frictional components and extension assist mechanism to offer better swing phase control for the user.

Method: We focus on three major areas: (1) knee design and proto-

type development, (2) structural testing, and (3) functional evaluation via a pilot study. We will use 3D Computer Aided Drawing (CAD) and Finite Element Analysis (FEA) software to develop and structurally optimize the prosthetic knee joint model. A prototype will then be constructed and a series of bench-top structural tests will be performed following the ISO 10328 to test for structural integrity. In the pilot study, a single subject with an unilateral transfemoral amputation will perform six-minute walk tests and gait assessment tests with his/her current prosthetic knee, as well as our prototype. Gait characteristics such as walking velocity, kinetics profiles including knee flexion angle and knee moment, and energy expenditure will be measured and analyzed in both trials. Differences in the key parameters listed above between the prototypes and the conventional knee will be used as an indicator for how functional the prototype is and indicate which design changes may improve areas of concern.

Results: In the current stage of the project, we designed and developed a 3D computer model of the paediatric prosthetic knee. In the model, our prototype is estimated to be 120mm tall and weighs about 355g, which is similar to current commercially available products. It also includes mechanical friction control and extension assist to facilitate the swing phase control for the user. Multiple iterations of FEA on the model were completed, and the results suggested that the design is capable of supporting the specified load listed in the ISO structural test. Therefore we will proceed to fabricating the prototype and performing the structural test imminently. The goal of this project is to prove the feasibility of implementing ASPL technology in a paediatric prosthetic knee, so ultimately it would be possible to provide well-functioning and affordable prostheses for child amputees around the globe.

SP066.3 - Frontal plane gait during cross-slope walking for able-bodied and transtibial amputees

Author(s): <u>Emily Sinitski</u>¹, Edward D. Lemaire¹, Nancy L. Dudek², Markus Besemann³

¹Crrd, The Ottawa Hospital Research Institute, Ottawa/CANA-DA, ²Faculty Of Medicine, University of Ottawa, Ottawa/CANA-DA, ³Canadian Forces Health Services Group, Ottawa/CANADA

Cross-slope surfaces are slopes in the frontal plane. Unlike level and inclined surfaces, cross-slope walking requires an asymmetrical gait pattern to keep the body vertical while adapting to different ground heights and angles. Although cross-slopes are a common real-world surface, cross-slope walking literature is predominately on the able-bodied population. For individuals with a lower limb amputation, lack of lower limb musculature may pose a greater challenge for maintaining balance and forward progression on cross-slopes. This research investigated compensatory adaptations in the frontal plane for able-bodied individuals and individuals with a transtibial amputation when walking on moderate cross-slopes.

Fourteen able-bodied (AB) and 14 unilateral transtibial amputees (TTA) participated in this study. Participants walked on a level and $\pm 5^{\circ}$ cross-slope treadmill at a fixed speed while full body kinematic data were captured within a CAREN-Extended virtual reality environment. Gait outcome measures included, speed, step width, and frontal plane joint angles (ankle, knee, hip, pelvis, and trunk) and sagittal plane joint angles (ankle and knee) at foot contact and during stance. Data were examined using a linear mixed model with a treadmill speed covariate. Post-hoc t-tests with a Holm-Bonferroni correction (p<0.05) were performed to examine differences between groups and walking conditions.

TTA participants walked slower than able-bodied (AB= 1.29 ± 0.06 m/s, TT= 1.11 ± 0.15 m/s; p<0.001). Step width (14.7 ±0.6 cm) was not significantly different between walking conditions and groups. Compared to level walking (LW), the limb at the top of the cross-slope (TS) had less ankle inversion at foot contact and ankle angle tran-

sitioned to eversion during stance (p<0.001). Conversely, the limb at the bottom of the slope (BS) required more ankle inversion than LW at foot contact and remained inverted during stance (p<0.001). Since the majority of TTA participants wore a prosthetic foot with a split toe, participants were able to achieve ankle in/eversion similar to the AB group for these moderate cross slopes (Table 1). However, during stance, TTA had more lateral trunk motion and smaller pelvis obliquity compared to AB. Prosthetic ankle and knee stance flexion was also smaller for TTA than AB. These findings demonstrated that TTA did not have sufficient prosthetic ankle dorsiflexion to shorten effective prosthetic limb length on the top-cross-slope. As a result, TTA increased lateral trunk motion to compensate for the ground height differences between limbs.

SP066.4 - Impact of gait modifications on hip joint loads during level walking

Author(s): <u>Masaru Higa</u>¹, Fusako Kawabata¹, Yoshihiro Kobayashi¹, Koji Fukuda²

¹Mechanical Engineering, University of Hyogo, Himeji/JAPAN, ²Human Science And Enviroment, University of Hyogo, Himeji/JAPAN

A lot of the literature suggests that walking mechanics have an intense impact on the progression of joint diseases such as osteoarthritis (OA). In knee OA, excessive medial tibiofemoral compartment loading is widely believed to contribute to the progression of medial OA. Although the feasibility of gait modifications for reducing knee joint loading has been studied widely, gait modifications have not been investigated to the same extent in people with hip OA. We hypothesized that high loading on the hip joint also contributes to the progression of hip OA. Hence, this study is aimed to show if hip joint forces during walking could be reduced by a slight gait modification. The hip loadings could be measured in vivo with an instrumented hip prosthesis. This method, however, is restricted to a few institutions and patients, and theoretical calculations are difficult. At the same time, the external hip adduction moment during walking is a useful measure for estimating internal hip joint loading. For this reason, we used the hip adduction moment as a quantitative target for gait retraining of hip OA patients. Six healthy adult subjects (mean (SD) age 22 (0.0) years, mean (SD) height 1.68 (0.04) m, mean (SD) weight 60.2 (7.9) kg) took part in this study. A series of normal walking trials at a self-selected speed (step length and cadence) and stride width were performed for each subject. Then the subjects had gait retraining during in which they were asked to alter their stride width by increasing abduction angles without changing any other kinematics. The amount of the modification was limited within a "normal looking" gait. The retraining was also aimed at retaining other motion parameters such as gait speed, step length, cadence, flexion angles and rotation angles of the hip as well as upper body movements. The subjects walked 10 trials for each gait pattern, and a total of 20

trials were performed. Experimental gait data (i.e., joint kinematics and ground reaction forces) and musculoskeletal computer models (OpenSim 2.1) were used to quantify hip joint moments. We also used an inverse dynamics approach to calculate the hip moments during a stance phase. Five of six subjects exhibited an average decreased adduction moment during modified trials (p<0.05). The changes in abduction angles did not have any effect on the shape of the hip adduction moment curve but changed its peak mean magnitude from 3.59 %BW*HT during normal walking to 1.81 %BW*HT during the modified walking at a representative subject. An increase in the peak external rotation of the hip, however, was also observed. This should be eliminated since external rotation could be harmful for patients with high femoral anteversion. In conclusion, we showed that a modified gait pattern can reduce the hip adduction moment. Given the results of this study, we believe that gait retraining may be an acceptable, noninvasive option for the treatment of patients with hip OA.

SP066.5 - The influence of the aquatic environment on the control of gait initiation

Author(s): <u>Andresa Marinho Buzelli</u>¹, Hossein Rouhani¹, Gustavo Fernandes², Kei Masani³, Milos Popovic⁴, Molly Verrier³ ¹Rehabilitation Engineering Laboratory, Toronto Rehabilitation Institute - University Health Network, Toronto/CANADA, ²Universidade Federal de Santa Catarina, Florianopolis/BRAZIL, ³Toronto Rehabilitation Institute - University Health Network, Toronto/CANADA, ⁴Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA

Background: Gait initiation is a common functional task defined as the transition from stationary standing to steady-state walking. It is vastly investigated in healthy subjects and in individuals with disability. The complex interaction between neuromuscular and biomechanical factors during gait initiation has been investigated mainly in two phases, anticipatory postural adjustments (APAs) and execution of the step. Despite the frequent use of therapy pools for walking training in early stages of locomotor recovery, the effects of immersion on the control of gait initiation have not been reported yet. The objective of the present study is to analyze the center of pressure (COP) trajectories, the vertical and horizontal forces and trunk acceleration (ACC) during APAs, as well as during execution of the first and second steps during gait initiation.

Method: Able-bodied young adults (3 female and 2 male) were requested to initiate gait from a waterproof force plate (AMTI OR6-WP-1000, Watertown) and to continue walking for 5 steps. Individuals performed 10 consecutive trials, on land and in water, on two consecutive days. Subjects initiated gait with the same foot position following a visual cue. Two inertial sensors (Physilog, BioAGM, Lausanne) were attached to L5/S1 vertebrae and to the shank of the initial stance limb. COP landmarks were used to identify APAs and execution of the first step. Shank ACC was used to mark the toe-off and heel strike of the second step. Lower trunk (LT) horizontal ACC (anteroposterior - AP and mediolateral - ML) during APAs and execution phases was computed. The parameters used for evaluation were: peak of anticipatory COP trajectory (APA_Peak); COP length during APAs; length and velocities of COP trajectories during execution of the first step; impulse forces in vertical and AP directions; root mean square (RMS) ACC of trunk during first and second steps. Wilcoxon Matched-Pair Signed-Rank test was used for comparisons between land and water conditions.

Results: Percentage of body mass offloading in water varied between 49% and 57%. COP movements during APA and execution of first step were significantly larger in water compared to land: APA_Peak in ML (5.1 ± 1.7 vs. 3.7 ± 1.5 cm); ML length of COP trajectory when body weight was transferred to the stance limb (22.8 ± 4.2 vs. 18.2 ± 3.5 cm); and ML length of COP during first swing (5.4 ± 1.8

vs. 2.8±1.1 cm). COP velocity in AP during the first swing was slower in water (16.7±4.2 vs. 26.7±4.9 cm/s). The vertical impulse of the stance limb was smaller in water compared to land (340.7±31.1 vs. 425.4±54.2 N.s). LT ACC were smaller in water compared to land with more accentuated change in AP RMS of LT ACC during first step (0.6±0.3 vs. 1.8±0.7 m/s²) and second step (0.7±0.2 vs. 1.6±0.3 m/s²).

Conclusion: Immersion in water increases mediolateral body displacement, and reduces trunk acceleration and vertical impulse force during gait initiation, suggesting potential implications for aquatic rehabilitation.

SP067 - Characterization of Detector Systems for Therapy Dosimetry: Part 2

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP067.1 - Reaction of three UV exposure to gafchromic EBT-2 and EBT-3

Author(s): <u>Toshizo Katsuda</u>¹, Rumi Gotanda², Tatsuhiro Gotanda³, Takuya Akagawa⁴, Nobuyoshi Tanki⁵, Tadao Kuwano⁶, Kouichi Yabunaka⁷

¹Department Of Human Relation, Tokai Gakuin University, Kakamigahara/JAPAN, ²Department Of Radiological Sciences, Ibaraki Prefectural University of Health Sciences, Ibaraki/JAPAN, ³Department Of Radiological Science, Faculty Of Health Sciences, Junshin Gakuen University, Fukuoka/JAPAN, ⁴Department Of Radiological Technology, Tokushima Red Cross Hospital, Tokushima/JAPAN, ⁵Center For Life Science Technologies, RIKEN, Kobe/ JAPAN, ⁶Graduate School Of Health Sciences, Okayama University, Okayama/JAPAN, ⁷Graduate School Of Medicine, Tokyo University, Bunkyou-ku/JAPAN

Gafchromic films (GAFs) are used for the X-ray dose measurement in the diagnostic examination. It is begun to use for the three-dimensional X-rays dose measurement using the high-resolution characteristic in computed tomography. However, it is necessary to solve a problem of unevenness of active layer of GAFs. It is suggested that the ultraviolet (UV) is substitute as an X-ray. However, wavelength of appropriate UV are unidentified. This study is to decide a wavelength of the UV.

Peak wavelength of 245 nm, 310 nm and 365 nm UV were irradiate to the EBT2 and EBT3. The UV rays were irradiated for 5, 15, 30 and 60 minutes, and irradiation was repeated afterwards until 360 minutes every 60 minutes. The images were split in RGB, and R images were used. ROI of the diameter 1/2 inch was set in the center of subtracted GAF images, and the graph of UV irradiation time and the mean pixel value were made.

There was a reaction in front and back of GAF EBT3 and back of EBT2 in UV-A and B. However, UV-C had few reactions with both aspects of GAF EBT2 and EBT3.

It should be used UV-A for a fact because a wavelength of UV-B may affect the human body.

SP067.2 - Characterizing FujiFilm CR Signal Storage Decay Rates

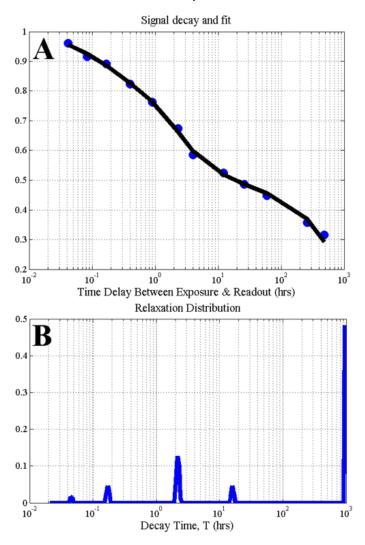

Author(s): <u>Thorarin A. Bjarnason</u>¹, C J. Yang² ¹Diagnostic Imaging Services, Interior Health, Kelowna/CANA-DA, ²Sindi Ahluwalia Hawkins Centre For The Southern Interior, British Columbia Cancer Agency, Kelowna/CANADA

Introduction

In this work we outline a method for characterizing x-ray signal retention on Fujifilm CR photostimulable phosphors (PSPs). In order to use CR plates as dosimeters and to ensure the accuracy of image quality and dose indicator metrics, the behavior of x-ray signal storage needs to be characterized. Based on electron-hole storage of PSPs, it is known that in addition to specific frequency light stimulation overcoming the band gap and releasing the stored signal, thermal processes can do likewise, but at slower rates [Rowlands].

Methods/Results

The same FujiFilm CR plate was exposed repeatedly to 700 (±20) uGy at 120kVp and readouts were spaced out between immediate and 20days, as shown as the blue dots in A. Raw pixel values were extracted from image data and converted to dose as per [Bjarnason1]. When exposures were performed on separate days, all data were normalized using image data scanned immediately on that day. CR plates were sandwiched between 4 mm lead to minimizing background radiation exposure during the measurement time delay. The resulting decay was fit (black line in A) using a sum of exponential decays as per [Bjarnason2], which makes no a priori assumptions as to the number of exponentials present. The resulting relaxation distribution was found (B) and the following decay components were identified: 0.014 @ 2.8min, 0.045 @ 10.3min, 0.126 @ 2.1hr, 0.046 @ 15.9hr, 0.48 @ 40days.

Discussion/Conclusions

In this work we characterized 20 days of CR signal retention. Signal fading of 25% is expected between 10min and 8hr, and then slower after [AAPM 93], but this behavior has not been fully characterized before. We found the signal decay to be multiexponential and can conclude that the first two decay components at 2.8 and 10.3min should minimally affect the CR dose indicator values because even though staff often quickly read the images while signal is being lost due to these decay times, their intensities only account for 5% of the total signal loss occurring after about 1hr. By characterizing the signal loss over longer times, we can use these data to calibrate CR plates for use as area dosimeters. Future work includes testing inter-

plate variability, assessment at different kVps, and assessment of different vendors using different PSP chemical compositions.

SP067.3 - Angular dependence of diode detectors and PinPoint ionization chamber in Gamma Knife dosimetry

Author(s): <u>Hrvoje Hršak</u>¹, Marija Majer², Zdravko Heinrich³ ¹Department Of Oncology, University Hospital Centre Zagreb, Zagreb/CROATIA, ²Laboratory For Radiation Chemistry And Dosimetry, Institute Ruđer Bošković, Zagreb/CROATIA, ³Department Of Neurosurgery, University Hospital Centre Zagreb, Zagreb/CROATIA

Dosimetry for Gamma-Knife radiosurgery beams requires detectors with high spatial resolution, minimal angular dependence of signal and linear dose response. Angular dependence for shielded (PTW60016 Diode P) and unshielded (PTW60017 Diode E) p-type silicon detectors and PTW31006 PinPoint ionization chamber was measured indirectly with 18, 14, 8 and 4 mm collimator helmet for the Leksell Gamma Knife Model C. Weighted angular dependence correction factors were calculated for each detector and collimator helmet. For Gamma-Knife beams angle range of 84°-54° Diode P detector shows considerable angular dependence of 9% and 8% for the 18 mm and 14, 8, 4 mm collimator, respectively. For Diode E detector this dependence is about 4% for all collimators. Compared to Diode E, Diode P shows stronger angular dependence which may be explained by the increase of electron backscattering from the metal shield of silicon active volume as the angle of incident photon beam decreases, i.e. more photons are entering silicon chip perpendicularly. PinPoint ionization chamber shows angular dependence of less than 3% for 18, 14 and 8 mm helmet and 10% for 4 mm collimator which is probably due to volumetric averaging effect in a small photon beam. Diodes P and E represent good choice for Gamma-Knife dosimetry, while PinPoint ionization chamber is not recommended for dosimetry with the 4 mm collimator helmets. When used for absolute and relative dosimetry of Gamma Knife beams, diodes and PinPoint ionization chamber response should be corrected for angular dependence.

SP067.4 - Determination of a correction factor to mitigate long term reader fluctuation of the Optically Stimulated Luminescence dosimetry system at the International Atomic Energy Agency

Author(s): Andrew Cole, Tomislav Bokulic, Paulina Grochowska, Joanna Izewska

Nuclear Sciences And Applications, International Atomic Energy Agency, Vienna/AUSTRIA

Introduction

The Dosimetry Laboratory at the International Atomic Energy Agency is commissioning an Optically Stimulated Luminescence (OSL) dosimetry system to provide radiotherapy dosimetry audits. The OSL readers' (Microstarii, Landauer) internal mechanism consists of a high powered light emitting diode (LED), optical components and a photo-multiplier tube (PMT). Inbuilt PMT response Quality Assurance checks along with standard measurements from control OSL dosimeters allow the daily performance of the readers to be monitored. Extensive measurements were conducted during a period of 6 weeks. In this time the PMT response showed a fluctuation of 1.7% and the control OSL dosimeters' results exhibited a fluctuation of 1.4%. A correction factor to mitigate this magnitude of reader fluctuation is necessary and was calculated with two separate methods.

Materials/Methods

In the first method, PMT response QA checks were periodically performed directly preceding measurements of a control batch of OSLDs. A linear correlation of the magnitude of control OSLD dose readout to the reader's PMT response was calculated. An inverse of the correlation was

calculated and applied as a reader's fluctuation correction factor.

The second method quantified the reader fluctuation in terms of the magnitude of deviation of OSL dosimeter readout values from postulated theoretical values, as demonstrated on an earlier model system [1]. These deviations were deemed attributable to reader fluctuations and the

magnitude was correlated to PMT response data to determine a correction factor. In an iterative approach, this method also allowed a more accurate theoretical model to be calculated.

Results

Reader fluctuation correction factors were determined by both methods and applied to daily control OSL readout data. The two methods of determination of reader fluctuation correction factors resulted in reduced long term fluctuation in control OSL readout values to 0.9% and 0.2%, respectively, over the 6 week period. Longer term investigation may allow this to be improved as more data is acquired.

Conclusion

To mitigate the influence of long term reader fluctuation on the determination of OSL dosimetry audit values, a reader correction factor has been determined from two methods. The application of this correction factor has achieved a substantial decrease in the magnitude of reader fluctuations over a period of 6 weeks and will be the basis of protocols to also reduce fluctuation on the short term.

SP067.5 - Reference and relative dosimetry of standard and small photon fields with new commercially available detectors Author(s): <u>Bryan R. Muir</u>, Malcolm R. Mcewen Measurement Science And Standards, National Research Council, Ottawa/CANADA

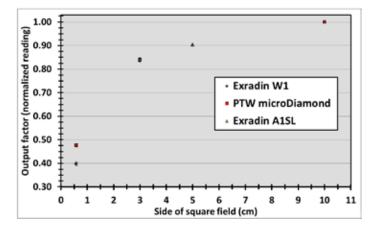

Two new detectors, the PTW microDiamond synthetic diamond detector and the Exradin W1 plastic scintillation detector (PSD), are now available that were designed for the dosimetry of small radiation fields. We investigate the performance of a single version of each detector when used for reference dosimetry of standard fields and relative dosimetry of small fields placing specific emphasis on the determination of associated uncertainties.

Measurements of detector response are made under reference conditions in 6, 10 and 25 MV photon beams from the Elekta *Pre-*

cise linear accelerator in 10x10 cm² field sizes relative to secondary standard reference chambers, calibrated in terms of absorbed dose directly against the National Research Council of Canada (NRC) primary standard water calorimeter. These absolute calibrations are used to derive detector energy dependence as well as short- (hours) and long- (months) term repeatability. Profiles are measured with these detectors in fields as small as 0.6x0.6 cm² shaped by the Ele-kta photon jaws and used for accurate detector positioning in small fields. Once detectors are properly positioned on the beam axis, small field output factors are measured, keeping the detector position constant and modifying the photon jaw settings. Measurements of output factors are repeated to investigate uncertainties caused by jaw positioning repeatability, detector positioning and the repeatability of the detector response and/or associated noise.

For both detectors, energy dependence is less than 1% comparing calibrations over the range 6-25 MV. The repeatability of the PTW microDiamond response for calibrations under reference conditions is within 0.3% after a period of almost two months. The repeatability of the response of the Exradin W1 PSD is generally also at this level, although sometimes unexpected differences of 1-2% were observed, which require further research for explanation. Profiles measured with the two detectors are in good agreement although the very small signal from the Exradin W1 is much noisier. The attached figure shows small field output factors (i.e., readings normalized to the value obtained in a 10x10 cm² field) with error bars representing type A uncertainties and variations in repeated measurements of output factors. For both detectors, standard uncertainties in reference dosimetry measurements are within 0.4% and are less than 2% for relative dosimetry measurements in very small fields.

Both detectors investigated in this work exhibit very impressive behavior for both reference and relative dosimetry measurements.

SP067.6 - Evaluation of detectors response for small field output factor measurement using multichannel film dosimetry Author(s): <u>Gunther Rucka</u>, Jean Claude Mouttet, Nathalie Asquier, Patrice Budillon

Centre De Radiothérapie St Louis, Croix-Rouge Française, Toulon/ FRANCE

Introduction

Most irradiation technics require dose computing from TPS. Calculation accuracy highly depends on the measurements used for beam modeling. Depending on their characteristics, available detectors may be best suited for specific field sizes when measuring Output Factors (OF). Recent studies compare several active with passive detectors and MonteCarlo calculation.

The goal of our study is to evaluate the response of several active

detectors exposed to 6 MV X-ray beams of different sizes, down to 1x1 cm², while considering EBT3 Gafchromic films as reference.

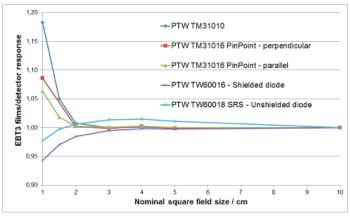

Materials and methods

Eight EBT3 films were irradiated with field sizes ranging from 1x1 to 10x10 cm². Measurements were done in a home-made RW3 solid water phantom. Multichannel film dosimetry was used for film opacity-to-dose conversion. All films (including background) were irradiated and scanned simultaneously using the efficient protocol described by D. Lewis et al.

Among available active detectors, two ionization chambers and two diodes were studied. Measurements were carried out in a water phantom.

OF measurements were also done by placing both chambers in the solid water phantom, in the same condition as the films. Results were compared to measurements done in water in order to verify scattering components correspondence for all field sizes. This allows active detectors irradiated in water to be compared to the films in RW3 slabs.

Results

OF obtained with the ionization chambers placed in the water and solid water phantom are identical for field sizes smaller than $15x15cm^2$.

As described in P. Andreo publication, active detector response for each field size was normalized with respect to the reference data. Figure 1 shows results. Concerning ionization chambers, the influence of partial volume averaging is similar to the published results. The three major effects mentioned for the diodes also appear in our results : the charged particles equilibrium between detector material and water, the over-response of the unshielded diode in broad beams and the partial volume averaging.

Conclusion

Our study confirms that partial volume averaging is not the only undesirable effect for OF measurement. Thus, the detector having the best spatial resolution is not systematically the best suited for small fields OF measurements.

SP068 - Development of New Methods in Therapy Dosimetry

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP068.1 - A Farmer ion chamber as reference to the calibration of CT chambers

Author(s): <u>Ricardo A. Terini</u>¹, Marco A. Guedes Pereira², Maria Carolina S. Campelo¹

¹Depto. De Física, Pontifícia Universidade Católica de São Paulo, São Paulo/BRAZIL, ²Laboratório De Ensaios Não-destrutivos, Instituto de Energia e Ambiente, Universidade de São Paulo, São Paulo/ BRAZIL

Introduction: Computed tomography (CT) is among the largest sources of collective radiation dose. The absorbed dose in CT exams can be ten times higher than in other common procedures of radiographic imaging. To assess the dose of radiation, the necessary meters should be properly calibrated in beams and setups like those measured in field [IAEA, Dosimetry in Radiology: An International Code of Practice, TRS 457, 2007.]. AAPM TG111 report [AAPM, Comprehensive methodology for the evaluation of radiation dose in X-ray computed tomography. AAPM report 111, 2010] has proposed improved metrics for CT dosimetry, using a small ion chamber, mainly considering helicoidal and multislice scanning. This study aimed to improve the methodology for CT ion chamber calibration in standard dosimetry laboratories, inspired on IAEA and AAPM recommendations.

Methodology: Initially, CT standard beams (RQT) have been characterized, using a calibrated PTW Farmer chamber as reference. Then, we have investigated some options to the setup to calibrate CT "pencil" type chambers in Air kerma-length product (PKL) by substitution: without any collimator (A) or with a reference collimator of aperture L=2cm (B.2) or L=5cm (B.5) in front of the chamber to be calibrated (Fig.1). Additionally, homogeneity of the pencil chamber response was checked shifting the chamber perpendicularly to the beam, behind the collimator, 1 by 1cm, and repeating the calibration with B.2 setup.

 Table 1 – Example of a 100mm CT pencil chamber calibration against the 0.6 cc Farmer reference chamber, for RQT beams, with and without collimation (methods B and A).

Standard	PPV HVL NPKL-user		NPKL-user	NPKL-user			
beam	(kV)	(mmAl)	(A)	(B.2) (L=2 cm)	(B.5) (L=5 cm)		
RQT 8	100.07	6.90	1.003(27)	0.983(20)	0.982(17)		
RQT 9	120.03	8.40	1.023(26)	1.001(19)	1.004(16)		
RQT 10	149.80	10.10	1.008(27)	0.987(19)	0.992(17)		

SP068.2 - Determination of the Uncertainty in the Cross-calibration of an Ionization Chamber Used in Radiation Therapy Author(s): <u>Pedro H.B. Cardoso</u>¹, Wellington F.P. Neves-Junior¹, Gustavo F. Tietz¹, Cecília M.K. Haddad¹, Ricardo A. Terini² ¹Radioterapia, Sociedade Beneficente de Senhoras Hospital Sírio-Libanês, São Paulo/BRAZIL, ²Depto. De Física, Pontifícia Universidade Católica de São Paulo, São Paulo/BRAZIL

It was performed an analysis of the uncertainties involved in a crosscalibration procedure of an ionization chamber used in Sírio-Libanês Hospital, according to the methodology proposed in IAEA-TEC-DOC-1585, based on ISO GUM. The overall uncertainty obtained was 2,55% (coverage factor k = 2), which meant an increase of 0,04% compared to the reference ionization chamber uncertainty reported by the dosimetry laboratory of LCI-GMR-IPEN/CNEN-SP. In such cases where the uncertainty of the calibration coefficient of the reference instrument is high, this uncertainty dominates the overall uncertainty of the cross-calibration. It was performed an analvsis of the uncertainties involved in a cross-calibration procedure of an ionization chamber used in Sírio-Libanês Hospital, according to the methodology proposed in IAEA-TECDOC-1585, based on ISO GUM. The overall uncertainty obtained was 2,55% (coverage factor k = 2), which meant an increase of 0,04% compared to the reference ionization chamber uncertainty reported by the dosimetry laboratory of LCI-GMR-IPEN/CNEN-SP.

Figure 1 – Setup detail for the CT chamber calibration.

Results and Discussion: Table 1 summarizes the obtained results for 100mm PTW chamber calibration coefficients. Results showed differences up to 2% in the obtained calibration coefficients, depending on the aperture of the used collimator. In the following additional tests, pencil chamber homogeneity just kept up to 3.5cm from the chamber center. Results were very similar for other CT chambers from Radcal Co..

SP068.3 - A study of uncertainties in the half-value layer measurement of a miniature kV x-ray source Author(s): Peter G. Watson. Marija Popovic. Jan Seuntiens

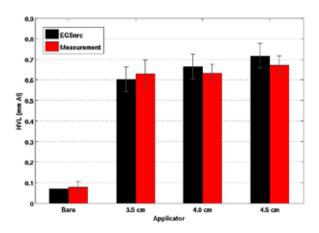

Author(s): Peter G. Watson, Marija Popovic, Jan Seuntjens Medical Physics Unit, McGill University, Montreal/CANADA

Air kerma standards for low energy x-ray devices used in electronic brachytherapy or intraoperative radiotherapy critically depend on accurate knowledge of the primary spectrum of the source. A model of a low energy x-ray source (INTRABEAM, Carl Zeiss) using the EGSnrc Monte Carlo (MC) code has been developed. To validate the model in-air, half-value layer (HVL) attenuation measurements were performed and compared with calculated values. For a meaningful comparison, the uncertainties in both the calculated and measured HVL must be well understood. In this work, we discuss the statistical and systematic uncertainties in HVL calculation.

The INTRABEAM source was modeled using the EGSnrc user code cavity. Photon fluence spectra emitted by the source were scored for the bare probe and spherical applicators of 3.5 cm, 4.0 cm, and 4.5 cm diameter. HVL was determined analytically from the simulated spectra by calculating the attenuation of air-kerma for a given thickness of aluminum and source-to-detector air gap. Beam collimation was provided by a lead cylinder surrounding the INTRABEAM source. Foils of high purity aluminum were placed at the exit of the collimator, and attenuation measurements were performed using a PTW 23342 parallel-plate chamber. The measured HVL was determined by curve fitting of the experimentally determined attenuation data. The statistical uncertainty in the MC-calculated HVL was determined by propagating the fluence spectrum uncertainty across the calculation of air-kerma ratio, taking into account photon cross-section uncertainty. The sources of MC systematic uncertainty considered were: the variation in polyetherimide (applicator material) density, collimator positioning error, and source-to-detector positioning error. In the experimental HVL measurement, the uncertainty was estimated by the tolerance

of aluminum attenuator thicknesses and the 95% confidence interval of the fitted attenuation curve. The accuracy of the HVL determination is a critical step in the reference dose calibration of

the INTRABEAM source. Our results indicate that the presence of the lead collimator, due to the emission of fluorescent x-rays, had a non-negligible effect on HVL measurement for the spherical applicators. In the MC calculation of spherical applicator HVLs, the collimator positioning error was found to be one of the dominant contributions to uncertainty (Δ HVL = 0.03 mm Al). For the simulated bare probe HVL, statistical errors and source-to-detector positioning contributed equally to the overall uncertainty. Upon comprehensive analysis of sources of experimental errors, we conclude that the simulated HVLs were in good agreement with measurement for the bare probe and spherical applicators.

SP068.4 - Low Energy Therapeutic X-Ray Calibration Methods Author(s): <u>Mehran M. Zaini</u>, Adam R. Schoen, Lida M. Arvan, Edward I. Marshall, Gene E. Robertson, Caleb G. Beck, Anton L. Eagle, Lawrence E. Sweeney

Northwest Medical Physics Center, Lynnwood/UNITED STATES OF AMERICA

The application of low energy X-rays has recently increased in the dermatology workspace, with the generating tube potential of these radiation beams spanning from 10 to 70kV. Absolute calibration of these low energy radiation units from three different manufacturers has been conducted. Various low-energy calibration protocols were considered for calibrating the low energy beams of the X-ray tubes from three different manufacturers. These protocols included the American Association of Physicists in Medicine (AAPM) Task Group 61 Report (for 40-300 kV beams), the UK Code of Practice from the Institution of Physics and Engineering in Medicine and Biology (IPEMB) for very low-energy X-rays (8-50 kV), International Atomic Energy Agency (IAEA) Technical Reports Series No. 398 (for X-ray up to 100 kV), and Report 10 of the Netherlands Commission on Radiation Dosimetry for low energy X-ray (50-100 kV). Review and comparison of the methodology of these protocols, pertaining to the energy range of Grenz-rays to superficial X-rays, is conducted.

In general, standard calibration laboratories provide an in-air calibration factor, Nk (air-kerma in Gy), and/or an in-water calibration factor, ND,w,Qo (absorbed dose to water in Gy). These factors can in turn be used in air or in a phantom in a clinical setting. The aforementioned protocols allow one or more of such calibration conditions. Because of the wider availability of Nk calibration factors from the US-based standard calibration laboratories and ease of using an in-air calibration technique for low-energy X-ray beams in a clinical setting, the AAPM-TG61 protocol and the data extracted from the British Journal of Radiology Supplement No. 25 were found to be the most practical for the calibration of low energy X-ray units for dermatological applications.

The issues with calibrating such low energies radiation units include having the appropriate equipment, creating a precise physical setup for measurements, and the low SNR when performing HVL measurements. The HVL setup needs to be stable and precise, due to the sensitive nature of these measurements. An air gap between the chamber and the source at these low energy units can change the results significantly. For example, a one millimeter air gap between a specially designed parallel-plate chamber and one of these lowenergy X-ray producing units can cause an error in the order of 3%.

SP068.5 - Energy response of a thimble-type ionization chamber for Ir-192 and Co-60 radiation beams Author(s): <u>Cecilia Kessler</u>, David Burns BIPM, Sèvres/FRANCE

A new international comparison for primary determinations of reference air-kerma rate using Ir-192 brachytherapy sources has been established by the Bureau International des Poids et Mesures (BIPM) and registered in the BIPM Key Comparison Data Base (KCDB) as an ongoing key comparison under the reference BIPM. RI(I)-K7.

The participants in this key comparison, the National Metrology Institutes NMIs, calibrate a thimble-type ionization chamber, model NE 2571, under reference conditions following the corresponding protocol. The comparison result, and thus the degree of equivalence between the NMI and the BIPM, is based on the ratio of the NMI calibration coefficient to that of the BIPM, the latter chosen as the Key Comparison Reference Value (KCRV).

As the BIPM has no primary facility for Ir-192 brachytherapy sources, the reference value is evaluated from the calibration coefficient

of the ionization chamber determined in the BIPM reference Co-60 beam, with a correction factor *k*en applied to account for the energy dependence of this type of chamber.

This correction factor is calculated using the Monte Carlo code Penelope [1]. The simulation of the chamber (dimensions, shape and materials) was made using the geometry code Pengeom, based on the manufacturer data sheet for the chamber. Using this code, a typical Ir-192 source used for therapy with its encapsulation was simulated.

In the first step the user code simulates the energy spectrum of the Ir-192 source and creates a phase-space file at 5 cm from the source reference point, recording the energy, spatial coordinates and direction of each particle. This file is used in the second step as an input to calculate the calibration coefficient of the ionization chamber at 1 m from the source.

Similarly, the calibration coefficient of the ionization chamber is evaluated for the Co-60 beam, using as input the existing phase-space file corresponding to the BIPM reference beam.

The correction factor *k*en for the NE 2571 ionization chamber is determined as the ratio of the calibration coefficient evaluated for Ir-192 to that for Co-60. Supporting calculations are made to estimate the uncertainty of *k*en. The results are compared with published work.

[1] Salvat, F., Fernandez-Varea, J.M., Sempau, J., Penelope – A Code System for Monte Carlo Simulation of Electron and Photon Transport, OECD 2009 NEA No. 6416 (ISBN 978-92-64-99066-1).

SP068.6 - Kilo-voltage X-Ray tube dosimetry Correction factors for in-water measurement in TG-61

Author(s): <u>Nima Sherafati</u>¹, David W.O. Rogers² ¹Physics, Carleton Laboratory for Radiotherapy Physics, Carleton University, Ottawa/ON/CANADA, ²Physics, Carleton Laboratory for Radiotherapy Physics, Carleton University, Ottawa/CANADA

For x-ray tube potentials > 100 kV, the AAPM TG-61 protocol for 40-300 kV x-ray beam dosimetry in radiotherapy recommends an in-water measurement which is based on ionization chambers calibrated in air in terms of air kerma. We studied the variation of the overall correction factor (PQch) and its components (known as corrections for the change in the chamber response due to the change in the spectrum distribution in phantom compared to that used for the calibration in air (kQ), displacement of water by the ionization chamber (Pdis) and displacement of water by the stem (Pstem)) as well as the correction for a waterproofing sleeve (Psheath) with depth and field size for 6 different beam qualities in the orthovoltage x-ray range (100 kV < tube potential < 300 kV). Based on TG-61, the absorbed dose to water at the reference depth (2 cm) is given by a Dw,z = Mair Nk PQch Psheath [($\mu en/\rho$)^{water}air]water , where PQch = kQ Pdis Pstem, M is the fully corrected chamber reading, Nk is the air kerma calibration coefficient for a beam-s quality, and $[(\mu en/\rho)]$ waterair] water is the ratio for water-to-air of the mean mass energyabsorption coefficient, averaged over the photon spectrum at the reference point in water in the absence of the chamber. In contrast with the EGS4 based values used in TG-61, we used the EGSnrc Monte Carlo system, which has a systematic uncertainty of ±0.1 percent while the values of TG-61 had been calculated using EGS4 which had ±1 percent systematic uncertainty for ionization chamber calculations. In addition we used the exact geometries of ionization chambers (e.g, NE2571) and better statistics (up to 1011 histories for each simulation giving statistical uncertainties of less than ± 0.1 percent) which made an improvement in the correction factorys precision. The results show a maximum 1.5 percent variation of PQch with depth (2 cm to 8 cm) and field size (20 cm²\$ to 100 cm²) for the NE2571 ionization chamber while the Psheath correction

factor is insignificant. The new values agree well with TG-61 values which demonstrates that the systematic uncertainties in EGS4 cancelled out since the factors are all ratios. Due primarily to its high-z electrode, the variation of PQch with depth and field size for the Exradin A16 ionization chamber is up to 10 percent and the variation with beam quality is up to 40 percent. This suggests ionization chambers with high-z electrodes should not be used for x-ray dosimetry. Depth and field size dependance of the PQch for the Exradin W1 scientilator detector are also being studied.

TRACK 06: NEW TECHNOLOGIES IN CANCER RESEARCH AND TREATMENT

SP069.1 - Synergistic Action of Ionizing Radiation with Platinum-based Chemotherapeutic Drugs: Soft X-rays and Low-Energy Electrons

Author(s): <u>Elahe Alizadeh</u>¹, Mohammad Rezaee², Darel Hunting³, Leon Sanche³

¹Department Of Chemistry And Biochemistry, University of Guelph, Guelph/CANADA, ²Princess Margaret Cancer Centre, Department Of Radiation Oncology, University of Toronto, Toronto/CANA-DA, ³Département De Médecine Nucléaire Et Radiobiologie, Faculté De Médecine Et Des Sciences De La Santé, Université de Sherbrooke, Sherbrooke/QC/CANADA

The biological impact of ionizing radiation results predominantly from the induction of a variety of lesions in cellular DNA via energy deposition into the DNA itself (direct effect) and its surrounding molecular environment (indirect effect) [1]. The most numerous of intermediate species arising from the direct effect of radiation are non-thermal secondary electrons [2], most of which having energies below 30 eV (i.e., low-energy electrons, LEEs). In the present study, we report results to evaluate the direct effect of ionizing radiation on the formation of both single and cluster lesions in a supercoiled plasmid DNA covalently modified by the platinum anticancer drugs (Pt-drugs) cisplatin, carboplatin and oxaliplatin. Since these Ptdrugs sensitize malignant cells to ionizing radiation, they are currently used in concomittant chemoradiotherapy for cancer treatment; however, the specific mechanisms of the interaction between these Pt-drugs bound to DNA and radiation still remain to be determined [3,4].

Freeze-dried nanoscale films (~10 nm) of either pure DNA or a Ptdrug covalently bound to DNA were prepared onto two different types of substrates, i.e., tantalum and glass surfaces. Samples were exposed to 1.5 keV X-rays, in the presence of dry nitrogen gas and no humidity [5]. The yields of single- and double-strand breaks (SSBs and DSBs) and interduplex cross links (CL) induced in both types of films by X-rays and the spectrum of photo-electrons emitted from tantalum were determined from the initial linear slopes of respective exposure-response curves. In addition, the ratios of the yields from the two different films were determined and referred as an enhancement factor (EF) to represent radiosensitization by the Pt-drugs.

Results presented in Table 1 clearly show that Pt-drugs substantially enhance the formation of DSB and CL in DNA irradiated by X-rays and LEEs, but have virtually no effect on SSB formation. Furthermore, the *EF*s for DSB and CL are larger for LEEs than X-rays in the presence of Pt-drugs. Since LEEs constitute a major portion of the secondary species generated by high-energy radiation, our finding suggests that in the presence of Pt-adducts, LEEs are the main secondary species responsible for the increase of DSB and CL in the irradiated platinated DNA via the direct effect. According to the linearity of the exposure-response curves, these damages result from a single-event process. Despite similarity between Pt-drugs in the enhancement of the DNA lesions, carboplatin and then oxaliplatin have higher efficiency than cisplatin in the radiosensitization of DNA. Table 1. Yields of DNA damage (× 10⁴ damage/Gy/bp) for soft X-rays and LEEs irradiation of DNA with and without modification by platinum anticancer drugs.

Irradiation	DNA Damage	Pure DNA	Cisplatin-DNA	Carboplatin-DNA	Oxaliplatin DNA
	SSB	199.0±25.3	204.0±26.8	237.2±29.7	215.3±37.3

SP069.2 - Cherenkov emission dosimetry for electron beam radiotherapy: a Monte Carlo feasibility study of absolute dose prediction

Author(s): Yana Zlateva1, Issam El Naqa2

¹Medical Physics Unit, McGill University, Montreal/CANADA, ²Medical Physics Unit, McGill University, Montreal/QC/CANADA

Current electron beam dosimeters face two major challenges. They are not water/tissue equivalent, and therefore require conversion to dose to water/tissue. Moreover, they must be placed in the radiation beam, which results in beam perturbation and dose averaging. These challenges limit their spatial resolution for intensitymodulated delivery or in vivo dosimetry. Yet, Cherenkov radiation by high-energy charged particles is emitted in water and in tissue, can be detected outside the beam, and is inherent to all high-energy radiotherapy beams. Despite these advantages, Cherenkov emission has yet to be implemented for clinical dosimetry. The work presented here investigates via first-principles derivation and Monte Carlo simulation the feasibility of absolute Cherenkov dosimetry for electron beam radiotherapy. A quantitative model for predicting absolute dose from Cherenkov intensity in a phantom was derived from first principles for high-energy charged particles of known incident energy with the assumption that all collisional energy loss is absorbed and all radiative energy loss escapes. The model was validated via simulation of 260 keV - 18 MeV electrons incident on water. Monte Carlo simulations were carried out in Geant4. The absolute Cherenkov dosimetry model presented here was able to predict absolute dose from Cherenkov intensity to within a clinically viable uncertainty of less than 3%.

SP069.3 - Detection of melanoma through image recognition and artificial neural networks

Author(s): <u>Cristofer I. Marín</u>¹, Germán H. Alférez¹, Jency Córdova², Verenice González²

¹Global Software Lab, Universidad de Montemorelos, Montemorelos Nuevo León/MEXICO, ²Departamento De Apoyo A La Investigación De Ciencias En Salud, Universidad de Montemorelos, Montemorelos,Nuevo León/MEXICO

The incidence of malignant melanoma has significantly increased in the last four decades. Dermatologists are rarely present in rural or remote areas to perform an early detection of malignant melanoma. Our contribution is a low cost software that automatically and objectively differentiates between a melanoma lesion and a benign nevus in a simple, noninvasive manner. Our approach is based on the "ABCDE" classification of lesions, image processing, and artificial neural networks. The software was developed using images of previously diagnosed malignant melanomas and non-malignant suspicious moles, obtaining a sensibility of 76.56% and a specificity of 87.58%.

SP069.4 - Clinical Implementation of an Intraoperative Radiotherapy Program

Author(s): Muthana Al-Ghazi¹, Varun Sehgal¹, Dante Roa¹, Suhong Yu¹, Qichi He¹, Jeffrey Kuo¹, Erin Lin², Alice Police² ¹Radiation Oncology, University of California, Irvine, Orange/UNITED STATES OF AMERICA, ²Surgery, University of California, Irvine, Orange/CA/UNITED STATES OF AMERICA

Purpose: To outline the process for setting up an intraoperative radiotherapy (IORT) program and its clinical implementation, including dosimetric data, radiation safety aspects and clinical procedures.

Background: IORT has been used in the past for clinical indications such as in the management of localized abdominal tumors. Where applicable, it is efficient and convenient as the radiation treatment is completed at the time of surgery. The modality was almost abandoned except for select large institutions due to the high cost incurred in installing dedicated linear accelerators and orthovoltage units and the requirement for extensive shielding of specially designed operating rooms.

Advances in design of miniaturized x-ray tubes operating at 50 KVp initiated resurgence of interest in this modality. The Zeiss system (Zeiss Inc., Jena, Germany) consists of a portable 50 KVp x-ray tube that is mounted on a robotic arm with 6 degrees of freedom. A sterile applicator is mounted on it and the latter is placed at the tumor bed for dose delivery. Accuracy of applicator position is verified using ultrasound image guidance. A 1 mm sterile tungsten (W) shield is wrapped around the applicator. The shield reduces the radiation levels in the room be a factor of 10³. The procedure can be safely performed in a regular operating room.

Methods: The dosimetric characteristics of the system are confirmed using a parallel plate chamber connected to an electrometer. Measurements are made in a specially designed water phantom. Clinical dose calculations are carried out using these parameters. A check list is developed for quality assurance and safety measures consistent with institutional requirements and manufacturer's recommendations for safe and accurate delivery of radiation treatment following accepted treatment protocols.

Importantly, a radiation survey is carried out around the operating room where IORT procedures take place to ascertain safe levels of exposure to personnel who are not classified as radiation workers. This is easily achieved using the W shield alluded to above.

Results: Dose delivery to patients undergoing IORT using the procedure outlined above can be carried out safely in a regular operating room. The exposure levels in adjacent areas are comparable to background. The procedure is cost effective due to the portability of the system and the low energy of the x-ray emission. Clinically, the system has been used to treat localized early breast tumors and abdominal sites. Detailed dosimetric, radiation safety and clinical data pertaining to the program will be presented.

Conclusion: An IORT program has been implemented at the University of California, Irvine Medical Center for the treatment of breast and abdominal tumors. The approach is convenient to patients as it delivers the radiation treatment at the time of surgery. This is espe-

cially important for patients who have to travel significant distances to radiotherapy centers.

SP069.5 - Performance of a Back-etched Silicon Detector Array Designed to Monitor Each Synchrotron Generated X-ray Beam in Microbeam Radiation Therapy

Author(s): Michael L.F. Lerch

Centre For Medical Radiation Physics, University of Wollongong, Wollongong/AUSTRALIA

Introduction: In Microbeam Radiation Therapy (MRT) the dose rate is ~20,000 Gy/sec. For patient safety, the system must provide real-time feedback to instigate a beam dump if the dose rate moves out of the desirable range.

Purpose: The 3DMiMiC project aims to develop multistrip silicon sensors with parallel readout for use in real-time treatment monitoring of each X-ray microbeam.

Methods and Materials: Silicon array sensors were designed at the Centre for Medical Radiation Physics, University of Wollongong, Australia, simulated using ISE TCAD at the Department of Physics and Technology, University of Bergen, Norway, and fabricated at the SINTEF MiNaLab facility, Norway. Detector tests were carried out at the X-ray Microscopy Beamline, ESRF, France and system testing was done under full MRT conditions at the biomedical beamline, ESRF.

Results:

Figure 1 shows the design (left) optical image (middle) and effective sensitive volume (red/yellow region in right image) when operated at -30 V bias. The central strips are surrounded by a common guard ring structure (clearly visible in the optical and combined fluores-cence-charge collection image). The effective volume is extremely well confined to minimise any cross talk between sensor strips (pitch 100 microns).

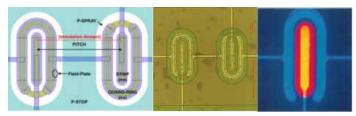

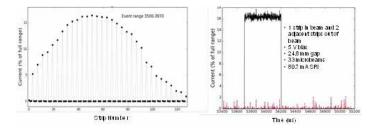

Figure 1.

Figure 2 (left) shows the response of 128 strips when exposed to 32 X-ray microbeams of pitch 102 microns. For every exposed strip, 3 strips are unexposed. The observed roll off in intensity is due to detector-microbeam pitch mismatch. Figure 2 (right) shows the temporal response of a strip in (black) and out (red) of the beam. The signal to noise ratio is excellent (integration time for each point is 14 microseconds).

Conclusion:

A new back-etched silicon detector array has been developed and characterised. Initial testing of the array integrated into a real-time microbeam monitoring system, shows very promising results.

SP069.6 - Dynamic Mechanical Characterization of a Poly(vinyl alcohol) Breast Palpation Phantom

Author(s): Gabriel A. Rodriguez

Carnegie Mellon University, Pittsburgh/UNITED STATES OF AMER-ICA

Breast phantoms model quantitative and qualitative parameters of bulk tissues to provide a foundation for the calibration and design iteration of different imaging methodologies, particularly for breast cancer screening. Existing breast phantoms can accurately emulate specific properties of tissues for conventional imaging modalities such as MRIs or ultrasound, but are inadequate for the large deformations associated with mechanical palpation. Polyvinyl alcohol (PVA) cryogels provide a unique solution because of stability at large deformations, although current cryogel processing methods suffer from inhomogeneity for large structures such as tissue phantoms. Established cryogel fabrication protocols tune the specific mechanical properties of PVA cryogels by varying concentration of PVA in the solution and the number of freeze-thaw cycles that the cryogel undergoes. Chaotropic salt inclusions in PVA promote amorphous behavior in the cryogels, resulting in an increase in the homogeneity to the bulk mechanical properties of the phantom. This study evaluates the effects of varied salt concentrations on the dynamic mechanical properties of cryogels to improve the stability of mechanical breast tissue phantoms. The elastic and viscoelastic properties of conventional cryogels are compared to cryogels with salt inclusions using dynamic loading. To characterize the tissue analogs for clinical utility, the experimental protocol uses simple compression, large deformations, and strain rates equivalent to those used in clinical palpation. Results are compared with literature values for fatty and fibroglandular breast tissues; the major constituents of the breast. By improving the homogeneity of PVA cryogels with the use of salt inclusions, this work builds on existing tissue analog technologies. The storage and loss moduli from the large deformation, dynamic mechanical analysis of the adapted cryogel technique described here are compared with literature values for both fatty and fibroglandular breast tissues. Further development of mechanically-accurate and multi-modal breast phantoms will provide low-cost and safe alternatives to clinical trials for the validation of developing breast imaging technologies.

SP070 - Molecular Imaging PET/SPECT: Part 2

TRACK 01: IMAGING

SP070.1 - Optimal Pixelated Crystal for a Molecular SPECT Scanner: A GATE Monte Carlo Study

Author(s): Mohammad Reza Ay¹, Hojat Mahani², Gholamreza Raisali², Alireza Kamali Asl³

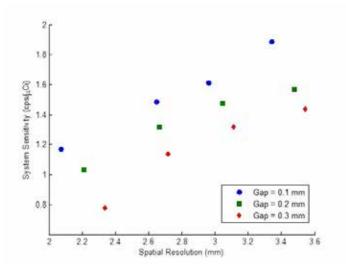

¹Department Of Medical Physics & Biomedical Engineering, Tehran University of Medical Sciences, Tehran/IRAN, ²Radiation Application Research School, Nuclear Science and Technology Research Institute, Tehran/IRAN, ³Shahid Beheshti University, Medical Radiation Faculty, Tehran/IRAN

Objective: It is well-known that resolution-sensitivity tradeoff is the most challenging design consideration in small-animal SPECT. In the present work, we addressed such a compromise from pixelated crystal point-of-view for HiReSPECT system, a high-resolution SPECT camera, developed at Research Center for Molecular and Cellular Imaging.

Materials and Methods: For this purpose, we performed GATE Monte Carlo package to simulate the HiReSPECT scanner and to assess the impact of various crystal configurations on tomographic resolution and system sensitivity, using a ^{99m}Tc point-like source and a flood-filed phantom, respectively. The crystals differed in material, pixel-size, and Epoxy pixel-gap. Point-spread-functions (PSFs) were iteratively reconstructed using a dedicated 3D OSEM algorithm. Equal importance factors were assigned to the two conflicting objectives, and pixelated crystal was then optimized using the weighted-sum method. In addition, the Monte Carlo simulations were validated by means of comparisons with the experimental data.

Results: A good agreement (4.3% difference) between simulated and measured tomographic spatial resolutions at 30 mm radius-ofrotation is observed. Likewise, there is a maximum 9.1% difference, at 120 mm source-to-collimator distance, between our Monte Carlo calculations and the experiments for system sensitivity, all for a 1 \times 1 mm² pixel-size and 0.2 mm Epoxy gap Csl(Na) configuration. The results show that Csl(Na) exhibits the highest sensitivity compared to Nal(TI) and YAP(Ce) as well as a slightly higher spatial resolution, and therefore is the crystal of choice. A sensitivity of 1.61 cps/µCi is achieved for a $1.5 \times 1.5 \text{ mm}^2$ pixel-size and 0.1 mm Epoxy gap Csl(Na)-based camera. Changing pixel-size from 0.5×0.5 mm² to 2 × 2 mm² leads to a 35.7% loss in tomographic resolution while sensitivity improves by a factor of 1.52. Based on our Monte Carlo optimization, the 1.5 × 1.5 mm² pixel-size and 0.1 mm Epoxy gap Csl(Na) is the optimal configuration by providing the best tradeoff between spatial resolution and system sensitivity. The crystal-optimized HiReSPECT system also offers a tomographic resolution of 2.98 mm, in terms of FWHM.

Conclusion: Our findings highlighted that performance of a preclinical SPECT imager can be highly affected by the pixelated scintillator configuration, and thereby searching for an optimum configuration is mandatory in order to obtain a more qualified SPECT image.

SP070.2 - Spinning Knife-Edge Slit-Hole: a Novel Collimation for High-Sensitivity Molecular SPECT

Author(s): Hojjat Mahani¹, Gholamreza Raisali², Alireza Kamali Asl³, Mohammad Reza Ay¹

¹Research Center For Molecular And Cellular Imaging, Tehran University of Medical Sciences, Tehran/IRAN, ²Radiation Application Research School, Nuclear Science and Technology Research Institute, Tehran/IRAN, ³Radiation Medicine Engineering Department, Shahid Beheshti University, Tehran/IRAN

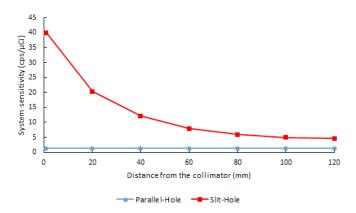

Objective: While conventional collimation systems are widely used in molecular SPECT, such collimators usually limit performance of the camera due to owing a low geometric efficiency. In the present study, we addressed this challenge by proposing a novel collimator offering a high-sensitivity HiReSPECT system, a high-resolution SPECT camera, developed at Research Center for Molecular and Cellular Imaging.

Materials and Methods: For this purpose, we performed GATE Monte Carlo toolkit to design and simulate the collimator for the HiReSPECT scanner. The prototype consists a centered single knife-edge silt-hole of 1.2 mm width extended across long-axis of camera's head, with 30 mm collimator's depth. Planar spatial resolution and in-air sensitivity were assessed at various distances using a ^{99m}Tc point-like source and a flood-field phantom, respectively. At each regular SPECT angle, 16 spin-projections over 180° were then acquired each with 3.75 s time-per-spin. The planar images were iteratively reconstructed using a dedicated MLEM-based algorithm. To speed up our Monte Carlo simulations, a variance reduction technique by ignoring transport of the secondary electrons was also implemented.

Results: Slit-hole geometry give rise to an increased background-subtracted sensitivity of 12.4 times that observed with parallel-hole collimator at 30 mm source-to-collimator distance. System sensitivity with slit-hole collimator falls off as filed-of-view of the camera increases and reaches to a value of 4.6 cps/ μ Ci at 120 mm distance while sensitivity of the system with parallel-hole collimation remains approximately constant over all distances from the collimator and has a value of 1.32 cps/ μ Ci. Slit-hole collimated HiReSPECT scanner provides a magnification factor of 3 and offers a planar spatial resolution, in terms of FWHM, of 3.32 mm compared to 2.91 mm obtained by a parallel-hole collimation, at 10 mm source-to-collimator distance. Implementation of the variance reduction technique in our Monte Carlo simulations results in a 1.51 acceleration factor while imposes no significant effect on spin-projection data.

Conclusion: Our preliminary findings highlighted that the spinning

slit-hole is a promising alternative for parallel-hole collimators with acceptable planar spatial resolution, and therefore the proposed collimator provides a better resolution-sensitivity tradeoff.

Comparison of system sensitivity for the parallel-hole and the slithole collimated HiReSPECT scanner. For the slit-hole collimation, the sensitivity is background-subtracted.

SP070.3 - Simultaneous estimation of the radioactivity distribution and electron density map from scattered coincidences in PET: A project overview

Author(s): <u>Hongyan Sun</u>¹, Mohammadreza Teimoorisichani¹, Bryan Mcintosh¹, Geng Zhang¹, Harry Ingleby², Andrew Goertzen¹, Stephen Pistorius¹

¹Physics And Astronomy, University of Manitoba, Winnipeg/CANA-DA, ²Radiology, University of Manitoba, Winnipeg/MB/CANADA

Quantitatively accurate PET images require correction of measured data for scattered coincidences. Additionally, an anatomical image is required to provide accurate attenuation correction and to facilitate the interpretation of the activity distribution. By taking advantage of accurately measured photon energies and the kinematics of Compton scattering, a 2D surface described by two circular arcs (TCA), which define the possible scattering loci and encompasses the annihilation position, can be identified. In 3D the annihilation is confined to the volume encompassed by the surface obtained by rotating the 2D arc around its axis. Using this premise, we have developed novel iterative reconstruction algorithms which use the scattered coincidences to 1) improve the activity distribution and 2) obtain an electron density map. The results have demonstrated the feasibility and benefits of incorporating scattered coincidences into the image reconstruction process. Incorporating scattered coincidences directly into the radiotracer reconstruction algorithm eliminates the need for scatter correction, and could improve both image quality and system sensitivity. The electron density map reconstructed from scattered coincidences can be directly applied to attenuation correction of the activity distribution, which removes energy scaling and registration problems.

SP070.4 - Generating a four-class attenuation map for MR-based attenuation correction of PET data in pelvis region using an automatic segmentation protocol

Author(s): <u>Hamid Saligheh Rad</u>¹, Mehdi Shirin Shandiz¹, Pardis Ghafarian², Mohamad H. Arabi¹, Mehrdad Bakhshayeshkaram², Naser Shafiei³, Mohammad Reza Ay¹

¹Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran/IRAN, ²Chronic Respiratory Diseases Research Center, National Research Institute Of Tuberculosis And Lung Diseases (nritld), Shahid Beheshti University of Medical Sciences, tehran/IRAN, ³Imaging Center, Payambaran Hospital, tehran/IRAN **Introduction:** It is well known that prostate imaging is one of the killer applications of PET/MRI systems. The main challenge of the current PET/MRI systems in this region field is inaccurate attenuation map (µmap), due to the fact the attenuation coefficients of the tissues are considered as soft tissue or fat in the generated µmaps. This issue leads to overestimation of the tracer uptake in the air cavities of rectum and bowel as well as underestimation of the tracer uptake in bone and adjacent areas to bone in the corrected PET images, especially in regions with thick cortical bones. The aim of this study is to increase the number of tissue classes of µmap in the pelvic area from one class or two classes in currently available PET/MRI scanners to four classes, namely cortical bone, air, soft tissue and fat, by means of a full automatic method. The proposed method consists of a combination of imaging technique, along with an image segmentation protocol.

Material and Methods: The proposed imaging technique was STE (short echo time) that it set on a clinical 1.5T scanner in the pelvis area of two volunteer. The acquisition parameters were 1.31 ms and 60 ms for TE and TR, respectively, with Ernest angle of 15°. The image processing protocol includes five major steps as follows: (I) intensity-inhomogeneity correction;(II) separation of cortical bone and air from other regions using a region-base level set method;(III) separation of cortical bone and air areas using shape analysis method, based on morphological characteristic including level of circularity and symmetry;(IV) separation of soft tissue and fat using thresholding and(V) generation of μ map. The validation of the proposed method was based on comparison with the μ maps generated by CT images as gold standard.

Results: Figure 1, shows acceptable performance the proposed method in segmentation and generation four-class μ map. Quantitative analysis on dice and sensitivity factor are 71% and 65% respectively in cortical bone segmentation as well as 78% and 76% in air segmentation and 82%, 93% respectively, for fat segmentation.

Discussion:The proposed strategy in this study showed that the four-class μ -map can be successfully generated from only one STE-MR image in order to save time, following by the proposed six steps protocol. The proposed method can be a potential alternative to Ultra short echo time (UTE) MR-based attenuation correction, particularly in more common hybrid PET/MRI systems.

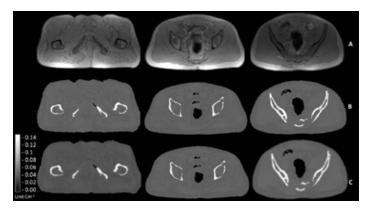

Fig 1. MR image(rowA);segmented image(rowB); µmap(rowC)

SP070.5 - Extracting PET activity distribution from scattered coincidences for non-ideal energy resolutions by modeling the probabilities of annihilation positions within a generalized scattering reconstruction algorithm

Author(s): <u>Hongyan Sun</u>¹, Stephen Pistorius² ¹Physics And Astronomy, University of Manitoba, Winnipeg/MB/ CANADA, ²Radiology, University of Manitoba, Winnipeg/MB/ CANADA

Scattered coincidences degrade PET images contrast and compromise quantitative accuracy, and corrections for this are required in conventional PET reconstruction algorithms. In contrast to this approach, we have developed an algorithm that extracts the radioactivity distribution by incorporating scattered coincidences into the reconstruction. Using the kinematics of Compton scattering, two circular arcs (TCA), as shown in Fig.1(a), describe the locus of all possible scattering positions and encompass the annihilation position for a scattered coincidence. PET images can be reconstructed from scattered coincidences by projection and backprojection within the area confined by the TCA if the detectors have perfect energy resolution. In our previous work, the varying probability of the annihilation position within TCA is not modeled and a uniform distribution is assumed. In practice, the estimated annihilation position is sensitive to the energy resolution of the detector, which limits the implementation of the proposed algorithm on existing clinical PET scanners. In this work, the probability map of annihilation positions within the TCA is modeled in a normalized coordinate system (See Fig. 1(b)). This map was blurred in the vertical direction to account for the non-ideal energy resolution of the system (see Fig.1(c)), and was incorporated into the generalized scattered (GS) reconstruction algorithm. The results demonstrated that by modelling the probabilities of the annihilation position within the TCA in a normalized coordinate system and by introducing this probability map into the reconstruction, the convergence of the reconstructed activity distribution is improved. The contrast for images generated from scattered events improved by 7% compared to those that did not include the probability distribution in the reconstruction (see Fig.2). For non-ideal energy resolutions of up to 6%, the proposed method improves the contrast and noise properties of the reconstruction.

SP070.6 - Quantitative Functional Imaging with Hybrid PET-CT Via Improved Kinetics Modeling: Application to 18F-Fluorocholine PET Imaging of Prostate Cancer

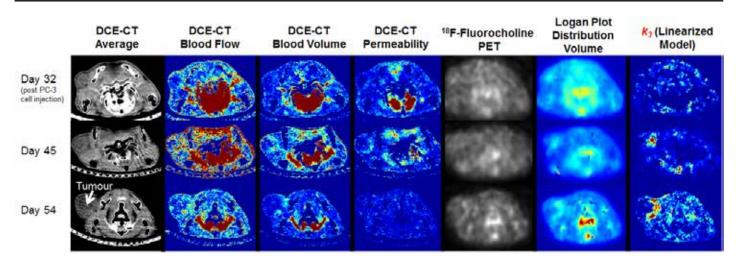

Author(s): Adam Blais, Mark Dekaban, Jennifer Hadway, Ting Yim Lee

Lawson Health Research Institute, London/ON/CANADA

Motivation: ¹⁸F-Fluorocholine (FCH) PET imaging is of interest for the localization of prostate cancer and has the potential to allow more accurate targeting for both biopsy and intra-prostatic radiation dose escalation. However, studies using the standardized uptake value (SUV) have been unable to differentiate prostate cancer from benign prostatic hyperplasia. We hypothesize that this is due to the confounding effects of blood flow and blood volume in the local vasculature, which cannot be discriminated using the SUV. Quantitative kinetic analysis of FCH PET can account for this confounding effect by estimating the k3 parameter, which represents the activity of the choline kinase enzyme, but this is difficult because high parameter covariance reduces the robustness of the k3 estimate.

Methods: We developed a hybrid DCE-CT/PET kinetic model, which uses DCE-CT functional maps to reduce the effect of parameter covariance. Furthermore, this linearized model form is solved with a non-negative least squares algorithm which has only one possible solution and is computationally efficient. Simulations were conducted to investigate the accuracy and precision of k3 estimates and an FCH PET imaging study of a PC-3 mouse model was analyzed to show proof of concept.

Results: Simulations showed a k3 bias of 76% with precision of 82.7%, which improved to 9.5% and 23.5%, respectively, when DCE-CT measurements were incorporated into the model (1,000 runs, signal-to-noise ratio = 10). Results from the PC-3 mouse model (below) show that k3 functional maps exhibit significantly higher tumor-to-background ratios compared to SUV maps and distribution volume maps calculated via graphical analysis with the Logan Plot.

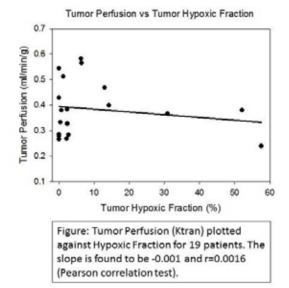

Conclusions: In summary, we have developed a computationally efficient technique for accurate estimation of k3 from noisy dynamic PET data that may be capable of differentiating malignant prostate cancer from benign tissue.

SP070.7 - Simultaneous Measurement of Perfusion and Hypoxia in Pancreatic Cancers with Dynamic PET-FAZA Imaging Author(s): Ivan Yeung¹, Cristiane Metran-Nascente², Doug Vines¹, Ur Metser³, Neesha Dhani², David Green¹, Michael Milosevic¹, David Jaffray¹, David Hedley²

¹Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/CANADA, ²Medical Oncology, Princess Margaret Cancer Centre, Toronto/CANADA, ³Medical Imaging, Princess Margaret Cancer Centre, Toronto/CANADA

Background: Pancreatic cancers are believed to be poorly perfusion and hypoxic, and these characteristics have been suggested to explain in part their aggressive biology and poor response to standard treatment. Method: We have developed a method to guantify perfusion and hypoxia in pancreatic cancers with dynamic PET imaging post injection of ¹⁸F-fluoroazomycin arabinoside (FAZA). A cohort of 20 patients with pancreatic cancers were scanned with the scanning protocol involving dynamic PET acquisition in the first 60 min followed by a single static scan at 2 hr. The dynamic data were binned for image reconstruction with intervals starting from 10s up to 5 min whereas the static scan was scanned with 2 bed positions of 15 min each. The images were viewed and tumor contoured by a radiologist. To quantify the perfusion component of the tracer kinetics of FAZA, the dynamic data (of 19 patients) were analyzed with a two-compartment model with which, 'Ktran' was calculated as a surrogate of perfusion. Repeated analyses were done on data over 1.5, 5.5 and 15 min to investigate the length of data required to estimate Ktran. The static images were analyzed with the 'Mortensen's method' for hypoxic fraction. The method determines, for each patient, the tumor to mean muscle (skeletal muscle) uptake ratio for each voxel in the tumor; those voxels with uptake ratio higher than unity plus 3 times the standard deviation of the population normalized muscle uptake will be classified as 'hypoxic'. The percentage of 'hypoxic' voxel within the whole tumor will give 'hypoxic fraction'. Results: Ktran estimates of 1.5 min data are found to be poorly correlated (r=0.60, 0.62) based on the Pearson correlation test with those of 5.5 min and 15 min, whereas the ktran estimates of the latter two are found to be highly correlated (r=0.98). The mean Ktran of 5.5 min data is 0.384±0.108 ml/min/g and the hypoxic fraction ranges from 0.0 to 57.6% with median hypoxic fraction of 2.2%. The Pearson correlation between Ktran values and hypoxic fractions gives a negligible slope of -0.001 and r= 0.0016 as shown in the figure. Conclusions: The preliminary results suggested that (i) data of 5.5 min are sufficient to provide robust estimates of Ktran, (ii) The preliminary results do not support the notion that pancreatic

cancers are highly hypoxic, and (iii) there is no significant correlation between perfusion and hypoxia in our cohort of patients.

SP071 - Scaffolds in Tissue Engineering

TRACK 02: BIOMATERIALS AND REGENERATIVE MEDICINE

SP071.1 - Optimization of Crosslinking Parameters for Biosynthetic Poly(vinyl-alcohol)-Tyramine Hydrogels Author(s): Khoon S. Lim, Yougambha Ramaswamy, Marie-Helene Alves, Rylie A. Green, Laura A. Poole-Warren, <u>Penny Martens</u> Graduate School Of Biomedical Engineering, UNSW Australia, Sydney/NSW/AUSTRALIA

Photo-polymerizable hydrogels have been widely researched as tissue engineering matrices. When designing a new photocrosslinkable, biosynthetic hydrogel system, a number of parameters need to be optimized, such as the polymerization conditions and amount of biological polymer included. This study aimed to investigate the crosslinking parameters (i.e., choice of initiator, light intensity and irradiation time), as well as the biological polymer (i.e., gelatin) content, for a degradable tyramine functionalized poly(vinyl alcohol) (PVA-Tyr) system. This PVA-Tyr can be photocrosslinked using a visible light initiated process composed of ruthenium (Ru) and persulfate compounds. Comparison of ammonium persulfate (APS) and sodium persulfate (SPS) showed that SPS supported fabrication of higher quality gels at lower concentrations than APS. The initiator concentration and irradiation conditions that were found to produce the best quality PVA-Tyr gels were 2 mM Ru/20 mM SPS and 3 minutes of 15 mW/cm² of visible light. Moreover, incorporation of gelatin into the PVA-Tyr gels successfully facilitated attachment of Schwann cells on the gels. The Schwann cells were able to survive and proliferate over 3 days on the PVA-Tyr/gelatin gels. Overall, this study showed that PVA-Tyr gels have high potential as biomaterials for tissue engineering applications.

SP071.2 - A synchrotron radiation microtomography study of wettability and swelling of nanocomposite Alginate/ Hydroxyapatite scaffolds for bone tissue engineering

Author(s): <u>Francesco Brun</u>¹, Gianluca Turco², Sergio Paoletti³, Agostino P. Accardo¹

¹Department Of Engineering And Architecture, University of Trieste, Trieste/ITALY, ²Department Of Medicine, Surgery And Health Sciences, University of Trieste, Trieste/ITALY, ³Department Of Life Sciences, University of Trieste, Trieste/ITALY

Wettability and swelling properties play an important role in a tissue engineering scaffold. An effective methodology for the characterization of these aspects is here presented and applied to nanocomposite Alginate/Hydroxyapatite scaffolds for bone tissue engineering. The methodology exploits synchrotron radiation computed microtomography and image analysis. Wet conditions with both water and simulated body fluid (SBF) were applied to the synthesized 3D constructs and the structure alterations were investigated after 21 days and 60 days of embedding. A quantitative analysis of wettability and swelling behavior through time is also presented and discussed. SP071.3 - ECM production and distribution in regenerated cartilage tissue cultured under traction loading. Author(s): Keisuke Fukuda¹, Seiji Omata², <u>Yoshinori Sawae³</u> ¹Graduate School Of Engineering, Kyushu University, Fukuoka/JA-PAN, ²Research Center For Advanced Biomechanics, Kyushu University, Fukuoka/JAPAN, ³Faculty Of Engineering, Kyushu University, Fukuoka/JAPAN

An arthrodial cartilage covers sliding surfaces of a diarthrodial joint, and it has important mechanical functions, such as impact absorption, friction reduction, etc. Mechanical stresses and strains exerted in articular cartilage during daily joint movements can stimulate the metabolism of chondrocytes. For the cells embedded in the cartilage, they play an important role to sustain the health and homeostasis of the cartilage tissue. Especially, upregulative effects of the cyclic compression and the hydrostatic pressure on the chondrocytes biosynthesis of extracellular matrix (ECM) have been studied extensively and utilized in the cartilage tissue engineering. However, the regenerated cartilage does not have sufficient dynamic functionalities compared with the normal arthrodial cartilage. The load which arises in a living body is not the simple in fact. The chondrocyte would be exposed to the dynamic and complicated strain field consisting of compression, tension and shear that exerted by both joint loading and friction at the cartilage surface. In this study, the relative motion between cartilage surfaces in a synovial joint is simulated by the rolling-sliding motion of the plastic roller on the cultured chondrocyte-agarose construct and its effects on the formation of regenerated cartilage tissue was investigated.

Chondrocytes isolated from cartilage tissues harvested from metacarpal-phalangeal joints of steers were seeded in agarose gel and cultured 2 or 3 weeks with a traction loading applied to the surface by a roller in the original traction loading machine. This machine consists of upper oscillating plastic roller and lower reciprocating specimen stage. Vertical movement and oscillation of the roller and horizontal reciprocation of the stage were independently driven by three AC servomotors, which were controlled by PC through a control board. The specimen fitted into the culture dish was mounted on the stage and the roller was rolled over its upper surface with a defined slip/roll ratio to apply the traction loading to the construct.

After the culture period, we evaluated the amount of Type II collagen and Glycosaminoglycan (GAG) and also observed the distribution on these ECM molecules in the construct. To identify effects of the traction loading, a control specimen with a same initial cell density and same dimensions was also prepared and cultured simultaneously under the free swelling condition. After the culture experiment, constructs cultured under the traction loading had a clear traction track on the upper surface. Therefore, samples for the analyses were divided into three groups, traction track, outside of the traction track and free swelling condition.

The experiment showed that the traction loading applied to the surface of chondrocyte-agarose constructs could not increase the amount of ECM molecules accumulated in the regenerated cartilage tissue. But, it brought the anisotropic nature in the elaborated cartilaginous tissue and ECM rich layer was formed in the articulating surface of the construct cultured under the traction loading. Therefore, the traction loading on the surface may have all potential to make the structural anisotropy like a natural articular cartilage in regenerated cartilage tissue.

SP071.4 - Alginate encapsulation: a solution for controlled infiltration of cells within artificial fiber constructs Author(s): Oleksandr Gryshkov, Holger Zernetsch, Nicola S.

Hofmann, <u>Birgit Glasmacher</u>

Leibniz University Hannover, Institute for Multiphase Processes, Hannover/GERMANY

Introduction

Tissue-engineered constructs containing living cells are promising in the field of regenerative medicine and cell- based therapies. The application of tissue engineering presents an engineered polymer-cell construct as an attractive option to treat cardiovascular disorders. A seeded scaffold faces the problem of the growth of cells only on the surface. On the other hand, by combining the encapsulation of cells within alginate beads with scaffold structures, one can develop 3D scaffolds with encapsulated cells [1]. The advantage of this approach, in contrast to direct cell seeding, is in the potential of alginate beads to protect encapsulated cells from shear stress, which occur upon seeding and culture.

Methods

The developed high voltage method was utilized to encapsulate NIH 3T3 cells in 1.5% sterile-filtered alginate solution at concentration of 3x106 cells/ml. After encapsulation alginate beads were washed twice with washing solution (WS, 10 mM HEPES, 1.5 mM CaCl2 at pH = 7.4). Polycaprolactone/polylactic acid fiber mats (PCL-PLA) were generated using electro-spinning. The embedding of alginate beads into PCL scaffold was performed manually at sterile conditions. Afterwards, PCL-PLA fiber mats with entrapped alginate beads containing 3T3 cells were washed twice with WS and cultured in a humidified incubator at 37°C, 5% CO2 for 24 days. Medium was exchanged every second day with a fresh one. The membrane integrity of 3T3 prior to encapsulation and after dissolution of alginate structure was analyzed using Trypan Blue exclusion method. The viability of encapsulated cells in alginate beads immediately after encapsulation and their presence within the scaffold was assessed using CalceinAM/EthD-1 live-dead viability assay. The presence of embedded alginate beads into fiber mats was confirmed using a scanning electron microscope.

Results

NIH 3T3 cells can be encapsulated into alginate beads (diameter 300μ m) using high-voltage electro-spraying without significant effect of high voltage on the viability of encapsulated cells postencapsulation (immediate viability 92% vs. initial 95%). In turn, electro-spinning process allowed generating multi-layered PCL-PLA scaffold with previously incorporated alginate beads containing living cells. Analysis of SEM images proved the presence of alginate beads in the scaffold. Long-term culture of these constructs for 24 days revealed the simultaneous degradation of alginate beads, release of encapsulated 3T3 cells and their attachment to PCL-PLA fiber mat within the scaffold. On the other hand, no viable and adherent cells were observed, if the alginate structure was treated with sodium citrate prior to long-term culture.

Conclusions and outlook

This work shows the perspectives of applying the high-voltage process to generate cell-containing tissue-engineered constructs for regenerative medicine, cell-based therapies and cardio-vascular applications. Further work will be performed to optimize the seeding process including its automatization, as well as to investigate the behavior of such constructs at dynamic conditions.

SP071.5 - Biomineralization and In vivo-Compatibility of LnPO4 Nanorods with Enhanced MR and Luminescence Imaging Author(s): <u>Zhongbing Huang</u>

Sichuan University, Chengdu/CHINA

Introduction: The biocompatibility of nanomaterials with dual-functions is very important for their clinical applications.

Methods: Eu-doped LnPO4 nanorods (NRs) in the template of silk fibroin (SF) peptides, including GdPO4, SmPO4 (named as SF-NRs), are successfully synthesized via a biomineralization process.

Results: lengths of Eu-doped GdPO4 and SmPO4 NRs with SF peptides (SF-NRs) are ~150 and 250 nm, respectively, and their diameter is ~10 nm. Compared to pure NRs, SF-NRs have stronger cell luminescence and higher T1 signal-enhancement of in vitro/in vivo MRI due to their higher ratio of Eu/Gd (~0.9/5) or Eu/Sm (~1.1/3) and more Eu²⁺/Eu³⁺ in SF-NRs. The images of cell ultrathin sections indicate that endocytosis of SF-NRs into the cytoplasm did not influence mitochondrial architecture at the NR concentrations of 100 mg·mL⁻¹ after 3 d of culture, because PBS/calf serum immersion tests indicate that SF peptide coating could slow metal-ions release and the crystal degradation from NRs. The histological analysis and bio-distributions in tumor-bearing nude mice suggest that, compared to pure NRs, SF-NRs have lower tissue/organ toxicities and could be safely cleared away through renal and fecal excretion in 3 d, especially the existence of more SF-NRs in the tumor field due to SF coating layer in NR surfaces. Furthermore, Eu-doped SF-NRs not only exhibit a higher T1 signal-enhancements (the longitudinal relaxivity r1 value is 1.32 (Gd mM·s)⁻¹ and 0.0145 (Sm mM·s)⁻¹) under a 7.0 T MR imaging system, and a series of in vivo T1-weighted MR images between pre- and post-injection in tumor regions in 9 h indicate that average intensity of post-injection of SF-NRs is enhanced 71%, higher the increased value of pure NRs (15.5%), but also show the better luminescence imaging of living cells under the fluorescence microscope.

Conclusions: Our results indicate that Eu-doped SF-NRs have potential as *T1* MR imaging contrast agents and optical imaging probe in tumor–detection field.

SP071.6 - Additive Manufacturing for Creating Multifunctional Tissue Engineering Scaffolds

Author(s): Min Wang

Department Of Mechanical Engineering, The University of Hong Kong, Hong Kong/HONG KONG

Tissue engineering has great potential in solving many medical problems that are currently unsolvable or in offering better and long-term solutions as compared to current medical treatments. For human body tissue regeneration, different approaches can be adopted: cell-based, factor-based or scaffold-based tissue engineering. In scaffold-based tissue engineering, cells are encapsulated in the matrices or seeded on the surface of 3D scaffolds, with the scaffolds serving as the extracellular matrix to direct cell adhesion, proliferation and differentiation and thus promote tissue

regeneration. Over the past two decades, many materials and scaffold manufacturing techniques have been investigated by numerous groups around the world for regenerating different body tissues. So far, materials for tissue engineering are predominantly biodegradable polymeric materials, natural or synthetic, and scaffolds are produced using either non-designed manufacturing techniques (solvent casting/particulate leaching, phase separation, gas foaming, electrospinning, etc.) or designed manufacturing techniques. Using designed manufacturing techniques, which include a host of additive manufacturing technologies (the so-called "rapid prototyping (RP) technologies" in previous decades), for making tissue engineering scaffolds has distinctive advantages over some commonly used chemical engineering methods in scaffold fabrication and hence has been attracting increasing attention in the biomedical field. Some additive manufacturing technologies impose stringent requirements for stock materials and studies are thus conducted on preparing stock materials and on evaluating the physical and mechanical properties of scaffolds made of these stock materials. Realizing the shortcomings of common biodegradable polymers as materials for tissue engineering scaffolds with regard to some specific tissues, various research groups now investigate new, more appropriate materials for the regeneration of targeted tissues, which include biodegradable ceramics (including glasses), composites and even metals. Considering the extracellular matrix of bone is a natural nanocomposite comprising nano-sized apatite and collagen fibrils, it is natural to develop polymer-based nanocomposites containing nanoparticles of bioactive and biodegradable ceramics as novel scaffold materials for bone tissue regeneration. Furthermore, mesenchymal stem cells (MSC) are increasingly used in tissue engineering. In this presentation, for illustrating developing biomedical nanocomposites and using additive manufacturing to form multifunctional scaffolds, our research in employing selective laser sintering (SLS), a well-established additive manufacturing technology, for obtaining osteoconductive and osteoinductive scaffolds for bone tissue engineering is introduced. Microspheres of nanocomposites (CHA/PLLA or Ca-P/PHBV) are firstly prepared as raw materials for SLS. Scaffold models of required features can be designed using data from computer-based medical imaging techniques (e.g., MRI). Nanocomposite scaffolds of good quality and consistent quality can be formed via SLS after process optimization. The growth factor rhBMP-2 can be incorporated on surface-modified nanocomposite scaffolds. It can be released from scaffolds in a controlled manner and cause osteogenic differentiation of MSCs in vitro. The osteoconductive (owing to the bioceramic nanoparticles) and osteoinductive (due to rhBMP-2) nanocomposite scaffolds formed by SLS stimulate bone tissue regeneration in vivo.

SP071.7 - Comparison of different dosage of lon implantation on electrospun collagen fibers to improve aqueous stability Author(s): <u>Nisha Sharma</u>¹, Jian Liu², Derek Boughner¹, Wankei Wan¹ ¹Biomedical Engineering, University of Western, NAB/CANA-DA, ²Western, London/CANADA

Comparison of different dosage of lon implantation on electrospun collagen fibers to improve aqueous stability

Nisha Sharma¹, Jian Liu², Derek Boughner^{1, 3}, Wankei Wan^{1, 2, 3} ¹ Biomedical Engineering Graduate Program, ² Department of Chemical and Biochemical Engineering, ³Department of Medical Biophysics Western University, London, Ontario, Canada

Introduction:

Engineering methods to construct biological tissue substituted has been inspired due to the shortage of donor organ transplantation. Where, the scaffold plays an important role as of assisting, an artificial extracellular matrix to accommodate cells and support three-dimensional tissue regeneration. An ideal scaffold should be biocompatible, biodegradable, malleable, mechanically strong, and highly porous with a large surface to the volume ratio. Such, ideal scaffolds are highly in demand, for surgical application, regenerative medicine, cell based therapy. An electrospun nanofibrous collagen scaffold is desirable for tissue engineering application, but as prepared, it is unstable in an aqueous environment including cell culture media. Stabilization of these nanofibers has been achieved to varying degrees of success using a chemical crosslinking approach with crosslinking agent such as glutaraldehyde, but they are cytotoxic.

Hypothesis:

lon beam implantation onto random oriented fibrous scaffold produced by the electrospinning will promote radial artery cells adhesion, migration, differentiation and proliferation. This is the first step towards the successful tissue engineering.

Materials and Methods:

In this study, Collage Rat tail –Type-1 is the material in used to fabricate the electrospinning fibers. These electrospun collagen fibers are crosslinked using a physical approach via ion implantation. Broad energy He⁺ (Helium) and N⁺ (Nitrogen) ion beams are used. Energies of 1.7 MeV and 520 MeV of N⁺ ion and He⁺ ion, respectively were used to surface modify the collagen nanofibrous scaffold. The dose of these ions with similar energies, where varied from (4*10¹⁵ ions /cm² - 1.2 * 10¹⁶ ions/cm²)

Results

These cross-linked scaffolds (nanofibrous) displayed stability in both water and cell culture media with controllable degrees of swelling, where established with two different dosage. The third dosage with the same ions and energy need to be tested.

Discussion and summary

So far, with one of the energy of 1.7 MeV N+ of dose of 1.2 * 1016 ions/cm2 and 520 MeV He+ of dose of 8 *1015 ions /cm 2 at room temperature. The, X-ray photoelectron spectroscopy (XPS) shows that with nitrogen implantation, two new chemical functional groups, amine and amide, are introduced, which could promote cell adhesion. And, these functional groups were not found in He+ implantation.

SP072 - Imaging

TRACK 04: RADIATION ONCOLOGY

SP072.1 - Variations in geometric distortion using static and moving table acquisition for radiotherapy treatment planning applications

Author(s): <u>Amy Walker</u>¹, Gary Liney¹, Lois Holloway², Jason Dowling³, David Rivest-Henault³, Peter Metcalfe²

¹Medical Physics, Liverpool and Macarthur Cancer Therapy Centres and Ingham Institute for Applied Medical Research, Liverpool/ AUSTRALIA, ²Centre For Medical Radiation Physics, University of Wollongong, Wollongong/AUSTRALIA, ³Commonwealth Scientific And Industrial Research Organisation, Australian E-Health Research Centre, Brisbane/QLD/AUSTRALIA

Purpose:

Geometric accuracy is essential when imaging patients for radiotherapy treatment planning (RTP). An increased use of MRI for RTP requires consideration of inherent geometric distortions. This study compared variations in geometric distortions observed during image acquisition utilising a continuously moving table, compared to a conventional static table. Continuous moving table acquisition allows for imaging of a longer scan length than static acquisition, a potential benefit for RTP.

Methods:

A new full field of view (FOV) phantom for measuring MRI geometric distortion for the purposes of RTP was designed in-house. Constructed from Dotmar Uniboard, 5830 vitamin E capsules were placed systematically throughout. Phantom dimensions were 500mm x 350mm x 513mm (x,y,z respectively). The phantom was scanned on a Siemens 3 T Skyra with a spoiled gradient echo (GRE) sequence (vendor 3D-correction applied). The phantom was imaged with a static couch and a continuously moving table (TimCT). The MR images were registered to a CT of the phantom to obtain distortion maps.

Results:

Table 1 compares the geometric performance of images acquired with and without a moving table. TimCT enabled imaging of the whole phantom. TimCT acquired with a table speed of 1.1mm/s resulted in the best geometric accuracy. However, the acquisition time was over 9 minutes compared to 2 minutes for the static acquisition. Increasing the table speed to 2mm/s decreased acquisition time, but resulted in increased blurring of the capsules by 170% at the FOV edges. TimCT was limited to 2 possible imaging sequences.

Conclusions:

MRI acquisition utilising TimCT offers a potential alternative for imaging large scan lengths which may be required for RTP, particularly for long FOVs. Both static and moving table image acquisitions are viable scanning options for imaging for RTP. Selection of the acquisition method would depend on the anatomical region under investigation.

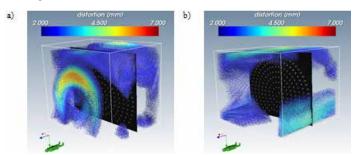

Table 1: Geometric performance of the spoiled GRE acquired with various table speeds

Sequence	Table speed (mm/s)	% phantom imaged	% phantom with distortion < 2 mm	Distance from isocenter where distortion ≤ 2 mm	Maxi- mum dis- tortion (mm)
TimCT	1.1	100	87	147 mm	4.4
TimCT	2	100	61	140 mm	5.8
Non TimCT	0	71	47	55 mm	6.1

SP072.2 - Translation of biomechanical deformable image registration (MORFEUS) to the RayStation radiotherapy treatment planning system

Author(s): <u>Michael Velec</u>¹, Joanne L. Moseley¹, Stina Svensson², Björn Hårdemark², Kristy K. Brock³, David Jaffray¹ ¹Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/ON/CANADA, ²RaySearch Laboratories, Stockholm/SWE-DEN, ³University of Michigan, Ann Arbor/MI/UNITED STATES OF AMERICA

Purpose: Deformable image registration accuracy can vary widely between imaging modalities and even implementations of similar deformation models. Biomechanical model-based deformable registration was implemented in a commercial radiotherapy system and validated on multi-modality imaging.

Materials and Methods: MORFEUS is a MATLAB-based registration algorithm previously developed and validated in-house. A multi-organ tetrahedral mesh model is generated from contours in the reference image, while a subset of additional surfaces is created from body, liver and spleen contours in the target image. These three organs undergo individual surface deformations to align the contours between images and serve as boundary conditions. Finite element analysis (FEA) solves the internal displacements including all of the remaining organs and tumors. Under research collaboration with RaySearch Laboratories, MORFEUS was implemented in a commercial treatment planning system. Results shown are from a pre-clinical release of RayStation (v4.4.100). The organ-specific material properties were optimized separately between implementations. The Poisson's ratios applied in-house (range: 0.4-0.499) differ by <10% from those applied in RayStation-MORFEUS. Variable Young's moduli are applied in-house (range: 1.5-500 kPa), whereas RayStation-MORFEUS effectively applies a uniform stiffness. Boundary conditions are achieved using guided-surface projections for the in-house MORFEUS, whereas RayStation-MORFEUS uses model-based segmentation which adapts a common mesh to corresponding contours. Different third party components are also used for mesh generation and FEA solver, although these function similarly. For 32 patients in total, registration of abdominal images was performed from exhale to inhale 4DCT (or MR), or exhale CT to MR. One patient with 4DCT and MR was previously evaluated in a multi-institution accuracy study, allowing for a comparison to other algorithms. For evaluation between deformed and actual target images, the target registration error (TRE) was guantified as the residual distance between anatomic liver landmarks (median: 5, range: 4-25). For 4DCT and MR-MR, the residual mean distances of the stomach and kidneys surfaces (organs excluded as boundary conditions) were additionally quantified.

Results: The Table demonstrates the registration accuracies of both MORFEUS implementations differ by <1 mm, and both accuracies

are similar to each image resolutions on average. In the multi-institution comparison, for 4DCT both MORFEUS implementations' TRE were within 1 mm of the best-performing algorithm. For CT-MR, the in-house and RayStation-MORFEUS TRE was 1.0 and 1.2 mm lower than the best-performing, non-biomechanical algorithm.

Madrida		D .	Mean (maximum) registration accuracy, in mm			
Metric	Data	Region	Baseline rigid	In-house Morfeus	RayStation Morfeus	
	4DCT (n=10)	Liver	7.8* (12.7)	2.7 (3.3)	2.7 (3.4)	
TRE	CT-MR (n=18)	Liver	6.1* (10.7)	4.0 (5.8)	3.8 (5.6)	
	MR-MR (n=5)	Liver	17.9* (23.5)	3.5 (5.9)	2.8 (3.7)	
	4DCT (n=10)	Rt. kidney	2.6* (4.2)	1.6* (2.6)	1.7 (3.0)	
		Lt. kidney	2.0* (3.0)	1.1* (1.8)	1.3 (1.8)	
Maan aurfaan diatawaa		Stomach	2.8 (4.1)	1.9 (3.4)	2.7 (3.4) 3.8 (5.6) 2.8 (3.7) 1.7 (3.0)	
Mean surface distance		Rt. kidney	4.1 (6.6)	1.9 (2.8)	2.3 (3.6)	
	MR-MR (n=5)	Lt. kidney	3.7 (4.9)	1.9 (2.7)	2.1 (3.2)	
		Stomach	5.8* (7.2)	3.0 (4.3)	3.5 (4.7)	
*p≤0.05 versus RayStation-Morfeus						

Conclusions: MORFEUS biomechanical registration was implemented in RayStation. Its registration accuracy and difference from the original implementation are on average within the voxel sizes on multi-modality abdominal imaging.

SP072.3 - Phantom Validation of a Point-Set Deformable Registration Method using Pig Bladder

Author(s): <u>Roja Zakariaee</u>¹, Ghassan Hamarneh², Colin J. Brown², Ingrid Spadinger³

¹Physics, University of British Columbia, Vancouver/BC/CANA-DA, ²Medical Image Analysis Lab, School Of Computing Science, Simon Fraser University, Burnaby/BC/CANADA, ³Medical Physics, BC Cancer Agency, Vancouver/BC/CANADA

Introduction

Deformable image registration (DIR) is widely used for registering medical images. While the main goal of registering images is to correspond different regions of interest (ROI) within the body, surrounding objects and image artefacts can confuse the DIR algorithm. This occurs, for example, in image-guided multi-fraction gyneocological brachytherapy treatment, which uses an intracavitary applicator. Therefore, in applications like dose accumulation for these treatments, an alternative approach is to non-rigidly register delineated ROI contours. However, validating the registration outcomes and accordingly choosing a suitable registration algorithm is challenging, especially for highly deformable ROI with no discriminating features or anatomical landmarks. In this work, a point-set deformable registration technique, called coherent point drift (CPD), is evaluated for registering the bladder surface across treatment fractions.

Methods

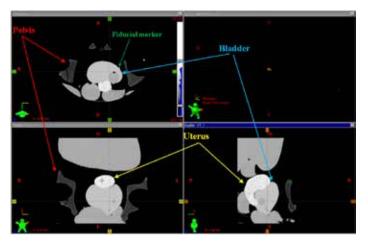

A house-made pelvis phantom was used with a freshly harvested pig bladder to model the human anatomy. Multiple plastic and rubber fiducial markers were glued onto the bladder surface at twelve different locations. The bladder was filled with varying amounts (90cc, 180cc, 360cc, and 480 cc) of a water-contrast mixture and CT-scanned each time. The variously filled bladder was contoured manually on each scan using the MIM Maestro software (MIM Software Inc.). In addition, the fiducials were identified on each scan and their positions recorded. The CPD toolbox for MATLAB (Mathworks Inc.) was used to register the contour point-sets of the three smaller bladder sizes to the largest size. The toolbox takes the *target* and moving structure coordinates and outputs the *de*- formed moving structure coordinates. The fiducial positions were used as landmarks to calculate the target registration errors (TRE) for different points on the bladder surface. Optimized input parameters for CPD registration were found experimentally by searching over the parameter space for values which minimized average TRE over all landmarks.

Results

The appearance of the phantom and the fiducial markers in the CT images was very satisfactory (Fig. 1). The average TRE value obtained for the 480cc-bladder as the *target* structure was 6.4 ± 2.3 mm. TRE values were obtained for alternate target structures, with the 360cc-bladder yielding the lowest TRE value of 5.5 ± 2.1 mm when selected as the target. These TRE values are reasonably small compared to the dimensions of the bladder.

Conclusion

Our validation method shows that the CPD deformable registration technique is a viable method for registering ROI contours, even when lacking distinctive features in the structure.

SP072.4 - Automatic bone and air segmentation during generation of synthetic CT from MR data in the brain Author(s): Joshua Kim, Weili Zheng, Indrin J. Chetty, Carri Glide-Hurst

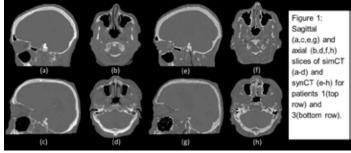

Radiation Oncology, Henry Ford Health System, Detroit/MI/UNITED STATES OF AMERICA

Adequate differentiation of short-T2 tissue types such as bone from air remains a significant challenge for generating accurate electron density maps. This work describes the integration of ultra-short echo time (UTE) datasets and derivative images into our automated brain synthetic CT (synCT) pipeline to generate synCTs for our MRonly radiation treatment planning (RTP) workflow. MR Data from five brain cancer patients were acquired using Philips' 1.0T Panorama open MR-SIM. T1-weighted fast field echo, T2-weighted turbo spin echo, FLAIR, and UTE-DIXON (TE = 0.144/3.4/6.9ms) sequences were acquired for all patients. Affine registrations to the UTE magnitude image (UTE1) were performed. A "bone-enhanced" image was generated from DIXON-water, DIXON-fat, and inverted UTE1 datasets. Images were integrated into an automatic routine using k-means clustering with five clusters and morphological operations to segment combined bone and air voxels. A novel method incorporating post-processed UTE phase maps was introduced, enabling automated segmentation of air voxels from bone via a six-kernel Gaussian Mixture Model. A truth table was constructed based on voxel intensity levels in acquired T1, T2, and FLAIR images to assign non-bone/non-air voxels to three classes: CSF, brain tissue, and fat. A voxel-based weighted summation method incorporating T2,

FLAIR, UTE1, and "bone-enhanced" images was implemented with synCT voxel values calculated by:

$synCTi = \sum k wk, r(i)Mk, i$

where Mk, i is intensity for voxel i of MR image k, r(i) is the voxel's assigned class, and wk,r(i) is a class-dependent weighting factor optimized by minimizing the sum of squares error between simulation CT (simCT) and synCT using a training subset. HU value differences were compared using mean absolute error (MAE). Figure 1 illustrates simCT and synCT images for two patients. Average full field-of-view MAE over all patients was 164.8±23.4 HU, showing close agreement with expected values. UTE phase-derived air maps were compared to threshold-derived simCT air contours, overlapping with 87.2±6.1% of simCT-based volumes. However, phase-derived air maps were often larger than simCT air contours, leading to higher average HU values for simCT versus synCT in air (-695±66 HU vs. -1024 HU). Another consequence was that the enlarged phasederived contours yielded lower average values in bone (761±86 HU vs. 841±75 HU). Automatic air and bone segmentation methodology was incorporated into a brain cancer synCT pipeline. Calculated HU values demonstrated good agreement with expected simCT values based on MAE, however further refinement of air masks using the phase-based approach is needed.

SP072.5 - Effect of Deformable Registration Accuracy Uncertainty on Lung Dose Accumulation

Author(s): <u>Navid Samavati</u>¹, Michael Velec², Kristy K. Brock³ ¹Ibbme, University of Toronto, Toronto/CANADA, ²Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/ CANADA, ³University of Michigan, Ann Arbor/MI/UNITED STATES OF AMERICA

Objective/Purpose: Deformable image registration (DIR) plays an important role in dose accumulation, such as incorporating breathing motion into the accumulation of the delivered dose based on daily CBCT images. However, it is not yet well understood how the uncertainties associated with DIR methods affect the dose calculations and resulting clinical metrics.

Methods and Materials: In the current study, a biomechanical model based DIR method and a biomechanical-intensity-based hybrid method, which reduced the average registration error by 1.6 mm, were applied to 10 lung cancer patients. Clinically relevant dose parameters were calculated for three dose accumulation scenarios using both algorithms. Dose scenarios included: *static, predicted,* and accumulated. *Static* dose refers to the clinical plan on the exhale phase of the 4DCT, which accounts for the breathing motion through the use of an asymmetric Planning Target Volume (PTV) margin, but does not account for the normal tissue motion in and out of the PTV during breathing motion. The *predicted dose* calculates the delivered dose based on the breathing motion observed on the 4DCT obtained at the time of treatment planning. The *accumulated dose* calculates the dose delivered based on the

4DCBCT obtained at the start of each treatment fraction. For each dose scenario, the relationship between the dose parameters and a combination of DIR accuracy (Target Registration Error, TRE, and Dice Similarity Coefficient, DSC), tumor volume, and dose heterogeneity of the plan was investigated.

Results: Depending on the dose heterogeneity, measured by Dose Heterogeneity Index (DHI), tumor volume, and DIR accuracy (measured by DSC), in over 30% of the cases differences greater than 1.0 Gy were observed in the minimum dose to 0.5cc (Dmin) of the tumor in the static dose calculation. Such differences were due to the errors in propagating the tumor contours from the reference planning 4DCT phase onto a subsequent 4DCT phase using each DIR algorithms and calculating the dose on that phase. The differences were more subtle when breathing motion was modeled explicitly (predicted dose) with only one case with over 1.0 Gy Dmin difference. Dmin Differences of up to 2.5 Gy were found in the total accumulated dose due to inter-fraction variations. Such dose uncertainties could potentially be clinically significant. Thus, clinical implications of DIR-based dose accumulation outcomes should be interpreted in the context of the geometric uncertainties associated with the DIR algorithm. More specifically, our results suggest that one might expect larger than 1 Gy differences in a specific Dmin (static, predicted, or accumulated) due to DIR choice in 10-60% of a patient population if two or more of the following criteria are met: 1) DHI of the plan is larger than 20, 2) DIR induced DSC differences in the tumor exceeds 0.08, and 3) tumor volume (or tumor volume difference) is larger than 10 cc (or 5%).

Conclusion: In summary, reductions in average uncertainty in DIR algorithms by 1.6 mm may have a clinically significant impact on the decision-making metrics used in dose planning and dose accumulation assessment.

SP072.6 - Development of a Multi-Modality 4D biomechanical Phantom for Evaluation of Simultaneous Registration/ Segmentation Algorithms

Author(s): <u>Daniel Markel</u>¹, John Larkin², Pierre Leger³, Ives R. Levesque⁴, Issam El Naqa²

¹Medical Physics Unit, McGill University, Montreal/CANADA, ²Medical Physics, Montreal University Health Centre, Montreal/CANA-DA, ³Oncology, Montreal University Health Centre, Montreal/QC/ CANADA, ⁴Research Institute of the McGill University Health Centre, Montreal/QC/CANADA

Purpose: Simultaneous registration and segmentation, known as regmentation, has the potential to improve both accuracy and efficiency of both procedures when using multimodal images or longitudinally acquired scans. Currently, no gold standard exists for the evaluation of regmentation algorithms, in contrast to existing segmentation or registration algorithms, where several systems have been developed. Presented is a phantom and software package that satisfies several criteria: PET/CT/MRI compatibility, realistic geometric deformations, and reliable ground truths for both segmentation and registration, sequential or simultaneous, with a high degree of consistency.

Method and Materials: The phantom consists of a pair of inflatable swine lungs connected to an in-house built programmable respirator (shown in figure 1) via an 8 meter long vinyl tube. This allows metallic components to stay outside the scan room and thus ensure MRI compatibility. The respirator is able to mimic the breathing traces of patients taken using respiratory bellows. The target was constructed in two compartments from vacuum-sealed sea sponges. The inner and outer compartments simulate a tumor and background respectively. Catheters lead into each compartment allowing for injection of radiotracer. The registration ground truth is determined using a bifurcation-tracking pipeline. The accuracy of the tracking pipeline was evaluated by applying a known virtual deformation to a CT volume of the swine lungs and comparing the known final locations to the ones detected by the pipeline. The segmentation ground truth was acquired by scanning the inner compartment seperately and rigidly registering it to the original scan.

Results: The average bifurcation tracking error was found to be 1.22, 1.26 and 2.26 voxel widths for displacement magnitudes of 2.6, 5.2 and 7.8 cm respectively using a CT scan of a human lung. The tracking error was similarly measured to be 1.36, 1.63 and 2.46 voxel widths for displacements of 1.14, 2.29 and 3.43 cm using the swine lungs. The respirator was able to match breathing traces with a maximum error of 2.2% and an average error of 0.5%.

Conclusion: The 4D biomechanical lung phantom has shown to be a reliable tool for evaluating regmentation algorithms. The bifurcation tracking pipeline's accuracy was measured on the order of a single voxel width up to an acceptable displacement. This is crucial in eliminating the unknown uncertainty with which manual selection of fiducial points may introduce into the evaluation of a registration algorithm.

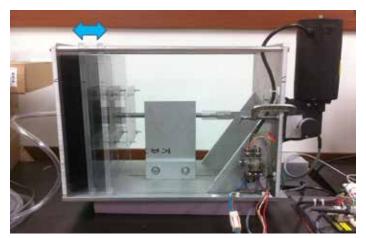

Fig. 1 The computer controlled respirator with it's 4 cm range of motion shown.

SP072.7 - Using Magnetic Resonance Image (MRI) alone in Treatment Planning and Treatment Localization

Author(s): <u>Shupeng Chen</u>¹, An Qin¹, Di Yan¹, Hong Quan² ¹Radiation Oncology, Beaumont Health System, Royal Oak/MI/ UNITED STATES OF AMERICA, ²School Of Physics And Technology, Wuhan University, Wuhan/CHINA

Purpose: Using MR image directly for dose calculation and patient treatment position localization has been expected. In this study, a method of creating a synthetic CT image from a MR image was proposed and evaluated using the corresponding CT image numbers, planning dose distribution, and accuracy of daily CBCT image registration.

Method: A pair of MR image and CT image was collected in same day from each of 10 prostate cancer patients. For each patient, the pair of MR and CT images was pre-registered using the deformable image registration (DIR). Then the corresponding CT images were deformed toward MR to create a CT-MR pair. ROIs on the pair of images, including bone, prostate, bladder, rectum and skin, were delineated and used to create ROI masks. 'Leave-one-out' test (9 atlas patients, 1 tested patient) was performed. For each test MR image, auto-segmentation and deformable vector field (DVF) were generated based on inter-patient DIR between the test MR image and the 9 atlas MR images. Synthetic CT was then generated using the paired CT and the corresponding DVF (MR, MR) in the atlas. The voxel intensity in the synthetic CT was determined based on the paired CT images and the corresponding masks based on the intersection of the masks. The evaluation included the comparison of the CT number, the corresponding calculated dose distribution and the corresponding registration to daily CBCT images between the resulting synthetic CT and the paired CT.

Result: The mean \pm STD of CT number error that calculated on 10 synthetic CT are (2.4 \pm 25.23), (-1.18 \pm 39.49), (-32.46 \pm 81.9) and (8.07 \pm 146.94) for prostate, bladder, rectum and bone, respectively. The dose discrepancy calculated using the synthetic CT and the actual CT is small, difference of D99 and D95 of target were < 1%, D40 and D5 of rectum and D50 of bladder were < 1.05%. Using the 10 synthetic CT as the reference planning CT for patient daily CBCT (364 fractions) localization achieved the similar results compared to using the actual CT. The translational vector difference were within 1mm with mean \pm STD (0.37 \pm 0.23mm), and the rotational discrepancy was within 1 degree in all 3 directions.

Conclusions: Synthetic CT created using the atlas of pre-registered CT and MR image pairs can be used to be the planning and localization CT image for dose calculation and daily patient position localization and correction.

SP073 - Robotics and Virtual Reality in Surgery

TRACK 07: SURGERY, COMPUTER AIDED SURGERY, MINIMAL INVASIVE INTERVENTIONS, ENDOSCOPY AND IMAGE-GUIDED THERAPY, MODELLING AND SIMULATION

SP073.1 - Augmented Reality in Image-guided Cardiac Interventions. Author(s):

Many inter-cardiac interventions are performed either via openheart surgery, or using minimally invasive approaches, where instrumentation is introduced into the cardiac chambers via the vascular system or heart wall. While many of the latter procedures are often employed under x-ray guidance, for some of these, x-ray imaging is not appropriate, and ultrasound is the preferred intra-operative imaging modality.

Two such procedures involves the repair of a mitral-valve leaflet, and the replacement of aortic valves. Both employ instruments introduced into the heart via the apex of the heart. For the mitral procedure, the standard of care for this procedure employs a 3D Trans-esophageal echo (TEE) probe as guidance. In spite of the clinical success of this procedure, many problems are encountered during the navigation of the instrument to the site of the therapy. To overcome these difficulties, we have developed a guidance platform that tracks the US probe and instrument, and augments the US mages with virtual elements representing the instrument and target, to optimize the navigation process. Results of using this approach on animal studies have demonstrated increased performance in multiple metrics, and a large reduction in the number of times an instrument intruded into potentially unsafe zones in the heart.

The same platform can be employed to guide Aortic valve replacements. Conventionally, aortic valves are replaced, either using an open procedure, or under X-ray fluoroscopy guidance. The former inflicts unnecessary trauma to the patient, while the latter suffers from the problem of high radiations dose, poor target visibility and potential kidney damage as a result of x-ray contrast administration. To overcome these limitations, we have adapted the above platform to achieve an ultrasound-only solution, again augmented with virtual models of instruments and key targets to guide aortic valve replacement procedures. Preliminary results of this approach on cardiac phantoms indicate that this approach may be as effective as the standard fluoroscopy-guided technique, but without the need for radiation and contrast agents.

SP073.2 - Assistant Laparoscopic Postural: Kinematic Behavior Author(s): <u>Daniel Lorias-Espinoza</u>, Arturo Minor Martinez Bioelectronics Section, Electrical Department,, CINVESTAV, MEXI-CO DF/MEXICO

A human laparoscopic assistant can help or hinder the work of the surgeon, so communication between the two must be natural and not cause any cooperation conflict in which the visual or motor perception of the human laparoscopic assistant hampers the optimal vision and concentration of the surgeon. This article shows a new Assistant laparoscopic called PMASS (Postural mechatronics assistant for laparoscopic solo surgery). The objective is to show their dynamic behavior.

SP073.3 - Workspace optimization of a surgical instrument for single port access surgery

Author(s): <u>Bastian Blase</u>, Sebastian Schlegel, Simon Albrecht Department Of Electromechanical And Optical Systems, Technische Universität Berlin, Berlin/GERMANY

Instruments for laparoscopic single port access surgery have to perform specific movements inside the human abdomen to enable surgeons to perform similar tasks they are familiar with from multiport minimally invasive surgery. Therefore, these instruments have to move apart before coming together at the surgical site to imitate an anthropomorphic position similar to standard access, thus facilitating handling at the desired target. These movements require additional joints. These joints weaken an instrument's shaft structure and often lead to reduced strength, whereas parallel structures reduce workspace. Hence, instruments with a segmented planar hybrid parallel-serial mechanism have been developed, combining the advantages of both structures. This mechanism is coupled serially with an end-effector. Within a set of several geometric parameters and boundaries, the favored mechanism is optimized by varying the segments' lengths for maximizing a so-called area of dexterity comprising all points that can be reached within an angular range of at least 60°. This area can be described in a cylindrical coordinate system in a phase space composed of the radial tool tip position and its inclination. The different movements of the mechanism and the end-effector are superposed and the phase space is analyzed using image evaluation methods. The optimized dexterous workspace by far exceeds a previously defined area of interest that was determined during in-vivo tests. The instruments based on this optimization proved to be agile in several tests like pick-and-place tasks.

SP073.4 - High-Dexterity Telemanipulation Robot for Minimally Invasive Surgery

Author(s): <u>Sebastian Schlegel</u>, Simon Albrecht, Bastian Blase Department Of Electromechanical And Optical Systems, Technische Universität Berlin, Berlin/GERMANY

A robotic telemanipulation system for single-port laparoscopy (SPL) is presented, introducing several advantages over known systems. Principally, the system offers great flexibility at the surgical site as the instrument arms are segmented and articulate within the abdominal cavity. The instrument arms were thoroughly designed to ensure stability while maintaining a small cross-section, thus keeping patient trauma to a minimum.

Apart from the arms' solidity, the need for strong actuators is another factor that arises due to the requirement for high manipulation forces during surgery. As, at the same time, available space is extremely limited, extensive research was conducted for finding suitable actuators. Several types of actuators as well as positions within the system were taken into account, prototypes built and tested. Also, as the need arose for some concepts, mechanisms for transporting kinetic energy from the actuators to the joints were examined.

Applying the results of this work, it was possible to build a telemanipulation system consisting of instrument arms, a support base, and a specifically designed user interface. A computer serves to calculate instrument trajectories and respective joint positions from the user input at the interface as well as to facilitate communication between the system's components.

The system exceeds previously defined goals concerning dexterity. Practical tests demonstrated the broad range of movement. At the same time, the extracorporeal components are considerably smaller than their counterparts in telemanipulators on the market, thus improving direct access to the patient during surgery. Furthermore, the complex kinematics of the instrument arms are controlled via an interface with simplified kinematics modelling the instrument's degrees of freedom (DOF), resulting in intuitive and precise handling.

SP073.5 - Integrated Sensors for a Single-Incision Laparoscopic Instrument

Author(s): <u>Simon Albrecht</u>, Bastian Blase, Sebastian Schlegel Department Of Electromechanical And Optical Systems, Technische Universität Berlin, Berlin/GERMANY

This paper describes different sensor types for integration into a minimally invasive instrument for laparoscopic robotic surgery. A bionic fiber sensor helps to avoid collisions between the instruments' arms and the abdomen during manipulation. Position measurement is included by means of magnetic sensors that deliver feedback signals for the drive mechanism. To provide the surgeon with a haptic feedback, two force sensors are studied to be incorporated into a single incision laparoscopic robotic instrument. Their individual characteristics and impact on haptic feedback are investigated, taking into account the individual sensors' locations.

SP073.6 - Development and Evaluation of an Open-Source 3D Virtual Simulator with Integrated Motion-Tracking as a Teaching Tool for Pedicle Screw Insertion

Author(s): <u>Stewart Mclachlin</u>, Brendan Polley, Mirza Beig, Jeremie Larouche, Cari Whyne

Sunnybrook Research Institute, Toronto/CANADA

Pedicle screw insertion techniques are traditionally taught with limited hands-on training, using artificial or cadaveric models, prior to guided supervision within the operating room. As residency programs move to competency-based curricula, more authentic and accessible teaching tools are required to train next generation spine surgeons. Virtual simulation can provide a valuable tool for practicing challenging surgical procedures; however, its potential depends on effective integration into student learning. The objectives of this work were to develop a freely accessible virtual pedicle screw simulator and to improve the clinical authenticity of the simulator through integration of low-cost motion tracking.

The open-source medical imaging and visualization software, 3D Slicer, was used as the development platform for the virtual simulation. 3D Slicer contains many features for quickly rendering and transforming 3D models of the bony spine anatomy from patient-specific CT scans. The virtual simulation needed to include both pre-operative planning and intra-operative pedicle screw insertion workflows. Pre-operative planning utilizes CT imaging to identify the vertebral levels requiring instrumentation and take anatomic measurements. The intra-operative screw insertion workflow requires identification of the correct entry point and trajectory to create a safe screw tract with a pedicle probe. This requires skill in complex 3D spatial perception and interpreting 2D images into real-world 3D positioning. To address this required skill development, virtual monitoring of the surgeon's simulated tool was assessed with a low-cost motion tracking sensor in real-time (~\$80, LeapMotion, San Francisco). This allowed a screw surrogate to be tracked as the surgeon defined the virtual screw's insertion point and trajectory on a 3D spine model.

Using a combination of existing and custom-written 3D Slicer Python scripts, an interactive virtual pedicle screw simulator was created. The surgical planning and operative screw insertion were simulated in a six step workflow: (1) identify vertebral levels on CT imaging, (2) choose the surgical region of interest, (3) select screw entry points, (4) take anatomic measurements, (5) define screw trajectory via the LeapMotion, and (6) grade final screw positioning. Initial surgeon feedback of the virtual simulator with integrated motion tracking was positive, with no noticeable lag and high accuracy between the real-world and virtual environments. The software yields high fidelity 3D visualization of the complex geometry and the tracking enabled coordination of motion to small changes in both translational and angular positioning.

The 3D Slicer-based virtual pedicle screw simulation overcomes accessibility issues of previously developed simulators by allowing distribution without the need for expensive commercial software. This will enable trainees to practice instrumentation techniques anywhere they have access to a computer. Further the interactivity provided by the low-cost LeapMotion represents a significant advancement in terms of the simulator's task authenticity. Future work will evaluate the benefit of this simulation platform with use over the course of resident spine rotations to improve planning and surgical competency and in quantitatively evaluating performance.

SP073.7 - A Robotic System with Ultrasound Imaging for Patient Setup and Monitoring during Fractionated Radiotherapy Author(s): Hasan T. Sen¹, Peter Kazanzides¹, Iulian Iordachita², Muyinatu A. Lediju Bell¹, Xiao Li¹, Lin Su³, Yin Zhang³, <u>Kai Ding</u>³, John Wong³

¹Department Of Computer Science, Johns Hopkins University, Baltimore/UNITED STATES OF AMERICA, ²Department Of Mechanical Engineering, Johns Hopkins University, baltimore/UNITED STATES OF AMERICA, ³Department Of Radiation Oncology, Johns Hopkins Univesity, Baltimore/UNITED STATES OF AMERICA

We are developing a cooperatively-controlled robot to assist with the application of ultrasound for patient setup and treatment monitoring of abdominal organs during fractionated radiotherapy. The proposed workflow introduces the robot for both simulation and treatment. During simulation, the operator places the 3D ultrasound (US) probe to visualize the target and the probe pose (position and orientation, in room coordinates) is measured by a ceiling-mounted optical tracker. The robot then holds a model probe at this pose during CT acquisition, and also records the probe contact force. The model probe has the same dimensions as the US probe but does not contain any metal parts that would cause CT artifacts. Treatment planning is performed on this CT image with probe-induced deformation. On each treatment day, the robot assists the operator to place the probe at the same pose and contact force as simulation. This cooperative control mode is enabled by a force sensor mounted between the robot end-effector and probe, which measures forces applied on the probe. Virtual springs guide the operator toward the recorded pose, but the operator can pull against the springsto override the recorded pose and replicate the US image

recorded during simulation. This may be necessary to compensate for patient setup errors or anatomical changes. Once the US probe is placed to match the simulation conditions, it can provide real-time monitoring during radiation delivery.

We performed canine experiments using a custom robot that had five active degrees-of-freedom (DOF) and eight passive DOF. In these experiments, three 2.38 mm spherical metal markers were implanted into the kidney of a canine. We followed the proposed workflow for simulation and six fractionated treatments, except that we acquired additional images to measure the markers. Our results showed that placing the US probe at the same pose (in room coordinates) can result in soft-tissue setup errors of up to 35 mm, even after employing conventional setup procedures. The large inter-fraction variation is due primarily to the difficulty in repeatably repositioning the anesthetized canine. In contrast, the virtual springs enabled the operator to override this pose based on US image feedback and reduce the setup error to within 7 mm. Our experiments also revealed ergonomic challenges, especially because the robot had fewer than six active DOF. We are therefore updating the design to use a commercial 6 DOF robot (UR5, Universal Robots, Odense, Denmark), as shown in Fig. 1.

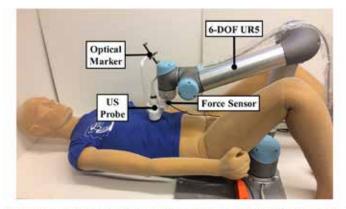

Figure 1: URS robot with force sensor for cooperatively controlled placement of ultrasound (US) probe for patient setup and treatment monitoring during fractionated radiotherapy

SP074 - Biomedical Monitoring and Bioelectromagnetism

TRACK 09: BIOSIGNAL PROCESSING

SP074.1 - Towards Dual Respiratory and Cardiac Gated Radiotherapy

Author(s): <u>Kirpal Kohli</u>¹, Feng-Yu Liu¹, Kalpagam Krishnan¹, Devin Schellenberg², Ash Parameswaran³, Steven Thomas⁴, Anand Karvat² ¹Medical Physics, BC Cancer Agency, Surrey/BC/CANADA, ²Radiation Oncology, BC Cancer Agency, Surrey/CANADA, ³Simon Fraser University, Burnaby/CANADA, ⁴BC Cancer Agency, Vancouver/ CANADA

Gating provides a potential solution for managing organ displacement during radiation treatment. In particular, respiratory gating of radiation therapy is an evolving field of study [1,2]. Cardiac gating, meanwhile, remains a largely unexplored area of potential benefit. Electrical impedance measurement has demonstrated its potential application in gating. In the present study, the respiratory and cardiac traces of three healthy human volunteers were recorded by using bioimpedance based simultaneous respiratory and cardiac monitoring circuitry developed in our previous study [3]. Each subject was instructed to maintain a normal breathing rate and hold their breath for a fixed duration. Respiratory motion was also monitored simultaneously using the existing Real-time Position Management[™] (RPM) system for validating the impedance trace based on the respiratory motion. Interference caused by the respiratory motion was observed on the recorded cardiac induced bioimpedance change. Comparison of the cardiac traces for both normal breathing and breath holding revealed that the amplitude of the cardiac trace appeared to be modulated by the respiratory pattern. For the signal traces to be potentially applicable for gating purposes, it is desirable that the rendered signal waveform has stable amplitude. The aim of the study is thus to develop a strategy for improving the usability of the cardiac induced bioimpedance trace for radiotherapy gating purposes. A strategy is developed for largely removing the interference in the cardiac signal caused by the respiratory motion based on amplitude demodulation. The following Figure 1 shows a sample bioimpedance trace of recorded respiratory and cardiac motions, together with the amplitude demodulated cardiac trace.

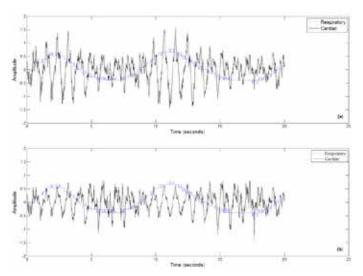

Figure 1: (a) Respiratory trace and cardiac trace of a volunteer subject breathing at a normal rate; (b) the same respiratory trace and the corresponding amplitude-demodulated cardiac trace.

The present study focuses on analyzing the correlation between the cardiac induced and respiratory induced impedance changes recorded and deriving a numerical technique for reducing the fluctuation in the amplitude of the cardiac signal. The technique developed will contribute to the potential application of bioimpedance signal on gating of radiotherapy.

SP074.2 - A mobile terminal to follow-up the evolution of chronic diseases

Author(s): <u>Hector Torres</u>, Rene Gonzalez, Daniel Campillo, Eyglis Ledesma

Medical Equipment Development, Central Institute of Digital Research, La Habana/CUBA

This paper presents the firmware design of a low cost and consumption portable device intended to collect (Bluetooth) and transmit (GSM/GPRS) biological signals to a website. This solution forms part of an ambulatory monitoring system for patients with related heart diseases like arrhythmia, hypertension and diabetes, giving a more close interaction between patients and doctors. The hardware is based on the MSP430F5419A microcontroller, the CC2540 Bluetooth Low Energy (both from Texas Instruments), and the SIM908 GSM/GPRS/GPS modem from Simcom. The real time operating system FreeRTOS was used in the firmware. QRS complexes are detected and processed in the ECG wave signal; blood pressure and glucose level are processed as well. A robust communication protocol was implemented and an easy graphical user interface also. A total of 50 different samples were uploaded to the website using developed prototypes in a safety way. This is an interesting solution to have into account in this kind of systems due to its low cost.

SP074.3 - Relationship between the tuning characteristics of stimulus frequency otoacoustic emissions and behavioral tests at moderate levels

Author(s): Yao Wang¹, <u>Qin Gong¹</u>, Tao Zhang² ¹Biomedical Engineering, School of Medicine, Tsinghua University, Beijing/CHINA, ²Tsinghua National Laboratory for Information Science and Technology (TNList), Beijing/CHINA

Frequency selectivity, the ability of the auditory system to resolve the frequency components of complex sounds, is typically estimated in humans using a subjective method, the measurement of psychophysical tuning curves (PTCs).Stimulus frequency otoacoustic emission suppression tuning curves (SFOAE STCs) potentially could assess frequency selectivity objectively. We compared PTCs and SFOAE STCs in 24 normal hearing subjects using moderate-level probes with center frequencies near 1, 2, and 4 kHz, showing that both measures of frequency selectivity are similar.

SP074.4 - An Axon Mimic for Medical Electrode Tests

Author(s): <u>Malcolm A. Latorre</u>¹, Adrian D.C. Chan², Karin Wårdell¹ ¹Department Of Biomedical Engineering, Linköping University, Linköping/SWEDEN, ²Department Of Systems And Computer Engineering, Carleton University, Ottawa/CANADA

Tissue's heterogeneity makes it ineffective as a test bench and calibration standard for biomedical electrodes. There is a need for an axon mimic that can generate a stable, repeatable, programmable, and physiological A-fiber like action potential (AP). The aim of the project is to assess an electronic A-fiber like system for its potential use as a biomedical electrode test bench.

An equivalent 40 nodes of Ranvier were mimicked using resin embedded gold wire ($\emptyset = 20 \ \mu m$). All nodes share one amplitude con-

trol (A) with programmable control for inter-nodal timing (t), duration (n) and propagation rate from a microcontroller running custom software. Statistically, a 20 μ m diameter A-fiber has characteristic inter-nodal spacing of 2 mm and propagation speed of about 120 m/s [1] which results in a 16 μ s increment time between activation of successive nodes. LabVIEW and DAQ from National Instruments (Version 8.2, National Instruments Corp. Texas USA) are used for acquisition and control. Custom software implements a simplified behavioral model based on Hodgkin and Huxley's equation [2] with a pulse train (|P(t)| propagating along the nodes.

The system was assessed by submerging the nodes in a bath of NaCl 0.9 % solution which acts as the intervening tissue mimic for testing. Data were collected using a pair of standard ECG-electrodes (4831Q, Unomedical a/s, Birkerød, Denmark) with gel removed. The electrode pair was used in a bipolar configuration positioned above the nodes. Fifty repeated measurements ($|P(\tau)|$) = 5, A = 1 V) verified the stability of the system where the time at maximum amplitude was tpk_max = 196.4 ± 0.06 ms, maximum amplitude was Vpk_max = 37.5 ± 1.3 µV, and noise floor was Vnoise = 0.07 ± 0.017 µV.

In conclusion, the system generated a traveling pulse, with programmable amplitudes, durations and times similar to those of a biological AP. The output is stable and repeatable, and most importantly can be coupled to bio-potential electrodes. This platform allows testing and comparisons between surface electrodes and some implantable electrode configurations, as well as general electrode verification, complete systems can also be tested and compared with this stable AP generator.

SP074.5 - Evaluation the Accuracy of Oscillometric Blood Pressure Measurement According to the AAMI SP10 Author(s): <u>Haiyan Xiang</u> Institute of Aviation Medicine, Beijing/CHINA

The auscultatory method is regarded as the golden standard in non-invasive arterial blood pressure measurement. The oscillometric method are used widely in most automated blood pressure measurement instruments recently. The limitation of oscillometric method is that both the systolic and the diastolic pressure are estimated using empirical criteria. In fact, there are large variance of the amplitude ratios among population. Therefore, the estimation of the systolic and diastolic blood pressure based on oscillomentic technique is not always accurate. In present study, an oscillometric method blood pressure measurement experiment system was established to acquire and analyze the blood pressure measurement data of the subjects with low, medium and high pressure. Eight-five subjects with a wide range of blood pressure were recruited. Each subject was measured three times. The experiment system acquires the cuff pressure and the oscillometric pulse. The manual auscultation measurement was performed on the same-limb simultaneously by two trained observers. The data were analyzed using self-programmed analyzing software based on Matlab. The averages of systolic and diastolic ratios are 0.50 and 0.71 respectively. Both the systolic and diastolic ratios fluctuate in a wide range, especially for the subjects with higher or lower blood pressure. Based on the golden standard, the accuracy of oscillometric method would not be generally accepted for the subjects with a wide range blood pressure.

SP074.6 - PEMF effects on chondrocyte cellularity and gene expression of the rat distal femoral metaphyseal articular cartilage.

Author(s): <u>Fernando Sotelo-Barroso</u>¹, Karla S. Vera-Delgado¹, Elena M. Castro-Rodríguez², Cipriana Caudillo-Cisneros¹, Sergio Marquez Gamino¹

¹Ciencias Aplicadas Al Trabajo, Universidad de Guanajuato, Leon/ MEXICO, ²Centro De Investigaciones Biomédicas, Universidad de Colima, Colima/MEXICO

In recent years, interactions between electromagnetic fields and biological systems have increasingly been studied. To date, pulsed electromagnetic fields (PEMF) have a number of well-documented physiological effects on cells and tissues; including the up regulation of gene expression of the transforming growth factor beta super family members, the increase in glycosaminoglycan levels, and anti-inflammatory actions. The purpose of the current study was to determine the effect of PEMF on the rat distal femoral joint cartilage, in terms of chondrocytic gene expression level and celullarity. Twenty female 84 days old Wistar rats, were randomly assigned into two groups: the experimental group received focused PEMF (30 mT/1 Hz/30 min/20 days) on the knee (MS). The control group (Non-MS), was managed similarly, except that PEMF stimulation was simulated. All the animals were euthanized for histological and gene expression evaluation of the knee joint tissues; 6 µm cartilage longitudinal sections were obtained from formalin fixed and paraffin embedded (FFPE) samples, then stained with a hematoxilineeosine technique. The sections were analyzed in a light clear field microscope in order to quantify the number of chondrocytes per optical field. To determine the expression levels of collagen type XI alpha 2 (col11a2), (sex determining region Y)-box 6 (Sox6), aggrecan (Acan), runt-related transcription factor 2 (Runx2), and alkaline phosphatase liver/bone/kidney (Alpl), total RNA was isolated by a FFPE RNAeasy Kit. For each sample RNA was reverse transcribed using oligo dT as primer. Real time PCR reactions were performed from 50 ng of cDNA. Statistically significant differences were found in joint cartilage cellularity when MS and Non-MS were compared $(101.13 \pm 26.61 \text{ vs } 69.66 \pm 15.55 \text{ cells per optical field, respectively;})$ p = 0.001). Collagen XI, Sox6 and Aggrecan expression levels were also different in magnetically stimulated tissues relative to control (Differences were evaluated by Student'st test and were considered as significant when p < 0.05). On the other hand RUNX2 and ALPL expressions showed no significant differences between groups (Student's t test, p > 0.05). These results are evidence that in vivoPEMF stimulation increases the number of well differentiated knee joint cartilage cells in healthy young adult rats. This finding indicates an in vivo trophic effect upon cartilage joint tissue. The action mechanisms could be associated to electrical characteristics of cartilage cells and could be related to new matrix production. The low gene expression of RUNX2 and ALPL supports that the chondrocytic response to PEMF do not correspond to a hypertrophic reaction. These results highlight the possible therapeutic future of PEMF in cartilage injuries, and on its ageing.

SP074.7 - Classification of responders versus nonresponders to tDCS by analyzing voltage between anode and cathode during treatment session

Author(s): <u>Isar Nejadgholi</u>¹, Travis Davidson², Cryatal Blais³, Francois Tremblay², Miodrag Bolic¹

¹School Of Electrical Engineering And Computer Science, University of Ottawa, Ottawa/CANADA, ²School Of Human Kinetics, University of Ottawa, Ottawa/CANADA, ³Nuraleve Inc., Ottawa/CANADA

Transcranial direct current stimulation (tDCS) has been shown to be beneficial as a potential treatment of several disorders such as depression, addiction and chronic pain. Despite promising results reported in research, there is variability in responsiveness to tDCS among subjects. However, the source of this variability is still

unknown. Creating a mechanism of determining non-responders (vs. responders) is a crucial step in order to either understand the physiology behind tDCS or increase the effectiveness of treatment. This work proposes a versatile method to predict whether a subject responds to tDCS by analyzing the voltage measured between anode and cathode during a tDCS session. Two groups of subjects are determined as responders and non-responders by assessing the effect of tDCS on their motor potential evoked by transcranial magnetic stimulation (TMS). Voltage measurements are modeled by a double Debye model and two relaxation times are extracted for each measurement. A quadratic classifier is trained to recognize responders and non-responders based on these relaxation times. Our classification results show that there is a significant correlation between relaxation times extracted from voltage and responsiveness to tDCS determined through motor evoked potentials. These results suggest that the relative speed of polarization processes occurring in electrodes and tissue may be associated the amount of current delivered to the brain.

SP074.8 - Matlab toolbox for bioelectric cardiac images analysis Author(s): Juan Alberto L. Cruz, Maycon Emely F. Farias Ribeiro, Ernando S. Ferreira

Department Of Physics, State University of Feira de Santana, FEIRA DE SANTANA/BRAZIL

The heart problems are recognized by the World Health Organization as a major cause of death of human beings. Supported by the concepts of bioelectricity is now possible to better understand the functioning of this organ. In the medical physics research is a priority not to study only new equipment to detect these biosignals, but also new paradigms for processing, allowing the extract improve information of heart activity. We describe isECG (Imaging System for Electrocardiography), a new MATLAB processing toolbox, for bioelectric cardiac image analysis. Using real data (magnetic resonance images and ECG data from 123 bioelectrodes from an anonymous patient) the 3D-realistic heart/thorax geometry, surface ECG-bioelectric potential mapping on torso and myocardium surface potential images were constructed. Specialized routines are available for solution the direct and inverse bioelectric problem, and the results displayed in visualization panels (windows) on the main graphical interface. All ECG bioelectrical potentials signals, are show in new graphical window, and permit it is analysis for an individual ECG signal. Preliminary results demonstrated that isECG is a toolbox that can be used for analysis and visualization of cardiac bioelectric images, and has shown promise for future studies in Bioelectromagnetism.

SP075 - SPECIAL SESSION: Appropriate Technology in Imaging and Radiotherapy - Functionality and Safety Aspects

TRACK 17: EDUCATIONAL AND PROFESSIONAL ACTIVITIES

SP075.1 - Appropriate technology in imaging and radiotherapy -Functionality and Safety aspects

Author(s): <u>Kin-Yin Cheung</u>¹, Adriana V. Berumen², Miriam Mikhail Lette², Joanna Izewska³

¹IOMP, Happy Valley/HONG KONG, ²WHO, Geneva/SWITZER-LAND, ³IAEA, Vienna/AUSTRIA

Every country faces resource constraints of some degree insofar as provision of healthcare services, a particularly critical problem in low-resource settings and in view of the rising trend of non-communicable diseases. 70% of cancer-related deaths occur in resourceconstrained settings that request access to quality and affordable technologies. In low and middle income (LMI) countries, such medical services for underserved populations are mainly provided by governments. The IAEA/WHO Directory of Radiotherapy Centres (DIRAC) indicates major radiotherapy equipment shortages in these countries. WHO data in the World Health Statistics describe the corresponding census of diagnostic and therapeutic radiation technologies and services. Prioritizing appropriate selection, allocation, use, provision and optimization of cost-effective health technologies and human resources is therefore necessary. Important elements when formulating policy for planning and procurement of healthcare technologies must take into account high cost imaging and radiotherapy equipment, and should be based upon needs assessments and country specific criteria to include compatibility with clinical needs and burden of disease, radiological safety, standard of service and practice, affordability, sustainability, minimum operating requirements, long term functionality in LMI settings in terms of working conditions and infrastructure, and access to maintenance. International guidelines, recommendations, and reports such as produced by the IAEA and WHO can be used in support of planning radiation medicine services. One particular IAEA initiative aims to propose affordable, appropriate and suitable radiotherapy equipment packages and solutions for LMI countries through an IAEA Advisory Group on Increasing Access to Radiotherapy Technologies in Developing Countries (AGaRT), promoting increased access to diagnostic and therapeutic technologies in LMI countries by encouraging the industry to offer complete and integrated solutions that are safe, affordable, highly reliable and effective for low resource settings. WHO has been advising governments for many years in the incorporation of health technologies, including for diagnostic imaging and radiotherapy. For example, the WHO has recently embarked upon a project to list priority medical devices needed for the continuum of clinical management of six highly prevalent cancers, including radiation technologies. WHO is also conducting a Global Initiative on Radiation Safety in Health Care Settings to promote safe and appropriate use of radiation in healthcare. Ten priority actions have been identified in the "Bonn Call for Action" to improve safety and quality in the medical use of radiation for diagnosis and therapy, jointly published by the IAEA and WHO in 2014; engagement of all relevant medical sector stakeholders is warranted to support implementation. The synergies between IOMP, IAEA, WHO and others can enhance the availability of these technologies. Keeping in mind that technology planning criteria are country specific and dynamically change over time as healthcare services and technologies evolve, this joint session provides an excellent forum for global healthcare professionals and experts from international organizations to exchange ideas and experiences, and explore ways of addressing challenges faced during planning and acquisition of appropriate healthcare technologies.

SP076 - Radiobiological Modelling

TRACK 19: BIOPHYSICS AND MODELLING

SP076.1 - Radiation Pneumonitis and Low Dose Radiation Hypersensitivity

Author(s): J. James Gordon¹, Karen C. Snyder¹, Hualiang Zhong¹, Ken Barton¹, Zhen Sun¹, Indrin J. Chetty¹, Martha Matuszak², Randall K. Ten Haken²

¹Radiation Oncology, Henry Ford Health System, Detroit/MI/UNITED STATES OF AMERICA, ²Radiation Oncology, University of Michigan Health System, Ann Arbor/MI/UNITED STATES OF AMERICA

Analysis of a University of Michigan (UMich) clinical trial dose-volume histogram (DVH) dataset is summarized, the goal of which was to improve radiation pneumonitis (RP) prediction. A family of dose-damage profiles featuring low-dose radiation hypersensitivity (RHS) achieved higher predictive accuracy than mean lung dose (MLD), motivating a novel RHS normal tissue complication probability (NTCP) model. Results of this model are summarized. If one makes reasonable assumptions regarding the institution-specific DVH mix, the model can reproduce published MLD – RP risk curves obtained in clinical trials at Duke University, Netherlands Cancer Institute (NKI), Washington University (WU) and the University of Milan (UMilan).

SP076.2 - Dose distribution optimization methods based on biological parameters: Impact of the objective function and reoxygenation and proliferation effects

Author(s): <u>Araceli Gago Arias</u>¹, Andrés Pérez¹, Beatriz Sanchez Nieto¹, Juan Pardo Montero², Christian Karger³, Ignacio Espinoza¹ ¹Instituto De Física., Pontificia Universidad Católica de Chile, Santiago/CHILE, ²Servizo De Radiofísica E Protección Radiolóxica, Complexo Hospital Universitario de Santiago de Compostela, Santiago de Compostela/SPAIN,³Department Of Medical Physics In Radiation Oncology, German Cancer Research Center (DKFZ), Heidelberg/ GERMANY

The non-uniform response of tumors to radiation may compromise radiotherapy treatment outcome when homogeneous dose distributions are used. Responsible for this behavior are mainly the inhomogeneous distributions of oxygen and clonogenic cell density within the tumor. To approach these issues, the delivery of inhomogeneous dose distributions was long ago proposed to increase the efficiency of radiotherapy.

Dose prescription is normally addressed as an optimization problem involving an objective function, OF. Two of the most frequently used OFs aim to: i) maximize the tumor control probability, which is equivalent to minimize the tumor cells survival or ii) seek a uniform density of surviving clonogens.

The published works applying any of these two approaches were implemented using different dose redistribution techniques (subvolume dose boosting, dose painting by numbers) to tumors with distinct radiosensitivity inhomogeneities. Furthermore, they analyzed the impact of different biological factors or employed mathematical tumors modeling these processes in different ways.

This work studies different methods of dose distribution optimization analyzing the above-mentioned OFs under a common methodology. Effects related to the dose heterogeneity allowed in the distribution and the impact of biological processes like reoxygenation and tumor cell proliferation are also studied. The response of a 2-cm-diameter hypoxic Head-and-Neck virtual tumor to radiotherapy was simulated using a previously published mathematical model [Med Phys. 2015 Jan; 42(1):90]. The model considers the following biological processes: tumor cells proliferation, neo-angiogenesis, diffusion-limited hypoxia, oxygen-dependent cell killing due to radiation, resorption of dead cells, tumor shrinkage and reoxygenation.

A dose painting by numbers approach was chosen to redistribute the dose keeping the average dose delivered to the tumor equal to 2 Gy per fraction.

The impact of the different OFs and dose heterogeneity constraints on treatment outcome was first isolated from other effects. At this stage no tumor cell proliferation was simulated and the tumor oxygenation status was considered to remain constant throughout the treatment. Dose distributions derived for fraction-by-fraction optimizations led to equal treatment outcomes for both OFs. In the dose distributions, the dose modulation was allowed to vary within a 10%, 25%, 35% and a 50% of 2 Gy per fraction. This led to a reduction of 3, 7, 8 and 10, respectively, in the number of fractions needed to achieve tumor control.

Dose distribution optimizations were then performed for a dose heterogeneity limit of 25% of 2 Gy simulating the tumor response considering all the abovementioned biological processes. The effect of changes in the tumor cell proliferation rate was studied for tumor cell doubling-times ranging from 50 to 5 days, including an accelerated repopulation regime arising after two weeks of treatment. The highest therapeutic gain from dose painting was achieved for the simulations with the highest proliferation rate (reduction of 13 fractions compared to the case using uniform dose). When accelerated repopulation is considered, the number of fractions needed to achieve tumor control was lowered from 34, for uniform dose distributions, to 23. The work shows that reoxygenation and tumor cell proliferation play an important role in the simulation of dose-painting.

SP076.3 - Healthy Tissues in The Present of Gold Nano Particles against 103Pd and 125I: Monte Carlo study Author(s): Mohammad Vahidian, <u>Somayeh Asadi</u>, Mehdi Vaez-Zadeh, Mahdieh Marghchouei

Physics, K.N.Toosi University of Technology, +/IRAN

The aim of the present Monte Carlo study is to evaluate the method of variation of energy deposition in healthy tissues in the human eye which is irradiated by brachytherapy sources in comparison with the resultant dose increase in the gold nano particle - loaded choroidal melanoma. The effects of GNPs on healthy tissues are compared between ¹⁰³Pd and ¹²⁵I as two ophthalmic brachytherapy sources. To this end, Human eye globe was simulated through the use of MCNP5 code by considering all parts of the eye. Dose distribution in healthy tissues and dosimetry differences in the eye phantom with existing tumor have been taken into account for both mentioned brachytherapy sources. In addition deviances observed in the comparison of simple water phantom and actual simulated eye in present of GNPs are also a matter of interest that has been considered in the present work. Hear, both water and eye phantoms were simulated in which the water phantom was the same as the eye phantom with the exception that, water was considered to be the eye composition in all parts of the human eye globe. The previous studies which compared the ophthalmic brachytherapy dosimetry between these two sources reported higher absorbed dose by the tumor for ¹⁰³Pd versus ¹²⁵I for an equivalent radiation time. However, the results of this study show that the calculated dose enhancement factor in the tumor for ¹²⁵I is higher than that of for ¹⁰³Pd. Also, the ratio of the absorbed dose by healthy tissues in the present of GNPs to the absorbed dose by the tumor for¹⁰³Pd is lower than that

of for ¹²⁵I.Choose of the optimum size and concentration for GNPs and also the suitable brachytherapy source to achieve the maximum dose in the tumor area and the minimum dose to healthy surrounding tissues need to more practical investigations which is under study and will report in future.

SP076.4 - Monte-Carlo model development for evaluation of current clinical target volume definitions for Glioblastoma using Boron Neutron Capture Therapy

Author(s): Leyla Moghaddasi, Eva Bezak, Wendy Harriss-Phillips Department Of Medical Physics, Royal Adelaide Hospital, Adelaide/ SA/AUSTRALIA

Introduction: Glioblastomas (GBM) are notorious for their extensive diffusion and high fatality rate. Boron Neutron Capture Therapy (BNCT) is a biochemically-targeted type of radiotherapy where thermal neutrons are captured by¹⁰B, resulting in the emission of high LET α -particles and recoiling ⁷Li atoms. BNCT has the potential to selectively deliver localized dose to tumour cells diffused into normal brain tissue, with minimal normal tissue toxicity. The aim of the current work is to develop a GBM model, taking into account cellular composition of brain with addition of appropriate ¹⁰B concentrations, to determine optimal Clinical Target Volume (CTV) margins for BNCT. It also aims to investigate the effectiveness of GBM cell death (i.e. in the presence of hypoxia and genetic heterogeneity) following BNCT.

Methods: A neutron beam model was developed in

GEANT4.9.6.p02 and verified against published data. The neutron beam spectrum was obtained from literature for a cyclotron-produced beam. The calculated percentage depth dose curves (PDDs) in water were compared with measured data to verify the neutron beam in terms of total depth dose and boron dose deposition. The GBM model was structured as follows: firstly, Microscopic Extension Probability (MEP) models were developed using MATLAB-2012a, based on clinical studies reporting on GBM clonogenic spread. Typical ¹⁰B concentrations in GBM and normal brain cells were obtained from literature. Each cell was then assigned a ¹⁰B concentration depending on its MEP status. Secondly, a Geant4 microdosimetry model was developed to calculate the dose deposited in individual voxels, each representing a GBM/normal cell; the system was defined as a cubic phantom voxelized to 20 um side voxels (the average size of glioma cells) and irradiated with an epithermal neutron beam. The material of each voxel was set to brain (ICRP-based NIST database) with added boron atoms from the ¹⁰B distribution imported from MATLAB. Results from the microdosimetry model and the MEP models were convolved to evaluate survival fractions (SF) for CTV margins of 2.0 & 2.5cm.

Results & Conclusion: Excellent agreement was achieved between the calculated and measured neutron beam PDDs (within 1%) (Figure 1). The resulting boron depth dose deposition was also in agreement with measured data. Ongoing work is focusing on determination of tumour cell SF following BNCT as a function of various MEP models and ¹⁰B concentrations.

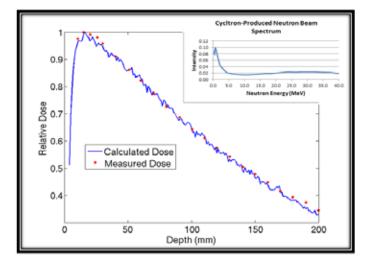

Figure1Comparison of calculated and measured total PDDs of a neutron beam in water (Insert: the neutron beam spectrum).

SP076.5 - Exploring RBE Dependence on Proton Track Angular Incidence

Author(s): <u>Piotr Pater</u>¹, Gloria Bäckström¹, Fernanda Villegas-Navarro², Anders Ahnesjö², Shirin A. Enger¹, Jan Seuntjens¹, Issam El Naqa¹

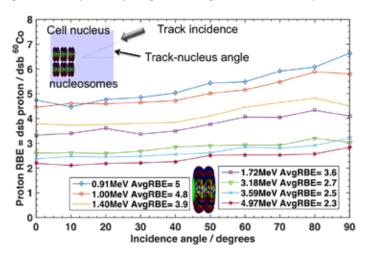

¹McGill University, Montreal/CANADA, ²Uppsala University, Uppsala/SWEDEN

The relative biological effect (RBE) of protons, taken as the ratio of double strand break (dsb) yields for an investigated radiation source to the yields by ⁶⁰Co, can be computed by overlaying event-by-event Monte Carlo (MC) particle tracks on a cell nucleus model. Strand breaks (sb) occur when energy depositions (ED) sites coincide with the DNA sugar-phosphate backbone. Dsbs are then modelled as arrangements with at least one sb on each strand within 10 base pairs (bp). Human DNA is tightly packed into higher order structures including chromosomes, chromatin fiber, and nucleosomes (beads on a string configuration).This work compares proton RBE for different angular orientations of nucleosomes relative to incident charged particle tracks within a cell nucleus model.

The MC code LlonTrack (Med.Phys.2013;**40**(6)) was used to generate proton (~1-5 MeV) and ⁶⁰Co ED tracks, including all secondary electrons (tracking cutoff of 50 eV). ED sites were subsequently overlaid on a simplified cylindrical cell nucleus (~2 um radius and half-height) at track-nucleus angles from 0 (normal incidence) to 90 degrees (parallel to nucleus axis). Fractions of ~2 Gy were simulated at each angle for each source. A nucleosome, consisting of a 2-turn, double stranded, and circular arrangement of 99 bps, is replicated in an ordered fashion approximately 3x10⁷ times in the nucleus and dsbs yields are computed for each fraction.

For ⁶⁰Co, no angular dependence was detected and the 95% confidence interval on the average angular dsb yield was [2.50 2.65] dsb Gy⁻¹ cell⁻¹, which was used as the reference to calculate RBE for protons. RBE was larger than one at all proton energies and incidence angles, with two significant trends As expected, the RBE increased with decreasing proton energy. However, RBE also significantly depends on the track-nucleus angle, due to a preferential track alignment with the nucleosomes at higher angles, but also to a higher probability of traversing the nucleus without hitting any DNA targets. For 1 MeV protons, the spherically weighted average RBE is 7 % higher and 22 % lower than the RBE for 0 and 90 degrees respectively. When simulating RBE, angular dependence of the dsb yields due to the nucleus model chosen should be investi-

gated and a spherically weighted average RBE should be reported.

SP076.6 - DNA Damage Induced in Glioblastoma Cells by I-131: A Comparison between Experimental Data and Monte Carlo Simulation

Author(s): Fereshteh Koosha

Medical Physics And Biomedical Engineering, Tehran university of medical sciences, tehran/IRAN

Objective: The passage of ionizing radiation in living cells creates clusters of damaged nucleotides in DNA. In this study, DNA strand breaks induced by the beta particle of iodine-131 (I-131), have been determined experimentally and compared to Monte Carlo simulation results as a theoretical method of determining1311 damage. Materials and **Methods:** For conducting this experimental study, Glioblastoma (GBM) cells were exposed to 10 mCi I-131, at a dose of 2 Gy, in order create single strand breaks (SSB) and double strand breaks (DSB) in the DNA of irradiated cells. Cells were evaluated quantitatively by the Fast Micromethod assay. The energy spectrum of electrons released in cells were obtained by the macroscopic Monte Carlo code (MCNP4c) and used as an input of the micro Monte Carlo code (MCDS). The percent of damage induced in cells was calculated by Manvitny test.

Results: A significant reduction (p<0.05) in fluorescence intensity in irradiated cells compared to control cells as determined by the Fast Micromethod assay represented induced SSB and DSB damages in the DNA of irradiated cells. By comparing the experimental and theoretical results, the difference between the percent of SSB per Gy was about 7.4% and DSB was about 1% per Gy.

Conclusion: The differences in experimental and theoretical results may be due to the algorithm of applied codes. Since the Fast Micromethod and other experimental techniques do not provide information about the amount of detailed and complex damages of DNA- like base damages, the applied Monte Carlo codes, due to their capability to predict the amount of detailed damages that occur in the DNA of irradiated cells, can be used in in vitro experiments and radiation protection areas.

SP076.7 - The stochastic extension of the Linear Quadratic model: Taking into account the uncertainty of radiobiological parameters.

Author(s): <u>Moises Saez-Beltran</u>¹, Francisco Saez-Beltran², Francisco Fernandez Gonzalez³

¹Servicio De Radiofisica Y Protección Radiologica, Complejo Asistencial Universitario de Salamanca, Salamanca/SPAIN, ²Servicio De Radiofísica, Complejo Asistencial de Zamora, Hospital Provincial, Zamora/SPAIN, ³Instituto Universitario Física Fundamental Y Matemáticas, Universidad de Salamanca, Salamanca/SPAIN

Introduction

We show the way to modify the Linear Quadratic model of cell survival used in Radiation Oncology to accommodate uncertainty in the radiobiological parameters (α , β). The objective is, given the probability distribution functions of α and β , find the probability distribution function of the biological equivalent dose, BED, and the probability of cell survival, p. And furthermore, find how this uncertainty propagates through a fractionation scheme. In this paper we show that this can be done in an explicit way without simulation.

Materials and Methods

The stochastic extension of the Linear Quadratic model consist in promoting α , β , p, BED from single value variables to random variables α , β , p, BED. The delivered dose per fraction, d, is considered as a non-random parameter. For a single fraction, there is an analytical relationship between α , β and BED and p, so we can use the rules of probability to get a formula to obtain the probability distribution functions of p and BED from the corresponding probability distribution functions of α , β . For a fractionation scheme of dose, we have to consider sums of stochastic variables, that involves repeated convolutions of probability functions.

Results

If we define equivalent treatments in the mean, for different fractionation schemes, we can recover the formulas of the usual Linear Quadratic model, substituting a, β by the expected value <a>, < β >. The variance of these treatments can also be shown to be different whenever the variance of a or β is different from zero. For a number of fractions large enough, **p** can be regarded as a log-normal stochastic variable, due to the central limit theorem.

Discussion

We have described a analytical way to take into account the uncertainty of radiobiological parameters as probability distribution functions into the Linear Quadratic model, without Montecarlo simulation. This higher level of complexity gives in return better information of the effect of this uncertainty on the treatment outcome. Whether these stochastic extensions may explain data variability better than any more sophisticated "non-stochastic" radiobiological model is yet a matter of experiment.

SP077 - Radiation Oncology

PRESIDENTS CALL

SP077.1 - Assessment of CT to CBCT Non-Rigid Image Registration in Prostate Cancer Radiation Therapy Author(s): <u>Pawel Siciarz</u>

Medical Physics, CancerCare Manitoba, Winnipeg/CANADA

Purpose: The goal of this project was to investigate the performance of three image registration algorithms implemented in two open source platforms: 3DSlicer and MedInria.

Material and Methods: The study describes CT to CBCT deformable registration by the application of following algorithms: two well known Affine and Fast Symmetric Forces Demons (3DSlicer) as well as Dense Anatomical Block Matching (MedInria) that is based on pyramidal block-matching approach. To the best of author knowledge it is the first study which attempts to investigate the performance of Dense Anatomical Block Matching Algorithm (DABM) for CT to CBCT deformable registration.

Pre-treatment CT (pCT) images of five prostate patients undergoing IMRT were selected for this work. Representative CBCT data sets were acquired in the middle of the radiotherapy treatment to provide the algorithms with realistically challenging registration problem. Deformable registration for each algorithm was followed by the initial Affine alignment of considered images. After registration, structures (GTV, Bladder and Rectum) delineated on pCT were first deformed using obtained vector fields, next propagated to CBCT images and finally compared to the contours delineated on CBCT by experienced Radiation Oncologist. The similarity between deformed CT (dCT) and CBCT images was also analysed.

Accuracy of registration was assessed by the application of the following metrics: Dice Coefficient and Mean Hausdorff Distance for structures comparison as well as voxel-to-voxel absolute intensity difference for dCT-CBCT images comparison. For visualization and better understanding of these numerical values author propose to present differences between considered organ contours as a surface map reflecting surface-to-surface distances for the closest neighbouring points. The map of absolute discrepancies in image intensity between dCT and CBCT for selected image slices are also provided.

Results: Early results clearly indicates very promising performance of Dense Anatomical Block Matching method for challenging non-rigid pCT-to-CBCT registration compared to Affine and Demons algorithms which can be seen at the figure 1. This quick quality assessment is expected to be confirmed by more detailed analysis of proposed similarity metrics. Additionally, smooth and unfolding DVFDABM shows the lack of any unphysical deformations.

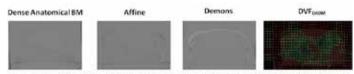

Figure 1. Image Subtraction (CBCT- registered image) for three registration algorithms and deformable vectorfield for Dense Anatomical Block Matching (DVF_{Datw}). SP077.2 - Use of flattening filter free photon beams for off-axis targets in conformal arc stereotactic body radiation therapy Author(s): <u>Ashley Smith</u>¹, Christopher Serago¹, Siyong Kim², Kathleen Hintenlang¹, Michael Heckman³, David Hintenlang⁴ ¹Radiation Oncology, Mayo Clinic, Jacksonville/UNITED STATES OF AMERICA, ²Radiation Oncology, College Of Medicine, Virginia Commonwealth University, Richmond/VA/UNITED STATES OF AMERICA, ³Biomedical Statistics And Informatics, Mayo Clinic, Jacksonville/UNITED STATES OF AMERICA, ⁴Biomedical Engineering, University of Florida, Gainesville/UNITED STATES OF AMERICA

Dynamic conformal arc therapy (DCAT) and FFF beams are commonly adopted for efficient conformal dose delivery in SBRT. Off-axis geometry (OAG) may be necessary to obtain full gantry rotation without collision, which has been shown to be beneficial for peripheral targets using flattened beams. We investigated dose distributions in OAG using FFF, and the effect of mechanical rotation induced uncertainty.

Sphere targets (2, 4, and 6 cm diameter) were placed at three locations (central axis, 3 cm, and 6 cm off-axis) in a representative patient CT set. DCAT plans were obtained for 6X, 6FFF, 10X, and 10FFF. Homogeneity index (HI), conformality indices (CI), and beam on time (BOT) were calculated. Mechanical rotation induced uncertainty was evaluated using five SBRT patient plans with laterally located tumors. For each, a plan was generated using FFF beams for OAG and CAG. Each was replanned to account for one degree collimator/couch rotation errors during delivery. Prescription isodose coverage, CI, and lung dose were evaluated.

HI and CI values were similar for flattened and unflattened beams; however, 6FFF provided slightly better values than 10FFF in OAG. For all plans HI and CI were acceptable with the maximum difference between flattened and FFF beams being 0.1. FFF beams showed better conformality for low doses and small targets. Variation due to rotational error for isodose coverage, CI, and lung dose was generally smaller for CAG compared to OAG, with some of these comparisons reaching statistical significance. However, variations in dose distributions for either technique were small and not clinically significant.

FFF beams showed acceptable dose distributions in OAG. 10FFF provides more dramatic BOT reduction, but generally provides less favorable dosimetric indices compared to 6FFF in OAG. Mechanical rotation induced uncertainty had an increased effect for OAG compared to CAG; however, variations for either treatment technique were minimal.

SP077.3 - Dosimetric evaluation of the interplay effect for non-gated VMAT treatment of moving targets with high dose rate FFF beams

Author(s): <u>Ashley Smith</u>¹, Christopher Serago¹, Kathleen Hintenlang¹, Siyong Kim², David Hintenlang³

¹Radiation Oncology, Mayo Clinic, Jacksonville/UNITED STATES OF AMERICA, ²Radiation Oncology, College Of Medicine, Virginia Commonwealth University, Richmond/UNITED STATES OF AMER-ICA, ³Biomedical Engineering, University of Florida, Gainesville/ UNITED STATES OF AMERICA

PURPOSE

Interplay effects exist between multi-leaf collimator movement and tumor motion when treating moving targets with intensity modulated radiation therapy. Dose deviations caused by the interplay effect can be decreased by reducing the dose rate. It is questionable whether flattening filter free (FFF) high dose rate will increase dose deviations caused by the interplay effect for volumetric modulated arc therapy (VMAT). This work evaluates the interplay effect using a moving phantom to simulate respiratory tumor motion for non-respiratory-gated VMAT treatment using FFF beams, and investigates the impact of dose rate.

METHODS

Two VMAT plans were selected from lung patients treated with 6 MV FFF beams. Dose distributions were measured using a 2D ion chamber array placed on a motor-driven motion platform. Respiratory phase was accounted for by dividing the breathing cycle into 8 equally spaced phases and irradiation was initiated at each of the phases. The 8 starting phases were used to simulate the clinical situation of starting the treatment at a random phase in the patient breathing cycle. All fields were delivered in their treatment geometries with and without phantom motion using 3 dose rates: 1400, 600, and 400 MU/min.

Measured dose was compared to planned dose using gamma analysis (3%/3mm), percent of pixels within 5% of pixel dose, and percent of pixels within 10% of pixel dose. Calculations were done for the 8 initial starting phases and repeated for a random sampling of starting phases for 1000 trials. Target coverage was evaluated by the dose difference for four points at the center of the target. Four points at the periphery of the target were used to evaluate planning target volume margin.

RESULTS

Results for 1000 trials of randomly selected motion phases are reported in Table 1. The delivered dose compared to planned dose in the center of the target region was within 5.0% for the static phantom condition and 7.4% for the moving phantom condition. At the periphery of the target the delivered dose differed from planned dose by -0.9% to 13% for the static condition and -28.8% to 39.7% for the moving condition.

CONCLUSION

Our results indicate the interplay effect had an impact on non-gated VMAT when treating a moving target with FFF, however using high FFF dose rate did not increase dose deviations compared to lower dose rates. The impact of the interplay effect on target coverage is acceptable, as long as sufficient margin is given.

Plan	Phantom	Dose Rate (MU/min)	Gamma 3%/3mm	Standard deviation	% of pixels within 5% of dose	Standard deviation	% of pixels within 10% of dose	Standard deviation

SP077.4 - In vivo Image Guided Brachytherapy Verification (IGBV) in high dose rate prostate brachytherapy – Initial Clinical Experience

Author(s): <u>Ryan L. Smith</u>¹, Annette Haworth², Jeremy L. Millar¹, Michael L. Taylor³, Rick D. Franich³

¹William Buckland Radiotherapy Centre, The Alfred Hospital, Melbourne/AUSTRALIA, ²Physical Sciences, Peter MacCallum Cancer Centre, East Melbourne/VIC/AUSTRALIA, ³School Of Applied Sciences, RMIT University, Melbourne/VIC/AUSTRALIA

Aim.

High dose rate (HDR) prostate brachytherapy treatment is widely practiced and is a well-established radiotherapy technique. Usually delivered in large dose fractions, poor execution in the delivery of a planned treatment would have significant clinical impact on the patient. The frequency and type of errors that may occur in HDR brachytherapy treatment are mostly unknown as there exist limited options for independent routine monitoring of treatment delivery to identify potential errors and ensure patient safety. We report our initial clinical experience with a novel, non-invasive, source-tracking system based on a flat panel detector (FPD) for treatment verification in HDR prostate brachytherapy: Image Guided Brachytherapy Verification (IGBV).

Materials & Method.

For IGBV, a FPD was mounted in our brachytherapy treatment couch under a customised carbon fibre couch top assembly. Six prostate patients (10 treatment fractions) were included in this clinical study of the IGBV system. At treatment, each patient was aligned on the brachytherapy couch with the target region (prostate) centred over the sensitive imaging area of the FPD. As the HDR treatment proceeded, images of the source position were acquired with the FPD in the form of patient exit radiation. These images were post-processed to determine the position of the source inside the patient and were compared to the treatment plan in order to identify potential errors and verify correct treatment delivery.

Results.

The measured source dwell positions confirmed correct transfer tube connection, afterloader indexer length, source step size and patient/plan selection. The mean linear distance between measured and planned source dwell positions was 2.37 mm (s.d. 0.96mm), after rigid registration with the treatment plan. The average dwell step size across all measured catheters was 2.54 mm (s.d. 0.24mm, n=112). The absolute position of the measured dwells, together with the implanted gold fiducial markers, visible on a pre-treatment radiograph, provided verification of programmed treatment indexer length and therefore delivery to the correct anatomical location. This unique brachytherapy verification process is non-invasive, with the patients virtually unaware of the verification imaging that is occurring during treatment delivery. The total impact on procedure time was less than 15 minutes.

Conclusion.

This novel, non-invasive HDR brachytherapy treatment verification system, IGBV, was implemented clinically, providing confirmation of many treatment parameters by tracking the position of the HDR source as treatment was delivered. An independent treatment monitoring system, such as the one described here, could validate the treatment delivery process in real time, enabling a safety interlock system. The clinical experience with the IGBV system provided confirmation that the treatment was delivered free of potential human related errors. This concept and system will meaningfully improve safety standards by allowing routine treatment verification in HDR brachytherapy across a range of clinical applications.

SP077.5 - Electronic Portal Imaging Device Dosimetry for IMRT: a Review on Commercially Available Solutions

Author(s): <u>Omemh Bawazeer</u>¹, Sisira Herath², Siva Sarasanandarajah¹, Pradip Deb¹

¹School Of Medical Radiation, RMIT University, Melbourne/AUS-TRALIA, ²Radiation Oncology, Peter MacCallum Cancer Centre, Melbourne/AUSTRALIA

Much research has been conducted about the utilization of electronic portal imaging devices (EPID) for dose verification during radiotherapy treatment. Currently a number of commercial solutions are available; Portal Dosimetry, EPIDose, Epiga, Dosimetry Check, and EPIgray software. Results from separate studies on clinical applications of these solutions are published. The objective of this paper is to review the accuracy of these dosimetry solutions when used for intensity modulated radiotherapy technique (IMRT). Although each solution has a different approach to dose verification, most of the IMRT dosimetry verification results are highly satisfactory. However, performance of one solution is less satisfactory when the patient-couch attenuation occurs. Moreover, none of these solutions correct the back scatter effect resulted from supporting arm. In addition, there are no comparative studies currently available about the accuracy of these solutions except one paper that compared Portal Dosimetry and EPIDose reporting the major differences between these systems. Further studies are needed to compare the accuracy of these commercially available EPID dosimetry solutions.

SP077.6 - The Nano-X Radiotherapy Machine: Lean Innovation Transforming Global Access to Cancer Care

Author(s): <u>Paul Keall</u>¹, Enid Eslick¹, Peter Lazarakis¹, Michael Jackson², Ilana Feain¹

¹Radiation Physics Laboratory, University of Sydney, University of Sydney/AUSTRALIA, ²University of New South Wales, Sydney/AUS-TRALIA

There are times in society in which problems with the descriptor "too hard to solve" can no longer be tolerated. The International Cancer Expert Corps, 2014

Time and Place

Radiotherapy is the recommended treatment for half of all cancer patients. Yet, access to radiotherapy is non-existent in 55 countries around the world and limited in most others, especially in regional and rural centres. Epidemiological studies prove an urgent need for 9,000 additional radiotherapy machines to treat a rising global cancer epidemic (International Global TaskForce on Radiotherapy for Cancer Control). Both WHO and IAEA have recently established programs to solve this crisis.

<u>Vision</u>

The Nano-X vision is to level the playing field in global access to radiotherapy. Where cancer patients in low and middle-income countries have access to appropriate treatment and care. Where the machine is designed from the ground up to deliver an affordable and viable solution for the people that need treatment, where they needs treatment, independently of where highly trained workforces live.

The Nano-X Solution

Nano-X, which will enter the international market by 2020, will launch on a wave of global awareness around this epidemic. Nano-X alleviates major obstacles to global radiotherapy utilization with lean innovation and a compact, affordable system for low and middleincome countries with drastically simplified hardware and workflow. A Nano-X schematic is shown: a full clinical prototype is now under construction and the shielded bunker is complete.

Conceptual Innovation: Nano-X will deliver a paradigm shift in radiation oncology by enabling affordable, accessible radiotherapy in resource-limited areas where capital costs and on-site operations are major issues. Nano-X increases patient throughput and decreases on-site staffing using sophisticated algorithms and leveraging telemedicine to enable centralised planning and local treatment with automated decision making. Methodological Innovation: Nano-X will treat patients with a fixed vertical beam and a patient rotation couch. This reduces costs enormously by reducing the (i) engineering complexity, (ii) size and radiation shielding requirements of the room (iii) onsite staffing requirements and (iv) time-consuming and inconvenient patient immobilisation procedures and treatment planning. Technological Innovation: For Nano-X, tumour motion will be substantial as patients themselves are rotated. The technological innovations in Nano-X are our algorithms for real-time image guidance and dynamic adaptation of the treatment beam to account directly for tumour motion.

SP077.7 - Development of an MR and CT compatible noninvasive temperature based optical fiber respiration sensor for use in radiotherapy

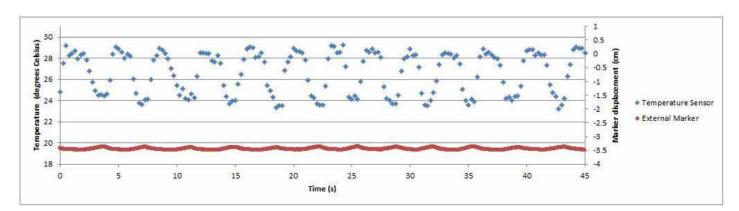

Author(s): <u>Ashley Smith</u>¹, Siyong Kim², Christopher Serago¹, Kathleen Hintenlang¹, Roberrt Pooley³, David Hintenlang⁴ ¹Radiation Oncology, Mayo Clinic, Jacksonville/UNITED STATES OF AMERICA, ²Radiation Oncology, College Of Medicine, Virginia Commonwealth University, Richmond/VA/UNITED STATES OF AMERICA, ³Radiology, Mayo Clinic, Jacksonville/UNITED STATES OF AMERICA, ⁴Biomedical Engineering, University of Florida, Gainesville/UNITED STATES OF AMERICA

We have developed a non-invasive temperature based respiration sensor to track the breathing cycle during respiratory gating that is not subject to the limitations of an external marker. The sensor tracks the breathing cycle by measuring the temperature of inspiratory and expiratory air (Figure 1). Because it doesn't rely on movement of the abdomen it can be used with forced shallow breathing (FSB) or thermoplastic body mask immobilization. The sensor is compatible for use in CT, MR, and linear accelerator environments.

Respiration signals were tested with five volunteers using FSB, and compared to simultaneously recorded signals from an external marker. Temperature readings were also tested in a CT, MR, and linear accelerator environment. The sensor's effect on image quality was evaluated for CT and MR.

The temperature sensor successfully recorded the breathing cycle for all volunteers, while the external marker had one failure (Figure 2). Fluctuations in temperature sensor signals were similar to background in both a CT and MR environment. There was greater signal fluctuation when the sensor was placed in a high energy linear accelerator field and given a high dose. The fluctuation was acceptable when the sensor was outside the radiation field. It is recommended that the sensor be placed outside the treatment field during treatment. Image quality was not affected by the temperature sensor for CT or MR.

We have shown that the temperature based respiration sensor can successfully track breathing cycles even when external markers fail. Performance is maintained in MR and ionizing radiation environments; however it is recommended that it not be used in the direct path of a high energy beam. We have verified that respiratory signals can be obtained without deterioration of CT or MR images. It is anticipated that this device would be highly suitable for respiratory gating in radiation therapy.

SP078 - Brachy Therapy: Part 2

TRACK 04: RADIATION ONCOLOGY

SP078.1 - The Effect of Bladder Preparation on Motion of Organs at Risk in High Dose Rate Gynecological Brachytherapy Author(s): <u>Parisa Sadeghi</u>¹, Robyn Banerjee², Tien Phan², Majed Alghamdi², Amandeep Taggar², Wendy L. Smith¹

¹Physics And Astronomy, University of Calgary, Calgary/CANA-DA, ²Radiation Oncology, Tom Baker Cancer Centre, Calgary/AB/ CANADA

Introduction: High Dose Rate (HDR) brachytherapy is part of the treatment protocol for advanced cervical cancer. The planning process for Magnetic Resonance (MR) guided treatment requires both Computed Tomography (CT) and MR imaging. This combines the high soft tissue contrast of the MR images with the ability of the CT scan to visualize the applicator inside the patient. However, this dual imaging requires multiple patient transfers and increases the overall patient motion. This can lead to changes in both the position and volume of the organs at risk (OARs) in the pelvic region, such as the rectum and bladder.

The purpose of this study is to evaluate the effect of bladder filling (often used to reduce bowel dose) on bladder motion, and quantify the motion of the rectum during HDR brachytherapy of cervical cancer.

Methods: A total of 15 cervical cancer patients were included in this study. Nine patients were treated without introducing bladder filling. Six patients had their bladder contents emptied and re-filled to a specific volume (120 – 200 cc). The change in bladder volume and center of mass (CM) position between the MR and CT imaging sessions, as well as the concordance index (CI) of the contoured bladders on both image sets were calculated using the Eclipse treatment planning system by Varian.

Results and Discussion: It is evident, from the data presented in Table 1 that the prepared bladders display a smaller change in volume compared to the bladders without the filling. In addition, prepared bladders show a mean positional change of 4.2 mm (range: 1.6-8.5 mm), while a positional change of 5.3 mm (range: 1.5-15.4 mm) is observed in the absence of bladder filling. This is interesting because the filling implemented for bowel sparing seems to have the added benefit of reducing bladder mobility. Also the prepared bladders seem to have a higher CI value. The rectum shows an overall positional change of 6.6 \pm 4.6 mm over the whole patient population.

Conclusion: Our results clearly display a trend where the bladder preparation leads to a smaller bladder motion, smaller volume change, and higher CI. Although preliminary statistical analysis did not reveal any significant difference between the two bladder preparation protocols, a larger sample size could provide more conclusive results.

	Bladder (Filled) (Mean ± SD)	Bladder (Not Filled) (Mean ± SD)	Rectum (Mean ± SD)
Volume Change (%)	18 ± 14	40 ± 55	17 ± 26
CM motion (mm)	4.2 ± 2.3	5.3 ± 4.4	6.6 ± 4.6
СІ	0.74 ± 0.06	0.59 ± 0.19	0.51 ± 0.11
D2cc (cGy)	697 ± 128	632 ± 130	460 ± 87
D1cc (cGy)	766 ± 143	703 ± 153	507 ± 95
D0.1cc (cGy)	930 ± 170	872 ± 244	629 ± 41

SP078.2 - Retrospective Monte Carlo dose calculations for permanent implant prostate brachytherapy using 125I Author(s): Paul Soubiran¹, <u>Justin Sutherland</u>¹, Nelson Miksys², Ali-Reza Mehan Haidari², Rowan Thomson², E Choan¹, Gad Perry¹, Joanna Cygler¹

¹Radiation Medicine Program, The Ottawa Hospital Cancer Centre, Ottawa/CANADA, ²Physics, Carleton University, Ottawa/ON/ CANADA

Clinical dose calculations for low dose-rate (LDR) prostate brachytherapy are currently performed following the protocols defined by the American Association of Physicists in Medicine (AAPM) Task Group no. 43 (TG-43) formalism. Using the TG-43 formalism, absorbed dose is calculated in a homogeneous water environment so the effects of tissue heterogeneities, interseed attenuation, and the finite dimensions of patients are not accounted for. This work retrospectively investigates differences between TG-43 and Monte Carlo (MC) calculated dose distributions for 105 patients treated with LDR prostate brachytherapy at The Ottawa Hospital.

Each of the 105 patients used in this study had a prescribed dose of 145 Gy (Drx) to the prostate through implantation of ¹²⁵I seeds (Model 6711 RAPID Strand[™]). Treatment planning and seed implantations were performed in real-time using ultrasound images. MC calculations were performed using the EGSnrc user-code Bachy-Dose. Computational phantoms for each patient were generated from CT images acquired 1 month post-implant by a Philips Brilliance CT scanner - Big Bore. Material compositions were assigned to each voxel within image contours based on CT number: prostate and calcification within prostate contours, air and muscle within rectum contours, urinary bladder within bladder contours, and ICRU 46 soft tissue and bone in the remainder of the phantom. CT number thresholds between tissue assignments were assigned consistently between patients and were determined by manual investigation of CT scans for several patients. The mass density of each voxel was derived from a scanner calibration of Hounsfield Units to density. To avoid misassignment of voxels to calcification and since Brachy-Dose models full seed geometries, seeds and metallic artifacts were removed from scans prior to tissue assignment by over-riding CT numbers above a threshold in the vicinity of the seeds. Dose to medium was calculated with sufficient histories to achieve a statistical uncertainty of less than 2% in prostate volumes.

Dose distributions calculated with BrachyDose differed considerably from those calculated with TG-43. The patient-averaged minimum dose to 90% of the target volume (D90) was 9.5 Gy lower as calculated by BrachyDose compared to TG-43. The average D99 was 52 Gy less than Drx as calculated by BrachyDose compared to 45 Gy less than Drx as calculated by TG-43. Similarly, the patient-averaged percentage volume that received at least 100% of the prescription dose (V100%) was 4% lower as calculated by BrachyDose compared to TG-43. While doses to organs at risk (OAR) also differed between BrachyDose and TG-43 calculated distributions, the differences were smaller. The patient-averaged highest dose received by 1 cc (D1cc) of the rectum was 103 Gy as calculated by BrachyDose and 110 Gy as calculated by TG-43: a 6.5% difference which may be clinically significant. D1cc for the bladder was 86 Gy for BrachyDose versus 88 Gy for TG-43 calculations, which is not clinically significant.

Retrospective MC calculated dose distributions for 105 Ottawa Hospital patients treated with LDR prostate brachytherapy showed a decrease in average dose coverage of target volumes and OARs as compared with TG-43 calculated dose distributions.

SP078.3 - Combining doses for prostate cancer patients receiving external beam radiotherapy and a HDR brachytherapy boost: Dosimetric parameters and dose-surface maps for patients with and without late rectal bleeding

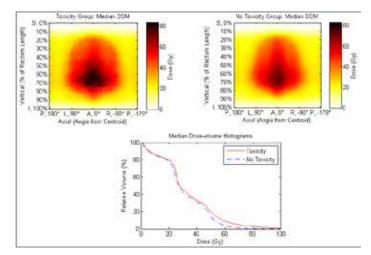

Author(s): <u>Calyn R. Moulton</u>¹, Michael House¹, Victoria Lye², Colin Tang², Michele Krawiec², Tim St Pierre¹, David J. Joseph², James W. Denham³, Martin A. Ebert²

¹School Of Physics, The University of Western Australia, Crawley/ WA/AUSTRALIA, ²Radiation Oncology, Sir Charles Gairdner Hospital, Nedlands/WA/AUSTRALIA, ³School Of Medicine And Population Health, The University of Newcastle, Callaghan/NSW/AUSTRALIA

OBJECTIVE: Are post-registration rectum dosimetric parameters and rectum dose-surface maps (DSM) different for groups of patients who did or did not have late bleeding?

Methods: 91 patients received external beam radiotherapy (EBRT) in 23 fractions of 2 Gy and high-dose-rate (HDR) brachytherapy in 3 fractions of 6.5 Gy. The EBRT CT was registered to the HDR CT with a rigid plus deformable multi-pass method (RD) or a rigid plus scale plus deformable multi-pass (RSD) method in Velocity Advanced Imaging. The unregistered EBRT and registered HDR dose distributions were summed after converting to equieffective doses at 2 Gy/fraction (α/β =3 and 5.4). The V1Gy to V100Gy (increment=1) and D1% to D100% (increment=1), D1cc, D2cc, D5cc and D10cc were calculated. Rectum DSMs were obtained by virtually unfolding the rectum surface dose slice-by-slice. Patients were classed into toxicity or no toxicity groups if they did or did not have a grade 2 LENT-SOMA rectal bleed from the period 3 months after radiotherapy onwards. The DSMs were spatially analysed by thresholding DSMs from 1 Gy to 100 Gy (increment=1). This analysis included the inferior-superior extent, left-right extent, area, perimeter, compactness, circularity and ellipse fit parameters. Significance (p<0.05) for median comparisons between groups was assessed via two-sided Mann-Whitney U-tests.

Results: The dosimetric and DSM results in the figure are for the RSD registration, HDR dose calculated with the Acuros algorithm and an α/β of 3; however, results were similar for alternatives. The V44Gy, V45Gy, V48Gy to V71Gy, D1% to D28%, D1cc, D2cc, D5cc and D10cc were significantly greater for toxicity (N=18) versus no toxicity (N=73) groups. Patients with toxicity had significantly greater left boundaries, greater right boundaries, greater widths and greater perimeters for various DSM isodose contours (e.g. 51-66 and 83 Gy). The ellipse fits at a number of dose thresholds (e.g. 83 Gy) indicated significantly greater lateral extent, greater eccentricity and greater horizontal orientation for bleeders. The lateral centroid components for some dose thresholds (e.g. 83 Gy) were significantly further to the right for bleeders. The proportions of ellipses filled by various thresholded doses (e.g. 50 Gy) were significantly greater for bleeders.

Conclusion: Multiple dose-volume parameters, derived from registered plans, correlated with bleeding. The lateral coverage of intermediate and high-dose regions was greater and located further to the right for bleeders. For bleeders, the doses in high-dose regions were greater and more contained within fitted ellipses.

SP078.4 - Implementation of Permanent Breast Seed Implants in British Columbia: Innovation and Early Results

Author(s): <u>Michelle Hilts</u>¹, Deidre Batchelar¹, Daniel Morton², Juanita Crook³

¹Medical Physics, BC Cancer Agency - Southern Interior, Kelowna/ CANADA, ²Physics And Astronomy, University of Victoria, Victoria/ CANADA, ³Radiation Oncology, BC Cancer Agency - Southern Interior, Kelowna/CANADA

Purpose:

Permanent breast seed implant (PBSI) is an attractive option for women with early stage breast cancer as the procedure is completed in a single outpatient session. In 2012 the BC Cancer Agency became only the second institution worldwide to offer this novel technique pioneered in Toronto. In this work we present technique innovations introduced at BCCA as well as preliminary results from our first 15 patients.

MATERIALS AND Methods:

Modelled after the technique introduced by Pignol et al, we use a template and US guided technique to implant needles pre-loaded with Pd-103 into the breast. CT planning (MIM Symphony) is undertaken to deliver 90Gy to a PTV, seroma+1.25cm cropped to skin and chestwall. A pre-treatment simulation step is included to check template position and transfer key landmarks from the treatment plan onto the skin. In the operating room a portable laser is used to confirm positioning and US is used throughout the procedure to monitor needle placement. Post-implant dosimetry is assessed using CTs obtained on day of implant (day0:reported here) and one month post-implant. Deformable image registration is used to define the post-implant seroma from the pre-implant contour. Implant quality is assessed on an evaluative PTV (PTVeval), seroma+0.5cm. In house software was utilized to measure seed displacements (planned to implanted positions) in 10 cases. Patient satisfaction is also reported.

Results:

Pre-implant volumes ranged from 4.1–20.2cc (median 7.0cc) and 31.4–114.2cc (median 47.4cc) for seroma and PTVs respectively. PTVs were well covered with V100 (mean \pm SD) of 96.1 \pm 2.7% using 77 \pm 22 seeds in 17 \pm 5 needles. Post-implant PTVeval dosimetry (day0) for all patients was (mean \pm SD): 90.4 \pm 9.4%, 86.9 \pm 10.8% and 64.4 \pm 14.9% for V90, V100 and V150 respectively and 87.1 \pm 25.3Gy for D90%. The corresponding PTVeval coverage (mean \pm SD) for the last 8 implants illustrates rapid convergence to consistently high quality implants: 96.5 \pm 2.6%, 93.6 \pm 4.6% and 70.9 \pm 12.1% for V90, V100 and V150 respectively and 87.9 \pm 1.1% for V90, V100 and V150 respectively and 103 \pm 16Gy for D90%. Mean seed displacement was 0.9 \pm 0.5cm for the 10 patients where seed matching was performed. All patients were very or extremely satisfied with the procedure, citing the single day treatment as a highlight.

Conclusions:

These early results indicate that PBSI is a safe and desirable treatment option for women with low risk breast cancer and technical innovation aimed at increased technique reproducibility has contributed to a rapid learning curve. Our aim, through ongoing technical innovation, is to continue to improve the standardization and reproducibility of PBSI to ultimately enable widespread implementation.

SP078.5 - Estimation of α/β for late rectal bleeding via minimum dosimetric differences for prostate cancer patients treated with external beam radiotherapy versus a HDR brachytherapy boost after external beam radiotherapy

Author(s): <u>Calyn R. Moulton</u>¹, Michael House¹, Victoria Lye², Colin Tang², Michele Krawiec², Angel Kennedy², Tim St Pierre¹, David J. Joseph², James W. Denham³, Martin A. Ebert²

¹School Of Physics, The University of Western Australia, Crawley/ WA/AUSTRALIA, ²Radiation Oncology, Sir Charles Gairdner Hospital, Nedlands/WA/AUSTRALIA, ³School Of Medicine And Population Health, The University of Newcastle, Callaghan/NSW/AUSTRALIA

OBJECTIVE: To estimate the α/β for late rectal bleeding via the difference in dosimetric parameters for patients treated with external beam radiotherapy (EBRT) versus a combined treatment of EBRT and high-dose-rate (HDR) brachytherapy.

Methods: In the RADAR trial, 723 patients received 66, 70 or 74 Gy (2 Gy/fraction) of EBRT and 91 patients received 46 Gy (23 fractions) of EBRT and 19.5 Gy (3 fractions) of HDR brachytherapy. HDR dose was calculated with both the Acuros and TG43 algorithms. For combined treatments, the EBRT CT was registered to the HDR CT with a rigid plus scale plus deformable multi-pass (RSD) method

in Velocity Advanced Imaging. The rectum D1cc, D2cc, D5cc and D10cc were calculated for patients receiving EBRT only and patients receiving combined EBRT/HDR. These parameters were correlated with bleeding for patients receiving combined EBRT/HDR. Patients from the two treatments were classed into toxicity groups if they had at least a certain grade (1, 2, or 3) LENT-SOMA rectal bleed from the period 3 months after radiotherapy onwards. The toxicity numbers for the EBRT only/combined treatment groups were 34/374, 18/183 and 5/66 for grades ≥ 1 , ≥ 2 and ≥ 3 . The parameters for patients with toxicity after EBRT only versus after combined EBRT/HDR treatments were compared as follows. (1) The medians of dosimetric parameters for the EBRT only toxicity group were converted to equieffective doses at 2 Gy/fraction with α/β from 0-11 (Increment=0.01). (2) This conversion was also applied to medians of the dosimetric parameters from the unregistered EBRT and registered HDR components for the combined treatment toxicity group. (3) The total median parameters for the combined treatment toxicity group were obtained by summing the converted median dosimetric parameters for the unregistered EBRT and registered HDR components. (4) The α/β with the smallest squared difference between the median converted dosimetric parameters for the two groups was determined and accepted if the squared difference was less than 0.01. (5) Bootstrapped 95% confidence limits (CI) for the α/β were calculated via (1)-(4) after resampling the two groups with replacement (10,000 resamples).

Results: The squared difference criteria for the median dosimetric values were not satisfied for some dosimetric parameters and toxicity criteria. The α/β for the dosimetric parameters, toxicity criteria and TG43/Acuros algorithm options varied from 0.710 to 4.84. The variability was greater across the parameters and toxicity criteria. The α/β (95% Cl) for the parameters (toxicity criteria) were 3.98 (0.260-10.1), 0.710 (0.100-6.18), 1.49 (0.0900-10.7) and 3.51 (2.45-8.03) for the D1cc (≥ 1), D2cc (≥ 1), D5cc (≥ 2) and D10cc (≥ 3) options applied with the Acuros algorithm. The mean α/β and mean 95% Cl across the parameters, toxicity criteria and TG43/Acuros algorithm options were 2.75 and 0.834-8.94.

Conclusion: The estimated mean α/β was 2.75 for late rectal bleeding. A conclusion on the early/late responding nature of the rectum was not feasible due to variability across parameters and wide confidence intervals. An increased sample size may result in more consistent and precise values across the dosimetric parameters and toxicity criteria.

ACKNOWLEDGEMENTS: NHMRC (1006447) and University of Western Australia.

SP078.6 - Failure Mode and Effects Analysis (FMEA) for improving quality assurance for Image-Guided High Dose Rate (HDR) brachytherapy

Author(s): <u>Shada Wadi-Ramahi</u>, Waleed Al-Najjar, Belal Moftah Biomedical Physics, King Faisal Specialist Hospital and Research Center, Riyadh/SAUDI ARABIA

Purpose:

To evaluate and develop quality assurance (QA) for image-guided high dose rate (HDR) brachytherapy by applying the failure mode and effects analysis (FMEA).

Method:

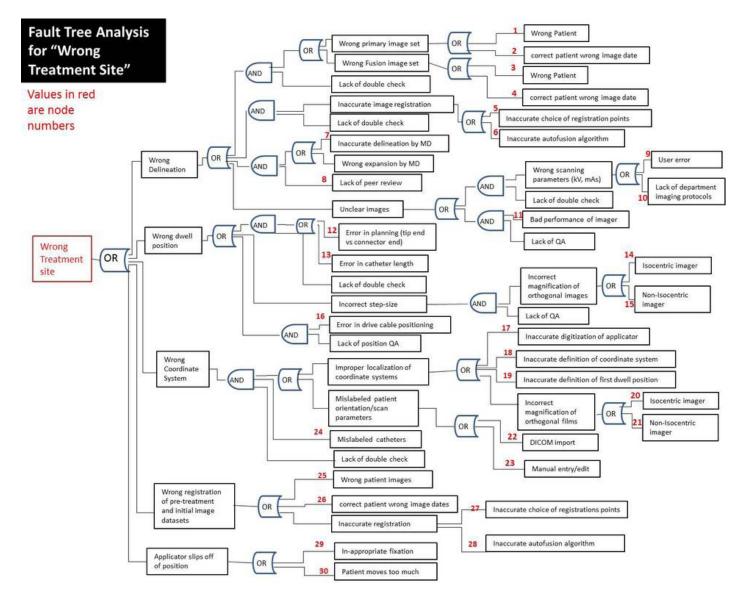

We started by mapping the major process tree of HDR brachytherapy, and highlighting the image-dependent steps. "Wrong Treatment Site" was identified as being the ultimate end-point that might result from errors in imaging procedures, and fault tree analysis (FTA) for this error was mapped with all the branches leading to it. The use of conventional imaging (2D) with isocentric and non-isocentric machines was also included for completeness. Potential risk for each branch was scored according to the risk priority number (RPN) scoring system (out of 10).

Results:

Fourteen major steps were identified: TPS commissioning, source installation and initial QA, patient diagnosis and selection, applicator insertion, primary image set acquisition, secondary image set acquisition, Image transfer and registration, organ delineation, applicator and coordinate system definition, plan optimization and dose calculation, plan transfer to treatment console station, source connectivity to patient, image verification of applicator position before treatment, and finally treatment delivery. Of these steps, six are image dependent and all leads to one error "Wrong treatment site". The FTA for "wrong treatment site" identified 30 potential failure nodes (2 are machine related, the rest are human related), see attached figure. Out of the 30, eleven are non-image related. Total RPNs ranged from 11 to 254. RPN for image arm ranged from 11 to 254, whereas for non-images RPN ranged from 45 - 192. RPN higher than 100 was considered potential for high risk. The errors were grouped into three major groups (human, procedural or machine). For each set, we took the analysis further by proposing corrective actions, such as development and implementation of departmental guidelines and QA.

The FTA, revealed a point during the HDR process (nodes 29 and 30) where QA is lacking. Those are non-image related; however, the error can be stopped from propagating by implementing a pre-treatment image verification procedure, which can be achieved by several methods depending on the user's capabilities.

Conclusion: We have applied FMEA process to image-guided HDR brachytherapy. The fault tree for "wrong treatment site" error identified areas of potential high risk and exposed areas where QA was lacking in the whole procedure. This helped us in re-prioritizing our QA procedures and guidelines.

SP079 - Motion Management: Part 1

TRACK 04: RADIATION ONCOLOGY

SP079.1 - Feasibility of respiratory gated radiotherapy using real-time positron emission tracking

Author(s): <u>Marc Chamberland</u>¹, Malcolm R. Mcewen², Bryan R. Muir², Tong Xu¹

¹Department Of Physics, Carleton University, Ottawa/ON/CAN-ADA, ²Measurement Science And Standards, National Research Council, Ottawa/ON/CANADA

Tumor motion due to respiratory motion can lead to dosimetric errors in the delivery of radiotherapy treatments. Respiratory gating can be used to address this issue but requires external markers or motion surrogates to monitor the breathing motion. However, these are not always well correlated to the true position of the tumor. We present a feasibility study of respiratory gated radiotherapy using a real-time positron emission tracking system.

The tracking system, called PeTrack, uses implanted low activity positron emission markers and position sensitive gamma ray detectors to track breathing motion in real-time. A LabVIEW interface is developed to synchronize gating between the signal from PeTrack and the NRC Elekta Precise linac. Prototype PeTrack detectors were mounted on an aluminum frame surrounding a dynamic anthropomorphic thorax phantom (Figure 1). Dose was delivered to the phantom in 500 monitor unit increments with a 3x3 cm² photon beam and with 6 and 10 MV nominal beam energies. Radiochromic films were inserted in the phantom to measure spatial dose distributions. The phantom lung insert was translated in the inferior/superior direction with sinusoidal and real patient breathing motion (±10 mm amplitude). The motion was tracked using a small ²²Na fiducial marker (0.43 MBg activity) embedded in the lung insert. The beam was turned off when the marker was outside of a 5-mm one dimensional gating window.

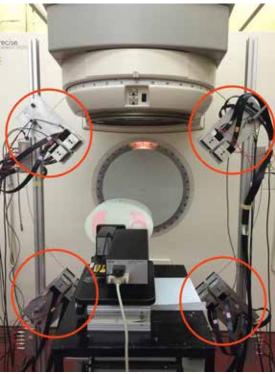

Figure 1: Prototype PeTrack detectors around dynamic phantom.

Clear improvement of the dose distribution is observed between gated and non-gated delivery (Figure 2). Monitoring of the beam on/ off times show synchronization with the location of the marker within the latency of the system.

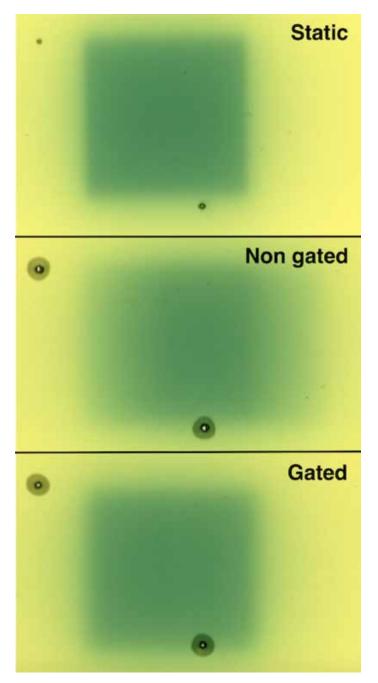

Figure 2: Radiochromic films after exposure.

This study shows the feasibility of using positron emission tracking to improve respiratory gated radiotherapy.

SP079.2 - The first kilovoltage intrafraction monitoring trial for gated prostate radiotherapy: Accuracy and dosimetric results Author(s): <u>Prabhjot Juneja</u>¹, Jin A. Ng², Emma Colvill², Ricky O'Brien², Thomas Eade³, Andrew Kneebone³, Per R. Poulsen⁴, Jeremy T. Booth¹, Paul Keall²

¹Institute Of Medical Physics, School Of Physics, University of Sydney, Sydney/NSW/AUSTRALIA, ²Radiation Physics Laboratory, Sydney Medical School, University of Sydney, Sydney/AUSTRA-LIA, ³Northern Sydney Cancer Centre, Royal North Shore Hospital, Sydney/AUSTRALIA, ⁴Department Of Oncology, Aarhus University Hospital, Aarhus/DENMARK

A new real-time IGRT system, kilovoltage intrafraction monitoring (KIM), is undergoing clinical evaluation through a first-in-world prospective clinical trial for prostate cancer patients. KIM uses kV fluoroscopy to monitor, in real-time, the 3D position of radio-opaque markers implanted into the prostate target. The real-time target position is used to guide the treatment: if the prostate moves outside the tolerance (motion exceeding 3mm for 5 seconds) the beam is paused and the patient is repositioned. The goal of this study is to investigate the localisation accuracy and dosimetric impact of the KIM system, in planned 30-patient gated prostate cancer radiotherapy trial.

To date, three patients have completed their 40-fraction treatments. Simultaneous intra-fraction kV and MV images from the 116 fractions were used offline to measure the accuracy of the KIM real-time measurements. The measured triangulated kV-MV marker positions were considered to be ground truth, and were compared to the KIM measurements. For the dosimetry, dose delivered during each fraction with KIM was measured using a motion-synchronized isocenter shift dose reconstruction method. In the fractions with a gating event, dose reconstruction was also carried out for a simulated treatment scenario with no KIM gating correction representing the current standard of care. Target and normal tissue dose volume statistics were compared for the planned treatment delivery, delivery with KIM gating and delivery with no KIM correction (see figure 1). KIM has a finite gating threshold and therefore, in the presence of motion, it will deviate from the planned treatment.

The mean error \pm standard deviation of KIM in the LR, SI and AP directions was 0.14 \pm 0.50, 0.38 \pm 0.27, and -0.48 \pm 0.45 mm respectively. In total, 14 fractions had successful KIM gating corrections. Prostate motion with KIM corrections and simulated with no KIM corrections were 1.9 \pm 1.2 mm and 3.8 \pm 1.4 mm respectively. Mean (range) differences between the planned and KIM corrected doses and the planned and no KIM correction doses were respectively: PTV D95% -1.4 (-3.4, 0.7) & -3.1 (-10.9, -0.7); CTV D100% -0.8 (-2.8, 0.7) & -0.1 (-7.0, 1.9); rectum V65% -3.5 (-9.4, 5.7) & -4.9 (-11.2,18.7); and bladder V65% 1.58 (-0.9, 5.8) & 2.8 (-1.0, 10.4).

In conclusion, the results demonstrated that both the accuracy and precision of KIM system are sub-millimetre, and KIM gating improves the agreement between the planned and delivered treatments for prostate radiotherapy. The KIM technology has wide-scale applicability as it is implemented on a standard linear accelerator with little modification.

SP079.3 - The impact of audio-visual biofeedback with a patient-specific guiding waveform on respiratory motion management: Comparison of two different respiratory management systems

Author(s): <u>Yujiro Nakajima</u>¹, Noriyuki Kadoya¹, Satoshi Kida¹, Takayuki Kanai¹, Kazuma Kishi², Kiyokazu Sato², Suguru Dobashi³, Ken Takeda³, Haruo Matsushita¹, Keiichi Jingu¹

¹Radiation Oncology, Tohoku University School of Medicine, Sendai/ JAPAN, ²Radiation Technology, Tohoku University Hospital, Sendai/ JAPAN, ³Radiological Technology, School Of Health Siecnes, Faculty Of Medicine, Tohoku University, Sendai/JAPAN

Purpose: Irregular breathing can influence the outcome of fourdimensional computed tomography imaging for causing artifacts. Audio–visual biofeedback systems associated with patient-specific guiding waveform are known to reduce respiratory irregularities. In Japan, abdomen and chest motion self-control devices (Abches), representing simpler visual coaching techniques without guiding waveform are used instead; however, no studies have compared these two systems to date. Here, we evaluate the effectiveness of respiratory coaching to reduce respiratory irregularities by comparing two respiratory management systems.

Methods: We collected data from eleven healthy volunteers. Bar and wave models were used as audio–visual biofeedback systems. Abches consisted of a respiratory indicator indicating the end of each expiration and inspiration motion (Fig. 1). Respiratory variations were quantified as root mean squared error (RMSE) of displacement and period of breathing cycles.

Results: All coaching techniques improved respiratory variation, compared to free-breathing. A typical case study showing improvements regarding respiratory irregularity is summarized in Fig. 2. Displacement RMSEs were 1.43 ± 0.84 , 1.22 ± 1.13 , 1.21 ± 0.86 , and 0.98 ± 0.47 mm for free-breathing, Abches, bar model, and wave model, respectively. Free-breathing and wave model differed significantly. Period RMSEs were 0.48 ± 0.42 , 0.33 ± 0.31 , 0.23 ± 0.18 , and 0.17 ± 0.05 s for free-breathing, Abches, bar model, and wave model, respectively. For variation in both displacement and period, wave model was superior to free-breathing, bar model, and Abches. The average reduction in displacement and period RMSE compared with wave model were 27% and 47%, respectively.

Conclusions: This study was to evaluate the efficacy of audio-visual biofeedback to reduce respiratory irregularity compared with Abches. Our results showed that audio-visual biofeedback combined with a wave model can potentially provide clinical benefits in respiratory management, although all techniques could reduce respiratory irregularities.

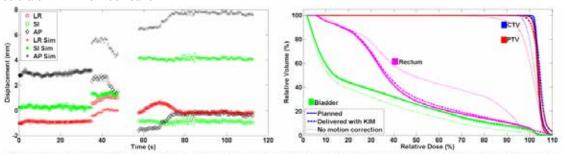

Figure 1. Sample motion (left) during the two are VMAT, and corresponding dose volume histograms (right) of the clinical target volume (CTV), planning target volume (PTV), bladder and rectum for the planned, delivered with KIM gating, and simulated delivery without KIM gating correction (no motion correction). This fraction had two gating events.

SP079.4 - Tracking Accuracy for Robotic Radiosurgery in the Liver

Author(s): <u>Jeff D. Winter</u>¹, Raimond Wong², Anand Swaminath², Tom Chow¹

¹Medical Physics, Juravinski Cancer Center, Hamilton/CANA-DA, ²Oncology, McMaster University, Hamilton/CANADA

Cyberknife® robotic radiosurgical treatment of liver employs an online motion management system to track and compensate for target motion during free-breathing. Lesion tracking on the Cyberknife is achieved using a room-mounted orthogonal x-ray system to localize internal fiducial markers as well as an optical camera system to measure the position of the patient's abdomen during breathing. The system establishes a correlation model linking internal target position to an external optically-tracked surrogate to enable nearreal-time robotic adjustments of the linear accelerator. However, inherent system delays (115 ms) require a prediction algorithm to estimate the future position. Throughout treatment, periodic x-ray images are collected to verify and update this internal-external correlation model.

In this study, our aim was to quantify key uncertainties in the targeting of liver lesions on the Cyberknife system. We analyzed the logged Cyberknife tracking information for a total of 28 patient treated over 124 fractions and isolated treatment images collected immediately prior to beam delivery. To assess target amplitude and absolute prediction errors, we isolated 20 s time intervals surrounding each treatment x-ray image. We computed target amplitudes using peak/valley detection and prediction errors using the absolute

difference between the predicted position and the modeled position calculated after 115 ms had elapsed. We computed model correlation errors using the difference between the correlation model's position estimate and the internal fiducial position from x-ray imaging. To estimate overall uncertainty, we quadratically summed the correlation, prediction and end-to-end targeting error ($\pm 0.5 \text{ mm}^1$) in each direction. We also tested the linear correlation between target amplitude and tracking errors for each direction.

Results showed that the cranio-caudal direction exhibited the greatest correlation and prediction errors, but total radial error was less than 5 mm (Table 1). Significant weak correlations (r = 0.08 - 0.19, p<0.0001) existed between target amplitude and correlation errors in all directions except left-right; whereas, strong correlations existed with prediction errors (r = 0.55 - 0.67, p<0.0001) for all directions.

Based on the overall 3D radial position errors, results suggest that for 95 % of the beam delivery time the target centroid will be within 4.6 mm of the planned target volume. These results along with consideration for internal fiducial migration, target rotation and liver deformation may help guide planning target volume expansion.

SP079.5 - Deep Inspiration breath hold lung SBRT- Can Flattening Filter Free beam based VMAT combined with gated CBCT facilitate precise treatment delivery with sufficient dosimetric accuracy?

Author(s): <u>Vallinayagam Shanmuga Subramanian</u>¹, Vellian Subramani², Kala Subramanian¹, Shanmugam Thirumalai Swamy¹, Murugesan Kathirvel³, Gandhi Arun³

¹Radiation Oncology, yashoda hospital, Hyderabad/INDIA, ²Radiation Oncology, All India Institute of Medical Sciences, New Delhi/ INDIA, ³Research And Development Centre, Bharathiar University, Coimbatore/INDIA

Objective(s):The combination of VMAT technique using high dose rate FFF beams along with the computer controlled deep inspiration breath hold technique provides opportunity to further reduce treatment margins in lung SBRT over free breathing (FB) approaches .The aim of this study was to investigate the potential benefits of VMAT based DIBH SBRT over FB SBRT. This was performed by conducting a dosimetric comparison of VMAT technique with IMRT technique using both DIBH & FB approaches.

Materials/Methods: Ten lung SBRT patients treated using 6MVFFF-VMAT based DIBH technique were retrospectively selected for this study. Treatment planning were performed in both DIBH & FB patient data set using IMRT & VMAT techniques. Treated patients dose prescription of 60 Gy in 5 fractions was used as standard dose prescription for the techniques. Plan evaluation was performed with RTOG0813 treatment planning criteria. Paired t test was used for statistical analysis. The dosimetric accuracy of the gated VMAT was assessed using a global gamma index (3% dose difference, 3mm DTA (Distance to agreement) and measured with 2D detector attached to a solid cube phantom. Actual patients number of breath hold cycles and total delivery time with breath hold phases of 20/25s and recovery phases of 25 seconds were also incorporated during QA procedures.

Results: Irrespective of the techniques, DIBH approach could very well satisfy the RTOG0813 treatment planning criteria for the studied patients. As shown in table mean average Dose conformity of 1.03 + 0.012 for VMAT-DIBH was significantly better as compared with IMRT-FB, VMAT FB & IMRT-DIBH techniques (p-0.03). Mean average Lung V20Gy volume was 4.84+ 2.4, 5.22+ 2.5, 10.07+ 2.3, and 10.27+ 2.04% for VMAT-DIBH, IMRT-DIBH, VMAT-BH, and IMRT-BH respectively. In terms of Heart V15cc and Esophagus V5cc maximum dose, VMAT-DIBH plans exhibit the lowest as compared with the other techniques. Both the IMRT & VMAT-DIBH plans could be accurately delivered despite undergoing multiple beam on/off cycles, with mean QA pass rate over 95% (IMRT-DIBH VS VMAT-DIBH - Mean 96.42+1.2 vs 97.8 + 1.1).Treated DIBH patients gated CBCT analysis showed that average mean setup error was 2.8mm (range 1.5-4.2mm) in latero-lateral, 3.4mm (range 2.2-4.8mm) in antero-posterior, 3.2mm (range 2.4-5.6mm) in cranio-caudal directions.

Table-1

Results:

The results from this study showed that with proper patient coaching FFF beam based DIBH lung SBRT combined with gated CBCT facilitate precise treatment delivery with sufficient clinical dosimetric accuracy.

SP079.6 - Feasibility of markerless tumor tracking by sequential dual-energy fluoroscopy on a clinical tumor tracking system

Author(s): <u>Jennifer Dhont</u>, Kenneth Poels, Dirk Verellen, Koen Tournel, Thierry Gevaert, Femke Steenbeke, Mark De Ridder Radiotherapy, Universitair Ziekenhuis Brussel, Brussels/BELGIUM

The purpose was to evaluate the feasibility of markerless tumor tracking through the implementation of dual-energy imaging into the current clinical dynamic tracking workflow of the Vero SBRT system. An innovative approach of fast sequential fluoroscopy sequences was implemented omitting the pre-requisite of fast-switching kV-generators.

Two sequential 20s (11Hz) fluoroscopy sequences were acquired at the start of one fraction for 7 patients treated with DT on the Vero system. Sequences were acquired using 2 on-board kV imaging systems located at ±45° from the MV beam axis, at respectively 60kVp (3.2mAs) and 120kVp (2.0mAs). Table 1 shows the kV imager positions that were selected based on marker visibility. Prior to evaluation, the implanted fiducial was removed on all images to be evaluated, to not bias the results. Offline, a normalized cross-correlation algorithm was applied to anatomically match the high (HE) and low-energy (LE) images. Per breathing phase (inhale, exhale, maximum inhale and maximum exhale), the five best matching HE-LE couples were extracted for DE subtraction. A contrast analysis according to gross tumor volume (GTV) was conducted between the DE and HE images based on contrast to noise ratio (CNR). Improved tumor visibility was guantified using an improvement ratio (IR=CNRDE/CNRHE).

DE subtraction through sequential fluoroscopy was incorporated on the Vero system with only minor adjustments to the imaging settings. Removing the implanted fiducial was successful on all images. HE-LE sequence matching was effective for 12 of 14 imaging angles, correlation coefficients per imaging angle can be found in Table 1.

Table 1 Mean correlation coefficient per imager (Im.) between high- (HE) and low-energy (LE) images, contrast-to-noise ratio (CNR) according to gross-tumorvolume for HE and dual-energy (DE) images, and relative improvement ratio (IR=CNR^{DE}/CNR^{HE})

Im.1 65°				p = 0.426			
patient 7	0.985 ± 0.004	0.12 ± 0.02	0.11 ± 0.02	0.87 ± 0.06			
Im.2 75°				p = 0.029			

Overlying bony anatomy was removed on all DE images; Figure 2 shows an example. CNR per patient and per imaging angle can be found in Table 1. With the exception of two imaging angles, the DE images showed no significantly improved tumor visibility compared to HE images. Qualitatively, it was observed that for these imaging angles that showed no significantly improved CNR, the tumor tissue could not be reliably visualized on neither HE nor DE images due to a total or partial overlap with other soft tissue.

Dual-energy imaging by sequential fluoroscopy was shown feasible by implementing an additional fluoroscopy sequence into the DT workflow of the Vero system. However, for most imaging angles, DE images did not provide improved tumor visibility over single-energy images, most likely due to an overlap of the tumor with other softtissue. Optimizing imager settings and angles is likely to improve the efficacy of dual-energy imaging.

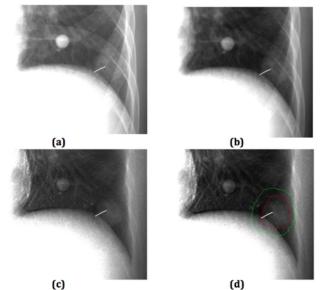

Fig. 1 A low-energy (a) and high-energy (b) image acquired at 160° , with the corresponding DE subtraction image without (c) and with (d) GTV and PTV contour, from a patient with a metastatic lesion in the right lower lobe.

SP080 - Other Radiation Oncology: Part 2

TRACK 04: RADIATION ONCOLOGY

SP080.1 - Estimation of the second cancer risk from adjuvant radiation therapy for stage I seminoma of the testis

Author(s): <u>Michalis Mazonakis</u>¹, Theocharris Berris¹, Charalambos Varveris², John Damilakis¹

¹Department Of Medical Physics, University of Crete, Heraklion/ GREECE, ²Department Of Radiotherapy, University of Crete, Heraklion/GREECE

Purpose: To estimate the second cancer risk associated with the adjuvant radiation therapy for stage I seminoma of the testis.

Methods: The study population consisted of eleven patients with stage I testicular seminoma who underwent postoperative radiation therapy with a 6 MV photon beam. Three-dimensional conformal radiotherapy plans based on CT scans were generated for all patients. Two parallel-opposed anteroposterior and posteroanterior fields were used to deliver 20 Gy to the para-aortic lymph node region. The organ equivalent dose (OED) to stomach, colon, liver and pancreas, that were partly included within the treatment volume, was determined using differential dose-volume-histograms and a plateau dose-response model. Furthermore, a previously validated Monte Carlo model of a linear accelerator producing 6 MV X-rays was employed to calculate the radiation dose at sites excluded from the primarily irradiated area. Para-aortic irradiation to 20 Gy with standard treatment field sizes was simulated on a computational humanoid phantom representing an average adult man. Monte Carlo calculations were performed to determine the average radiation dose (Dav) received by each of the following out-of-field organs: brain, salivary glands, oral mucosa, thyroid, lung, esophagus, urinary bladder and prostate. The Dav and OED values together with organ-specific risk coefficients were used to estimate the excess absolute risk (EAR) of cancer induction at the age of 70 years due to radiotherapy of a typical 35-year-old patient.

Results: Monte Carlo simulations showed that the out-of-field organ dose from para-aortic irradiation varied from 0.004 Gy to 0.37 Gy. The mean OED value for stomach, colon, liver and pancreas, as derived by the patient study, was equal to 2.50 Gy, 1.88 Gy, 1.43 Gy and 5.60 Gy, respectively. The organ-specific EAR for developing second cancer at sites outside the treatment volume was (0.002-0.9) per 10000 persons per year. The corresponding risk range for the partially in-field organs was (2.5-10.6) per 10000 persons per year. The highest EAR value was found for stomach cancer.

Conclusions: The risk of out-field cancer after adjuvant radiotherapy for stage I seminoma of the testis is low. However, the above treatment may lead to an increased probability for carcinogenesis at sites exposed to primary radiation. This elevated risk should be taken into account during the follow-up of testicular cancer survivors.

SP080.2 - 3D Slicer Gel Dosimetry Analysis: Validation of the Calibration Process

Author(s): Kevin M. Alexander¹, Csaba Pinter², Jennifer Andrea², Gabor Fichtinger², L John Schreiner³

¹Department Of Physics, Engineering Physics And Astronomy, Queen's University, Kingston/ON/CANADA, ²School Of Computing, Queen's University, Kingston/ON/CANADA, ³Department Of Medical Physics, Cancer Centre of Southeastern Ontario, Kingston/ON/ CANADA

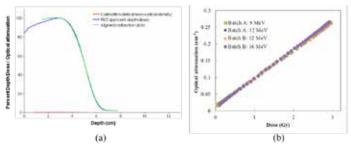

Advanced three-dimensional conformal radiation therapy tech-

niques have rapidly developed in recent years. The techniques generate dose distributions with steep dose gradients to cover the tumor and spare healthy tissue, and these deliveries need validation. Three-dimensional dosimetry tools, such as gel dosimeters, have been shown to be promising tools for measurement and verification of radiation dose deliveries, particularly during commissioning of new treatment techniques.

Gel dosimetry consists of three-dimensional chemical systems that quantify the effects of radiation-induced chemical changes in a gelatin matrix which can then be imaged using various systems, such as the Vista optical CT scanner (Modus Medical Devices, London, Canada). By its very 3D nature, gel dosimeters require extensive post-irradiation data processing. In our clinic, gel dosimeter analysis was traditionally performed using Matlab coupled with the Computational Environment for Radiotherapy Research and would take several hours to process and analyze data. To reduce analysis time and to produce a more robust analysis system, a gel dosimeter analysis workflow was developed using a custom extension in 3D Slicer (an open source and customizable computational tool used for image analysis and visualization). Gel dosimeter analysis using the extension now takes 5-10 minutes.

A major component of gel dosimetry analysis is the calibration relating the optical response of irradiated gel to dose. Here, we present a calibration method using measured depth dose data from well characterized electron beams compared to optical depth dose data in an imaged gel. Four 1L jars from two batches of Fricke gel dosimeter were made and irradiated with 6x6 cm² beams using three different beam energies. To validate the robustness of the calibration component of the 3D Slicer extension, the calibration gel jars were analyzed five times and the mean sensitivity of each of the gels was determined. Consistency of measurements for a single user examining the four gel irradiations was shown to have high reproducibility, with a relative standard deviation of 0.1%. To examine the effect of inter-user variability of the gel calibration process, the analysis was performed by three different users. The mean sensitivities determined by the three users had a maximum relative standard deviation of 0.6%.

Overall, the calibration step of the 3D Slicer Gel Dosimetry Extension makes gel dosimeter analysis more consistent and about 20 times faster than previous dose readout approaches.

(a) Ion chamber percent depth dose data (blue) and scaled and aligned gel dosimeter calibration data (green), as displayed in the extension's graphical user interface

(b) Mean calibration curves, averaged over five calibration trials, showing good agreement between all four calibration gels

SP080.3 - Whole body interactive 3D visualisation of both the benefits and risks of radiotherapy for common cancers: a tool to guide decision making

Author(s): David Edmunds, Ellen Donovan

Joint Department Of Physics, The Royal Marsden Hospital, Sutton/ UNITED KINGDOM

Purpose

More people who have had a common cancer are surviving. Radiotherapy is contributing to this success but it has long-term consequences. There is a complex relationship between the benefits of radiotherapy and the risks of adverse effects (e.g. cardiac damage or second cancer induction). These vary with many factors including disease stage, age at exposure to radiotherapy and radiation dose. The modern era of radiotherapy planning and delivery methods results in a wide variety of delivered dose to organs outside the treated region. Standard treatment planning systems calculate and display dose within the region of a planning scan. There is no tool describing doses beyond this region, or providing information on the benefits and risks of the radiotherapy based on plan specific doses and patient characteristics such as age.

We have developed the aRRESt (Radiotherapy Risk Evaluation System) program, which provides an interactive 3D visualisation of cardiac risks and second cancer risk estimates for radiosensitive organs throughout the body.

Method

A cross-platform graphical user interface (GUI) was developed using the C++ programming language, with 3D visualization and interaction provided by the Visualization Tool Kit (VTK) module. The GUI provides an indication of the lifetime risk of second cancer induction [1], and of major coronary event risk [2] for any treatment plan input. Dose cube and outlined regions of interest (ROI) are extracted from DICOM files exported from a commercial treatment planning system. Mean organ doses are used to estimate the lifetime/cardiac risks.

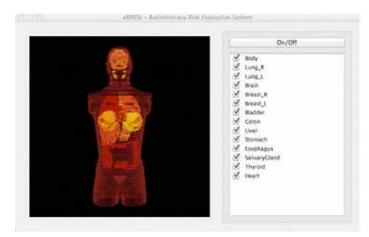

Figure 1

An image from the 3D interactive visualisation tool, which can be switched between dose and the risk of an adverse effect from radiotherapy for a selectable organ. The display shown is from a CT scan of an anthropomorphic phantom, extracted from the Pinnacle treatment planning system.

Conclusion

The aRRESt program provides a quick and convenient method of visualising the benefit-risk relationship for different radiotherapy treatment deliveries and patient characteristics. Currently based

on a generic body model, the ultimate aim is to use patient specific information. The tool will be used in combination with the standard treatment plan to assist decision making on a per-patient basis.

SP080.4 - A Software App for Radiotherapy with In-situ Dose-painting using high Z nanoparticles

Author(s): <u>Mohammed Jermoumi</u>, Altundal Yucel, Yao Hao, Gizem Cifter, Erno Sajo, Wilfred Ngwa

Department Of Physics And Applied Physics, Medical Physics Program, University of Massachusetts, Lowell/UNITED STATES OF AMERICA

The purpose of this work is to develop a user friendly and free-todownload application software that can be employed for modeling Radiotherapy with In-situ Dose-painting (RAID) using high-Z nanoparticles (HZNPs). The RAID APP is software program written in Matlab (Mathworks, Natick, MA, USA) based on deterministic code developed to simulate the space-time intra-tumor HZNPs biodistribution within the tumor, and the corresponding dose enhancement in response to low dose rate (LDR) brachytherapy of I-125, Pd-102, Cs-131 and kilovoltage x-rays such as 50 keV and 100 keV. Through the graphical user interface (GUI) of the RAID APP, the user will be directed to different features to compute various parameters related to the dose enhancement and the biodistribution of NPs within high risk tumor sub-volumes. The software was developed as a tool for research purposes with potential for subsequent development to guide dose-painting treatment planning using radiosensitizers such as gold (Au) and platinum (Pt).

SP080.5 - Performing radiation therapy research using the open-source SlicerRT toolkit

Author(s): <u>Csaba Pinter</u>¹, Andras Lasso², An Wang³, Gregory C. Sharp⁴, Kevin M. Alexander⁵, David A. Jaffray⁶, Gabor Fichtinger² ¹School Of Computing, Queen's University, Kingston/CANA-DA, ²School of Computing, Queen's University, Kingston/CANA-DA, ³Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/CANADA, ⁴Radiation Oncology, Massachusetts General Hospital, Boston/UNITED STATES OF AMERICA, ⁵Department Of Physics, Engineering Physics And Astronomy, Queen's University, Kingston/CANADA, ⁶Techna Institute, University Health Network, Toronto/CANADA

Purpose: Radiation therapy (RT) is a common treatment option for a wide variety of cancer types. Although we have seen significant improvements in this technique over the past years, performing research in RT is limited to using either expensive, closed, proprietary applications or heterogeneous sets of open-source software packages with limited scope, reliability, and user support. Our SlicerRT toolkit aspires to overcome these limitations by providing an extensive set of RT research tools leveraging the advanced visualization and image analysis features of its base platform 3D Slicer (see http:// http://slicer.org).

Methods: The SlicerRT toolkit (see http://slicerrt.org) comprises of a set of 3D Slicer extensions: SlicerRT core [1], Matlab Bridge, Multi-dimensional Data, and Gel Dosimetry. The SlicerRT core extension contains 26 modules, many of which provide common RT tools used in most RT research scenarios. Numerous core modules employ the advanced algorithms provided by the Plastimatch library [2]. Matlab Bridge provides a convenient way for connecting the researchers' existing MATLAB algorithms to the SlicerRT ecosystem. Multi-dimensional Data offers a feature set for handling multi-dimensional datasets, such as longitudinal or 4D data. Finally, Gel Dosimetry [3] facilitates gel dosimetry analysis workflows through a streamlined, workflow-based end-user application. The toolkit is an open-source resource that is developed and maintained according to the highest standards in the industry, including flexible, maintainable architecture, automated testing, and the use of a software collaboration suite that enables accurate tracking of our efforts and plans.

Results: Four 3D Slicer extensions have been implemented, each of which can be downloaded from the 3D Slicer Extension Manager. Using these open-source software tools makes it possible to conduct cutting edge RT research without parallel development efforts. Essential RT tools are provided by SlicerRT core, augmented with the extensions Matlab Bridge and Multi-dimensional Data, supporting special use cases. Gel Dosimetry acts as a proof of concept for quick prototyping of advanced applications accommodating complex workflows. The user base of the toolkit is constantly expanding, with 30+ groups having adopted it so far. SlicerRT acts as a medium into which researchers can integrate their methods into, and which they can use to perform comparative validation, develop novel RT techniques, or transition advanced methods into routine clinical practice.

Future work: As SlicerRT has matured to contain most of the planned functions, our focus has shifted from feature development to usability and stability. Thus we propose to perform a complete overhaul of the current Contours mechanism to be more complete and more flexible. To enhance user experience, we plan to significantly improve our user documentation to make it as straightforward and helpful as possible. Also, although we have performed validation on core algorithms, it only covers a subset of the tools SlicerRT provides. It is also among our goals to validate the rest of the algorithms.

SP081 - Validation and Verification of Therapy Dose Delivery: Part 1

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP081.1 - Validation of Eclipse Treatment planning system Commissioning using Octavius 4D

Author(s): <u>Paul B. Ravindran</u>¹, Aung Thaung² ¹Department Of Radiation Oncology, The Brunei Cancer Center, Brunei/BRUNEI, ²Radiation Oncology, Pinlon Hospital, Yangon/ MAYANMAR

The accuracy of dose calculation in a treatment planning system mainly depends on the algorithm used for calculation, the beam data configured and the beam modelling in the treatment planning system. The Eclipse planning system uses the Analytical Anisotropic Algorithm (AAA) and the Acuros XB (AXB) for dose calculation and these have been extensively verified for its accuracy. The commissioning and quality assurance of a treatment planning system has been studied comprehensively ever since the computerised treatment planning system came in to use. Generally the validation of a TPS is limited to verification of point doses and dose profiles. The availability of the Octavius 4D enables a full 3D dose comparison.

Purpose: The purpose of this study was to validate the commissioning of Eclipse treatment system for photon beams of Clinac IX unit with Octavius 4D system that enables volumetric comparison of dose distribution.

Methods: Beam data configuration was performed on an Eclipse planning system (Version 13.0) for a Clinac IX dual energy linear accelerator with 6MV and 10 MV photon beams and six electron energies viz 6 MeV, 9MeV, 12 MeV, 15 MeV, 18 MeV and 22 MeV. The calculations for the validation were carried out with Analytical Anisotropic Algorithm (AAA) version 13 implemented in Eclipse planning system. Absolute point dose verifications were performed with 1D water phantom and 0.6 cc ion chamber supplied by PTW. The 729 detector array of the Octavius 4D system was used independently for 2D planar dose verification. The rotational unit of the Octavius 4D system with the inclinator and the 729 detector array was used for dose verification in 3D. Profile comparisons, 2D and 3D gamma analysis were performed to validate the Eclipse system for photon beam dose calculation.

Results: Good agreement was observed between the measured absolute point doses and the AAA calculated doses in water phantom. The agreement was within 2% and less than 1% at most points in the central axis. The 2D comparison of dose distributions pass rate for 3%/3mm gamma index criteria were 95% are above and the failed points were mostly in the penumbral region. The gamma analysis for 3D dose comparison also had pass rate of 96%-99% with 3%/3mm criteria for both 3D CRT and IMRT verifications.

Conclusions: The calculations performed by the Eclipse Treatment Planning system with the configured beam data and the Analytical Anisotropic Algorithm were accurate. The Octavius 4D system with the 729 detector array is a useful tool for comprehensive validation of the Treatment planning system for photon beams.

SP081.2 - Evaluation of Electron Beam Algorithm of Prowess Panther Planning System for Customized Electron Cutouts of different Sizes.

¹Medical Physics, Gujranwala Institute of Nuclear Medicine and Radiotherapy, Gujranwala/PAKISTAN, ²Medical Physics, Institute of Nuclear Medicine and Oncology,Lahore, Lahore/PAKISTAN, ³Department Of Physics And Applied Mathematics, Pakistan Institute of Engineering and Applied Sciences, Islamabad/PAKISTAN, ⁴Nuclear Medicine And Oncology, Director Medical Sciences, Islamabad/ PAKISTAN, ⁵Medical Radiation Physics, institute of nuclear medicine and oncology lahore pakistan, lahore/PAKISTAN

Evaluation of Electron Beam Algorithm of Prowess Panther Planning System for Customized cutouts of Different Sizes

Abstract: In this comparative study electron beam dose calculation algorithm used in prowess panther TPS is evaluated. This is done by comparing PDDs and OPFs (Output Factors) of different cutout sizes with minimum field size dimension of 2 cm for electron energies of 6 MeV,9 MeV,12 MeV,15 &21 MeV. Cutouts are designed in TPS and then fabricated in mould room using lipowitz. The measurement of PDDs and OPFs are carried out by using CC01 and Omnipro-Accept software in 3D water phantom and Dose 1 electrometer. The OPFs are measured at D max of each energy and cutout size. The calculated PDDs and OPFs from Prowess Panther are compared. OPFs and PDDs comparison were made for both SSD 100 cm and SSD 110 cm. The R20 - R90 region of PDD is selected for comparison with an increment of 10 points. Data analysis is carried out by calculating mean difference and standard deviation for PDDs and percentage difference for OPFs between measured and treatment planning calculations.

The values of mean difference between calculated and measured PDDs at 100cm SSD are less than 2mm for 2cm diameter circle up to 12 MeV. Higher than 12 MeV the values of mean difference are greater than 3 mm. Similar results are obtained with squares and rectangles of different sizes like 2cm square and 9x2 rectangle and the mean difference is less than 2mm for 6MeV, it increases with increase in energy. For cutout sizes having large dimensions from 3cm the agreement is within 2mm irrespective of cutout shape size and applicator size. Overall trend shows that with increase in energy mean difference increases although increase is more prominent for 2cm circle at 21MeV as compared to squares and rectangles at same energy. For extended SSD 110cm, the mean difference of depth doses follow the same trend as in case of standard SSD 100cm. In case of higher energies the calculated results are lower in upper part of the curve from R90 to R60 while in lower part the calculated values are higher. Calculated and Measured OPFs are also compared .OPFs are in good agreement for fields greater than 4 cm. But for fields smaller then 4cm disagreement is more than acceptable limits. The Planning algorithm over estimate dose in case of small field sizes as compared to measured results.

Prowess panther accuracy depends on field size and energy and slightly depends on field shaping. Accuracy of prowess panther does not agree well for field size which has any dimension as small as 4 cm, especially for low energies. Additional correction factors must be applied on MUs calculated from Prowess panther for field sizes smaller than 4cm.

SP081.3 - Standard Measurements and MU Calibrations for Carbon Beam Therapy of SAGA-HIMAT

Author(s): <u>Manabu Mizota</u>, Takeshi Himukai, Yoshikazu Tsunashima, Hiroshi Sato, Mitsutaka Kanazawa, Masahiro Endo Ion Beam Therapy Center, SAGA HIMAT Foundation, Tosu/JAPAN

Purpose

At SAGA-HIMAT(Saga Heavy Ion Medical Accelerator in Tosu) facility, we have started radiotherapy with carbon beam from the end of August 2013. The treated patient number reached up to 547 at the end of December 2014 and is steadily increasing.

In case of particle radiotherapy using passively modified beams, dose calibration measurements should have been executed prior to the treatment in order to determine the monitor unit(MU) for each therapeutic beam. Increase in the number of treatments leads to increase of MU measurements and consumption of the machine time for therapy including QA activities. We are preparing to introduce the MU calculation method in order to save machine time and avoid the errors from wrong measurement.

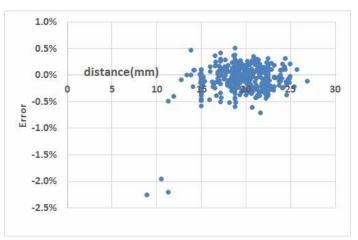

Methods

Routinely, a standard calibration measurement is repeated under the same condition at every port at each beam energy. We use beam energy of 400MeV/n and 290MeV/n for the correction of MU calibration in the corresponding energy. So we firstly checked its trend and the correlation among ports or among energies.

Secondly, we studied the applicability of MU calculation method which was developed at NIRS(National Institute of Radiological Sciences). In carbon beam dosimetry, MU depends primarily on the 3-dimensional field condition of broad beam method and secondarily on the aperture made by collimator. The aperture varies infinitely depending on the shape of target whereas the number of field conditions is limited. Precise field-size(aperture) effect calculation is done using kernel-beam model which is composed of two Gaussian functions.

Results

The good correlation between the two energies was obtained at each port. Also the MU calculation showed good agreement. The calculated values for MU have been compared with the measured ones used for therapy at beam energy of 400MeV/n in horizontal port of treatment room B. Figure shows the comparison results in vertically and the minimum distance between collimator and beam axis along horizontal axis. This calculation procedure reproduced succesfully almost all the measured value within 0.5% accuracy, except for three case where the reference point is very near to a collimator edge. The discrepancy at these region seems to be due to the simplicity of the beam model.

Conclusion

The effectiveness of the MU calculation method was verified at SAGA-HIMAT. We are trying to put to practical use as soon as possible. Then the more efficient operation of the treatment beam would be possible.

SP081.4 - 3D "Bridge" Silicon Microdosimeter for RBE Studies in 12C Radiation Therapy

Author(s): Anatoly B. Rosenfeld¹, Linh T. Tran², Lachlan Chartier¹, Dale A. Prokopovich³, Susanna Guatelli¹, Marco Petasecca¹, <u>Michael</u> <u>L.F. Lerch¹</u>, Naruhiro Matsufuji⁴, Michael Jackson⁵ ¹Centre For Medical Radiation Physics, University of Wollongong, Wollongong/AUSTRALIA, ²Centre For Medical Radiation Physics, University of Wollongong, Wollongong/NSW/AUSTRALIA, ³Institute Of Materials Engineering, Australian Nuclear Science and Technology Organisation, Sydney/NSW/AUSTRALIA, ⁴Medical Physics Research Program, National Institute of Radiological Science, Chiba/ JAPAN, ⁵University of New South Wales, Sydney/AUSTRALIA

Radiotherapy using heavy ion beam such as Carbon-ion has the advantage of an enhanced dose distribution over conventional radiotherapy with X-rays due to the Bragg peak (BP) energy deposition profile. The Relative Biological Effectiveness (RBE) of a carbon-ion radiotherapy beam greatly depends on a depth of the target volume in the body and the nuclear fragmentation process that occurs in the BP or spread-out BP(SOBP) as well as neutrons. It is important to understand the RBE of the heavy ions in hadron therapy applications in order to deliver correct dose.

Microdosimetry is extremely useful technique, used for dosimetry in unknown mixed radiation fields typical of hadron therapy. Conventional detectors for microdosimetry consist of tissue equivalent proportional counters (TEPC) which have advantages of a spherical sensitive volume and tissue equivalency through use of a tissue equivalent gas. However, TEPC has several limitations such as high voltage operation, large size, which reduces spatial resolution and introduces wall effects, and an inability to simulate multiple cells.

A new silicon microdosimeter with 3D sensitive volumes (SVs) has been proposed to overcome the shortcomings of the conventional TEPC. The new microdosimeter is called "bridge" microdosimeter as it has thin Si bridges between the SVs to support the AI tracks over the SVs. The charge collection study of the new device and its application for RBE determination in ¹²C radiation therapy at the Heavy Ion Medical Accelerator in Chiba (HIMAC), Japan is presented. Derived RBE10 values based on the Microdosimetric Kinetic Model and SOI bridge microdosimetric spectra is presented in Fig.2. The RBE10 values match very well with those obtained from the TEPC measurements. Due to the high spatial resolution of the microdosimeter, more detailed RBE10 measurements were obtained at the end of the SOBP compared to the TEPC. It should be noted that the bridge microdosimeter measurements were done in a PMMA phantom while the TEPC measurements were carried out in water.

This work presented the first RBE10 derivation in a ¹²C ion therapeutic beam using a high spatial resolution SOI microdosimeter and demonstrated a simple and fast method for Quality Assurance in charge particle therapy using silicon microdosimeter.

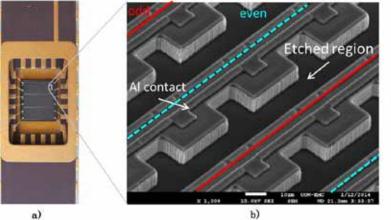

Fig. 1 a) A bridge microdosimeter mounted on a DIL package, b) a SEM image of arrays of SVs

Fig.1a shows the 3D bridge microdosimeter mounted on a dual-inline (DIL) package and Fig.1b shows SEM image of arrays of SVs where the etched region outside the SVs was clearly visible. This new technology provided well-defined micron sized 3D SVs of similar dimensions to biological cells.

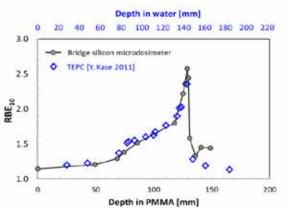

Fig. 2 Derived RBE₁₀ along the central axis of the ¹²C ion beam, obtained by SOI bridge microdosimeter and TEPC at NIRS [2]

SP081.5 - Characterization of a ZnSe(Te) inorganic scintillator for scintillation dosimetry applications

Author(s): <u>Patricia Duguay-Drouin</u>¹, Sam Beddar², Luc Beaulieu¹ ¹Radio-oncologie Et Axe Oncologie Du Centre De Recherche Du Chu De Québec, CHU de Québec, Québec/CANADA, ²University of Texas MD Anderson Cancer Center, Houston/TX/UNITED STATES OF AMERICA

Purpose: The purpose of this work is to characterize a ZnSe(Te) inorganic scintillator for future application in scintillation dosimetry. This study will determine the usability of this scintillator within a multipoint scintillation detector system.

Methods: Different lengths of a ZnSe(Te) scintillator (MolTech GmbH) ranging from 0.5 to 3.0 mm were tested and optically coupled to a 15 m optical fiber (ESKA GH-4001). The photodetectors used in this study are a spectrometer (QE65Pro, Ocean Optics) and a photomultiplier tube (H10721, Hamamatsu). The detector was irradiated using an orthovoltage device (Xstrahl 200) at 120, 180 and 220 kVp, and a linear accelerator (Varian Clinac iX) at 6 and 23 MV for photons beams and at 6, 12 and 18 MeV for electrons beams. The energy, particle type, dose and dose rate dependencies were examined. Also, the attenuation within the scintillator was measured and its emission spectrum was characterized under various irradiation conditions.

Results: The scintillator demonstrates energy and particle type dependence for both the light production and spectral shape. The ZnSe(Te) measured spectrum ranges from 550 to 800 nm for beam energies listed above. For electron beams and MV photon beams, a component at 690 nm is added and the peak at 771 nm is shown to increase with energy (fig. 1). For a given energy, linear dose dependence is observed for all beams tested (R^2 >0.996). Moreover, the scintillator exhibits no dose rate dependence for MV photons beams tested. However, at 120 kVp, a dose rate dependence obeying a power function (R^2 =0.998) is observed (fig. 2).

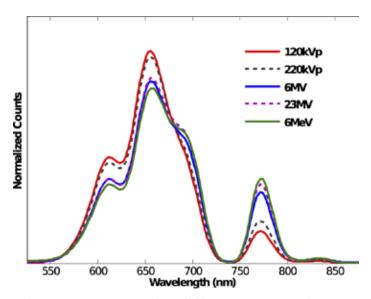

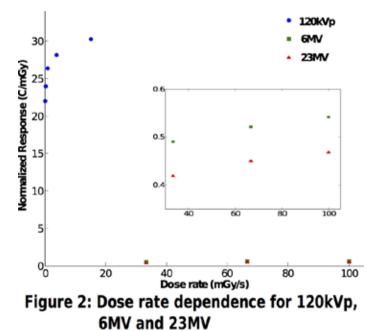

Figure 1: Spectra for different energy beams

Conclusion: The ZnSe(Te) inorganic scintillator has been characterized for dosimetry applications. When using this scintillator, one must takes into account the dose rate, energy and particle type dependences. Despite these dependencies, this scintillator with a spectrum of higher wavelength remains a good candidate for multipoint applications.

SP081.6 - Determination of correction factors for the use of ionization chambers in the presence of magnetic fields Author(s): Gabriel O. Sawakuchi, <u>Geoffrey S. Ibbott</u>, Michelle V.P. Mathis

Radiation Physics, The University of Texas MD Anderson Cancer Center, Houston/UNITED STATES OF AMERICA

Various groups in Europe, North America and Australia are currently developing magnetic resonance imaging (MRI) guided radiotherapy technology by integrating an MRI scanner to a linac (MRI-linac). MRI-guided radiotherapy will provide exquisite images of soft-tissue with high temporal resolution to allow tracking tumor and organ motions in real-time. One of the challenges to implement MRI-linac technology in clinical practice is to calibrate the radiation output under the presence of a strong magnetic field (B-field). The addition of the permanent B-field from the MRI affects the response of ionization chambers (ICs) (Meijsing et al. 2009, Phys. Med. Biol. 54 2993-3002; Smit et al. 2013, Phys. Med. Biol. 58 5945-57; Reynolds et al. 2013, Med. Phys. 40 042102). In this work we show preliminary results of Monte Carlo (MC) calculations of beam quality correction factors under the presence of a B-field for various ICs. We used the Geant4 toolkit throughout this work. First we established the best set of parameters for the Geant4 condensed history algorithm so that the code passes the Fano test within 0.5% (Poon et al. 2005, Phys. Med. Biol. 50 681-94). Then, we used well-established methods from the literature (Muir and Rogers 2010, Med. Phys. 37 5939-50) to calculate kQ values for several ICs in a SL25 6 MV beam without (kQ) and with (kQB=1.5T) the presence of a 1.5 T B-field. The maximum percentage difference between our kQ values and TG-51 (McEwen et al. 2014, Med. Phys. 41 041501) results for a set of seven chambers was 1.4%, demonstrating that our MC model is adequate (Table 1). Our results in Table 1 show that kQB=1.5T values strongly depend on IC model/geometry and material composition of the ICs, i.e., for identical geometry but different collector and wall materials, kQB=1.5T values were different. For the set of ICs

investigated we observed corrections of up to 4.4% for the Exradin A19 chamber. Among the investigated chambers, the PTW 30011 presented the smallest correction factor (1.2%). Our future work will use a realistic energy spectrum of an MRI-linac unit (Atlantic, Elekta Inc.) to calculate kQB=1.5T values for selected ICs. Future work is also needed to validate calculated kQB=1.5T values against experimental data.

Table 1: kQ values calculated using Geant4 with and without the presence of a 1.5 T B-field. The B-field was perpendicular to the beam and perpendicular to the axis of the cylindrical ICs.

SP082 - Nonlinear Dynamic Analysis

TRACK 09: BIOSIGNAL PROCESSING

SP082.1 - Aging Process: Central Pressure Waveform Loss of Complexity

Author(s): <u>Ricardo L. Armentano</u>¹, Leandro J. Cymberknop², Walter E. Legnani¹, Manuel R. Alfonso², Franco M. Pessana³ ¹School Of Advanced Studies In Engineering Sciences, National Technological University, Ciudad Autónoma de Buenos Aires/AR-GENTINA, ²Buenos Aires Regional Faculty, National Technological University, Ciudad Autónoma de Buenos Aires/ARGENTINA, ³Faculty Of Engineering And Exact And Natural Sciences, Favaloro University, Ciudad Autónoma de Buenos Aires/ARGENTINA

Introduction: Aging is defined as the age-related decline in physiological function where arterial stiffening and hypertension constitute related disorders in the cardiovascular system. Age can be considered as one of the most powerful determinants of cardiovascular risk, usually been viewed as a chronological, unmodifiable and even untreatable factor. Arterial mechanical properties of the small vessels are known to be altered with advancing age (dilating and stiffening), leading to a rise in pulse pressure (PP). In this sense, central pulse pressure (cPP) has been more closely related to cardiovascular events than peripheral pulse pressure (pPP). From the point of view of chaos theory, multiscale and nonlinear complexity (structure and interactions of individual subsystems) appears to degrade with aging and disease. In our previous studies, waveform complexity of arterial pressure (AP) was related to stiffness variations as well as to the presence of wave reflection. Additionally, age related changes were also analyzed in cPP waveform. **Objective**: The aim of the present study was to evaluate changes in the waveform complexity of cPP as a result of the aging process. Material and Methods: Continuous, noninvasive blood pressure measurements were analyzed in 16 healthy subjects (8 young, 20-29 yr and 8 aged, 50-69 yr). Individuals with cardiovascular disease risk factors were excluded from the experiment. A generalized transfer function was used to obtain the cPP waveform from the pPP (measured by applanation tonometry) using a customized software (SphygmoCor, AtCor Medical, Sydney, Australia). Time series waveform complexity was assessed by means of fractal dimension (FD) calculation, based on the method provided by Higuchi. Statistical analysis was carried out using an unpaired Student's t-test. A value of p<0.05 was considered statistically significant. Results: A significant decrease in FD values was obtained in cPP waveform for aged subjects (1.09±0.02 to 1.04±0.01), concomitant to a cPP increase. Conclusion: Considering previous studies, the loss of complexity has been hypothesized to be an indicator of the transition from normal aging to frailty. In the present work, loss of waveform complexity was observed as a consequence of the aging process in cPP. Arterial structural changes were reflected in FD variations, independently of the AP calibration, due to the space filling property and the fine structure of the waveform were analyzed. Further studies are necessary in order to determine if changes in waveform complexity can be utilized as a complementary factor of vascular aging.

SP082.2 - Changes in COP scaling behaviour in quiet stance after mTBI

Author(s): Coren Walters-Stewart, Andre Longtin, Heidi Sveistrup University of Ottawa, Ottawa/CANADA

The analysis of centre of pressure (COP) timeseries is well suited to the evaluation of balance control. Balance control is often interpreted as a physiological control system with coordinating sensory inputs and muscle outputs. COP variables can provide clues about the controlling mechanisms affecting balance. Mild traumatic brain injury (mTBI) often results in functional impairments including balance impairments that seem to suggest altered signalling within the brain. It was hypothesized that the altered mechanisms affecting balance after mTBI might be reflected in altered scaling properties of COP. University football players (n=74) were tested at the beginning of the season as a baseline and were retested if they sustained an mTBI during the season (n=6, tested an average of 15.7±7.2 days after injury). Players who did not sustain an mTBI were also retested at the end of the season for comparison (n=17). Each participant was asked to stand quietly with eyes closed for 90 seconds on a portable force platform. Scaling behaviour was determined by (1) classifying the timeseries using the beta estimate, (2) identifying how many scaling regions exist, and (3) calculating scaling estimates for each region. Data for mTBI and uninjured groups were compared to their own respective baselines. Results demonstrated that while typical scaling behaviour of COP timeseries were always the sameshort-term persistence (H1>0.5) and long-term anti-persistence (H2<0.5)-the group who had sustained mTBIs demonstrated a significant change (between baseline and post-mTBI) toward less random short-term values in the mediolateral direction whereas the uninjured players did not (see Figure 1). While the overall ability to maintain balance is not altered, demonstrated by the unchanging long-term scaling behaviour and by the fact that no players were falling over, some subtle changes to how the COP is being controlled in balance do occur after an mTBI. This method of measuring changes to balance may be useful in determining whether or not players are being returned-to-play when still impaired in ways that may lead to re-injury.

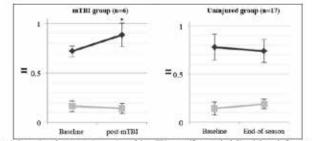

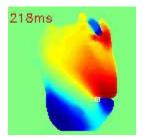

Figure 1 Comparisons between testing sessions of the mTBI group (figure to the left) and the end-of-senson group (figure to the right) showing the short-term (H₀, \blacklozenge) and long-term (H₀, \dashv) scaling parameters (mean \pm standard deviation). The attentist(*) indicates a significant change (p=0.05) from baseline of the short-term scaling parameter in the mTBI group. Only results for the mediolateral direction are shown.

SP082.3 - Tracking algorithm of spiral wave core in a cardiac tissue using Hilbert transform and phase variance analysis Author(s): <u>Naoki Tomii</u>¹, Masatoshi Yamazaki², Haruo Honjo², Ichiro Sakuma¹

¹The University of Tokyo, Tokyo/JAPAN, ²Nagoya university, Nagoya/JAPAN

Arrhythmia is a common and increasing disease, especially in developed countries. There are several treatment approaches toward arrhythmia such as anti-arrhythmic drug, radio frequency ablation and electrical stimulation. To investigate about mechanism of arrhythmia and improve efficacy of these treatments, optical mapping system has been used in many previous works. Optical mapping is an useful measurement system of cardiac excitation. This mapping system is mainly composed of isolated heart dyed with voltage sensitive dye, high brightness excitation light, and high speed camera. Because emitted spectrum of voltage sensitive dye changes with a change of transmembrane potential of each cardiac cell, we can measure the activation potential at each points and it's propagation as the change of fluorescence spectrum. Using this system, propagation of excitation in cardiac tissue can be measured in high speed (more than1000 fps) and in high resolution (less than 0.05 mm / pixel). Spiral wave propagation of excitation in a cardiac tissue (spiral reentry) is known to play key role to cause and sustain dangerous arrhythmia, such as tachycardia and fibrillation both in ventricular and atrium. It has been reported that stability of the center of spiral wave (spiral core) is related to the sustainability of spiral reentry. Thus detection and tracking of spiral core in optical mapping images is important to analyze spiral reentry. Bray et al. proposed phase analysis of spiral reentry using Hilbert transform. In this method, core of spiral is mathematically defined as "phase singularity point" around which the contour integration of phase value is 2π or -2π. However, applying this definition to detect the spiral core in optical mapping images is difficult because there are huge amount of surrounding counters in an image. In this work, we present novel detection algorithm of the core of spiral reentry in optical mapping images. Using angular dispersion of phase values in a bounding box, we detected high dispersion point as the core of spiral. We will report the accuracy of the detection and the computational cost of this algorithm.

SP082.4 - Mapping the Fractal Dimension of Arterial Pressure Author(s): Leandro J. Cymberknop¹, Ricardo L. Armentano², Franco M. Pessana¹, Manuel R. Alfonso¹, Walter E. Legnani³ ¹Buenos Aires Regional Faculty, National Technological University, Ciudad Autónoma de Buenos Aires/ARGENTINA, ²Faculty Of Engineering And Exact And Natural Sciences, Favaloro University, Ciudad Autónoma de Buenos Aires/ARGENTINA, ³School Of Advanced Studies In Engineering Sciences, National Technological University, Ciudad Autónoma de Buenos Aires/ARGENTINA

Introduction: The cardiovascular system is constituted by a complex network of vessels, where highly uniform hierarchical branching structures, that cover a wide range of diameter scales, are regulated by the anatomy and local flow requirements. In recent years, homeodynamic and holistic concepts such as fractal and nonlinear analyses were proposed to be helpful to study the complexity of physiological functions. In the systemic circulation, arteries bifurcate many times before they became capillaries where the scaling factor of vessel length, diameter and angle between two children branches is established at each level of recurrence. For these reason, this type of vascular system can be described using a fractal scaling principle. In this sense, it was observed than the basic pattern of blood distribution is also fractal, imposed both by the anatomy of the vascular tree and the local regulation of vascular tone. In our previous studies, arterial pressure time series (AP) waveform complexity changes were evaluated by means of a fractal dimension (FD) measure. To our knowledge, a holistic analysis of FD variations throughout the arterial network has not been previously reported. Objective: The aim of the present study was evaluate the variation of arterial pressure waveform complexity considering its anatomical location in the branching structure. Material and Methods: Continuous, AP measurements were obtained in the following sites: left ventricle and descending thoracic aorta (five male mongrel dogs, instrumented with solid-state implantable pressure sensors, Konigsbeg inc., Passadena, USA) and carotid and femoral arteries (five male middle-aged subjects, without cardiovascular risks factors, evaluated by applanation tonometry, Millar Inc., Houston, USA). Due to experimental limitations, invasive (in animals) and non-

invasive (in humans) measuring methodologies were performed. Assessment of FD in AP time series waveforms was developed by applying Higuchi's method. Topological dimension was not considered in FD relative changes (Δ FD) calculation. Statistical analysis was carried out using the paired Student's t-test. A value of p<0.05 was considered statistically significant. Results: A significant increase in Δ FD was observed at the thoracic aorta (higher complexity) in respect to ventricular pressure FD values (+233.06±75.34%). On the other hand, femoral artery AP manifested a decrease in ΔFD (lower complexity) in comparison to the carotid site (-56.51±13.62%). Conclusion: A holistic evaluation of AP waveform complexity in the arterial network was performed, where its FD changes were related to the vascular site. While the ventricular pressure time series was observed to be 'fractalized' at the aortic level (due to the waveform is more exposed to the multiple wave reflections), AP showed a loss of complexity at distant sites from the cardiac muscle, manifesting an 'unwrinkling' phenomenon.

SP082.5 - Moving deterended fluctuation analysis for inspecting time evolution of scale invariant structures in biomedical signals

Author(s): <u>Hamidreza Saghir</u>, Tom Chau, Azadeh Kushki Ibbme, University of Toronto, Toronto/CANADA

Detrended fluctuation analysis (DFA) is commonly used for characterizing the fractal structure of biomedical signals. One of the underlying assumptions of DFA is that the fractal structure is consistent [AK1] in time and can be characterized by a single scaling exponent. However, the scale invariant structures of multifractal signals are modulated in time and lead to the existence of a spectrum of scaling exponents. Conventionally, Multifractal analysis has been used to study the statistical distribution of a range of scaling exponents. However, these methodologies do not provide any information about the time evolution of scaling exponents.

This article introduces a new methodology based on DFA, called moving deterended fluctuation analysis (MDFA) for examining the evolving scale-invariant structure of a signal in time through phasecouplings between temporal scales. Instead of using non-overlapping time intervals as in conventional DFA, MDFA computes the root mean square of the detrended residuals in a moving window at each time scale, resulting in a time- and scale- dependent root-meansquare measure. The scaling exponent is then numerically calculated as the linear slope of the log-log plot of root mean squares versus scale at each time instant.

We used MDFA to inspect time evolution of scaling exponents in ECG signals during a movie-watching task as well as an anxiety-inducing task (Stroop Color-Word Interference task) in 33 participants (n=33, age: 12.5 +/-2.9 years, full-scale IQ: 112.9 +/- 14.1, 19 male[AK2]). The results show that the modulation of the local scaling structure was significantly influenced by condition (i.e. relaxed, stroop practice, anxious, p=0.04). This modulation was not significantly different for a white noise series of the same length. MDFA returns an average scaling exponent of 0.5 [AK3] for white noise which is consistent with the results of other methods. These results suggest that MDFA is a useful tool for inspecting the time evolution of scale-invariant structures in multi-fractal signals and should be further investigated.

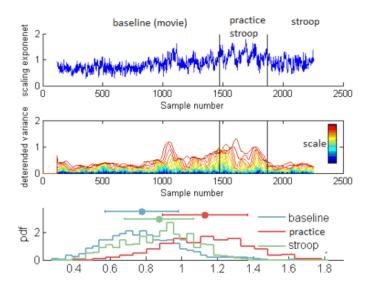

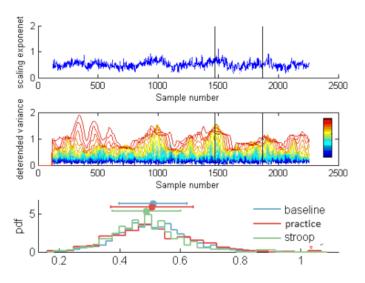

figure 1. Example of MDFA for one participant (left) compared to white noise (right). Top panel demonstrates the time modulation of scaling exponents. Middle panel shows the evolution of root mean square residuals across time and scales. Bottom panel shows the probability distribution of scaling exponents in anxious (stroop) and relaxed (baseline) conditions. (practice is a transitory state in which the participant practices the task a few times before starting the stroop task)

SP083 - Lower Limb Injury Assessment and Treatment & Prosthetics and Assistive Devices

TRACK 10: REHABILITATION MEDICINE, SPORTS MEDICINE, REHABILITATION ENGINEERING AND PROSTHETICS

SP083.1 - Design of a braking simulator for the assessment of lower limb fracture recovery

Author(s): <u>Andrew O'Connell</u>¹, Alvan Buckley¹, Andrew Furey¹, Maria Doyle², Amy Hsiao²

¹Faculty Of Medicine, Memorial University of Newfoundland, St. John's/CANADA, ²Mechanical Engineering, Memorial University of Newfoundland, St. John's/CANADA

"When can I drive?" is a question frequently asked of orthopedic surgeons following injury and surgery of the lower limb. Surgeons are left to make a difficult decision, as there are no specific guidelines on when patients should be cleared to drive, and there are significant discrepancies between mean recovery times for different procedures in the literature. Although there is no clear consensus between law enforcement, insurers, road authorities and the medical community, the decision as to whether an orthopedic patient can adequately brake an automobile following surgery is generally defaulted to the surgeon. Surgeons are faced with the dilemma of managing their duty to the patient, to the public, and the medicolegal risks involved with giving patients advice on when they can get back on the road. Studies suggest that a simulator may be useful in assessing braking capacity following surgery of the lower limb; however, they are currently not widely used by surgeons. Significant recurring issues exist with current or proposed simulators: (1) they generally cannot be used to assess trauma patients due to the need for baseline testing preoperatively, (2) limited data is available to demonstrate their ability to evaluate a patient's braking performance, (3) braking forces are not translated into stopping distances or indeed not considered at all, (4) and the devices are often not practical in an outpatient setting. In order to drive safely, one must be capable of stopping a vehicle in an emergency. Braking capacity depends on a host of patient variables including visual acuity, neurological function, musculoskeletal function, and the influence of drugs among others. Our intention is to develop a method to evaluate performance of the lower limb, specifically. This work presents the design of a simulation device that will provide surgeons with an objective assessment of their patient's breaking performance in an outpatient clinic. This simulator will compare calculated total stopping distances after the appearance of an emergency stimulus with the total stopping distance recommended for specific driving speeds in the literature. Alternatively, this maximum stopping distances will be inferred using recommended brake reaction times and forces to provide a benchmark for the assessment of braking performance.

SP083.2 - Quantitative measurement of subtalar joint passive stiffness in children with cerebral palsy

Author(s): <u>Wei Chen</u>¹, Fang Pu¹, Yang Yang¹, Jie Yao¹, Li Z. Wang¹, Yu B. Fan^{*2}

¹Key Laboratory of Rehabilitation Technical Aids, Ministry of Civil Affair, School of Biological Science and Medical Engineering, Beihang University, Beijing 100191, P. R. China, Beijing/CHINA, ²National Research Center for Rehabilitation Technical Aids, Beijing 100176, P.R. China, Beijing/CHINA

Subtalar joint (STJ) passive stiffness is critical to foot valgus defor-

mity for children. The aim of this study was to develop a STJ passive stiffness measuring device to obtain the STJ passive stiffness. The reliability of clinical measurements was used to assess the STJ passive stiffness in weight bearing between normal children and those with cerebral palsy (CP). Ten feet of five non-disabled children and ten feet of seven with CP taken of affected foot were collected to measure their STJ passive stiffness (6.5 ± 2.1 years vs 6.3 ± 1.9 years). The Intraclass Correlation Coefficient (ICC) was used to assess the reliability of the device for measuring STJ passive stiffness. Statistical analysis was conducted using one-way ANOVA to assess between-group differences. ICCs were 0.98 for inter-reliabilities STJ passive stiffness of CP group and 0.99 for control group. STJ passive stiffness of foot valgus deformity. It is concluded that STJ passive stiffness is a reliable measurement due to its high repeatability.

SP083.3 - Differences in the parameters of impedance between knees with and without meniscal injury in female athletes Author(s): <u>Marysol Garcia-Pérez</u>, Marco Balleza-Ordaz, Miguel Vargas-Luna, María Raquel Huerta-Franco División De Ciencias E Ingenierías, Universidad de Guanajuato, León, Guanajuato/MEXICO

Introduction. The medical trials used to diagnostic these pathologies are the x-ray and MRI techniques. The x-ray reveals injuries in hard tissues (bones), while MRI evidences the injuries in soft tissues (meniscus and tendons). These kind of medical diagnosis techniques are expensive in most cases. Our research group propose the electrical bio-impedance (EBI) technique as an option to assess the knee condition.

Objective. The main objective of this research is to compare the impedance parameters between knees with and without meniscal injury in female athletes.

Materials and methods.

a) Volunteers. In this study participated 6 sportswomen (Age: 19.5±0.8 years, BMI: 20.4±3 kg/m²). Previously, all volunteers were assessed for meniscal problems comparing right and left knees by a sports medical professional staff. All volunteers had physical condition according to the parameters of the American College of Sports Medicine. Body composition were measured to all volunteers.

b) Procedure. The bio impedance parameters where assessed with a BIOPAC System (MP150), which injects an electrical current of 1 mA at different frequencies (12.5 kHz, 25 kHz, 50 kHz, 100 kHz).

In order to monitor the knee condition by bio-impedance, four electrodes were placed in each knee. All volunteers were asked to fully extend each leg in periods of 5 seconds to perform the test at 30 seconds.

c) Signal processing. All the data were analyzed using the Matlab software. The impedance data were analyzed and compared at different impedance frequencies. Subsequently, these results were correlated with the clinical findings made to all the volunteers.

d) Statistical analysis. The comparison of impedance parameters between knees with and without meniscal injures were made using a t-test for independent groups.

Results. All the volunteers had meniscal injure in the right knee; however there were not statistical differences when we compare the length of the lower pelvic limb the mean and standard deviation (X±SD), were: 91.9 ± 7.4 vs. 91.8 ± 7.0 , for right and left limbs (t=0.02, p=0.98). The mean and standard deviation of the bio impedance parameters were as follows: 48.9 ± 10.7 vs. 71.5 ± 19.1 . When we compare with a t-test we found significant differences between knees with and without injure (t=-3.58, p=0.002), see figure 1.

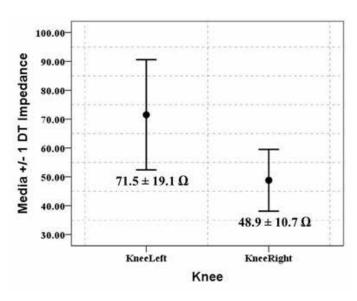

Fig 1. Differences in the mean and SD of impedance parameters of right and left knee with and without meniscal injures, t=-3.58, p=0.002.

Conclusions. In this study we demonstrated that the impedance technique could be a good option in order to monitor the knee condition.

SP083.4 - Development and evaluation of a mechanical stance controlled orthotic knee joint with stance flexion utilizing a timing based control strategy flexion

Author(s): <u>Hankyu Lee</u>¹, Matthew J. Leineweber², Jan Andrysek² ¹Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA, ²Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto/CANADA

Medical conditions such as spinal cord injury, spina bifida poliomyelitis and others can result in severe loss of lower limb muscle function and lead to impairments in mobility. For patients who have the potential to walk, orthotic treatments including knee-ankle-foot-orthosis are commonly used to address problems with knee instability. Recent advancements have led to the development of more sophisticated orthotic knees that restrict knee flexion during stancephase while allowing articulation during the swing-phase. These stance-control orthotic knee joints stabilize the knee joint during the stance-phase of gait without restricting swing-phase flexion, thus achieving a more normal gait for individuals with quadriceps muscle weakness. However, there are inherent challenges in ensuring safe weight-bearing capabilities while allowing for maximum knee flexion during swing-phase over a range of walking speeds. The work here presents a new type of stance control strategy and stance controller design employing a mechanical timing system, which was modelled using empirical data and functionally tested in a gait laboratory.

Pilot clinical testing was performed on a prototype stance-control orthotic knee joint incorporating a novel timing system for controlling knee lock during swing- and stance-phase. Our timing-based control strategy was developed using empirical models of gait cycles at normal and fast walking speeds. Clinical feasibility of this approach was tested on a poliomyelitis patient using spatiotemporal, kinematic, and kinetic gait data captured using a standard motion capture system and floor-mounted force plates. Walking trials were performed with the orthotic in its unlocked functional mode, as well as in a locked mode to represent traditional knee-ankle-foot-orthoses.

The results of these tests showed that our prototype design provided reliable knee stability while facilitating swing-phase flexion, for more normal knee joint kinematics in both the swing and stance phases. In particular 44 degrees of swing-phase flexion and 15 degrees of stance-phase flexion were achieved, compared to 5 degrees stance-flexion in the locked conditions. Our empirical stance-control model indicates that the timer can range from 0.572 to 0.963 seconds while allowing for successful operation for both normal and fast walking speeds. During clinical evaluation, all trials were completed with the subject being able to consistently unlock the knee during walking without incidence of instability when the knee would not unlock.

The stance control mechanism was effective for gait initiation, steady state walking and gait termination, however further testing is needed in-situ to assess other mobility condi-

tions. Critical to the reliability and robustness of the proposed strategy, was the requirement of the chosen triggering conditions to be sufficiently independent of variations in walking speed. Our analysis shows that a large enough window exists for which a single timer duration would ensure the timely locking of the knee joint, to ensure both swing-phase initiation and proper locking throughout stancephase. In addition to providing stance control and stance flexion, the knee joint design was significantly decreased size and weight from current stance-controlled orthotics.

SP084 - New Designing Ideas

TRACK 12: MEDICAL DEVICES

SP084.1 - Soprano - Nasogastric Tube Insertion Guide

Author(s): Karthik Kannan¹, Sum Kok Meng², Foad Kabinejadian³, Hwa Liang Leo¹

¹Department Of Biomedical Engineering, National University of Singapore, Singapore/SINGAPORE, ²Singapore General Hospital, singapore/SINGAPORE, ³Department Of Surgery, National University of Singapore, Singapore/SINGAPORE

Nasogastric Tubes (NGTs) are used for feeding and administering oral medication in patients with either impaired swallowing mechanisms or obstruction in the upper aero digestive tract that prevents oral feeding. They are inserted through the nose into the stomach and represent an important means of long-term feeding especially in patients with neurological diseases (e.g. strokes). In the US alone, 1.2 million NGTs are inserted yearly. NGT placement entails a significant risk of malpositioning that may result in death from aspiration of liquids into the lungs and expose healthcare institutions to significant medicolegal liability risks. Yet, current methods of confirming correct placement are not foolproof. Moreover ensuring proper placement consumes significant resources- e.g. Chest x-rays for confirmation, hospitalization for costly alternative endoscopic and radiological guided placement methods.

Our device, Soprano is coined on the concept of frugal engineering. With a simple, elegant and innovative solution, we addressed a clinical problem that demands immediate attention and possibly save numerous lives and millions of dollars. Our basic specifications were easy steerability and an accurate and reliable feedback mechanism to identify the correct placement of NGT in the esophagus. (1) Our device is a semi-rigid guide that has a specific elliptical cross-sectional profile that acts as a funnel through which the NGT can be passed through easily into the esophagus and thereby all the way into the stomach. (2) The guide has been specifically designed with an inherent curvature conforming to the anatomy of the nasopharynx area that enables easy steering. (3) Additionally, the guide provides an accurate audio feedback that works on the basis of our inherent inhalation and exhalation cycles. This produces an audio feedback should the guide be wrongly inserted into the trachea. However, no sound is produced if the guide is correctly inserted in the esophagus. Further research into human physiology and sound frequency produced within the esophagus would allow us to the further improvise Soprano to accurately detect the frequency of sound produced when correctly placed in the esophagus, giving a positive signal instead of the current negative confirmation. (4) The NGT can then be passed through the guide and the guide later removed via a special slit and having a perforated guide. Soprano promises to be a simple, cost and time-effective solution that for both patients and healthcare professionals alike.

SP084.2 - High Output Impedance Current-Conveyor Oscillator for Electrical Bioimpedance Applications

Author(s): <u>Pedro Bertemes-Filho</u>¹, Volney C. Vincence¹, Dejan Krizaj² ¹Electrical Engineering, Universidade do Estado de Santa Catarina, Joinville/BRAZIL, ²Laboratory For Bioelectromagnetics, University of Ljubljana, Faculty of Electrical Engineering, Ljubljana/SLOVENIA

The objective of this work is to investigate the use of a current conveyor oscillator with current output for tissue excitation in a wide frequency range. It was implemented using a sinusoidal oscillator that provides an output current in a wide frequency range with a maximum amplitude of 650 µApp. It uses a second generation class AB current conveyor developed with CMOS AMS-0.35 µm technology and is configured in a Wien bridge structure. It has a low power oscillator supplied by \pm 1.5 V with a consumption of approximately 400 µW. The simulation results showed a frequency sweep between 1.04 to 1,230 kHz by using an integrated bank of capacitors. The maximum total harmonic distortion was 1.8% in the frequency range. The output impedance was bigger than 46 MΩ at lower frequencies but 2.4 MΩ at 1 MHz. The development of a low power current source without using an external voltage generator might be very attractive for measuring cell impedance at the electrode site and for designing battery powered bioimpedance systems.

SP084.3 - Healthcare Device for People Affected by Dementia Author(s): <u>Sara M. Velez</u>, L V. Wilches

Mechatronics Engineering, Escuela de Ingeniería de Antioquia, Envigado/COLOMBIA

Dementia may be defined as a progressive disorder that affect cognitive abilities in a level enough to cause disability to face everyday life [1]. Around 44 million of people worldwide suffer Dementia and it is expected that this number will reach until 75 million to 2030. Almost 60% of them live in countries without high incomes and have a weak public health service. Although the term Dementia refers to a group of illness that can produce similar symptoms, the Alzheimer's disease is the main of them in terms of patients affected. The symptoms can be devastating because of they include a total memory loss and the lack of recognize familiar objects, remember and perform basic activities. In addition, changes in personality and the necessity of professional assistance affect not only the patients but also their families and friends [2, 3].

At least 25% of the hospitalized patients in clinical services have dementia, and many of these admissions could be prevented if their relatives provide a better support at home [4]. Although this condition implies a save of significant health resources, there are risks related to an inadequate healthcare of patients affected by Dementia outside of a hospital. In this way, the first problem to solve is their technical support.

Technical support can be defined as one device that aims to monitor, assist, prevent, or alleviate a disability without losses in the quality of life of the patients that require it. As a response of this necessity, it has developed a device to allow the technical support of the patients with Dementia, without direct vigilance from their caregivers. The device is a bracelet that reminds the users about his or her daily activities through easy recognition signals. A tracking system that uses sensors in limited areas provides information about the patient's location. In addition, a record system allow regulation of medicines, activities and other relevant information about patients in real time. This device provide autonomy and independence when the Dementia is in its early or middle stage.

The main features of this device are their low cost, easy construction and simple functioning compared to other options available in the market. These differences allow to extend its use in countries with emerging economies without significant investments. In addition, its use could help to relieve the saturation of health services and save resources in different medical assistance levels.

SP084.4 - Wide Field-of-View Fluorescence Imaging with Curved Sample Chamber for Point-of-Care CD4 Test Author(s): Kyunghoon Kim, M. Mohiuddin K. Shourav, Subin Kim, Jung Kyung Kim Kookmin University, Seoul/KOREA

It is a technical difficulty to acquire large field image under the complexity and cost restrictions of diagnostic and instant field research purpose. The goal of developing our wide field-of-view imaging system is to achieve tolerable resolution to detect fluorescently-labeled micron-sized particles or cells in the entire image field without the field curvature effect, while maintaining a cost-effective procedure and simple design. In order to obtain a large field image with a simple lens-based optical imaging system, we designed a curved sample chamber. We conducted a systematic study including optical simulations and experiments with a curved sample substrate to ensure a simple and practical design of the proposed system, aimed for a clearer and wider large field of view on a flat plane image sensor. In order to apply our system to point-of-care CD4 test, which can monitor HIV/AIDS disease progression by counting absolute number of CD4 T-cells in a known volume of the blood, the curved sample chambers were manufactured by an injection molding technique. The curved sample chamber reduces the field curvature and image distortion at acceptable level for the CD4 test without using a sophisticated optical elements. The optimal design has a field-of-view of 13 mm and a magnification factor of 0.54. The designed system enables us to image the objects at a spatial resolution > 8 µm and it can be also used for dynamic measurements, such as microscale flow dynamics and micro-organism behavior, by time-lapse imaging and particle tracking methods. Potential applications include a point-of-care medical diagnosis as well as a rapid environment monitoring in field study.

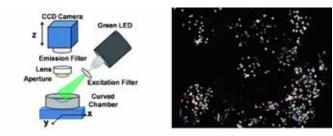

Fig. 1. Experimental setup for wide field-of-view fluorescence imaging with a curved sample chamber.

Fig. 2. Trajectories of fluorescent beads moving on the curved substrate (12 mm x 12 mm) incorporated in wide field-of-view fluorescence imaging system.

SP084.5 - Moisture effect on antibody longevity on paper substrate and the role of hydroxyl groups in the concept of "bio-compatible paper" Author(s): Ziwei Huang, Junfei Tian, Wei Shen

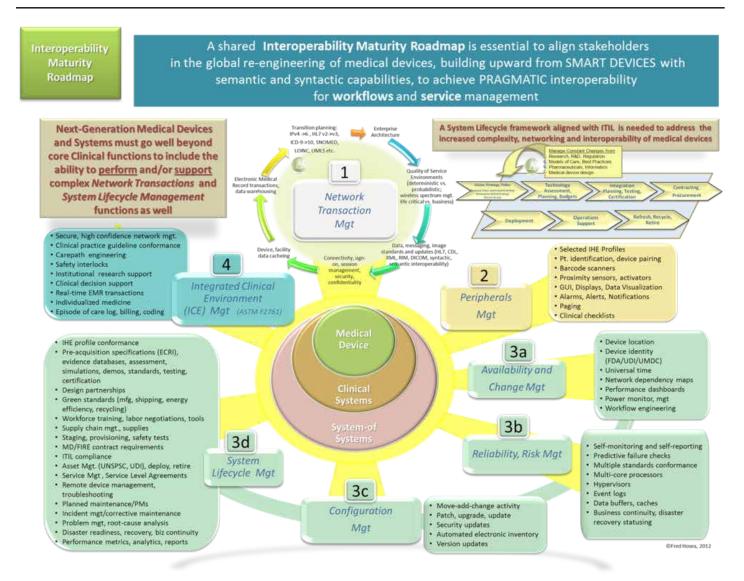

Biopria, Chemical Engineering, Monash University, Clayton/AUSTRALIA

Paper is a bio-compatible alternative for different biological analyses. For example, paper-based blood grouping device is being developed based on the fact that antibody bioactivity can be maintained on substrates as ubiquitous as paper towel. The most common reasons for antibody bioactivity loss on paper due to a molecular change resulting from decreasing water content in the system. However, this is currently a mere hypothesis without any systematic study regarding the moisture effect on antibody longevity on a paper substrate. Additionally, the current paper-based biosensors have used different commercial products of paper, each containing different additives. Whether paper remains bio-compatible without any additives is also unknown. To answer these two questions, a systematic study of antibody longevity was performed with different paper substrates under different relative humidity (RH) environments. Three different kinds of paper were used: pure paper without any additives (30 gsm hardwood paper, PP), pure paper (30 gsm hardwood paper) with 2% of polyamideamine-epichlorohydrin (P-PAE), and commercial paper towel (PT). Our results show that antibodies quickly lose their bioactivity on PP when compared with PT, and a high RH environment accelerates antibody bioactivity loss on both PP and PT. This result suggests that paper without any additives is not bio-compatible and the antibody bioactivity lasts longer under a low RH environment. One significant difference between PP and PT is that the latter employs polymers to increase the wet strength of paper, where the polymer will block some of the hydroxyl groups on the paper surface. Indeed, research has shown that the amount of "free" hydroxyl groups in paper substrate increases under a high RH environment. Therefore, we hypothesize that antibody bioactivity loss is closely related to the amount of "free" hydroxyl groups on the substrate surface. Based on this theory, we used PAE to block partial hydroxyl groups of PP and made P-PAE to carry antibody longevity study under 100% RH. The result of this study has shown a significant increase in antibody longevity with P-PAE, which indicates that "free" hydroxyl groups on the substrate surface is essential in antibody longevity on paper. In conclusion, moisture decreases antibody longevity on paper substrates due to the increasing amount of "free" hydroxyl groups. More importantly, paper without any additives to block the "free" hydroxyl groups can hardly be bio-compatible regarding the antibody longevity. Blocking the hydroxyl groups on the solid substrates can improve the performance of many bio-sensors relying on the antibody bioactivity and further improve the prospects of future paper-based diagnostic devices.

SP084.6 - An Interoperability Maturity Roadmap for Medical Device Design and Alignment with IT Systems Author(s): Fred W. Hosea

Clinical Technology, Kaiser Permanente, Oakland/UNITED STATES OF AMERICA

Despite the existence of numerous standards bodies and professional associations, there are nevertheless very significant gaps between the ways that medical devices and IT systems are designed and integrated, resulting in problems of interoperability and integration that are expensive to resolve in the operational stage of the system lifecycle. The ITIL (Information Technology Infrastructure Library) model of process management is proposed as an essential bridging framework that will enable medical device and IT industries to work together at the design stage, to align their product roadmaps and create a more coherent staging of functionality over a 5-10 year period.

New technological capabilities (such as multi-core processors with hypervisors) are enabling medical devices to execute a much wider range of functions than has been historically possible. Next generation medical devices will be able to support or perform a wide range of process control functions and business functions that augment their value beyond the core clinical functions. "Intelligent" medical devices will be able to identify themselves on the network, support heightened security safeguards, do periodic self-tests and status reports, support remote diagnosis and repairs, issue predictive failure alerts, perform essential functions autonomously offline, enforce safety "guardrail" precautions against user error, and interface automatically with service and asset management processes to enable real-time updates, configuration management, and performance monitoring.

Four major stages of interoperability maturity are proposed, with specific functions assigned to each stage and sub-stage. (1) Net-workTransaction management, (2) Peripherals management, (3a) Availability and Change Mgt, (3b) Reliability, Risk Mgt, (3c) Configuration Mgt, (3d) System Lifecycle Mgt, (4) Integrated Clinical Environment (ICE, ASTM 2761). Key functions are identified that will enable more rigorous standardization of data and process models.

SP085 - Women in Medical Physics

TRACK 18: GENDER, SCIENCE AND TECHNOLOGY

SP085.1 - Women in medical physics: Current status Results from IOMP survey

Author(s): <u>Virginia Tsapakis</u> Konstantopoulio General Hospital, Athens/GREECE

Introduction: The gender composition of medical physicist (MP) workforce around the world is principally unidentified. Acknowledging this issue, IOMP decided to perform a survey to investigate the percentage of women MPs in different countries as compared to total MPs. It was expected that the survey would provide information on gender imbalance, if it existed, and provide a basis for establishment of a subcommittee. Moreover, the results of the survey could provide an opportunity for countries as well as IOMP, for a more in-depth analysis and deliberate on further actions.

Materials and **Methods:** An online questionnaire was created, prepared as a Google Forms survey asking the country, the total number of MPs, the number of women MPs and finally the gender of the person providing the data. The questionnaire was sent to all 6 regional member organizations of IOMP and a major country, the USA. The regional organizations were asked to distribute it among national member organizations (NMOs) and even to non-IOMP member countries.

Results: Sixty-six countries responded to the survey. The results cover more than 3/4 of the MP manpower in the world. The total number of MPs was 17024, of which 28 % were women (4807). The median values of percentages of women were 21 % in the USA, 47 % in Europe, 35 % in Asia, 33 % in Africa and 24 % in Latin America. It was noted that a substantial number of European countries were far away from the target that the European Commission has set, that is 40 %. On the other hand, there were countries in other regions of the world such as the Middle East and Asia, in which women MPs outnumbered men MP. Interestingly enough, there were countries where only women MPs existed and all these were developing countries

Conclusion: This is the first international survey ever that investigated the gender situation on MPs around the world. Due to these very interesting findings, IOMP decided to perform a more in-depth study in the very near future.

SP085.2 - Is there a 'Leaky Pipeline' for Women in Clinical Medical Physics in Canada?

Author(s): Leigh Conroy¹, Elizabeth Watt¹, <u>Wendy L. Smith²</u> ¹Department Of Medical Physics, Tom Baker Cancer Centre, Calgary/AB/CANADA, ²Department Of Oncology, University of Calgary, Calgary/AB/CANADA

We examined the role of women in clinical medical physics in Canada through a representative career path. Gender data for centers affiliated with the Commission on Accreditation of Medical Physics Education Programs (CAMPEP)-accredited residencies and graduate programs were found through departmental websites and informal surveys. Historical certification data was obtained from the Canadian Organization of Medical Physicists (COMP).

Canadian medical physicists receive certification of competence through Canadian College of Physicists in Medicine (CCPM) examinations. Members (MCCPM) must have a minimum level of work experience and fellows (FCCPM) must have additional work experience and significant contributions in the field. A cross-sectional view of the proportion of women at each career stage is shown in Figure 1.

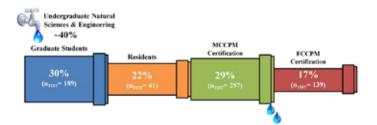

Fig. 1 Proportion of women in 2014 at each stage of a representative career. Female representation at the MCCPM level was comparable to graduate students; however there was decrease at the FCCPM level.

We hypothesized that the paucity of women with FCCPM certification could be due to the natural time delay between career stages. Figure 2 shows the historic trends of the number of CCPM *members in total* (members and fellows) and fellows separated by gender.

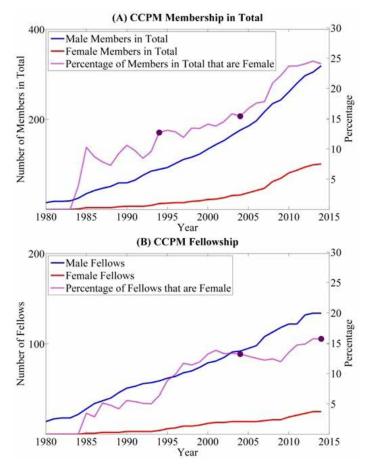

Fig. 2(A) CCPM members in total and (B) fellows. The purple dots demonstrate that in the past decade, the proportion of FCCPMs that are women has echoed the membership of the previous decade.

There were a lower proportion of women at the highest levels of clinical medical physics. Of the 41 identified CAMPEP-accredited director positions (clinical, residency, and graduate program directors), only 7 were held by women.

Overall, we found that women who choose to enter clinical medical physics remain and progress; however, there are comparatively fewer women in leadership positions. This may change in time as the increasing number of women entering the field advance through their careers.

SP085.3 - Women in Medical field in Brazil: gender equality? Author(s): Lidia V. De Sá, <u>Simone K. Renha</u>

Medical Physics Department, NATIONAL NUCLEAR ENERGY COM-MISSION, RIO DE JANEIRO/BRAZIL

The women participation in the Brazilian workforce has increased greatly since 1970; however, it is still lower than men in many specialized professions. In 2013, for a population around 200 million people, the female birth rate was 49.3%. Despite that, at the age of vocational training (20 to 25 years old) this percentage reverses to 50.4%, reaching 53.8% for women older than 60 years, retirement age. In order to verify the presence of women in the medical field a study was carried out including physicians, nurses and medical physicists based on the Brazilian Health System and professionals associations records. The results showed that for physicians there is already gender equality among professionals, presenting an increase from 37% to 52% in ten years for female professionals. For nursing, approximately 80% are women, showing the predominance of this gender due mainly to the characteristics of "caretakers" of this profession. For medical physics area, the scenario is not the same. The country has a reasonable number of certified medical physicists (MP) in radiotherapy, 273, considering that there are 275 linear accelerators, 68 cobalt equipment, 88 high dose rate (HDR) and 61 low dose rate (LDR) brachytherapy devices in use. However, only 36% of these professionals are women. In nuclear medicine, there are in total only thirty certified MPs while only 30% of them are female with the appropriated skill to attend the demand that currently comprises 814 SPECTs, 110 PETs devices and more than 3000 therapy procedures. Diagnostic radiology presents an even more critical situation, with sixty nine certified MPs for a large number of devices, around 3648 CTs, 22052 X-rays, 4250 mammography units, among others practices, where only 36% are women. In conclusion it can be observed that the women representation in scientific and technical workforce is growing fast in the last decade. However, for medical physics field, the women representative in the medical physics area is not expressive and has not been increasing at the same rate of the others medical professionals. Significant efforts should be made on professional formation, emphasizing the female MP education.

SP085.4 - Women Biomedical Engineers as Consultants in Clinical Engineering Field in Latin American Countries: Case of Study

Author(s): Gabriela Jimenez Moyao, Carmen Rendon Isguerra, Sandra Galan, <u>Claudia D.C. Cárdenas Alanís</u>, Erendira Jimenez, Maria Fernanda Zumpano Romero, Stefany Penafort Flores, Paola Salgado Rodriguez, Pamela Lopez Uroza Escala Biomedica, Mexico City/MEXICO

The Consultancy in the engineering field has been a common practice since many years ago; the Biomedical Engineering is not an exception; the multidisciplinary of the career gives the biomedical engineers a wider perspective in the clinical practice, infrastructure planning, management, logistics and engineering fields and the analytical results of this convergence promotes the problem solving and high accuracy advices. Women Biomedical Engineers in the consultancy field are a growing hired staff in Mexico and a specific case of study is a clinical engineering consultancy company in Mexico City with projects mostly in Mexico and Latin America, whose staff is mainly formed by women.

The objective of this article is to define the consultancy model inside and outside the company describing how the women inside the company have been educated based on an inspirational leadership, mostly since the school by the company's founder experience about the clinical engineering field and the motivation to follow values such as truth and justice and also to develop skills such as leadership, effective communication, strategic thinking, innovation and creativity and a systematic improving of their technical knowledge in order to be creative in the problem solving in the consultancy field.

Furthermore, outside the company, describing the challenges women have faced during the consultancy work in the different work fields with different stakeholders such as Hospital Staff, Planning Hospitals Teams, Medical Equipment Vendors, how it has been faced and the solutions and the contribution of these experiences to positioning the company and the women staff members in a competitive mostly men labour field.

In the article there is reference to the interviewed women and also there are mentioned significant testimonies that confirm the hypothesis about the huge impact of the women consultancy work in the clinical engineering field within work teams in the healthcare sector. As a conclusion the experiences described suggest that the women biomedical engineers with leadership skills and good technical knowledge are valuable for the improvement of the healthcare sector and the impact is huge when the knowledge is share inside different organizations through the consultancy efforts.

SP086 - Biological Effects of Ionizing Radiation

TRACK 19: BIOPHYSICS AND MODELLING

SP086.1 - Sensitization of DNA to Ionizing Radiation by Platinum Chemotherapeutic Drugs

Author(s): <u>Mohammad Rezaee</u>¹, Darel Hunting², Leon Sanche² ¹Nuclear Medicine And Radiobiology, University of Sherbrooke, Sherbrooke/QC/CANADA, ²Département De Médecine Nucléaire Et Radiobiologie, Faculté De Médecine Et Des Sciences De La Santé, Université de Sherbrooke, Sherbrooke/CANADA

Concomitant chemoradiotherapy is a common treatment modality for various types of cancers, including upper aerodigestive tract, gastrointestinal, gynecological and genitourinary malignancies, and has improved patient survival. The most significant clinical rationale supporting the use of concurrent chemotherapy with radiation is the role of chemotherapeutic drugs as radiosensitizers. Among the anticancer drugs, platinum analogues are most commonly administered. Their radiosensitizing properties results essentially from their binding to nuclear DNA. Although several mechanisms such as increase in the radiation damage to DNA and inhibition of their repair have been proposed, the contribution and efficiency of the underlying molecular mechanisms of radiosensitization remain unknown. The present study investigates the relative efficiency of the platinum chemotherapeutic drugs (Pt-drugs) in the sensitization of DNA to the direct and indirect effects of ionizing radiation. In particular, it addresses the role of low-energy electrons (LEEs), hydrated electrons and hydroxyl radicals in the radiosensitization of DNA modified by Pt-drugs.

With respect to the direct effects of radiation, LEEs are found to be the main species responsible for the enhancement in DNA damage, particularly cluster damage including double-strand break (DSB) and interduplex cross-links. Irradiation with 10-eV electrons of a 3199-basepair plasmid DNA modified by an average of two Pt-drug adducts results in significant increases in the DSB formation by factors of 3.1, 2.5 and 2.4, respectively, for carboplatin, cisplatin and oxaliplatin relative to unmodified DNA (Table below). Irradiation of these samples with subexcitation-energy electrons (i.e., 0.5 eV) produces substantial number of DSB in the modified DNA, while no DSB is observed in the unmodified DNA. Since 0.5 eV is well below that energy required for the electronic excitation of organic molecules, dissociative electron attachment must be the main mechanism responsible for the formation of strand breaks in the presence of Pt-adducts. Our results also indicate that carboplatin and oxaliplatin have higher efficiency than cisplatin in the enhancement of radiation damage to DNA (Table below).

For the indirect effects of radiation, our results show that both hydroxyl radicals and hydrated electrons are responsible for the enhanced formation of damage in modified DNA. In the presence of Pt-adducts, hydroxyl radicals mainly contribute to the formation of single-strand break, while hydrated electrons are the main species responsible for the DSB formation.

In conclusion, Pt-drug modification is an extremely efficient means of enhancing the formation of DNA DSBs by both LEEs and hydrated electrons created by ionizing radiation.

DNA dan	DNA damage yield (10-8/Gy/bp) for electron-irradiation of unmodified and Pt-modified DNA.								
	DSB-Formation				SSB-Formation

SP086.2 - Lymphoma and Choroidal Melanoma cells in the presence of gold nanoparticles: In-Vitro study Author(s): <u>Somayeh Asad</u>¹, Mehdi Vaez-Zadeh¹, Sahar Balagholi², Mostafa Olfat¹, Mozhgan Rezaeai², Fatemeh Alikarami² ¹Physics, K.N.Toosi University of Technology, Tehran/IRAN, ²Ophthalmic Research Center,, Shahid Beheshti University of Medical Sciences, Tehran/IRAN

The aim of this work is to investigate the effects of different sizes and concentrations of gold nanoparticles (GNPs) on the cell viability in both lymphoma and choroidal melanoma cells.To this end, GNPs were synthesized following the Fern's method in three sizes of 20, 40 and 60 nm. Both Melanoma and Lymphoma cells were grown in 6 (24-well) plates so that the first three plates containing Melanoma cells and the last three plates containing Lymphoma cells. In all six plates, the first five wells were coated with five different concentrations of GNPs and the sixth of them was assigned as control. For both Melanoma and Lymphoma cells, one plate was injected by GNPs with the diameter of 20 nm in five different concentrations of 200, 150, 100, 50 and 25µg and two plates were injected by GNPs with the concentrations of 600, 400, 200, 100 and 50 in which the nanoparticles have a diameter of 40 nm in one of them and 60 nm in another. MTT method was used to assay the cell viability after incubating the cells for 48 hours at 37°C. Compared to the control, in all six plates the results show that both melanoma and lymphoma cells grown were decreased in the present of nanoparticles. However, there was difference on cell grown between Melanoma-GNPs and Lymphoma-GNPs exposures in-vitro. For instance, at the concentration of 200 µg the present GNPs in Lymphoma cells showed strong decrease of cell viability, while, the viability decrease in melanoma cells was not very considerable. Choose of the size and concentration of GNPs to achieve the best results in ophthalmic brachytherapy are depend on the tumor. Considering the sensitive tissue which the eye is involved in, the dose to normal tissues in comparison with the resultant dose increase in the tumor is of outmost importance in investigation of GNPs effects on ophthalmic brachytherapy dosimetry which require In-Vivo study. Also, further in vivo cytotoxicity tests are required before high-concentration GNPs can be used for choroidal melanoma treatment.

SP086.3 - Multiple Code Comparisons of Proton Interactions in the Presence of Gold Nanoparticles in the Human Eye Author(s): <u>Mohammad Faraz Samavat</u>, Somayeh Asadi, Hanie Tavassoli, Mehdi Vaez-Zadeh, Shaghayegh Gaeeni Physics, K.N.Toosi University of Technology, Tehran/IRAN

The main focus of the present study is to investigate dose enhancement effects in presence of gold nanoparticles (AuNPs) in proton delivery site of the ocular melanoma by the use of fixed pencil beam method associated with the Harvard ocular nozzle in a series of Monte Carlo simulations. Moreover, this paper also aims to present a comparison of the obtained results between the actual eye model, consisting of all sections of the eye and realistic compositions in the presence of AuNps, and in the exact same organ, albeit in privation of the mentioned material. Previous Monte-Carlo simulations have strained to acquire the same results obtained through latest experiments that have considered dose enhancement effects of proton treatments with existence of AuNPs, but to no avail; thus, multiple simulation codes such as MCNP, GEANT4, and FLUKA have been taken into account to insure the least possible deviation from in vivo findings. Rigorous libraries and models have been used, and all physical processes involved have been accounted for; furthermore, for the sake of accuracy, the production of the most probable secondary particles due to interactions with matter has also been examined.Contribution to dose enhancement effects are due to stopping losses, coulomb interactions, and elastic and nonelastic collisions of proton itself, as well as from secondary particles that are produced in mentioned processes. The attempt of such

paper is to shed light on the endless possibilities of escalating the efficiency of medical endeavors through interdisciplinary methods which combine various aspects of science and technology to attain desired results.

SP086.4 - An in-vitro method for calibrating the gamma-H2AX DNA double strand break focus assay in blood lymphocytes for radionuclide therapy

Author(s): <u>Uta Eberlein</u>¹, Harry Scherthan², Michel Peper², Maria Fernández¹, Michael Lassmann¹

¹Department Of Nuclear Medicine, University Hospital of Würzburg, Würzburg/GERMANY, ²Bundeswehr Institute of Radiobiology, Munich/GERMANY

Objectives: Radiation-induced DNA Double strand breaks (DSBs) cause, in their vicinity, the phosphorylation of the histone H2AX (then called γ -H2AX) and the accumulation of the 53BP1 protein that binds to and signals damaged chromatin at a DSB site. This leads to the formation of microscopically visible nuclear foci containing both markers which thus mark radiation-induced DSBs. The aim of this study is to develop a method that allows generating a calibration curve for the DNA DSB focus assay in-vitro after internal irradiation with radionuclides. The samples should be exposed to radionuclide used in radionuclide therapy, nowadays also called molecular radiotherapy (MRT), simulating absorbed doses and dose-rates that are similar to the ones that have been observed in patients.

Therefore, we studied the induction of radiation-induced co-localizing γ -H2AX and 53BP1 foci in lymphocytes as surrogate markers for DSBs, and correlated the obtained foci per cell values with the *invitro* absorbed doses to the blood for the two most frequently used radionuclides in MRT (I-131 and Lu-177).

Methods: We investigated blood samples of 3 healthy blood-donors. 9 experiments were carried out (2 experiments with I-131 and 1 with Lu-177 for each volunteer). For each experiment we withdrew approximately 28ml of blood at different time-points. One sample without radioactivity was used to determine the individual background focus rate. Radionuclides of known activities were diluted with NaCl and mixed with whole blood (3.5ml) to result in radioactive blood samples with different nuclide concentrations to deliver absorbed doses rates between 5mGy/h and 100mGy/h. Each vial was incubated for 1h at 37°C on a roller-mixer to uniformly blend the samples during the exposure. Thereafter, white blood cells were recovered by density centrifugation and washed in PBS followed by fixation in 70% ethanol. Samples were subjected to two-colour immunofluorescence staining and the average frequencies of the radiation-induced colocalizing γ -H2AX and 53BP1 foci/nucleus were counted manually using a red/green double band pass filter on a fluorescence microscope by an experienced observer. From each blood sample an aliquot was recovered for determining the activity with a calibrated germanium detector. The average absorbed dose rates to the blood per nuclear disintegrations occurring in 1ml of blood were calculated for both isotopes using the radiation transport code MCNPXv2.71.

Results: Overall 55 blood samples were evaluated in a dose range between 6mGy and 95mGy. Only minor nuclide-specific, intra- and inter-subject deviations were observed. We obtained a linear relationship between the number of DSB-marking γ -H2AX and 53BP1 foci/nucleus and the absorbed dose to the blood (R²=0.92) which agrees well with published values for external irradiation.

Conclusions: This *in-vitro* calibration method for the DNA double strand break focus assay will provide additional information for in-vivo measurements in patients after molecular radiotherapy and will further improve the absorbed dose to the blood calculation method.

SP086.5 - Dose enhancement during concomitant chemoradiotherapy using FDA approved concentrations of carboplatin and oxaliplatin nanoparticles

Author(s): Gizem Cifter¹, Yucel Altundal², Alexandre Detappe¹, Erno Sajo², Ross Berbeco¹, G. M. Makrigiorgos¹, <u>Wilfred Ngwa¹</u> ¹Department Of Radiation Oncology Division Of Medical Physics, Harvard Medical School Dana Farber Cancer Institute, Boston/ UNITED STATES OF AMERICA, ²Medical Physics, University of Massachusetts Lowell, Lowell/UNITED STATES OF AMERICA

Radiation boosting has been shown in a number of studies to be effective in the prevention of cancer recurrence. To further the effectiveness of this technique, we propose a new method of enhancing dose locally by administrating nanoparticles of carboplatin (CaNPs) and oxaliplatin (ONPs) as adjuvants to brachytherapy and external beam therapy (EBRT). To investigate the efficacy of this method, dose enhancement calculations were carried out to calculate the energy deposited by photoelectrons and Auger electrons produced by low energy photons from either (EBRT) or brachytherapy sources with CaNPs and ONPs. Our results show a significant increase in the dose enhancement for various carboplatin and oxaliplatin concentrations up to their allowed FDA limits.

SP087 - Educational and Professional Activities: Part 2

PRESIDENTS CALL

SP087.1 - The potential role of IFMBE in improving the state of medical equipment in developing countries Author(s): Anna Worm¹, Andrel Linnenbank²

¹Tropical Health and Education Trust, London/UNITED KING-DOM, ²Electrical Engineering, Mathematics And Computer Science, Delft University of Technology, Delft/NETHERLANDS

In developing countries medical equipment is often non-functional. Well known reasons for that are donations of already broken equipment and lack of spare parts and consumables. It is to be expected that current state of the art medical equipment is even less suitable for donation, given the way they are designed to function under conditions that are hard to find in rural areas in low resource countries. The key to start solving these problems lies in improving technical education at all levels in these countries. This paper explores how the IFMBE can work together with several other institutions (WHO, local professional organizations, non-profit organizations, Ministries of Health and Education,...) to train and sustain a competent technical workforce that can do maintenance, repair, and design of biomedical equipment using locally available materials and knowledge.

SP087.2 - Biomedical Engineering Education through Outreach Programs in Hospitals

Author(s): <u>Franco Simini</u>¹, Fernando Leon Moloney¹, Jorge De Giobbe²

¹Núcleo De Ingeniería Biomédica, Universidad de la República, Montevideo/URUGUAY, ²Rio Negro, Hospital ASSE, Fray Bentos/ URUGUAY

Health expenditure is a measure of the share of activity related to health care, both preventive and curative. Industrialized Countries spend around 10% of Gross Domestic Product (GDP) [1] with a high 17.9% for the USA. Middle income Countries, such as Uruguay, have lower figures, but growing as does the dissemination of medical actions in larger portions of the population. More hospitals are build and more equipment are installed every year. Traditional Engineering Education is slow at developing Biomedical Engineering (BME) Programs, because initial demand is scarce and because existing Electrical or Mechanical Engineers usually take over specific functions after some training by equipment providers. Uruguay has a 120 years old University but is only starting to train BME graduates. Job offers greatly exceed qualified staff available, which led us to suggest urgent training programs based on an Outreach Program in Hospitals (OPH), therefore at low cost.

OPH based BME training is build upon existing Electrical Engineering and Systems Engineering Programs, using courses of maths, physics, chemistry, software development, electrical engineering and management. Six optional courses are added, from electronic design to medical image processing and management (DICOM, PACS), electrical safety standards, medical terminology, physiology and anatomy.

A full year design project of a biomedical equipment is assigned to groups of three students, to both foster collaborative attitude and to obtain a functional solution to a clinical instrumentation problem.

Students are then assigned in their fourth University year to a full time six months intern-ship in a Secondary Level Hospitals, where

BME is non existent. This is done within a University Outreach Program. As the only technological reference persons in the Hospital Director's office, BME students face a variety of maintenance, purchasing, staff training, safety measures enforcement, documentation and installation/removal of equipment. Every student is assigned a remote instructor who acts as a reference available on call or otherwise. The instructors are University teachers in capital city Montevideo, while students are in remote (100 Km to 600 Km) hospitals, where a basic "intern-ship" salary is paid, in addition to feeding/lodging on premises.

Results of this low budget, OPH based BME program are promising with first graduations expected June 2015. The main results are (1) self confidence and sense of responsibility acquired by student (2) its low cost and (3) the interest of BME firms for future employment.

From the Hospital Point of view, equipment documentation, staff safety instruction and maintenance purveyors relations are the benefits so far.

This model of integrated, easily implemented BME Program based on University Outreach has the potential to be considered in other settings in Latin America, the Caribbean and elsewhere, where quick BME staffing requirements must be met at low cost, helping to reduce Health Expenditure.

SP087.3 - Clinical Engineer: a health professional to recognize Author(s):

Background

In latter years, Clinical Engineer's figure is taking on more and more importance in health technology management, due to his technical knowledge and capacity to interact with different fields professionals. Unfortunately, this situation does not reflect reality: in many low and medium income countries this figure does not exist and in many high income countries Clinical Engineer is not recognized as health professional, but very often compared as biomedical technician. Internationally Clinical Engineers, as subset of Biomedical Engineers, belong to Unit Group 2149 "Engineering Professionals Not Elsewhere Classified" under the International Standard Classification of Occupations produced by the International Labour Organization.

Objective

Clinical Engineers community is strictly collaborating with World Health Organization (WHO), in particular with Adriana Velazquez Berumen, Senior Adviser on Medical Devices, to recognize Clinical and Biomedical Engineer's figure worldwide.

The main aim is to stress the importance of Clinical Engineer in healthcare facilities. This work will be a chapter of Human Resources for Medical Devices, part of *WHO Medical device technical series*.

Methods

The approach used in this work analyses the main activities carried out by Clinical Engineer, in order to give awareness of all activities involving this figure. Therefore the analysis focuses on Clinical Engineer's role at national level, in particular within the Ministries of Health of different Countries. This analysis was possible through several statements by professionals who work at national level. Finally the analysis gives attention to Clinical Engineering's diffusion worldwide in the six WHO regions (*African Region, Region of Americas, Eastern Mediterranean Region, European Region, South-East Asia Region, Western Pacific Region*) through data from Clinical Engineering Societies around the world.

Conclusions

Clinical Engineer is without doubt a professional who needs to be recognized worldwide with more support. He is a fundamental resource in health technologies management and contributes both to healthcare organization and patient health.

SP087.4 - "Rehabilitation Enginering: Designing for Ability" - A summer outreach course for attracting talented high school students to the rehabilitation engineering field

Author(s): <u>Vicki Komisar</u>¹, Emily C. King², Eve Moore³, Sabah Hassan⁴, Aaron Marquis⁵, Justin Chee⁶, Rosalie H. Wang⁷, Sunita Mathur⁸, Tilak Dutta², Cesar Marquez-Chin⁵ ¹Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA, ²Department Of Mechanical And Industrial Engineering, University of Toronto, Toronto/CANADA, ³Handy-Metrics Corporation, Toronto/CANADA, ⁴Central Neighborhood House, Toronto/CANADA, ⁵Toronto Rehabilitation Institute - University Health Network, Toronto/CANADA, ⁶Rehabilitation Sciences Institute, University of Toronto, Toronto/CANADA, ⁷Department Of Occupational Sciences And Occupational Therapy, University of Toronto, Toronto/CANADA, ⁸Department Of Physical Therapy, University of Toronto, Toronto/CANADA

Motivation: We need to inspire talented students to pursue rehabilitation engineering, and develop the technologies that will help our aging population overcome disabilities and live fulfilling lives for as long as possible. Our team experiences a perennial challenge of attracting top-quality students to important yet often unglamorous facets of this field (e.g. supporting independent toileting for people with mobility challenges), partly because prospective students may not recognize these challenges, or see how they can be addressed through science and engineering. In response, we developed a week-long course in rehabilitation engineering for high-school students through the University of Toronto's "Da Vinci Engineering Enrichment Program", which we have led every summer since 2012.

Course structure: The course was designed provide students with memorable interactive experiences in a range of rehabilitation engineering applications. To discover accessibility challenges, students completed a "Built Environment Obstacle Course", where they navigated UofT while simulating mobility and vision deficits, then assessed how built environment features affected their experience. Students participated in hands-on demonstrations in Toronto Rehab's Challenging Environment Assessment Laboratories and Neural Engineering Lab to understand how engineering technologies are being applied to problems such as preserving hand dexterity in cold weather, and allowing people who are 'locked-in' to control their own environments. Guest speakers included engineers, clinicians and an entrepreneur who could communicate authentically to the students about the challenges, importance and rewards of developing and commercializing technologies to improve the lives of people with disabilities. The week culminated with a "Home-Care Design Challenge", focused on solving problems related to aging-in-place. These design problems were selected from real client case studies presented by a home-care field educator.

Student feedback: Students reported significant improvements in their understanding of key learning objectives (Figure 1). Students appreciated the Toronto Rehab visits, the diverse topics, the design challenges, and the instructional team's ability to make the content understandable, interactive, and relevant.

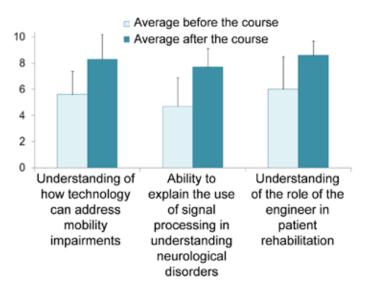

Figure 1: Mean student responses to learning objective questions before/after the 2013 course (scale of 1-10). 22/25 students responded.

Expected outcomes: All of the participating students gained an awareness of the problems faced by older adults and the societal importance of finding solutions. Those who pursue engineering will better understand their potential roles in rehabilitation engineering and the importance of including stakeholder perspectives. Conversely, those who pursue other medical disciplines will appreciate the importance of engineering in medicine and the potential for collaboration with engineers to advance their work.

SP087.5 - A Novel Approach to Train Biomedical Engineers in a Ugandan Setting

Author(s): <u>Robert T. Ssekitoleko</u>¹, Philippa N. Makobore² ¹Physiology, Makerere Univesity, Kamapla/UGANDA, ²Instrumentation Division, Uganda Industrial Research Institute, Kampala/ UGANDA

Whereas many universities in the developed countries are now offering degrees in Biomedical Engineering or closely related subjects, Africa sees very few such programmes being offered. The Biomedical Engineering degree programme offered at Makerere University is seen to be the first of its kind in Sub-Saharan Africa. It has been running for less than three years with some other institutions in the country offering Diplomas.

The degree has been designed in such a way that student internship is an integrated part of the training where the students are actually graded for their performance. This was brought about to improve the awareness of the Biomedical Engineers and students in hospitals as well as companies where they were otherwise unknown. Internship posts have been secured in all government hospitals and many private hospitals and companies. Companies Such as SinoAfrica Uganda, Joint Medical Stores have continuously offered placements for the students. The students are given clear objectives with specific outcomes from each placement. They get a placement supervisor as well as an academic supervisor to monitor their progress.

The Uganda Industrial Research Institute (UIRI) has gone a step further in supporting the degree programme. They not only provide placements for the students but also over dedicated training such as embedded systems and programming that students can take to improve their knowledge and skills.

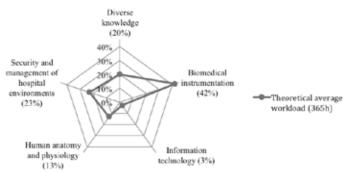

Such engagement with different organisations has helped students

not only to gain more confidence in the degree programme but to also identify potential jobs in a country where the field is just growing.

SP087.6 - A Health Information Technology Management Course for Brazilian Clinical Engineers

Author(s): Fernando O. Andrade, Saide Calil Department Of Biomedical Engineering (deb), State University of Campinas (UNICAMP), Campinas/BRAZIL

The excessive and inappropriate adoption of computerized technologies in the healthcare system have, greatly increased the occurrence of incidents, transforming these new resources into potential sources of risk. As manager of healthcare technologies, the clinical engineer (CE) should establish the necessary management measures to ensure the safety of patients and operators. This study aims to present a process to develop curriculum directives for a distance education course for professional specialization of CE, on risk management of health information technology (HIT). The method starts by evaluating the curricular training courses on clinical engineering in Brazil and identifying the areas of knowledge. It was analysed 160 diciplines from 11 training courses for CE in Brazil. The content of the disciplines were analyzed and classified into five categories presented below.

The process for developing the proposed curriculum was performed by structuring the types of knowledge needed for risk management on HIT obtained through the exploration and study of the environment in which these technologies are embedded. The exploration of the literature and specific standards to manage IT risks pointed out several incidents involving the use of HIT. It was also investigated the types of risks associated with the use of HIT, the professional characteristics of IT professionals and the necessary requirements to apply the standards for risk management on the healthcare system. This investigation has shown the kind of knowledge required by the CE professionals. The proposal curriculum to train clinical engineers for managing HIT are shown at Table 1.

N°	Module	Workload (h)	
1	Introduction on health information systems	50	
2	Medical IT-network	70	
3	Usability, ergonomics and accessibility	30	
4	Technology project management	30	
5	Safety and risks of IT-network	70	
6	Risk management	30	
7	New technology in healthcare	50	
8	Multidisciplinary and hospital infrastructure	30	

The proposal here intended not only to upgrade the expertise of the clinical engineering professionals, but also aims to improve the inte-

gration and the teamwork with professionals in the field of information technology. The course is already in progress and currently has 63 students from different regions of Brazil.

SP087.7 - A Successful High School Science Mentorship Program: Students on the Beamlines at the Canadian Light Source Author(s): Tracy Walker¹, Tomasz W. Wysokinski¹, Mark A. Webb¹, Ning Zhu¹, George Belev¹, Cécilia Barrette-Leduc², Katarina Stevanovic², Lylia Xiao², Sara Marrè², Shu Yi Zhai², Yu Xin Zhuang², Marie-Eve Brassard², Denise Miller¹

¹Bmit, Canadian Light Source Inc., Saskatoon/CANADA, ²Pensionnat Saint-Nom-de-Marie, Montreal/CANADA

Canada's only synchrotron is an extremely brilliant source of X-ray and infrared light for research in a multitude of disciplines. We also have a unique program that engages high school students in authentic science research experiences. The Students on the Beamlines (SotB) [1] program connects high school students from across Canada with scientists at the Canadian Light Source (CLS) for mentorship through an authentic science research experience. "Authentic" indicates that we facilitate a research project that is as close to what professional scientists do as a high school student is capable. These are not demonstration experiments. Students must design a project that builds on previous work (through literature review) and ask a scientific question that requires synchrotron techniques to address. The results of their experiment are expected to potentially produce novel information that is of interest to the scientific community. It is this negotiation between the goals of producing 'good science' and creating an 'educational and learning experience' that is part of what makes this program unique. Key to the program is that the students function as primary investigators. Their mentors facilitate, direct and advise the students, but the project belongs to them and they make the decisions.

The case study presented is one from Pensionnat Saint-Nom-de-Marie, a girls' school in Montreal, Canada. Honey bees in Canada are suffering significant winter death due to infestations of the Nosema fungus. It is known that the infestation deforms the digestive system of infected bees. Students used the Biomedical Imaging & Therapy (BMIT) beamline at CLS to collect x-ray projection and CT images of healthy and infected bees clearly showing the bees' digestive system.

More than 500 students have participated in SotB so far and report that the experience has had a profound impact on their view of research, careers in science and of scientists. Teachers are eager to involve their students because the program fits with current educational initiatives encouraging student engagement through the use of inquiry methods in the science classroom. Several other synchrotron research facilities are emulating the program. The point of this presentation is to share our experience so the concept of student participation in mentored authentic science research can spread. In our case, using a synchrotron is the context and a hook to attract student participation. Any research context would work similarly.

SP088 - Computer Aided Diagnosis

TRACK 01: IMAGING

SP088.1 - Automatic Analysis of Plantar Foot Thermal Images in at-Risk Type II Diabetes by Using an Infrared Camera

Author(s): Luis Vilcahuaman¹, Rachid Harba², Raphael Canals², Martha Zequera³, Carlos Wilches³, M.T. Arista¹, L. Torres¹, H. Arbanil¹ ¹Biomedical Engineering, PUCP, Lima/PERU, ²Prisme, University of orleans, Orleans/FRANCE, ³Electronic Department, School Of Engineering, Pontificia Universidad Javeriana, Bogota/COLOMBIA

Temperature of the plantar foot surface is an important feature in type II diabetes as abnormal temperature variations can be an early sign of foot diseases. In this paper, automatic way to analyze these temperature variations is presented by using an infrared camera. A robust acquisition protocol is proposed and an image processing software is developed. Three types of analysis are performed. First, the mean plantar foot temperature of both feet results from a segmentation procedure based on the Chan and Vese active contour method. Second, the point-to-point absolute mean difference between the 2 feet is assessed by using a rigid registration method. Third, significant hyperthermia regions such that the point-to-point absolute difference is greater than 2.2°C are highlighted. All these measures are fully automatic and do not need manual intervention. 82 type II diabetic subjects in a pre-ulcerative state were recruited in the Dos de Mayo hospital (HNDM) in Lima, Peru. These persons were classified in two risk groups of developing an ulcer based on a medical exam: a medium risk group, and a high risk group. Results show that the mean temperature of the plantar foot surface is higher of 1°C in the high risk group compared to the medium risk group. The mean point-to-point absolute difference shows identical values in the 2 groups. Finally, 9 subjects out of the 82 ones show significant hyperthermia of one foot compared to the other (6 in the medium risk group and 3 in the high risk group). It is expected that the new opportunity to automatically analyze foot temperature in hospitals or in diabetic health centers will help in reducing foot ulcer occurrence for type II diabetic persons.

SP088.2 - Computer Assisted Diagnosis of Sclerotic Bone Lesions from Dual Energy CT

Author(s): Duc Fehr¹, Charles R. Schmitdlein¹, Sinchun Hwang², Joseph O. Deasy¹, <u>Harini Veeraraghavan³</u>

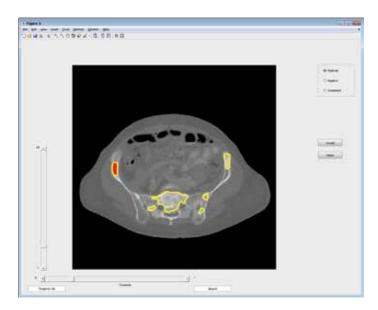

¹Memorial Sloan Kettering Cancer Center, New York/NY/UNITED STATES OF AMERICA, ²Radiology, Memorial Sloan Kettering Cancer Center, New York/NY/UNITED STATES OF AMERICA, ³Medical Physics, Memorial Sloan Kettering Cancer Center, New York/UNIT-ED STATES OF AMERICA

Purpose: To develop a computer assisted diagnosis (CAD) tool for the detection of sclerotic bone lesions in the pelvic region from dual energy computed tomography (DECT). Automatically identifying every single bone metastatic lesions from CT images is difficult owing to (a) large number of such lesions, and (b) very low contrast between the lesions and the marrow or bone.

Method: We developed a CAD tool that automatically detects sclerotic bone metastases from DECT images from the pelvic region. Our method consists of two stages. In the first stage, the bone and marrow regions are automatically segmented through a voxel-wise classification of the DECT image represented as a composition of multiple materials by using support vector machine classifier, followed by morphological smoothing. The appropriate material composition is determined through a learning using SVM that selects the best material composition for segmenting the bone and marrow from the rest of the image. In the second stage, the contrast inside the bone and marrow regions are enhanced through bi-histogram equalization followed by mean shift clustering. Mean shift clustering groups voxels with similar intensities into single clusters. Finally, the segmented regions extracted from the mean shift clusters are scored by the their shape. The following parameters including area, eccentricity, solidity, major axis, minor axis, perimeter, and the medial axis are used as constraints on the shape. Shape filtering prefers isolated regions that are solid, with small elongation and smaller size rather than highly elongated shapes (such as the bones). The shape filtering outputs potential sclerotic bone lesion regions, which can then be validated by a radiologist.

Results: We compared the candidate regions generated by our method with the ground truth regions manually identified by a radiologist. Our results agreed with the radiologist marked regions despite the presence of confounding metal artifacts and the low contrast between healthy bone and the lesions.

Conclusions: We developed a CAD tool that automatically detects sclerotic bone lesions in the pelvic areas from dual energy CT. The detected lesions using our approach highly similar to the radiologist identified regions despite the presence of confounding structures with similar intensities including the sclerotic lesions, healthy bone and metal artifacts.

SP088.3 - Mutual Information Based Template Matching Method for the Computer Aided Diagnosis of Alzheimer Disease Author(s): Esra Polat, <u>Albert Guvenis</u>

Institute Of Biomedical Engineering, Bogazici University, Istanbul/ TURKEY

Background

Early and reliable detection of Alzheimer Disease (AD) from Positron Emission Tomography images using computerized methods is a desirable objective for the effective management of that disease. Several characteristics of the computer aided diagnostic system (CAD) are important for improving this process: (1) Taking advantage of the growing number of images in databases (2) Ability to search a database for similar cases (3) Robustness with respect to data acquisition and processing factors (4) Full automation. In particular the third and fourth requirements are important in view of the fact that many CAD systems require user intervention.

Purpose

Our goal was to develop a fully automated CAD system for detecting AD that can meet meet these requirements.

Method and Materials

We have used the Alzheimer's disease Neuroimaging Initiative (ADNI) database for this study. Images for each patient were corregistered in order to correct for patient motion and had voxel sizes of 160 x 160 x 96. Voxel size was 1.5x1.5x1.5 in mm. There was 397 PET images including 259 normal and 138 AD patients.

A similarity measure based on mutual information (MI) was used to determine the closest matches for a new case. A K-Nearest Neighbor algorithm based distance measure was used to decide if a new image was from a healthy or AD patient. A leave one out evaluation method was implemented. Evaluation results were computed using ROC analysis. All development was carried out in a Matlab environment.

Results

Initial ROC analysis resulted an area under the curve (AUC) equal to 0.744 ± 0.025 for this dataset. Much higher AUC values are expected for the nonlinearly registered images across patients. This is work in progress.

Conclusions

First results show that it is possible to discriminate between AD and healthy individuals by using template matching and mutual information as a similarity metric. Further studies are underway in order to improve these results by introducing nonlinear registration methods and by adjusting the image size and grey scale parameters used in the process. Robustness, adaptation ability to growing databases without having to retrain the system and case based reasoning possibilities will be some advantages of the new CAD system.

SP088.4 - Development of an Anatomical Measurement and Data Analysis Tool Based on the Kinect Sensor for Physical Rehabilitation Applications.

Author(s): David A. Duarte-Dyck¹, Gerardo S. Romo-Cardenas², Alejandra Guillen-Peralta³, Lucas Callorda-Fedeczko³ ¹School Of Engineering And Technology, Montemorelos University, Montemorelos/MEXICO, ²School Of Engineering, Montemorelos University, Montemorelos/MEXICO, ³School Of Health Sciences, Montemorelos University, Montemorelos/MEXICO

Cyber-physical systems (CPS), integrate computer systems and communication capabilities for the monitoring and control of physical systems through hardware and embedded systems. These consider methods and technologies whose scope have applications in medical and biological areas.

A particular case on the application of these systems, relates to the field of physical rehabilitation, where using the detection capabilities on environments and bodies in 3 dimensions by means of specific positioning devices, like the Kinect sensor developed by Microsoft. Many studies have reported efforts developed in this direction.

At the Biomedical Engineering Laboratory of the Montemorelos University, we have developed a system called "ETMASD" (Environment Track, Measurement and Analysis of Skeletal Data) which allows appropriate locate joints and measure distances between them, as well as the positioning of a subject in a tridimensional plane, all of this through the skeletal mapping system done with the Kinect on a MATLAB environment. A specific algorithm was developed in order to measure the caput-collum-diaphyseal angle, making this an alternative for the traditional x-rays, given the chance to use this development for both scientific and physical rehabilitation applications. This paper describes the progress made on the development of a computational application focused on the initial diagnostic evaluation of anatomical pathologies.

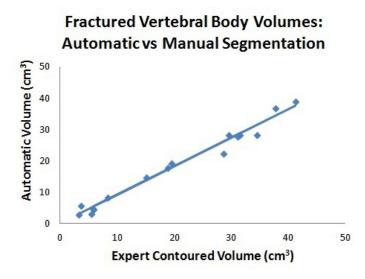

SP088.5 - Quantitative CT Assessment of Vertebral Fracture Severity

Author(s): <u>Curtis Caldwell</u>¹, Trinette Wright², Arjun Sahgal³, Cari Whyne⁴, Michael Hardisty⁴, Mikki Campbell⁵

¹Medical Imaging, Sunnybrook Health Sciences Centre, Toronto/ CANADA, ²Physical Sciences, Sunnybrook Research Institute, Toronto/CANADA, ³Department Of Radiation Oncology, University of Toronto, Toronto/ON/CANADA, ⁴Orthopaedic Biomechanics Laboratory, Sunnybrook Research Institute, Toronto/CANADA, ⁵Radiation Therapy, Sunnybrook Health Sciences Centre, Toronto/CANADA

The intent of this is work is to develop a simple semi-automated method of quantitatively assessing the severity of vertebral fractures based on imaging to assist in clinical management. Fractures may be relatively stable and asymptomatic, while others may be mechanically unstable leading to pain, neurological complications and progression. Severity may be assessed by a visual determination of the extent of vertebral volume and/or height reduction, yet such subjective assessments can be difficult and time consuming for even expert observers. In the absence of pre-fracture radiographs, visual estimation of changes may be subject to significant error. These subjectively determined imaging factors (vertebral volume, height reduction, etc.) are combined with other clinical factors into scoring systems (Genant, SINS, TLICS) that guide management. CT has been less commonly used to assess bone fracture due to its relatively high radiation dose. However, in some populations, such as patients with spinal metastasis being planned for treatment with radiation therapy, there is less concern for diagnostic CT dose levels. It is easier to assess changes in bone volume from a 3D imaging modality such as CT than with a 2D-x-ray approach. In this study, CT scans of 13 patients known to have spinal metastases and vertebral fractures were assessed; 3 of the 13 patients

also had imaging prior to fracture. An expert Radiation Therapist manually contoured the residual bone within the fractured vertebral body. A system based on Claron Technology Inc's "Spinemapper" application that automatically identifies vertebral levels and seqments vertebral bodies, previously applied in unfractured vertebral bodies was extended to automatically contour the volume of each fractured vertebral body. The automatic method produced volumes highly correlated (R²=0.994) with, but approximately 9% less than the expert contoured volumes. Using a curve fit to the volumes of adjacent "normal" vertebrae, the percentage change in volume in the fractured vertebra was estimated. Based on such curve fits, the estimated percentage volume loss ranged from 5% to 40% in the patient group studied. For the three subjects where both pre- and post-fracture CTs were available, the post-fracture assessment of predicted percentage volume loss matched the measured value based on pre- and post fracture data within 10%. This study demonstrates the viability and precision of this method to automate the analysis of fractured vertebral body volume and height reduction. These factors can then be incorporated into the scoring and management of patients with vertebral fractures.

SP089 - Tissue Modelling

TRACK 03: BIOMECHANICS AND ARTIFICIAL ORGANS

SP089.1 - The protective effect of the eyelid on ocular injuries in blunt trauma

Author(s): <u>Xiaoyu Liu</u>¹, Lizhen Wang², Jing Ji², Yubo Fan³ ¹School of Biological Science and Medical Engineering, Beihang University, Beijing/CHINA, ²School of Biological Science and Medical Engineering, Key Laboratory for Biomechanics and Mechanobiology of Ministry of Education, National Key Lab of Virtual Reality Technology, Beihang University, Beijing/CHINA, ³National Research Center for Rehabilitation Technical Aids, Beijing/CHINA

The instinctive blink reflex makes the eyelid close when a foreign body is approaching the eye. This study aimed to investigate the protective effect of evelid on ocular injuries in blunt trauma. A finite element model of the eyelid model was created and was incorporated into a validated eye model. The process of a projectile impacting on a naked eye and an eyelid-covered eye were reproduced in dynamic simulation. Dynamic responses on the cornea and retina were performed to evaluate the risk of damage to the tissues. The simulation indicated that the eyelid significantly protected the cornea against damage from blunt impact, especially for a smallsize projectile. This is because the eyelid distributes the local stress concentration to the whole ocular surface. However, the eyelid failed to provide the retina with an effective protection against damage in blunt trauma. This is because the retinal damage is a typical contre-coup injury, which is the result of shockwave propagation in the eyeball. In conclusion, the eyelid has different protective effects on ocular injuries caused by different injury mechanisms for eye closure.

SP089.2 - A Tale of Two Tendons: The Tradeoff between Strength and Fatigue Resistance

Author(s): <u>Samuel P. Veres</u>, Tyler W. Herod, Neil C. Chambers Saint Mary's University, Halifax/CANADA

Two predominant, functional classes of tendons exist: energy storing tendons and positional tendons. Energy storing tendons operate under much greater in vivo stresses than positional tendons, and are more prone to injury. Using a bovine forelimb model, we assessed the ultrastructural differences between superficial digital flexor (SDF, energy storing) and common digital extensor (CDE, positional) tendons. Scanning electron microscopy was used to study the ultrastructures of 4 SDF/CDE tendon pairs from 4 different animals at magnifications up to 90,000X. SDF tendons were found to have significantly smaller diameter collagen fibrils than CDE tendons (77.3±26.6 vs. 134.9±51.7 nm; p<0.0001). The collagen fibrils in SDF tendons were often bundled together by a dense network of filamentous webbing that ran predominantly perpendicular to fibrils' longitudinal axis. Similar webbing was not observed in the CDE tendons. Hydrothermal isometric tension analysis of intermolecular collagen crosslinking, conducted using 7 SDF/CDE pairs from 7 different animals, showed that the energy storing SDF tendons had significantly more crosslinking (denaturation temperature: 65.2±1.1 vs. $62.9 \pm 1.1^{\circ}$ C; p = 0.0003), and significantly more thermally stable crosslinking (proportion of samples that survived the temperature ramp to 90°C: 85.7% vs. 0%; p = 0.0006) than the paired, positional CDE tendons. Thermal assessment using differential scanning calorimetry confirmed SDF and CDE tendons to have markedly different collagen crosslinking. Samples from paired SDF and CDE tendons had significantly different onset temperature (64.2±0.7 vs. 63.1±1.0°C; p=0.0035), endotherm full-width-at-half-maximum

 $(1.6\pm0.1 \text{ vs. } 3.0\pm0.5^{\circ}\text{C}; p=0.0055)$, and enthalpy of denaturation (34.0±9.4 vs. 54.8±12.7 J/g; p=0.0349). We related ultrastructral characteristics of the SDF and CDE tendons to their ability to resist rupture and fatique damage. Samples from 4 SDF/CDE tendon pairs from 4 different animals were tested in tension until rupture. The positional CDE tendons were found to be both significantly stronger (37.6±8.1 vs. 23.1±7.7 MPa; p=0.0038) and tougher (14.3±3.6 vs. 6.8±3.4 MJ/m³; p=0.0108) than the paired energy storing SDF tendons. Ultrastructual examination of samples from the ruptured tendons showed that collagen fibrils from the CDE tendons underwent extensive plastic deformation during overload (discrete plasticity damage), while fibrils from the SDF tendons did not deform plastically. A second set of samples from the 4 SDF/CDE tendon pairs were subjected to 500 cycles of tensile loading to 30% of their ultimate stress, determined from the strengths of the matching ruptured samples. Samples from the cyclically loaded tendons were examined for fatigue damage using scanning electron microscopy. CDE tendons were found to readily accumulate nanoscale fatigue damage in the form of sharp folds that laterally traversed multiple fibrils, and longitudinally repeating kinks, characteristic of discrete plasticity damage. SDF tendons, on the other hand, were highly resistant to fatigue damage, showing no ultrastructural differences compared to the control tendons. It appears that tendons may suffer from a structure-function tradeoff: the ultrastructural characteristics required for strength optimization may result in poor fatigue quality, and vice-versa. Subsequent study of how energy storing and positional tendons develop may lead to novel therapies that can induce ultrastructural change in order to achieve target mechanical properties.

SP089.3 - Dynamic plantar pressure simulation integrated in case specific multibody gait simulations

Author(s): Wouter Aerts¹, Friedl De Groote², Zimi Sawacha³, Ilse Jonkers⁴, Jos Vander Sloten¹

¹Department Of Mechanical Engineering, Biomechanics Section, KU Leuven, Leuven/BELGIUM, ²Department Of Mechanical Engineering, Pma, KU Leuven, Leuven/BELGIUM, ³Department Of Information Engineering, University of Padova, Padova/ITALY, ⁴Department Of Kinesiology, KU Leuven, Leuven/BELGIUM

INTRODUCTION

Insoles and customized footwear are used to alter the plantar pressure (PP) distribution during gait. However, so far, it is not possible to predict the effect of these interventions on PP. This would undoubtedly enhance the customization process. The aim of this study is to evaluate a newly developed contact model, which allows to calculate dynamically the PP within a multibody gait simulation framework.

METHODS

Standard gait analysis was performed on 10 healthy subjects (mean age 62.2 ± 4.6 years, mean BMI 24.6 ± 2.2 kg/m²). The experimental setup included a 6 cameras BTS stereophotogrammetric system (60Hz), synchronized with 2 Bertec force plates (960Hz) and 2 PP systems (Imagortesi, 150Hz).

The PP simulation is performed during a moment-driven forward analysis using the experimental 3D kinematics and ground reaction forces in combination with a scaled generic musculoskeletal model as input in OpenSim. A scattered bed of spring-damper systems [1] was used as contact surface attached to the calcaneus of the model, which was obtained from a CT-scan of a healthy subject. An optimization procedure optimized the contact parameters and geometry position based on the experimental ground reaction force. The performance of the contact model is evaluated by comparing the simulated and measured peak pressure curves (fig. 1)

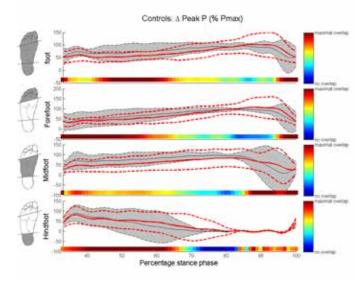

Figure 1: The plots show the measured (gray) and simulated (red) peak pressure curves for the 4 regions: whole foot, forefoot, midfoot and hindfoot, subdivided using anatomical masking [2]. The curves are averaged over the 10 subjects, with its nominal 95% bootstrap prediction bands [3]. The overlap between the bands is indicated by the colored bar, with blue representing no overlap and red maximal overlap.

RESULTS

A good agreement between simulated and measured peak pressure was found for all regions (see Fig. 1). In the first part of stance (30-60%) the overlap was nearly maximal, while around 80% of the gait cycle the overlap was lower. The hindfoot contact is prolonged during the simulation compared to the measurements.

DISCUSSION

The newly developed contact model showed a good performance in predicting the peak PP over time. With respect to finite element contact simulation, this contact model allows a continuous simulation of PP at a limited time. Due to its characteristics this contact model has potential to be used in the design of insoles and customized footwear.

SP089.4 - 3D numerical investigation of the effects of altered mechanical loading during skeletal growth

Author(s): <u>Kamel Madi</u>¹, Peter D. Lee¹, Katherine A. Staines², Andrew A. Pitsillides², Andrew J. Bodey³, Brian K. Bay⁴ ¹Manchester X-ray Imaging Facility, University of Manchester, Didcot, oxon/UNITED KINGDOM, ²The Royal Veterinary College, London/UNITED KINGDOM, ³I13-2 Branchline, Diamond Light Source, Didcot/UNITED KINGDOM, ⁴School Of Mechanical, Industrial & Manufacturing Engineering, Oregon State University, Corvalis/OR/ UNITED STATES OF AMERICA

Purpose

Abnormal growth plate closure during endochondral ossification and subsequent deformity resulting from altered mechanical loading has key implications in the progression of joint deformities such as varus and valgus. Despite several studies investigating changes in bone growth in response to mechanical loading [1], there is a lack of 4D data (3D with time) quantifying the relationships between the closure of the growth plate and the local micro-mechanical environment that the cells in the epiphyseal growth plate may experience. We aimed to combine X-ray computed tomography and computational modelling to investigate whether there is a correlation between the 3D high resolution images of growth plate cartilage topology, the octahedral shear stress (believed to promote endochondral ossification [2]) and the spatial localisation of the bridges.

Methods

Synchrotron-based micro-CT imaging of joints from a mouse strain (Str/ort) with natural susceptibility to OA and age-matched CBA (control) mice was performed at different stages of the disease on the Diamond-Manchester Branchline I13-2 (effective pixel size: 1.1 μ m). Novel image processing methods were developed to map the location/density of the bridges onto the joint surface and to characterise the 3D topology of the growth plate cartilage. In parallel, 3D volumetric meshes of the entire tibia including the growth plate cartilage were generated from the tomographic images and finite element computations were carried out to simulate static compressive tests (sustained loading).

Results

Compared to control mice, the growth plate cartilage of late-OA joints is thicker with higher local curvature (Fig. 1), suggesting different remodelling and local stress state. Our first micro-FE computations in a late-OA joint revealed that the bridges seem to act as stress concentrators and are hence more likely to fracture under loading and/or to redistribute stresses within these particular vicinities of the growth plate cartilage.

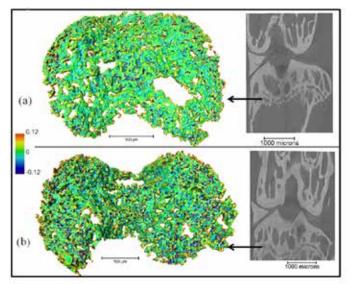

Fig. 1 Distribution of the local mean curvature in the growth plate cartilage of adult mice: (a) CBA mice (control, average thickness = 49 ± 17 μm, surface area-tovolume ratio = 0.146), (b) Str/ort mice (average thickness = 67 ± 24 μm, surface area-to-volume ratio = 0.101).

Conclusions

Our data reveal changes in the internal 3D topology of the growth plate cartilage in a model of spontaneous mouse osteoarthritis that could be linked for the first time to the micro-mechanical environment experienced by the growth plate during skeletal growth. Further investigation at earlier disease stages will reflect how these different topologies impact the stress and strain distributions and whether this may correlate with growth rate, greater bridge clustering found in late OA and the location of articular lesions that characterise osteoarthritis.

SP089.5 - Effects of changing small airway mechanics and inspiratory flow waveforms on pulmonary ventilation: a modeling study

Author(s): <u>Tianya Liu</u>¹, Yuxing Wang¹, Jian Ma¹, Deyu Li¹, Yubo Fan² ¹Key Laboratory For Biomechanics And Mechanobiology Of Ministry Of Education, International Research Center For Implantable And Interventional Medical Devices, School of Biological Science and Medical Engineering, Beihang University, Beijing/CHINA, ²National Research Center for Rehabilitation Technical Aids, Beijing/CHINA

Introduction and **Objectives:** For patients with chronic obstructive pulmonary disease (COPD), pathological changes of small airways can cause air trapping and lung overinflation, which can easily be aggravated during mechanical ventilation. Understanding the effects of small airways on pulmonary ventilation will be helpful in guiding mechanical ventilation for patients with COPD. Studies investigating pulmonary ventilation during mechanical ventilation did not address the behavior of small airways, especially the collapse of small airways. Therefore, the effects of small airways on pulmonary ventilation were analyzed theoretically in this study.

Methods: A nonlinear model of breathing mechanics with two parallel alveolar compartments was developed. Each of the alveolar compartments was in series with a collapsible airway segment and a lower airway segment, whose parameters represented pathological changes in small airways of patients with COPD. Parameter values of small airways in one alveolar compartment were changed according to the pathology of COPD. Four inspiratory flow waveforms, including the constant, decelerating, accelerating and sinusoidal flow, were studied.

Results: Change in the collapsible airways resulted in more severe air trapping of the affected branch than change in the lower airways, but resulted in reduction in maldistribution of ventilation. The decelerating flow got the most even distribution of inspired gas and peak alveolar pressure regardless of changes in airway mechanics, but the patterns of inspiratory flow had little influence on air trapping. **Conclusion:** The results suggest that the collapsible airways play an important role in air trapping and the lower airways have a large effect on ventilation distribution. In addition, the decelerating flow results in the most even distribution, indicating the decelerating flow is preferred during mechanical ventilation.

SP090 - QA Measurements for Therapy Dosimetry

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP090.1 - Response Characteristics of a Large-Area Ion Chamber with Various Radiotherapy Beams

Author(s): <u>Makan Farrokhkish</u>¹, Andrew J. Jung², Yinkun Wang², Bern Norrlinger², Robert K. Heaton², Mohammad K. Islam² ¹Radiation Physics, Princess Margaret Cancer Centre, Toronto/ON/ CANADA, ²Radiation Physics, Princess Margaret Hospital, Toronto/ ON/CANADA

Introduction: Previously described Integral Quality Monitoring (IQM) system, utilizes a large area gradient ion chamber mounted at the collimator to measure the "dose-area-product" of field segments. The gradient in spatial response is created by a slope in separation between electrode plates. The system verifies the dose delivery by comparing the measured and predicted signals in real-time. Since the signal of the ion chamber is comprised of the beam fluence through the open aperture as well as the attenuated beams through collimating structures, it creates a new dosimetric paradigm in Radiation Therapy. This presentation describes several dosimetric performances of the IQM detector including the response variation with various field sizes, beam energies, dose rates, and spatial sensitivity of treatment fields in several Linear Accelerator (Linac) platforms.

Method: Dosimetric measurements were performed in Elekta Synergy (80 leaf-MLCi2) and Infinity (160 leaf-Agility), as well as Varian iX and TrueBeam (160 leaf- Millennium) Linacs. The beam energies across these platforms were 6, 10, 18 MV, 6 MV Flattening Filter Free (FFF) and 10 MV FFF. All the beams deliver 1 cGy/ MU for a 10×10 cm² field at a dmax-depth, with the source to detector distance of 100 cm. The chamber was mounted on the accessory tray of Elekta and the upper wedge tray of Varian Linac.

Results: The chamber signals, expressed in IQM Count, for a 10 × 10 cm² field with 6 MV beams were 1946 and 2259 Counts/MU for TrueBeam and Infinity respectively. The difference in counts can be attributed primarily to: (i) differences in the source to chamber distance (ii) differences in MLC and jaw transmission factors and the back-up jaw configuration. The field size factors for 6 MV beams, normalized to a 10 × 10 cm² field, ranged from 0.008 to 4.352 for TrueBeam and 0.023 to 3.941 for Infinity for fields ranging from 1 × 1 cm² and 20 \times 20 cm² respectively. The relative energy response varies widely with field size, machine model, and beam filtration. A maximum difference in response for 10 MV, 18 MV, 6 MV FFF and 10 MV FFF beams, relative to 6 MV beams in corresponding Linac were found be 20.6, 23.4, 23.9, and 39.4 % for field sizes ranging from 1 \times 1 cm² to 20 \times 20 cm². When a 3 x 3 cm² field was shifted by 3.0 cm in the direction of increasing gradient, signal difference of up to 12 % and 10 % were observed for TrueBeam's 10 and 6 MV beams respectively. For a 10 VM FFF beams however, no measurable difference in signal was observed for the same shift, due to the combined effect of chamber gradient and off-axis profile

Conclusion: Since the IQM Chamber intercepts the entire projected area defined by the primary jaws, the signal is comprised of the open beam and the attenuated beam through the MLC and jaws. A significant difference in some key dosimetric response is therefore expected across various beam energy, filtration and Linac models.

SP090.2 - Very small circular fields output factors: Comparison of MC calculations, EBT3 film and micro-diamond measurements

Author(s): Eyad A. Alhakeem¹, Sergei Zavgorodni² ¹Physics & Astronomy, University of Victoria, Victoria/CANA-DA, ²Medical Physics, BC Cancer Agency, Victoria/CANADA

The purpose of this work was to obtain output factors (OFs) of 6MV beam collimated by customized circular cones of 1.3 and 3.5 mm diameter at isocenter. We also compared OFs from these cones with OFs from BrainLab[™] of 10, 12.5, 15 and 40 mm cones.

OFs were measured using GafChromic EBT3 films and micro-diamond detector. Detectors were placed isocentrically in a water phantom at 1.5 cm depth. Two sets of EBT3 measurements were extracted from different image resolutions as shown in Table 1. Micro-diamond detector was also used to measure cone OFs with detector axis orthogonal to the incident beam. BEAMnrc/DOSXYZnrc codes were used to calculate OFs and dose profiles in water with 1x1x1 mm³ voxels for the 10-40 mm cones and 0.1x0.1x0.1 mm³ voxels for the 1.3 and 3.5 mm cones, respectively.

Results for OFs (relative to 40 mm diameter cone) are shown in Table 1. Differences of 15.4% and 15.9% were found for cone 1.3 and 3.5, respectively. Maximum differences of up to 4.0%, 2.9% and 1.9% were found for cones 10, 12.5 and 15 mm, respectively. Scanning resolution of the films was critical for the two smallest fields and the differences between two EBT3 OF's measurement set were 6.7% and 14.3% for cone 3.5 and 1.3, respectively.

In conclusion, differences in output factor were within 4% for cones with 10 mm diameter and greater. However, larger differences were observed for the 3.5 and 1.3 mm field sizes. Scanning resolution has significant effect on the output factor of the smallest cones in this work.

Table 1. Output factors measured and calculated for a range of circular cones. Statistical uncertainty of MC calculations was within $\pm 2.5\%$.

Cone diameter (mm)	1.3†	3.5†	10	12.5	15	40

SP090.3 - Investigation of pass rate variability in ArcCheck measurements

Author(s): <u>Harald Keller</u>¹, Albert Chen², Daniel Létourneau² ¹Radiation Oncology, University of Toronto, Toronto/ON/CANA-DA, ²Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/ON/CANADA

Spine SBRT (stereotactic body radiation therapy) is an emergent radiation therapy treatment technique for bone metastasis in the spine. Such treatments are nowadays delivered using volumetric modulated arc therapy (VMAT). The ArcCheck detector (Sun Nuclear Corporation, Melbourne, FL) is part of the patient-specific QC process to routinely evaluate the ability to accurately deliver VMAT plans. It was found that the results of such ArcCheck measurements for spine SBRT plans can vary widely from patient to patient, more so than for other treatment sites. The purpose of this work was to investigate potential sources of this variability in order to streamline the QC process for spine SBRT patients.

A set of 144 spine SBRT treatment plans published between July 2012 and May 2014 was available. All plans used a single 360 degree arc with isocenter in the spine. The vast majority of treatment plans were delivered on a single linac (Elekta Beam Modulator (TM)).

Absolute dose pass rates (ADPR) are the percentage of values (detectors) in a measured dose map (cylindrical surface within the ArcCheck phantom) that have passed a set of criteria, usually a 3% dose-difference and 2 mm distance-to-agreement criterion with respect to the calculated dose map obtained from the planning system (Pinnacle, Philips). The number of detectors participating in the comparison is set by a dose threshold (TH).

For this work, the pass rates and their variability were studied for several parameters associated with the measurement and analysis of the dose map: the TH threshold, sensitivity of the results to ArcCheck phantom (dose map) shifts, global and local gradients in the measured dose maps and the degree of beam modulation as assessed by the number of monitor units per delivered dose (MU/ cGy) of the arc. For efficient analysis, an emulation of the pass rate algorithm was implemented in Matlab and validated against the commercial software (SNC patient, Sun Nuclear).

The ArcCheck results for the spine SBRT plan set showed a mean ADPR of 86% with a wide range between 60% and 98%. ADPR was largely constant for most patients as a function of TH, except for TH below 10% where most pass rates dropped significantly and increased variability within the set. As expected, ADPR decreased with applied dose map shift for most instances, but ADPR was not correlated to the degree of ADPR sensitivity to these dose map shifts. The within-set ADPR variability was almost independent of "flatness" of the dose map (quantified as the sum of the gradient taken over the dose map). Only for very flat dose maps with small gradients the ADPR was consistenly above the set mean (around 90%). Degree of beam modulation had some correlation with ADPR (correlation coefficient 0.608) where higher/lower beam modulation resulted in lower/higher pass rates, respectively.

In summary, there is no known single parameter that is driving the variability of the ADPR. Multivariate analysis should be performed and parameters that influence the computation of the dose map need to be incorporated as well.

$\ensuremath{\mathsf{SP090.4}}$ - Characterization and image quality evaluation for a clinical 2.5 MV in-line portal imaging beam

Author(s): Jeniffer Owen¹, <u>Jose E. Villarreal-Barajas</u>², Rao Khan², James Grafe²

¹Physics And Astronomy, University of Calgary, Calgary/AB/CANA-DA, ²Oncology, University of Calgary, Calgary/CANADA

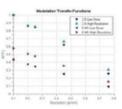

Characterization and image quality evaluation for a clinical 2.5 MV in-line portal imaging beam

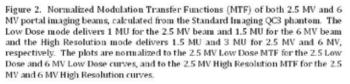

Recently, a 2.5 MV inline portal imaging beam has been made available on Varian TrueBeam[™] Linacs. The aim of this work is to present our initial investigations of the 2.5 MV beam characterization and imaging quality assessment.

The 2.5 MV beam output was calibrated following the AAPM TG-51 procedure. The beam output has been stable over four months to within 1%. The PDD was measured with a CC13 chamber, a Markus chamber, and Gafchromic EBT3. The resulting depth of maximum dose, dmax , and PDD at 10 cm depth (%dd(10)) was measured to be 5.7 mm (51.7%), 6.1 mm (51.9%), and 5.1 mm (51.9%) for a 10×10

cm² field size at 100 cm SSD for the CC13, Markus and EBT3 film, respectively (Figure 1). The beam quality is slightly lower than that of a ⁶⁰Co beam; however we estimated a kQ value of 1.00 for output calibration purposes. Additionally, the measured HVL was 9.8 mm Cu (14.8 mm Cu for 60Co), corresponding to an effective energy of approximately 550 keV. The relative entrance dose as measured with EBT3 films was 63%, compared to 23% for a 6 MV beam.

The image quality was assessed with the Standard Imaging Phantom QC-3. The estimated MTF for the MV-imaging system shows that 2.5 MV has better spatial resolution than the 6 MV beam (Figure 2). The 2.5 MV exhibited nearly three times higher surface dose than the 6 MV, however, for a separation of 20 cm, the 2.5 MV midseparation dose is 78% of the 6 MV dose and the exit is only 58% of the 6 MV dose. Future work will focus on the clinical implementation and development of quality control protocols for this novel imaging beam modality.

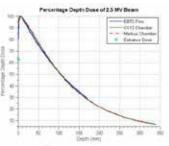

Figure 1. Percentage-depth dose plots of the 2.5 MV imaging beam measured with EBT3 Gafchromic film, a CC13 ion chamber, and a Markus ion chamber for a 10×10 cm² field at 100 SSD. The entrance dose was measured using EBT3 film placed perpendicularly to the beam on a solid water phantom.

SP090.5 - Usefulness of the commercialized EPID based dMLC QA tool for Elekta Agility MLC

Author(s): <u>Samju Cho</u>¹, Woonhoon Choi¹, Ho Lee¹, Kwangwoo Park¹, Jungil Lee¹, Jeongmin Yoon¹, Eungman Lee¹, Suk Lee², Sang Hoon Lee³, Juree Kim³, Jinho Choi⁴, Sangwook Lim⁵, Ki Chang Keum¹ ¹Radiation Oncology, Yonsei University, Seoul/KOREA, ²Radiation Oncology, Korea University, Seoul/KOREA, ³Radiation Oncology, Catholic Kwandong University, Seoul/KOREA, ⁴Radiation Oncology, Gachon University, Seoul/KOREA, ⁵Radiation Oncology, Kosin University, Busan/KOREA

The dynamic intensity modulated radiation therapy(dIMRT) and volumetric modulated arc therapy (VMAT) requires accurate leaf position, leaf speed, gantry position and gantry speed while modulating the dose rate. The Elekta Agility linear accelerator(Elekta AB, Stockholm, Sweden) could be to meet these characteristic with

accurate leaf positioning and rapid leaf speed 3.5 cms⁻¹. Considering the time consuming procedures in dynamic MLC QA, dedicated EPID based dynamic MLC QA program was widely used. The purpose of this study is to monitor several month results of EPID based dMLC QA and is to establish the reference parameters and tolerance levels for each QA category. We commissioned ARTS-CAN[™](AQULLAB, Lille, France) for four Agility MLCs and validated six category including calibration of image, dMLC dosimetry, static picket fence, VMAT picket fence, doe rate/gantry speed and MLC speed for dynamic MLC QA. We acquired 21 EPID images using vender provided dynamic delivery MLC file and validated it as an analysis protocol(Figure 1).

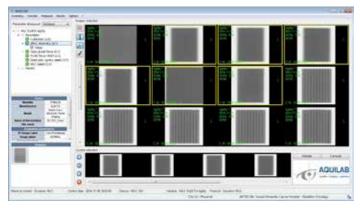

Figure1 Validated EPID images for dMLC QA

The acquisition of images and analysis of results took about 25 min. We performed dMLC QA using same dynamic delivery MLC file for 3 month in the 4 Agility linac MLC and averaged result parameters. These parameter values were established as our reference and tolerance level. We could figure out Agility MLC changing trend using ARTISCAN report tools after the parameters were validated. The EPID based dMLC QA program not only improve the QA procedures by reduce the time consuming process, but also guaranties the dosimetric accuracy of dIMRT and VMAT by verification of MLC/gantry position and speed.

SP090.6 - In-vivo and pre-treatment quality assurance software validation and verification

Author(s): Eleonora Vanzi¹, Luca Reversi², Giuliano Giani², Chiara Arilli¹, Pierluigi Bonomo³, Marta Casati¹, Antonella Compagnucci¹, Daniela Greto³, Livia Marrazzo¹, Silvia Scoccianti³, Stefania Pallotta², Marta Bucciolini², <u>Cinzia Talamonti²</u>

¹Sod Fisica Medica, Azienda Ospedaliera Universiataria Careggi, firenze/ITALY, ²Department Of Experimental And Clinical Biomedical Sciences, "mario Serio", University of Florence, Florence/ITA-LY, ³Sod Radioterapia, Azienda Ospedaliera Universitaria Careggi, Firenze/ITALY

The aim of this study is to test the accuracy of the dose calculation algorithm available in DosimetryCheck (DC, MathResolution®), a patient QA software for both pre-treatment QA and in vivo dose verification, that uses the EPID measured fluence of the treatment fields to reconstruct the dose distribution in the CT planning model of the patient.

First tests were performed on the IBA "I'mRT" phantom to assess DC performances in the steps of entrance fluence estimation and dose calculationm both for pre-treatment and in-treatment measurements. The central insert was filled with three different materials (air, bone and homogeneously with RW3) and different square field sizes (FS) were irradiated to evaluate the isocenter dose in the homogeneous phantom. The global accuracy was assessed by comparing OFs and PDDs evaluated with TPS with that reconstructed by DC.

Then, DC was run pre-treatment and in-vivo for 15 patients: 1) 7 IMRT prostate cases, 2) 3 abdominal VMAT cases, 3) 5 head VMAT cases. Gamma analysis (3%, 3mm) was used to compare measured with calculated dose distribution.

Isocenter dose was equal within 1.75% for pre-treatment and in – treatment measures and for all FS. Due to the use of a pencil beam algorithm, high OF and PDD differences (up to 64.2% and 110%, respectively) were found in the air filled phantom at small FS.

In patients, gamma passing rates evaluated on the whole treatment volume were above 98% and 94% for pre-treatment and in vivo prostate cases respectively; above 92% for both pre-treatment and in vivo abdominal VMAT patients, and above 89% and 73% for head VMAT patients.

In conclusion, DC is capable of successfully reconstruct the dose distribution in the patient from the EPID measured exit fluences, even if a more accurate algorithm is needed when low density regions are involved.

Learning Objectives:

1. To review the current status of targeted alpha-therapy and its role in treatment of metastatic cancer.

2. To gain understanding of mechanisms of gold nanoparticle radiosensitization.

3. To review future trends in novel systemic targeted and nanoparticle therapies.

Targeted Alpha-Therapy

Despite the latest technological advances in radiotherapy, cancer control is still challenging for several tumour sites. The survival rates for cancers, such as ovarian and pancreatic, have not changed over the decades. The solution to the problem lies in the change of focus: from local treatment to systemic therapy [1].

Radio-immunotherapy is one such approach where cancer cells are targeted by vectors labelled with a radioisotope. In a specific case of targeted alpha-therapy (TAT), a tumour-specific antibody/ protein is radiolabelled with an alpha-emitting radionuclide, termed a radioimmunconjugate (RIC). This radioimmunoconjugate attaches preferentially to tumour-specific antigens, and releases high-linear energy transfer (LET) α -particles of a few MeV kinetic energy. Alpha radiation has the shortest range and highest energy transfer (and correspondingly high radiobiological effectiveness), resulting in localized but significant ionization damage (e.g. to DNA). Alpha-emitting radioisotopes can be used to kill isolated cells, small cell clusters and to regress tumours [2]. The high-LET α -radiation produces increased rates of DNA double-strand breaks. The LET is ~100keV/µm, giving a higher probability of causing DSBs; ratio SSB/ DSB ~20 compared with 60 for low-LET radiation.

Over the past 20 years the development of RICs has enabled TAT to progress from in vitro studies, through to pre-clinical in vivo experiments and clinical trials. The dose to normal tissues provides a limitation to the injected dose and to that received by the tumour. However, TAT can achieve cancer regression within the maximum tolerated dose (MTD) for normal tissues. TAT was originally thought to be an ideal therapy for leukaemia and micro-metastases, because the short radioisotope half-lives were sufficient to target blood-borne cancer cells. At present, studies and clinical trials of TAT for several cancers have been reported. Alpha-therapy is demonstrating efficacy in leukaemias and in glioblastomas, where results from intracavity administration are promising, with a 52-week median survival. The use of peptides for targeting GBM is also under investigation [3]. In phase-1 trials of intra-lesional and systemic therapy in metastatic melanoma patients, TAT was found to be safe and demonstrated some evidence of anti-tumour activity [4]. Consequently, in the clinical setting of small-volume disease, TAT may complement current anti-melanoma therapies.

However, for solid tumours the promise of TAT is greatly extended by the development of tumour antivascular alpha-therapy (TAVAT); i.e. killing of tumour capillary endothelial cells that results in disrupting of tumour capillary networks and shrinking tumours [5].

High-Z Nanoparticle Radiosensitization

High-Z nanoparticles (NPs) have been a topic of interest in medical research since 1950s. It has, however, only been in the last 20 years that the practical use of NPs for imaging and radiotherapy has been demonstrated [6]. It has been shown that the presence of gold (or other high-Z material) nanoparticles improves the cell-killing effect of radiation *in-vitro* and with *in-vivo* mouse models. High-Z nanoparticles are being used in human trials for sensitization of tumour in radiation therapy, yet the mechanisms of enhancement are still being investigated [7, 8].

In a specific case of gold, NPs generally have an individual diameter between 1nm-1µm and are suspended in an aqueous solution. The high atomic number of gold relative to tissue means that when gold is introduced into a tumour, it acts as a contrast agent for imaging and it amplifies the biological damage in the case of external beam therapy. Cell death after radiotherapy occurs due to DNA damage induced by Reactive Oxygen Species (ROS). The ROS are generated from interactions of the incident radiation with atoms, emissions and scattering from those atoms, and subsequent interaction with oxygen based molecules. This process relies on emission of photo-electrons and Auger electrons, Compton Scattering, and Pair production.

Increasing localised dose deposition can improve therapeutic outcome, but needs to be done so that healthy tissues are not compromised by spurious dose deposition that nanoparticles may cause. It is very difficult to quantitatively analyse a statistically relevant number of individual cells for both nanoparticle content and biological markers. X-ray-Fluoresence (XRF) microscopy can be used to correlate nanoparticle content of individual cells with biological consequence to identify specific mechanisms of radiosensitization. This information is critical for understanding implications of such technologies as they move into human trials. XRF microscopy has only recently been able to rapidly image large area samples, and is uniquely available at the Australian Synchrotron [9]. This is a notable advance in the technique and is unique in the world. It can be used to quantify the mass of gold in each cell and hence deduce the number of nanoparticles. Subsequently, number of DNA breaks and Au content can be correlated to investigate the role of variables.

This lecture gives an overview of clinical results in an endeavor to recommend whether and how TAT and High-Z NPs can be integrated into the therapeutic armamentarium for cancer.

SP091.2 - Enhanced uptake of gold nanoparticles coated with polyethylene glycol

Author(s): <u>Charmainne Cruje</u>, Devika B. Chithrani Department Of Physics, Ryerson University, Toronto/ON/CANADA

Polyethylene glycol (PEG) has promoted the prospective cancer treatment applications of gold nanoparticles (GNPs). In vivo stealth of GNPs coated with PEG (PEG-GNPs) takes advantage of the enhanced permeability and retention effect in tumor environments, making them suitable for targeted treatment. Because PEG minimizes gold surface exposure, PEG-GNP interaction with ligands that mediate cancer cell uptake is lower than uncoated GNPs. Hence, the cellular uptake of PEG-GNPs is significantly lower than uncoated GNPs in vitro. As intracellular localization of GNPs maximizes its therapeutic enhancement, there is a need to improve the uptake of PEG-GNPs. To enhance uptake, a peptide sequence containing an integrin receptor binding site, or RGD, was conjugated with PEG-GNPs of varying core sizes. Spherical GNPs of diameters 14, 50 and 70 nm and a PEG chain length of 2 and 5 kDa were used to determine a preferred core size and chain length for uptake in vitro in HeLa and MDA-MB-231 cells. Results show that enhanced cancer cell uptake may be achieved with the peptide sequence used for all sizes of PEG-GNPs in HeLa cells. For MDA-MB-231 cells, higher cancer cell entry was observed less significantly and only for a size of 14 nm. Hence, improved cancer cell entry of PEG-GNPs into HeLa cells may be achieved with the use of an RGD peptide, while a different peptide sequence would have to be used for MDA-MB-231 cells.

SP091.3 - Nuclear targeting of gold nanoparticles for improved therapeutics

Author(s): <u>Celina J. Yang</u>, Devika B. Chithrani Biomedical Physics, Ryerson University, Toronto/CANADA

The combining of nanotechnology and medicine is gaining more and more interest in the field of biomedical sciences. Gold nanoparticles (GNPs) have been extensively used in cancer research due to their ability to act as an anti-cancer drug carrier for chemotherapy and as a dose enhancer in radiotherapy. Most GNP research in the past involved a system where GNPs were in the cytoplasm of the cell as unmodified GNPs enter the cell through a receptor mediated endocytosis. However, it is predicted that therapy response can be further enhanced if GNPs can be effectively targeted into the nucleus. Nuclear targeting requires a modification to the GNPs to escape the regular endo-lyso pathway and target to the nucleus. An effective strategy for designing a GNP-peptide complex for targeting the nucleus will be presented. Two different sequences of peptides where conjugated onto GNPs. The role of one peptide enhanced the uptake into the cell, while the other induced nuclear delivery. With nuclear targeting, there is a possibility in producing additional low-energy secondary electrons in response to irradiation within the nucleus. This can cause more damage to the DNA. This research will establish a more successful NP-based platform for combining treatment modalities that can lead to a more effective approach in the treatment of cancer.

SP092 - Neural Signal Processing: Part 1

TRACK 11: NEUROENGINEERING, NEURAL SYSTEMS

SPO92.1 - Delta-Modulated High Frequency Oscillations Linked to Pathological Brain in Female Mecp2-Deficient Mice

Author(s): <u>Sinisa Colic</u>¹, Min Lang², Rob Wither², Liang Zhang³, James H. Eubanks⁴, Berj L. Bardakjian⁵ ¹Electrical And Computer Engineering, University of Toronto, Toronto/CANADA, ²Department Of Physiology, University of Toronto, Toronto/CANADA, ³Department Of Neurology, University of Toronto, Toronto/ON/CANADA, ⁴Department Of Surgery, University of Toronto, Toronto/CANADA, ⁵Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/ON/CANADA

Mutations in the X-linked gene encoding methyl CpG-binding protein 2 (MeCP2) have been linked to a neurodevelopmental disorder known as Rett syndrome. Rett syndrome is predominantly found in females, occurring 1 in 10,000 live births. Among other impairments the clinical manifestation of Rett syndrome typically involves epileptic seizures, providing a unique genetic model of epilepsy. Mecp2-deficient mouse models recapitulating many of the deficits of Rett syndrome have been developed to examine the seizure-like activity from intracellular electroencephalogram (iEEG) recordings. The majority of the studies to date have focused their analyses on the low frequency oscillations (LFOs) associated with the epileptiform discharge rhythm occurring in the 6 - 10 Hz frequency range. However, some more recent studies on Mecp2-deficient mice have revealed the existence of high frequency oscillations (HFOs) in the frequency range 80 - 600 Hz and shown that these HFOs interact with the phase of the LFOs. HFOs are an important clinical biomarker for seizure-onset zone, often used by clinicians to determine resection areas in patients with intractable epilepsy. Furthermore, recent clinical studies are suggesting that by examining the LFO-HFO interactions it may be possible to achieve a more accurate identification of the epileptogenic zone which would potentially lead to more successful resection outcomes. In this study the coupling of HFOs to the phase of the LFOs was examined in female Mecp2deficient mice before and after mecp2 gene reactivation therapy. Our analyses show that the modulations could be subdivided into two distinct categories, coupling between the phase of the delta LFO (3 – 6 Hz) with the amplitude of the fast ripple HFO (400 – 600 Hz) and coupling between the phase of the theta LFO (6 - 10 Hz)with the amplitude of the fast ripple HFO (400 - 600 Hz). Examining the differences in modulation before and after mecp2 gene reactivation revealed that the delta with fast ripple modulation was abolished, whereas the theta with fast ripple modulation diminished. This matches the findings of a recent clinical study showing that the modulation of the delta with the fast ripple was an indicator for epileptogenic onset zone, and when that region was resected it would lead to successful surgical outcome. As the mecp2 gene is reactivated the animals show significant improvements suggesting that an interplay exists between the delta LFOs and the fast ripple HFOs leading to a pathological brain. Understanding this interaction could potentially be used as a biomarker for accurately identifying pathological seizure activity and potentially lead to better treatment outcomes.

SPO92.2 - Contrast between Spectral and Connectivity Features for Electroencephalography based Authentication Author(s): <u>Chungmin Han</u>¹, Sangkyong K. Kim¹, Heenam N. Yoon¹, Wonkyu K. Lee¹, Cheolsoo S. Park², Kokeun K. Kim³, Kwang Suk Park⁴

¹Interdisciplinary Program Of Bioengineering, Seoul National University, Seoul/KOREA, ²Department Of Computer Engineering, Kwangwoon University, Seoul/KOREA, ³Center for Cognition and Sociality, Institute for Basic Science, Seoul/KOREA, ⁴Department Of Biomedical Engineering, The College Of Medicine, Seoul National University, Seoul/KOREA

Biometrics using electroencephalography (EEG) have received attention as a strong security method and has been investigated by many researchers. Studies applied spectral and connectivity features to identify individuals. However, comparison of spectral and connectivity features are not yet conducted in the aspect of stability. In this paper, we present contrast between spectral and connectivity features for EEG based authentication with signals measured in different days. Spectral features are represented as power spectrum density (PSD) over 2-40Hz with 1Hz resolution provided from each channel. Connectivity features are presented as coherence (COH) of two channels combined, frequency range of 2-40Hz with 1Hz resolution. Total of 20 subjects participated and measured 32 channels of EEG for 10 seconds in eyes-closed resting state in three different days. We evaluated false authentication rate (FAR), false rejection rate (FRR) and half total error rate (HTER) as performance of authentication system designed: by using data measured in first day as train data (600 trials) and others as test data (1,173 trials). The similarity of data is measured using correlation modified Euclidean distance. During the decision making process, two values of threshold were set. The results were achieved with minimum of 10.45% HTER when using PSD, and 17.45% of HTER when using COH. It is well known that PSD features are relatively stable over time thus we post-analyzed coherence characteristics of EEG measured over three different days to evaluate stability. To assure stability, those that failed to reject ANOVA and highly correlated (over 0.8) were filtered in each subject in alpha band (8-13Hz) and composed coherence map for each participant. We concluded that considering both PSD and COH, feature filtering is necessary in order to guarantee efficient EEG based authentication.

SPO92.3 - EMG artifact removal using ICA-based dipole distribution from scalp EEG of epileptic patients

Author(s): <u>Chunsheng Li</u>¹, Daniel Jacobs¹, Trevor Hilton¹, Jose Martin Del Campo², Peter L. Carlen², Berj L. Bardakjian¹ ¹Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA, ²Toronto Western Hospital, Toronto/ CANADA

Biomarkers used to guide the resection of the epileptogenic zone depend on proper placement of intracranial electrode sets, which in turn depend on analysis of scalp EEG. Under normal conditions, such signals are contaminated by muscle artifact. Neck, eye, face and mouth muscles are major sources of this artifact. Due to volume conduction, the artifact can be detected across the entire head. In this study, we introduce an artifact removal method based on component source analysis to identify the generator of the muscle artifact. The goal is to objectively identify the components which would otherwise require time-consuming manual inspection.

Methods:

The proposed method examines the dipole source distribution of the independent components (ICs) produced by independent component analysis (ICA) with respect to the underlying muscle anatomy, as well as their spectral characteristics. Firstly, dipole fitting method (DIPFIT) is used to reconstruct each IC's dipole in a four layer head

model. The head model is divided by seven regions based on the anatomical basis shown in Fig. 1.

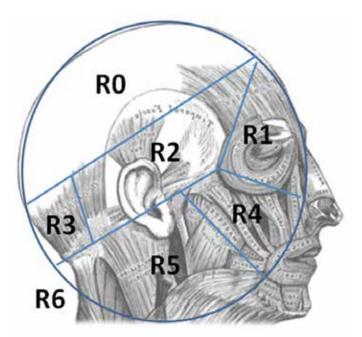

Fig.1 Sphere space partition, central region (R0), forehead (R1), temporal (R2), occipital (R3), mouth (R4), neck (R5) and outside regions (R6). (Adapted from Shackman et al. 2009).

Each dipole is assigned to one of the seven regions. Dipoles assigned to R0 are assumed to be EMG free since there are no muscle sources in that region. All other regions contain functionally independent EMG sources which can be identified by computing various spectral signatures. For example, the linear decrease of EEG power spectrum with linear increasing log frequency can be used in identification of an EMG component. Other signatures include peaks in frontalis activity around 25Hz, whereas temporalis generates a low peak around20 Hz and broad plateau centered around 40–80 Hz (Goncharova et al. 2003). Scalp EEG for 4 patients with epilepsy from the Toronto Western Hospital was analyzed.

Results:

Combining the dipole distribution and spectral characteristics, artifactual ICs can be removed. Sources modeled from synchronous iEEG data are used to validate sources modeled from the artifactremoved EEG.

This work is supported by NSERC, CIHR, and China Scholarship Council.

SPO92.4 - Power based features of epileptic iEEG rhythms to demarcate brain regions for resection

Author(s): Joshua A. Dian¹, Yotin Chinvarun², Peter L. Carlen¹, Berj L. Bardakjian¹

¹University of Toronto, Toronto/CANADA, ²Phramongkutklao Hospital, Bangkok/THAILAND

Epilepsy impacts up to 1% of the populations and despite optimal care with anticonvulsant medications 33% of patients continue to suffer uncontrolled seizures. Resection surgery provides a subset of these patients an alternative treatment which promises seizure freedom; however, identification of regions suitable for resection remains a challenging problem and results in many patients not achieving meaningful improvement despite surgery.

Intracranial EEG (iEEG) data was obtained from grid electrodes (8x8 or 8x6) implanted in epilepsy patients in preparation for resection surgery. Recorded time series were filtered to remove line noise and differentially referenced resulting in 4x8 or 4x6 channel grids. Previous studies have identified low frequency oscillations (LFO) (<30 Hz) and their relationship with high frequency oscillations (HFO) (>80 Hz) as key markers in classifying ictal events and delineating the epileptogenic zone. In particular, our group has previously shown that amplitude modulation of the HFO activity by the delta rhythm can be used to delineate electrodes of interest for resection.

Here we investigate the use of computationally efficient power based features of the iEEG in order to identify target regions suitable for resection. Empirical mode decomposition (EMD) was used to extract rhythmic components of the iEEG which corresponded to both LFOs and HFOs. Power ratios computed on temporal windows of the extracted LFOs and HFOs formed the feature space. A support vector machine (SVM) classifier was trained/validated using the features extracted from Engel Class I patients and was subsequently used to identify grid electrodes suited for resection. Consistent with previous reports, classification accuracy was state dependent as the characteristic features varied at different phases of the ictal event. The classifier was further able to selectively mark electrodes that were consistent with good surgical outcomes (Engel Class I).

SPO92.5 - The alpha rhythm in a rodent model of epilepsy is enhanced when adenosine receptors are blocked Author(s): <u>Vanessa Breton</u>, Peter Carlen, Berj L. Bardakjian University of Toronto, Toronto/CANADA

There are observable spectral markers of seizures in the electroencephalograms and intracranial recordings of epileptic patients. A closer inspection of the pathological rhythms underlying these seizures may aid in the identification of certain neuronal and glial cell populations or synaptic networks involved in the transition through the seizure events. In epilepsy, it has been suggested that the ketogenic diet has a therapeutic effect on seizures by metabolically down-regulating the enzyme adenosine kinase thereby increasing ambient adenosine and activating the adenosine A1 receptor in the cortex. During seizures, it has been proposed that adenosine levels rise, which cause binding of this ligand pre- and post-synaptically to these A1 receptors, inhibiting the excitatory synaptic network and terminating seizures. Mice that have been kindled with pentylenetetrazol treatment experience generalized seizures and show an increase in the cell surface expression of the A1 receptor in many brain regions, including the somatosensory cortex. This finding validates the use of a mouse model of epilepsy in the study of the adenosinergic actions on seizures. What has yet to be identified is the direct effect of the adenosine-A1 receptor complex on the rhythms underlying these epileptic events. The purpose of this investigation is to first assess whether or not a common rodent cortical seizure model shows similar spectral features as clinical cases, and then whether or not there is a pathological frequency band that is restrained due to the presence of extracellular adenosine. Local field potentials were recorded from 500um thick coronal slices from layers 2 and 3 of the mouse somatosensory cortex. Omitting the magnesium in the extracellular artificial cerebral spinal fluid induced two forms of spontaneous field events: long duration seizure like activity and short duration bursts. The pathological oscillations underlying these bursting events were characterized by time-frequency spectral analysis using the continuous wavelet transform. The A1 receptor antagonist DPCPX was applied extracellularly at various concentrations. Dose dependent changes in the power of certain frequency bands were quantified. This model was shown to contain pathological rhythms in the delta (1-3Hz) and theta (4-8Hz) bands. It has been observed that although this antagonist does not significantly alter the duration of the long duration seizure like events, it does increase the total number of shorter duration bursts between

these events and selectively enhances the overall power of the alpha rhythm (9-14Hz) in a dose dependent manner. During the initial phase of the long duration seizure like events the power of the alpha rhythm was enhanced under DPCPX + low magnesium compared to similar intervals taken from seizure like events in the low magnesium model. The change in rhythms underlying subsequent phases of the long duration seizures and short duration bursts are currently being characterized.

SP093 - Health Technology Assessment and Cost Effective Technologies for Developing Countries and Usability and Human Factors Engineering for Medical Devices and System Design: Part 1

TRACK 16: CLINICAL ENGINEERING, CLINICAL PHYSICS, AND PATIENT SAFETY

SP093.1 - The maintenance needs of oxygen concentrators in low-resource settings and implications for technician training: Experience from The Gambia

Author(s): <u>Beverly D. Bradley</u>¹, Samantha Chow², Ebrima Nyassi³, David Peel⁴, Yu-Ling Cheng¹, Stephen R. Howie⁵ ¹Centre For Global Engineering, University of Toronto, Toronto/ CANADA, ²University of Toronto, Toronto/CANADA, ³Biomedical Engineering, Medical Research Council Unit The Gambia, Fajara/ GAMBIA, ⁴Ashdown Consultants, Essex/UNITED KINGDOM, ⁵Child Survival, Medical Research Council Unit The Gambia, Fajara/GAM-BIA

Oxygen is an essential medicine for treating pneumonia, the leading cause of death in children under five worldwide. Yet, providing a sufficient and reliable supply of oxygen is a major challenge for many health facilities in the developing world, particularly in paediatric care units. The cost-effectiveness of oxygen concentrators versus compressed gas cylinders as a source of oxygen in low-resource health facilities has been demonstrated. However, some maintenance and repairs are required to optimize their longevity. To date, evidence of their long-term functionality in the field has been scarce.

The Biomedical Engineering Department at the Medical Research Council Unit in The Gambia manages and maintains 27 oxygen concentrators at several sites across the country, and has kept electronic records of all repairs and preventive maintenance (PM) on these devices since 2006. Through a retrospective analysis of about 800 repair and PM records between 2006 and 2013, we found that the majority of concentrator repairs were low-cost and required a low technical experience level to complete. For example, the most common repairs were filter, battery or valve replacements, and faulty tubing - all were repairable for less than US\$10 each. Median cost of replacement parts per concentrator over the entire analysis period was US\$9.44 [interquartile range: US\$0, US\$63.40]. Seventy-one per cent of all parts replaced contributed only 7% (approximately US\$135) to the total amount spent on parts since 2006. More expensive and complex repairs were rare, and typically occurred after 2.5 years of operation. The concentrators had received an average of over three PM checks per year. Of the 27 concentrators introduced since 2006, 85% are still in service with a median age of over 6 years. We estimate that the useful lifespan of oxygen concentrators in low-resource settings could reasonably exceed 7 years provided a system is in place for repairs and preventive maintenance.

Additionally, we used these repair data for a skill-mapping analysis whereby we identified 31 basic biomedical engineering technician skills that would be sufficient for the repair of over 90% of observed oxygen concentrator failures. Most of the skills identified were drawn from the library of Biomedical Technician Assistant (BTA) skills developed by Duke University's Developing World Healthcare Technologies Lab and Engineering World Health (http://library.ewh. org). Each of these skills can be taught to a BTA in 2 hours. We used this skill-mapping analysis to propose an evidence-based training

curriculum specifically tailored to the maintenance of oxygen concentrators in low-resource settings.

This work has provided insight into on the broader support ecosystem required to manage and maintain oxygen concentrators and other low-complexity medical devices in low-resource settings. Specifically, some of the key elements for the successful use of oxygen concentrators in our Gambian setting have been: uniform and context-appropriate device selection; trained technicians and an established health technology management program; a system for routine preventive maintenance; and resources for and access to spare parts. With this support ecosystem in place, oxygen concentrators can be an appropriate and low-cost technology for supplying medical oxygen in low-resource settings.

SP093.2 - Global Medical Devices Pricing Survey

Author(s): Adriana Velazquez Berumen, Maria E. Moreno Carbajal, Olumurejiwa Fatunde, Yael A. Rodríguez-Guadarrama His/emp/pau/medical Devices, World Health Organization Headguarters, Geneva/SWITZERLAND

To guarantee equitable access to medical devices, reliable information must be available for policy-makers and procurers. Due to lack of information on medical devices pricing, Low and Middle-Income Countries (LIMC) face several disparities during the acquisition process; a public procurer in Latin America paid 300% more for the same device as a public sector organization in Europe. A few countries, such as Brazil, Japan, and Iran have made several efforts to provide reference information to procurers within their countries. However, the majority of countries have no such information available. Since health technology is an essential building block to achieving Universal Health Coverage, information transparency and pricing regulation should treated as priorities by high-level health authorities.

Since 2011, the WHO Medical Devices Unit has begun to address the issue of pricing inequity by building an evidence base. Two studies have been completed by the Medical Devices Unit. The first study detailed price components throughout the supply chain as well as a breakdown of the operational costs generated by 7 selected medical devices (excluding medicines, drugs and vaccines). This study conducted a pilot survey that includes defined parameters to measure price components and operating costs of medical devices over a worldwide representative countries sample and industry sector. The second study provided a conceptual framework for financial access to medical devices. This work supported the pilot of Global Medical Devices Pricing Survey (GMDS), which was launched in 2013. For the GMDS, quantitative information on price components of 21 medical devices were collected from several stakeholders within the health sector, qualitative information on procurement, industry and trade were collected as well. Technologies, brands and models were selected thorough research and evaluation of the products used most commonly throughout the world.

Results from surveys derived from these studies shared a common dilemma: a lack of responses with comparable and useful information. In the first case, only 6 out of 24 countries had completed the survey. For the GMDS, only 15 organizations worldwide submitted responses. Most survey responders chose to report general information on industry, procurement, and trade, rather than medical devices price components. As a result, it is necessary to do an extensive review of the selected medical devices as well as the surveyed participants.

In order to improve global data collection for the forthcoming GMDS, WHO is taking into account the outcomes of the pilot of GMDS, the Global Atlas of Medical Devices (GAMD) 2013 and efforts made by other countries. This includes redefining qualitative information and reselection of medical devices to be included on the

forthcoming survey. To prevent the lack of responses, the survey will exclude industry stakeholders and will be addressed only to global funding organizations, international procurers and countries which have national level of procurement, private health providers and helpful information submitted in the GAMD 2013.

Availability of reliable information on medical devices pricing is the first step in the long path to achieve transparency and pricing regulation policy, possible solutions for disparities within the medical devices market for LIMC.

SP093.3 - Methodology to evaluate physical environment parameters in healthcare services

Author(s): Gustavo A. Elias¹, Saide Calil²

¹Department Of Electronics And Biomedical Engineering, CEFET-MG, Belo Horizonte/BRAZIL, ²Department Of Biomedical Engineering, Unicamp, Campinas/BRAZIL

The physical environment in hospitals should provide adequate conditions in terms of lighting, thermal comfort, air quality, noise level, and workplace. If such conditions are not appropriate, both workers and patients may be negatively affected. The main objective of this work is to develop a human factors and ergonomics based methodology to enable the evaluation of the physical environment in patient care areas. In order to do so, the methodology was developed according to six steps. First, literature research was performed to determine the parameters to be evaluated, which were, then, organized in six groups: work area, noise, lighting, environmental parameters, power outlets, and medical gas outlets. Second, three methods to evaluate the selected parameters were defined: measurement, observation, and written survey. In the third step two forms were created to aid in the parameters measurement and observations. The fourth step involved the development of a written survey in the form of a questionnaire to be applied to healthcare staff. The fifth step consisted of the creation of a method to process the collected data (measurements, observations, and written survey). Finally, in the sixth step, dashboards were developed to report the collected data. The methodology was applied in two intensive care units (ICU) of a public teaching hospital, generating two reports. The analysis of these reports showed that the temperature, relative humidity, and noise in some ICUs were not always in accordance with the established limits. Moreover, the fact that some workers were negatively affected by physical environment parameters such as noise, lighting, and temperature could be verified through survey answers. In addition, there were complaints regarding risk of slip, trip or fall; reflex, glare or shadows; annoying drafts, unpleasant odors, and air quality; as well as the number and positioning of power outlets and medical gas outlets. The methodology met its targets, having generated results that allowed the diagnosis of the effect of some environmental parameters on workers. In addition, the ICU clinical board used the study results in order to develop a campaign aiming at noise reduction.

SP093.4 - HB-HTA method for the evaluation of exclusive Medical Devices

Author(s): <u>Paolo Lago</u>, Ilaria Vallone, Antonio Scarso, Corrado Gemma, Cosimino Russo

Clinical Engineering Dept., San Matteo Hospital, Pavia/ITALY

Introduction:

The Hospital Based Health Technology Assessment (HB-HTA) method is applied to the purchasing process of exclusive and so called "irreplaceable" medical devices, to support the decision of hospital managers.

Objectives:

According to Lombardy region rules for transparency and anticorruption, our hospital adopted a standard procedure for the assessment of exclusive medical devices. It involves a panel of experts: clinical engineers, physicians and economists. Clinical Engineering Department collects informations and collaborates with healthcare professionals in order to write short reports about each technology for hospital decision makers.

Methods:

The evaluation method, according to HB-HTA approach, is focused on the most important aspects of the clinical use of the technology such as security, reliability and organization impact. The standard procedure starts with the compilation of a form in which physicians describe the clinical needs related to a specific innovative medical device, then a scientific literature research and a market survey are carried on. From the data collected in the Italian Medical Devices Database (CND Classification) of the Ministry of Health, possible technical and clinical alternatives are evaluated and compared.

Conclusion:

The final aim of Medical Device assessment is a structured report for healthcare management. Quality informations make decisions more robust, consistent, transparent and verifiable in order to maximize the health gains for the patients and to minimize costs and resources, through a better purchasing method.

SP093.5 - Applying Heuristic Evaluation on Medical Devices User Manuals

Author(s): Fernando O. Andrade, Leonardo N. Novaes, Guilherme A. Wood, Saide Calil

Department Of Biomedical Engineering (deb), State University of Campinas (UNICAMP), Campinas/BRAZIL

Driven by the importance of user manuals as a complement to training courses on the operation of medical devices, the objective of this paper is to verify if the heuristic evaluation approach proposed by Zhang and co-authors is applicable to such manuals. After applying the method in the evaluation of a non-medical device user manual and finding some difficulties to interpret the original terms and definitions, we adapted some of the usability heuristics so they would be more directly related to manuals than to devices. The adapted heuristics were applied on the usability evaluation of a linear peristaltic infusion pump's user manual. Although no healthcare professionals were present in the evaluation team, heuristic violations associated to diverse usability heuristics were identified, including some classified as usability catastro- phes (the ones which could lead to patient's harm). Even with adaptations, members of the team reported difficulties in fo- cusing on the user manual when the current usability problems seemed to be on the medical device itself. Despite the difficul- ties, the evaluation provided enough data on the user manual problems to formulate some corrective recommendations for the device manufacturer. Additional studies are required to confirm if modifications to some of the original fourteen usa- bility heuristics are really necessary and, if so, what adaptations would be most adequate.

SP094 - Biological Modelling

TRACK 19: BIOPHYSICS AND MODELLING

SP094.1 - Finite Element Analysis of Dynamics of Two Microbubbles Under Ultrasonic Field

Author(s): <u>Xiao-Hui Qiu</u>¹, Li Li Zhou¹, Yang Yang¹, Xiao-Jian Wang² ¹Information Engineering Institute, Gannan Medical University, Ganzhou/CHINA, ²Department of Chemotherapy, Ganzhou Tumor Hospital, Ganzhou, China, Ganzhou/CHINA

The finite element numerical model of the two microbubbles in the microvessel is built in our study. The model is solved by finite element analysis softwave. The pressure of observing point P (away from one of two microbubbles A 3 μ m) is used to express the intensity of ultrasonic cavitation. The results show that the pressure on point P is higher than single microbubble case because of the aggravation of thecavitation effect, and with the increasing of the distance of two microbubbles, the effect of adjacent microbubble on point P decreases. These results lay the foundation of the research of the agent concertration effect on clinical diagnosis and treatment.

SP094.2 - The value of individual measurements for tumor control probability predictions in head and neck patients Author(s): <u>luliana Toma-Dasu</u>¹, Mattias Hedman², Alexandru Dasu³ ¹Medical Radiation Physics, Stockholm University and Karolinska Institutet, Stockholm/SWEDEN, ²Department Of Oncology, Karolinska University Hospital, Stockholm/SWEDEN, ³Department Of Radiation Physics, Linköping University Hospital, Linköping/SWEDEN

In the age of personalized cancer medicine, individual measurements of in vitro radiosensitivity and proliferation parameters have great potential for predicting treatment outcome. However, cellular radiosensitivity is quite heterogeneous and therefore concerns exist towards its impact on treatment predictions. It was therefore the purpose of this study to investigate this aspect. Individuallydetermined radiosensitivities and potential doubling times, as well as tumor volumes from 46 head-and-neck carcinomas treated with radiotherapy, were used to predict tumor control probabilities (TCP) under various biologically-relevant assumptions for heterogeneity in radiosensitivity. TCP predictions were then compared to clinical local control using a ROC curve analysis. The analysis showed that TCP calculated under the assumption of heterogeneous radiosensitivity have the same power of distinguishing between patients with or without local control as from single values for the radiobiological parameters (a sensitivity of 66% and a specificity of 80% for an area under the curve of 0.69). The only difference was in the discrimination criterion (TCP>93% for single parameters and TCP>65% for heterogeneous parameters), illustrating the difference in appearance of the TCP curve under the assumption of heterogeneity. Nevertheless, the results showed that individually determined radiobiological parameters could be quite effective towards predicting treatment outcome for individual patients.

SP094.3 - A Novel Technique for Measuring Electrical Permittivity of Biological Tissues at Low Frequencies (100 KHz or lower)

Author(s): <u>Seyyed Hesabgar</u>¹, Karen Lam¹, Ravi Menon², David Holdsworth², Abbas Samani³

¹Medical Biophysics, Western University, London/ON/CANA-DA, ²Robarts Research Institute, Western University, London/ON/ CANADA, ³Electrical & Computer Engineering, Western University, London/ON/CANADA

Accurate measurement of electrical permittivity (EP) of biological tissues is highly important for a broad range of applications including ECT (Electrical Capacitance Tomography), EPT (Electrical Permittivity Tomography), bone health assessment (Meaney et al.), interaction of electromagnetic fields with biological tissues (Peyman et al.) and food quality classifications (Ngadi et al.). As such many researchers in the past three decades have conducted numerous measurements to obtain electrical properties of biological tissues but despite the fact that most of the researchers have traditionally used an openended coaxial cable and vector network analyzer (VNA) for their measurements, a robust and accurate method of measuring biological tissues EP especially at low frequencies has not been developed yet. It is noteworthy that, EP imaging at low frequencies has a good potential to provide valuable diagnostic information. Gabriel et al. indicated that the uncertainty and error percentage of using openended coaxial probe and VNA which has been applied in the past three decades as a conventional way of measuring biological tissues EP is quite significant at low frequencies. Computer simulation also indicates that the accuracy of EP measurement for ex-vivo biological samples from conventional procedure (using open-ended coaxial probe and VNA) depends highly on the size and thickness of the samples. This implies that an accurate and reliable measurement of biological tissues EP at low frequencies (100 KHz or lower) may not be achievable by using the conventional technique. In this work we introduce a novel and reliable technique which is capable of measuring the EP of biological tissues at low frequencies in an accurate and robust way. In this technique, we use a highly sensitive capacitive sensor we developed in our laboratory. This sensor consists of two plates that sandwich the tissue sample before its electrical excitation followed by highly precise measurement of the capacitance formed by the two plates and the sample. In order to estimate the sample's EP, an initial guess of the sample's permittivity along with its known geometry is fed into an inverse Finite-Element (FE) algorithm we developed for this estimation. This algorithm follows a nonlinear optimization framework which changes the sample's permittivity in its FE model systematically until the capacitance obtained from the FE model matches the experimental capacitance. The last permittivity value is considered as the estimated permittivity of the tissue sample. The mentioned technique has been utilized to extract the EP from ten freshly excised bovine heart and bone samples. Our results indicate that the average EP of 571F/m and 22418 F/m at 32 KHz for the bone and heart samples which compare well with values reported in the literature. Also the standard deviation of 50.8 F/m and 1609.3 F/m for the mentioned samples are guite low, which suggest that the proposed technique is highly repeatable.

SP095 - Biosignal Processing & Pulmonary & Respiratory

PRESIDENTS CALL

SP095.1 - Power Spectral Density Analysis of Tonic Electrodermal Activity for Sympathetic Arousal Assessment Author(s): <u>Hugo F. Posada-Quintero</u>, Ki Chon Biomedical Engineering, University of Connecticut, Storrs Mans-

field/UNITED STATES OF AMERICA

Electrodermal activity (EDA) has become a promising technique for assessing sympathetic nervous system (SYM) arousal. Afferent neurons from the sympathetic axis of the autonomic nervous system innervate eccrine sweat glands, and their activity modulates conductance of an applied current. Sympathetic innervation of sweat glands is revealed in quantifiable fluctuations in skin conductance at the skin's surface, termed EDA. EDA comprises slow and more rapid transients. Tonic EDA states have been assessed using two main measures: skin conductance level (SCL) and nonspecific skin conductance responses (NS.SCRs). The aforementioned measures require manual scoring and human visual verification in the time domain which is cumbersome and often subjective. Hence, there is a need for quantitative signal processing techniques to assess the SYM arousal. To this end, we applied power spectral density (PSD) analysis to EDA signals in order to determine correlations between frequency-domain EDA index (0.045 to 0.15 Hz) and EDA measures in the time-domain (SCL and NS.SCRs). We employed the same range of frequency used for sympathetic assessment in heart rate variability analysis, which corresponds to low frequency (LF) index. We also tested the ability of those indices to discriminate between levels of sympathetic arousal. Sympathetic arousal was elicited using orthostatic stress (supine, standing and sitting positions). Seven subjects were recruited and 4 minutes of EDA signals were recorded for each position. Two minutes of clean signal (after one minute of starting recording and one minute after asking the subject to change position) were used for further processing. LF-EDA and SCL was weakly correlated (r = 0.374, p = 0.055); LF-EDA and NS.SCRs more correlated (r = 0.545, p = 0.032) than SCL. SCL and NS.SCR presented statistically significant differences between sitting and supine, but not between standing and sitting. However, LF-EDA showed statistically significant differences between the three positions. This shows a potential of PSD of EDA for assessing sympathetic arousal under orthostatic stress.

SP095.2 - Multivariate Analysis Classification Based on Multi-Channel EMG Multisite Microelectrode Recording, Principal Component Analysis, and Hierarchical Clustering Author(s): <u>Venkateshwarla R. Raju</u>

Biomedical Eng & Neurology & Neurosurgery And, Nizam's Inst of Medical Sciences (NIMS) University & Hospital, HYDERABAD/INDIA

Hypothesis/Rationale The main HYPOTHESIS is that when a Writer's cramp (WC) subject writes with an abnormal posture, it is difficult to determine if that posture is because of the primary dystonic force or if a compensatory force (applied by the WC subject) has overcome the primary dystonic force and has resulted in that posture. One way to differentiate between those two would be is to look at the mirror movements. Mirror movements (MMs) are seen in the right hand (RH) while writing with the left hand (LH). In case the primary dystonic force is resulting in the abnormal posture while writing with right hand, the MMs would be in the same direction i.e., they would be**concordant**. If a compensatory force (overcoming the primary dystonia) has resulted in the posture, this would be seen in

the MMs which would be in the opposite direction i.e., they would be discordant. We hypothesize that there is no EMG recognizable difference in MMs of concordant and discordant subjects. If the data reveal that there are significant differences in MMs of the two groups of subjects (as we expect it to be) our expectation that there is EMG recognizable difference between the groups is justified and the analysis can lead to (clinically) meaningful insight. This study showed significant quantifiable EMG differences in the signals seen while writing with the right and left hands between those writer's cramp subjects with concordant mirror movements (C group) versus those with discordant mirror movements (D group). These differences were robust and seen in every measure of dispersion, such as in the patterns of significance of f-values for ratios of variances. Cluster analysis and more sophisticated analyses using advanced multivariate techniques leading to effective data summarization and measures of dissimilarity between subjects as reflected in the signals recorded and consequent possible clustering among them, however, did not lead to any meaningful clinical conclusions. These analyses could possibly be applied to longitudinal follow-ups and correlations with a normal control population in future to better comprehend the WC-phenomenon. The work on muscle signals and their application in neurological disorders as well as disabilities of dexterous movement, such as writing and the results in a vast data regarding the functioning on the muscles certainly and gainfully utilized by the biomedical scientists for further modeling of EMG.Background: Prevalence-rate-of-generalized/focal_dystonia according to various studies (Muller J and many other scientists) varies from 0.17 to 5 per 100,000 population and 3 to 732 per100,000populations (USA30/(100,000), Europe12, Germany10, Italy732, Norway16, N. England13, Serbia14, Israel, China3, Japan6, Egypt10). In a community based study from India, by Das et al., crude prevalence rate of primary dystonia was 53.91 per 100,000 population and that of focal dystonia varied according to type of dystonia. Objective: to develop a computational modeling- using the model to develop a new clinical experimental setup, to design and build a multi-channel EMG machine and attempt to differentiate between those with concordant (C) and discordant (D) MMs in WC, in order to establish that there is a quantifiable difference between these two groups.

SP095.3 - Blanket Fractal Dimension for Estimating Tidal Volume from the Smartphone Acquired Tracheal Sounds: Preliminary Results

Author(s): <u>Natasa Reljin</u>, Bersain Reyes, Ki Chon Biomedical Engineering, University of Connecticut, Storrs/CT/UNIT-ED STATES OF AMERICA

Tidal volume is one of the parameters used for monitoring respiratory activity. Various methods exist for measuring the tidal volume; however, all of them require the use of specialized equipment. Due to their attractive specifications and portability, smartphones are becoming more popular and suitable for measuring vital signs and health monitoring in nonclinical and everyday settings. In this paper, we propose the use of blanket fractal dimension (BFD) for estimating the tidal volume from a smartphone acquired tracheal sounds. Tracheal sounds, as part of respiratory sounds, are non-stationary and stochastic signals, and as such are suitable for fractal analysis. Blanket method creates a strip around the tracheal signal, thus closely following the changes within the signal. As the signal changes faster, the value of BFD becomes higher. In this study, we recorded tracheal sounds with an Android smartphone, while simultaneously we collected the respiratory inductance plethysmography signal via Respitrace system. Prior to every recording, the Respitrace signal was calibrated with a spirometry system, and the obtained calibration errors were less than 10 % (which is in accordance with the manufacturer's manual). Signals were collected from five (N=5) healthy and non-smoker volunteers. Each volunteer performed the experiment two times; first to obtain linear and

exponential fitting models, and then to fit new data onto the existing models. Thus, the total number of recordings was 10. The estimated volumes were compared to the true values, obtained with a Respitrace signal, which was considered as a reference. These reference volumes were limited to a range from 0.2 to 1 L, as it is the normal breathing range, and consequently, only the corresponding portions of tracheal sounds were used in analysis. Since Shannon entropy (SE) is frequently used as a feature in tracheal sounds' analyses. we also estimated the tidal volume from the same sounds by using SE. The evaluation of the performed estimation, using BFD and SE methods, was quantified by the normalized root-mean-squared error (NRMSE). The results show that the BFD outperformed the SE (at least twice smaller NRMSE was obtained during both days). The smallest NRMSE error of 15.877±9.246 % (mean ± standard deviation) was obtained with the BFD and exponential model. In addition, it was shown that the fitting curves calculated during the first day of experiments could be successfully used for at least one following day. These results indicate the possibility of obtaining a portable system for tidal volume estimation, which can be used for more than one day without the need to calculate fitting curves during every day's experiment.

SP095.4 - A Robust and Realistic Framework for Clinical Classification of Myocardial Infarction

Author(s): Yasin Yazıcı¹, Yasin Mamatjan²

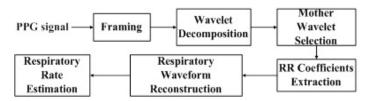

¹Zirve University, Gaziantep/TURKEY, ²Mars Centre, Princess Maragret Cancer Center, Toronto/ON/CANADA

Early detection of Myocardial Infarction (MI) or heart attack is important to reduce mortality rate of cardiac diseases and automatically recognize them in order to help the diagnoses and eventually effective treatment of MI patients. Although various advanced algorithms have been published previously, there are a number of issues regarding reproducibility, public availability, clarity that even some of them 'over fitted' the classifier and performed biased pre-processing (feature selection) with all the data set to achieve high accuracy. We aim to create a robust and realistic framework for clinical classification of MI. To achieve this, firstly, we set the requirements for realistic clinical evaluation using predictive modelling and validation as well as proposed practical guidelines for reproducibility. Secondly, to detect MI efficiently and accurately, a novel approach based on Stacked Autoencoder (SAE) is used which has deeper representation power and also needs less pre-processing. We also give essential insight on why and how SAE works for different ECG data. Thirdly, we conducted systematic comparisons of the newly proposed SAE method and Continuous Wavelet Transform (CWT) based Linear Discriminant Analysis (LDA) using real ECG data set. Lastly, based on the predefined requirements, we reflected the clinical reality and corrected some other papers mistake while considering the realistic aspect of separating training and testing dataset to avoid 'over fitting' and biased feature selection and thus performed cross validation (with 2 level 10 fold cross validation). SAE always outperformed CWT based LDA approach. The accuracy of SAE is 87 % while the biased and 'over fitted' model produced an accuracy of over 99 % which is clinically unrealistic. We are improving SAE approach as it is new for ECG application, so there are more room for future improvement. The novel classification approach developed in this paper can reliably and efficiently provide useful information to clinicians and alert when state of the heart patient changes, could help clinicians realistic diagnoses and eventually effective treatment of cardiac patients.

SP095.5 - A Mother Wavelet Selection Algorithm for Respiratory Rate Estimation from Photoplethysmogram Author(s): Dan Guo, Zhijian Li, Huijun Ding Department Of Biomedical Engineering, School of Medicine, Shen-

zhen University, Shenzhen/CHINA Photoplethysmogram (PPG) is known as a low-cost optical measure for detecting the blood volume changes. Recently, a new attempt at estimating respiratory rate (RR) from PPG signal becomes an active area. It can be implemented by different algorithms among of which wavelet based methods are commonly used with good performances achieved. In previous work, several popular mother wavelets, including db10, sym8, bior6.8, rbio6.8 and coif5, are compared and db10 exhibits the best performance on restoring the useful respiratory information from PPG signal. However, the study on the reason why different mother wavelets have different performances on RR estimation as well as how a suitable wavelet can be easily selected

is insufficient. In order to explore this issue, a mother wavelet selection algorithm is proposed in this paper shown in the following figure.

In our approach, the input PPG signal is decomposed by six popular mother wavelets, namely db10, db12, sym8, bior6.8, rbio6.8 and coif5, and the results are compared in terms of the sum of decomposition coefficient magnitudes in every frame. The mother wavelet with maximum value is chosen to extract the wavelet coefficients containing RR information. By using the extracted coefficients, the reconstruction process is applied to form the respiratory waveform. In the experiments, the proposed algorithm is compared with the related six mother wavelets working separately. Two datasets are used, one of which has 21 PPG signal segments recorded by our PPG acquisition system and the other has 16 PPG signal segments randomly selected from the MIMIC database. Two evaluation tools, root mean squared normalized error (RMSNE) and Bland & Altman plot, are adopted. In RMSNE comparison between reference RR and estimated RR, the proposed algorithm obtains the minimum error rates of 2.37% and 1.4% on two datasets respectively. For Bland & Altman plot where smaller range between 95% limits of agreement indicates a better performance on RR estimation, the proposed algorithm obtains the minimum ranges of [-0.013, 0.011] Hz and [-0.003, 0.007] Hz on two datasets respectively. The above evaluation results demonstrate the better performance of the proposed algorithm. In addition, the finding reveals that the mother wavelet with a larger sum of coefficient magnitudes has a better performance on RR estimation from PPG signal which can be used as wavelet selection criteria in this area.

SP095.6 - Mathematical assessment of variability in respiratory airflow patterns

Author(s): <u>Saravana K. Raman</u>, Christopher Druzgalski California State University Long Beach, Anaheim/CA/UNITED STATES OF AMERICA

Mathematical approach was used to study and determine unsteady respiratory airflow dynamics for inspiratory and expiratory breathing cycles and to analyze pulmonary data under different levels of ventilatory conditions. The work involved acquiring and processing of respiratory airflow patterns from healthy subjects under varying levels of induced obstruction. A set of mathematical equations based on the Fourier series model were developed to describe the airflow patterns. Coefficients obtained from the Fourier series model were evaluated to obtain their ranges of values for different levels of ventilations. The goal to assess the airflow mechanics is approached by numerical modeling of the respiratory airflow network. Graphical methods were used to evaluate the goodness of fit and their statistics including the SSE, R-Square, Adj R-Sqr and RMSE. Basic statistical analysis which includes the mean and standard deviation for the airflow signals was obtained. In order to study the variability of airflow limitations, different size mouthpieces were used.

SP095.7 - Spectral Analysis of Respiratory and Cardiac Signals Using Doppler Radar

Author(s): Philip Tworzydlo, Adrian D.C. Chan

Systems And Computer Engineering, Carleton University, Ottawa/ CANADA

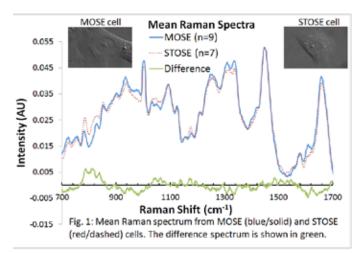

Inmate injuries and deaths remain a significant problem for correctional institutions, increasing the need for continuous monitoring of inmates. A Doppler radar device is investigated for use as a contactless method of vital sign monitoring (e.g., breathing and heart rate) in a single cell setting. The recorded radar signal is analysed in both the time domain, and in the frequency domain. The radar signal and its frequency spectrum is compared against the signals and frequency spectrums obtained from an electrocardiogram and a respiratory inductance plethysmography band. The breathing and heart rate estimates obtained from the radar match up with the estimates provided by the respiratory band and electrocardiogram. Results show that the radar device demonstrates good potential for contactless vital sign monitoring.

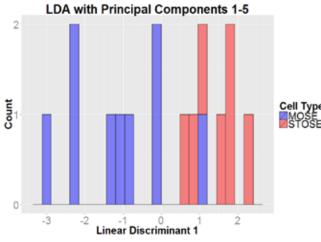

SP096 - Optical Imaging: Applications

TRACK 01: IMAGING

SP096.1 - Live-cell Raman microspectroscopy to differentiate between normal and malignant ovarian surface epithelial cells Author(s): Santa Borel¹, Emil A. Prikryl², Nhung Vuong³, Barbara Vanderhyden³, Brian C. Wilson⁴, Sangeeta Murugkar² ¹Department Of Medical Biophysics, University of Toronto, Toronto/ ON/CANADA, ²Department Of Physics, Carleton University, Ottawa/ ON/CANADA, ³Department Of Cellular And Molecular Medicine, University of Ottawa, Ottawa/ON/CANADA, ⁴Ontario Cancer Institute, Toronto/ON/CANADA

Raman microspectroscopy (RMS) is a non-invasive, label-free optical technique that is based on the inelastic scattering of light by vibrating molecules. It provides a fingerprint of the common molecular bonds in specimens, including cells and tissues. This technique, in conjunction with multivariate statistical analysis methods, has been applied successfully for the label-free classification of living cells based on their molecular composition, which can be correlated to variations in protein, DNA/RNA, and lipid macromolecules. Here, RMS is applied to normal mouse ovarian surface epithelial (MOSE) cells, M0505, and spontaneously-transformed ovarian surface epithelial (STOSE) cells, which are derived from the MOSE cells and are a model for high-grade serous ovarian cancer. The Raman spectra collected from individual cells undergo initial preprocessing (background subtraction, normalization and noise reduction) to yield true Raman spectra representative of the cells for subsequent statistical analysis. The means of these spectra are shown for both types of cells in Fig. 1. Although the corresponding images (differential interference contrast microscopy) of the MOSE and STOSE cells shown in the inset appear identical, there are clear differences observed in the spectra that are attributed to differences in molecular concentrations. Using Principal Component Analysis (PCA) followed by Linear Discriminant Analysis (LDA), a clear separation of the cells into the two groups (MOSE and STOSE), with the exception of one outlier, is evident in the preliminary data shown in Fig. 2. The objective of this ongoing work is to characterize the spectral differences between the two cell types in order to correlate them with specific molecular or structural changes. The multivariate classification model constructed using such Raman spectra of MOSE and STOSE cells could thereby potentially be utilized for early detection of ovarian cancer.

SP096.2 - Quantitative image analysis of fluorescence endomicroscopy video sequences for mesenchymal stem cell tracking in regenerative lung treatment

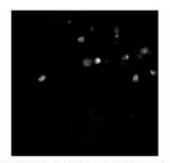

Author(s): <u>Jessica R. Perez</u>¹, Norma Ybarra², Frederic Chagnon³, Olivier Lesur³, Issam El Naqa¹

¹Biomedical Engineering/medical Physics, McGill University, Montreal/CANADA, ²Radiation Oncology, McGill University health center, Montreal/CANADA, ³Sherbrooke University, Sherbrooke/CANADA

Introduction: Fluorescence endomicroscopy is a powerful new minimally invasive tool that allows real-time visualization of fluorescently labeled cells within the lungs in clinical and preclinical models. In the context of regenerative medicine for lung damage, the objective of this project is to gain insight into the behaviour of mesenchymal stem cells (MSCs) in the lung of a rat model of lung injury post-radiotherapy. Interpretation and analysis of large video sequences is important to quantify the efficacy of such treatment under different experimental scenarios. In this work, we are proposing an image segmentation method to quantify the number of cells present in the field of view at each timepoint in the acquired endomicroscopy video sequence.

Materials and Methods: MSCs were labeled in culture with a membrane dye (DiD) prior to administration. MSCs were delivered endotracheally into the lung and followed by fluorescence endomicroscopic imaging. Images were acquired in the red channel (660 nm) through a tracheotomy procedure. We followed the rats for a week period and images were acquired on days 1, 2, 5 and 7. Regarding video sequence analysis, we treated each frame individually as a stand-alone image. We used a granulometry approach to determine the size of objects (cells) present in the image and performed morphological opening to detect them. Opening is a morphological operation that dilates then erodes the image with a selected structuring element, in this case a disk, in order to remove small erroneous objects and only select cells. A threshold was subsequently applied to the resulting image to select fluorescent cells over background and each detected object was counted.

Results: We were able to detect labeled MSCs in the lungs in vivo and followed them for a period of one week. At any given time point during the movie we were able to obtain an estimate of the corresponding number of cells present in the field of view. Figure 1 shows a representative endomicroscopy image with the resulting corresponding cell count of 15 cells. We compared this automated method to manual cell counting on a test set of 30 frames and achieved a good accuracy with a root-mean-squared error (RMSE) of 4 cells per frame.

Representative endomicroscopic image of cells in the lungs

Cell count at the cells position

Conclusion: We determined the feasibility of lung fluorescence endomicroscopy for tracking of MSCs in vivo and developed an automated image analysis method to quantify the number of cells in different experimental conditions.

SP096.3 - Shape-Based Diffuse Optical Tomography for Reconstruction of Photothermal Lesions in Prostate Focal Therapy Author(s): <u>Robert A. Weersink</u>¹, Jie He², Sahil Chaudhary², Kenwrick Mayo², Brian C. Wilson³

¹Radiation Onclogy, University Health Network, Toronto/ON/ CANADA, ²University of Toronto, Toronto/CANADA, ³Ontario Cancer Institute, Toronto/ON/CANADA

Near-infrared interstitial photothermal therapy is undergoing clinical trials as an alternative to watchful waiting or radical treatments for patients with low/intermediate-risk focal prostate cancer. MRI-based thermography is currently used to monitor target tumor destruction based on the measured tissue temperature and calculated thermal energy dose. This indirect method of imaging the treatment zone is used to assess if treatment fully covers the target volume while avoiding damage to adjacent normal tissues, particularly the rectal wall. As an alternative, we are developing transrectal diffuse optical tomography (TRDOT) to directly monitor the photothermal therapy by imaging the photocoagulation boundary based on changes in tissue optical scattering.

In this presentation, we describe the development of shape-based diffuse optical tomography as applied to the particular problem of monitoring the expanding photothermal lesion. Standard methods of diffuse optical tomography present an ill-posed inverse problem since the number of source-detector combinations is less than the variant parameters (optical properties within the volume). Hence, there are typically no unique solutions for standard DOT reconstructions. Current practice resolves this situation by imposing spatial or spectral constraints on the solutions.

In our clinical problem, the shape of the coagulated/treated tissue rather than the optical properties is of primary interest. We present a shape-based diffuse optical tomography solution in which shape parameters are used to set varying optical properties within the tissue volume. The shape is an ellipse symmetric about its short axis for a general lesion shape plus spherical harmonics to model small variations from the general ellipsoidal shape. The optical properties of the thermal lesion may vary, but with the assumption that these properties are invariant within the lesion shape.

The solution is applied to simulations of photothermal focal therapy, modelling a growing thermal lesion around a linear 10mm diffusing treatment fiber placed 10mm from the prostate wall. The modelled lesion grows in 1mm radius increments to a final radius of 9mm. Tissue scattering of the thermal lesion was set at 4X the scattering of the surrounding tissue, similar to measured tissue results. Axial and longitudinal source-detector configurations relative to the essentially elliptical thermal lesion were modelled. The shape-based tomography successfully recovered the correct shape of the thermal lesion for lesion radii >3mm, with the error in the radius <0.5mm. Accuracy improved as the radius increased, equivalent to the lesion boundary approaching the prostate surface. Increasing noise added to the simulated data had little impact on the shape recovery: for lesions within 4mm of the prostate surface, radii error < 1mm up to 16% noise, for smaller lesions, ellipse radii error <3 mm when the noise was greater than 10%. Since the actual optical properties of the lesion may be difficult to recover, the robustness of the shape-based tomography to recover a correct solution when the reconstruction assumes different optical properties than the actual properties, the shape parameters were recovered within \pm 1mm.

Shape-based DOT is a viable, accurate method of recovering thermal therapy treatment lesions.

SP096.4 - Transrectal diffuse optical tomography to monitor photocoagulation during interstitial photothermal theraphy of focal prostate cancer

Author(s): Jie He¹, <u>Robert A. Weersink</u>², Israel Veilleux³, Brian C. Wilson¹

¹Department Of Medical Biophysics, University of Toronto, Toronto/ CANADA, ²Radiation Onclogy, University Health Network, Toronto/ ON/CANADA, ³University Health Network, Toronto/CANADA

Near-infrared interstitial photothermal therapy is undergoing clinical trials as an alternative to watchful waiting or radical treatments for patients with low/intermediate-risk focal prostate cancer. Currently, MRI-based thermography is used to monitor thermal energy delivery and determine indirectly the completeness of the target tumor destruction while avoiding damage to adjacent normal tissues, particularly the rectal wall. As an alternative, transrectal diffuse optical tomography (TRDOT) is being developed to directly monitor the photothermal therapy by imaging the photocoagulation boundary based on the changes in tissue optical properties, particularly scattering. Numerical simulations of optical signals were performed using Nirfast to assess the sensitivity of changes in the optical signals to a growing coagulated lesion with higher optical scattering contrast to normal tissue, for varying light source-detector separations in both longitudinal and transverse imaging geometries. The simulations were validated experimentally in tissue-simulating phantoms using an existing continuous-wave TRDOT system. A MR compatible TRDOT applicator probe with a source-detector configuration that is capable of acquiring optical measurements and representative of the potential intended clinical use is assembled and used in these experiments. Phantom measurements and numerical simulations provide critical guidance for the optimum design of a further version of the transrectal applicator probe, in achieving maximum sensitivity to the presence of the coagulation boundary and, consequently, the highest accuracy in determining the boundary location relative to the rectal wall.

SP096.5 - The first in vivo, optical images of neuroblasts migrating away from the subventricular zone deep in mouse brain reveal two patterns of migration: implications for future therapeutic use

Author(s): Ben Kemp, <u>Teresa A. Murray</u> Biomedical Engineering, Louisiana Tech University, Ruston/LA/ UNITED STATES OF AMERICA

Neural stem cells exist naturally in the adult brain in humans, mice and other animals. Their existence has sparked hope for treating neurodegenerative diseases, stroke and brain injury. In mammals, adult neural stem cells divide and begin differentiating in one of two bilateral germinal zones. One of these is the lateral subventricular zone (SVZ). Partially differentiated cells exit the SVZ and migrate to other regions of the brain. When neural stem cells in the SVZ of mice begin to differentiate into neural precursor cells, or neuroblasts, they normally travel in clusters to the olfactory bulb. This pathway is called the rostral migratory stream. However, after a cortical injury, some of these migrating cells change course and migrate into the cortex. This has piqued interest in manipulating the mechanisms of neurogenesis to repair neural damage. Yet, what is known about neuroblast migration relies predominantly on brain slice studies. These studies have produced conflicting observations regarding mechanisms that drive proliferation and migration, and the rates of movement. To overcome the limitations and confounds inherent in slice preparations, an in vivo imaging system was created using a permanently implanted, optimized gradient index (GRIN) lens and multiphoton microscopy. The SVZ is in a subcortical region that is beyond the reach of standard multiphoton microscopy. The implanted lens overcomes this depth limitation. A preliminary longitudinal study was conducted using mice that express green fluorescent protein under the dcx promoter to label neuroblasts. This study is the first to produce images of neuroblasts migrating away from the SVZ in live mice. As expected, most neuroblasts traveled in clusters toward the rostral migratory stream. Surprisingly, a few neuroblasts did not travel with a cluster. These individual cells moved at markedly faster rates and frequently changed directions. In future studies, we will determine what factors influence the migratory path of these lone neuroblasts with the goal of redirecting large numbers of neuroblasts for future therapeutic uses.

SP097 - Quantitative Imaging: Part 2

TRACK 01: IMAGING

SP097.1 - Ischemia-time dependent CBF threshold for infarction determined in a porcine model of stroke using CT Perfusion and F-18 FFMZ PET imaging

Author(s): Eric A. Wright¹, Christopher D. D'Esterre², Laura Morrison³, Neil Cockburn³, Michael Kovacs⁴, Ting Yim Lee⁵ ¹Robarts Research Institute, London/ON/CANADA, ²Department Of Radiology, Foothills Medical Center, Calgary/CANADA, ³Lawson Health Research Institute, London/ON/CANADA, ⁴Department Of Medical Imaging, Western University, London/ON/CANADA, ⁵Medical Biophysics, The University of Western Ontario, London/CANADA

Introduction: CT Perfusion (CTP) derived cerebral blood flow (CBF) has been proposed as the optimal parameter for delineating the infarct core prior to reperfusion (1), however lack of ischemia-time dependent CBF thresholds for infarction has been problematic. Previous CTP-CBF threshold derivation studies have been limited by uncertainties caused by infarct expansion, and DWI lesion reversibility (2). This study proposes a porcine model for determining ischemia-time dependent CBF thresholds for infarction using contemporaneous CTP and 18F-fluroethylflumazenil (FFMZ) PET imaging, with the objective of deriving a CBF threshold for infarction after 3h of ischemia.

Methods: Cerebral ischemia was induced in the left hemisphere of 11 pigs by injecting endothelin-1 (ET-1) into the cortex through a burr hole in the skull. CTP scans were completed at baseline, 10, 30 then every then every 30 until 180min post ET-1 injection. If the CBF map at any time point showed reperfusion of the ischemic tissue then a second dose of ET-1 was administered. F-18 FFMZ was injected 2.5h after the first ET-1 injection and a 25min PET acquisition was started 25min post F-18 FFMZ injection. CBF maps from each CTP imaging time point were co-registered and a median CBF map was produced by taking the median value of each pixel. The median CBF maps, the PET images, average images from the baseline CTP study, and blood volume (BV) maps from the 10min post ET-1 CTP study were co-registered. ROIs were drawn over the cortex on the affected and contralateral side and superimposed onto all maps and images. Infarct pixels were identified on PET images as having signal less than the average minus 2 standard deviations from the contralateral ROI. Average images were used to segment out white matter within the affected side ROI by removing pixels with CT number less than 40HU. Blood vessel pixels were excluded if they had a BV greater than the average plus 2 standard deviations from the affected side ROI or if they had median CBF over 100mL100g-1min-1. The remaining infarct and non-infarct grey matter ROIs were superimposed onto the median CBF map and pixel values were imported into Matlab for logistic regression and ROC analysis. This process was repeated for each animal that developed infarction.

Results: 6 of the 11 animals developed infarction with an average infarct volume of 1.41 ± 0.38 cm³. The optimal operating points of the ROC curves corresponded to CBF values of 14.2, 11.8, 18.9, 13.4, 13.9, and 19mL100g⁻¹min⁻¹. The average of these 6 values was calculated to find a 3h ischemia-time CBF threshold for infarction of 15.2 ± 1.2 mL100g⁻¹min⁻¹.

Conclusions: The 3h ischemia-time infarction CBF threshold of 15.2mL100g⁻¹min⁻¹ agrees well with the threshold of 12mL100g⁻¹min⁻¹ derived in a previous study (3). The ET-1 stroke model has the potential to derive CBF thresholds for infarction at other ischemia times by varying the time between the ET-1 injection and the start of PET imaging.

SP097.2 - Characterization of scatter factors in thyroid studies using a pinhole collimator by Monte Carlo Simulation. Author(s): Adlin Lopez Diaz¹, Sunay Rodriguez², Angelina Diaz², <u>Aley Palau¹</u>, Juan Miguel Martin¹ ¹Nuclear Medicine, Hospital Hermanos Ameijeiras, La Habana/ CUBA, ²Physical Researsh, CEADEN, Havana/CUBA

To study the scatter factors during I-131 thyroid scintigraphic studies with a pinhole collimator (5mm hole) was developed a Monte Carlo (MC) simulation using GAMOS code. First, to check the accuracy of the Monte Carlo model, simulated and measured data using a thyroid phantom were compared. The accuracy of the Monte Carlo model was verified by the good agreement between measured and simulated energy spectra and the maximum discrepancies of 2% in the counts/sec/MBq. Next, simulations to investigate scatter were performed for different tissue thickness between the thyroid and collimator (5-15mm). The image's scatter contribution was significant in the 5mm pinhole, being between 27-40%. On the basis of the separated scatter from direct count included in window energy spectra, a preliminary evaluation of multiple window energy correction methods was performed. For the simulated thyroid geometry with pinhole, the reduce inferior double energy window methods (15% on 364keV photopeak window) provides a reasonable correction for scatter. This study is the first approach; we recommend including real thyroid geometry with different thyroid depth-thickness and mass.

SP097.3 - Fluid Quantification Using Temporal Subtraction: Comparing Single to Dual-Energy Digital Chest Radiography Author(s): <u>Shailaja Sajja</u>¹, Samuel Richard², Ali Ursani¹, Fatima Ursani¹, Megan Hickey³, David Foos², Narinder Paul¹ ¹Department Of Medical Imaging, toronto general hospital, toronto/ ON/CANADA, ²Research And Innovation Labs, Carestream Health, rochester/NY/UNITED STATES OF AMERICA, ³Brock University, Saint Catherines/CANADA

Background: Accurate quantification of thoracic water content is integral to assessing patient health in many disease states. Computed tomography (CT) provides tissue characterization and quantification but is generally not available for critically ill patients. Portable chest radiography (CXR) is often the only imaging modality available to immobile patients; however, it has limited ability for estimating fluid content. Temporal subtraction (TS) provides temporally separated projections for quantifying differences in tissues over time, but performance is limited by image misregistration. Dual-energy (DE) CXR removes overlapping ribs and can reduce structures that are challenging to register. This research investigates the utility of portable TS-CXR and TS-DE-CXR for the detection and quantification of thoracic water.

Evaluation: Temporal subtraction of CXR images taken pre- and post-operation were used to determine change in fluid volume. The algorithm utilized the difference in x-ray attenuation signal between images to derive water thickness and to estimate the difference in water volume. 1-5 solid water blocks (40 ml each) were added (total volume of 200 ml) into the thoracic cavity of a static anthropomorphic chest phantom. CXR (120 kVp) and DE-CXR (60/120 kVp) were acquired after addition of each solid water block. A set of TS-CXR and TS-DE-CXR images were generated by subtracting the nowater image from the set of images with added water, from which volume estimates were derived. The experiment was repeated on a horizontally-moving phantom to simulate motion. Intensity-based rigid image registration was performed between pre- and post-op-

eration images followed by temporal subtraction. Image segmentation of the lung region was improved with TS-DE-CXR due to a clear demarcation between lung space and remaining thoracic region without the confounding impact of ribs. In addition, TS-DE-CXR had fewer misregistration artifacts resulting in improved registration performance and superior accuracy in estimation of water volume. The root mean squared error (RMSE) was 4.74 ml using TS-DE-CXR and 8.9 ml using TS-CXR. The range of error percentage was -7% to +2% with TS-DE-CXR and +6.3% to +16% with TS-CXR.

Discussion: TS-DE-CXR images are superior to TS-CXR images in providing accurate estimation of thoracic water volume. TS-DE-CXR has potential to enhance the diagnostic utility of DE-CXR for immobile patients.

Conclusions: TS-DE-CXR provides an accurate estimation of the volume of thoracic water. Further work will target validation of the TS-DE scheme on clinically acquired CXR images.

SP097.4 - Quantitative low-kVp CT angiography in carotid artery imaging

Author(s): Tingyu Mao¹, Meili Yang¹, Pengwei Wu¹, Gaofeng Wang¹, Xiangyang Tang², Hongjie Hu¹, <u>Tianye Niu</u>¹

¹Sir Run Run Shaw Hospital, Institute of Translational Medicine, Zhejiang University, Hangzhou/CHINA, ²Department of radiology, Emory University, Atlanta/GA/UNITED STATES OF AMERICA

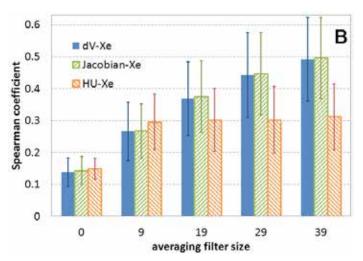

Shading and streaking artifacts brought by beam hardening and photon starvation is commonly observed in low-kVp CT angiography (CTA) for carotid artery imaging. Image quality is thus significantly degraded and a faithful observation of carotid artery is impeded. In this paper, we propose a novel quantitative image postprocessing scheme to eliminate these artifacts. In shading correction, we follow general knowledge of the relatively uniform CT number distribution in one tissue component, and continuous and low-frequency shading artifact distribution in projection domain. Coarse image segmentation is first applied to construct an ideal template image where each structure is filled with the same CT number of that specific tissue. By forward projecting the difference between uncorrected CT image and the ideal template, we estimate the continuous and low-frequency shading error signal in projection domain using lowpass filtering. An error map is then reconstructed using standard filtered back-projection algorithm from the error signal and added to the original image to correct for the shading artifacts. To suppress the increased noise and streaking artifacts, we first perform a texture extraction to estimate the noise distribution in the image and then incorporate the estimated noise variation into a nonlocal filtering method. The proposed scheme is evaluated in carotid CTA scan using a dual-source CT at 80 kVp, in which the shading and streaking artifacts can be successfully corrected by reducing the CT number error from 246 HU to 63 HU and spatial non-uniformity by a factor of 2.2, respectively. In the volume rendering generated from the corrected CT images, the visualization of carotid artery is improved substantially and comparable to that generated from a CTA scan at 140-kVp. The proposed method is implemented directly on the CT image without access to the raw projection data and is thus attractive for clinical application in low-dose CTA.

SP097.5 - Evaluation of the ΔV Ventilation Calculation Method Using In Vivo XeCT Ventilation Data

Author(s): <u>Geoffrey G. Zhang</u>¹, Kujtim Latifi¹, Kaifang Du², Joseph M. Reinhardt³, Gary E. Christensen³, Kai Ding⁴, Vladimir Feygelman¹, Eduardo G. Moros¹

¹Radiation Oncology, Moffitt Cancer Center, Tampa/UNITED STATES OF AMERICA, ²Human Oncology, University of Wisconsin School of Medicine and Public Health, Madison/WI/UNITED STATES OF AMERICA,³Biomedical Engineering, University of Iowa, Iowa City/IA/UNITED STATES OF AMERICA, ⁴Radiation Oncology, Johns Hopkins University, Baltimore/MD/UNITED STATES OF AMERICA

Ventilation distribution calculation using 4DCT and deformable image registration (DIR) has shown promising potential in several clinical applications. This study evaluated the direct geometric ventilation calculation method, namely the ΔV method in which the local volume change is calculated geometrically using a deformation transformation, with Xenon-enhanced CT (XeCT) ventilation data from four sheep as the gold standard. The results are also compared to two other published ventilation calculation methods, namely the Jacobian and the Hounsfield Unit (HU) methods. The Diffeomorphic Morphons (DM) method was applied as the deformable image deformation (DIR) technique, and it was evaluated using the 4DCT data of the sheep with manually delineated landmarks in the end-expiration and end-inspiration phases in this study. Spearman correlation coefficient (SCC) and Dice similarity coefficient (DSC) were used for evaluation and comparison. The average target registration error of the landmarks by the DM method was 1.9 \pm 1.5 mm. The average SCC with one standard deviation was 0.49 \pm 0.13 with a range between 0.36 and 0.67 between the XeCT and ΔV ventilation distributions; 0.50 ± 0.13 (range 0.37 - 0.67) between the XeCT and the Jacobian ventilation distributions, and 0.31 \pm 0.10 (range 0.23 - 0.44) between the XeCT and the HU ventilation distributions. The average DSC value for upper 30% ventilation volumes between the XeCT and ΔV ventilation distributions was 0.82 \pm 0.03 with a range between 0.79 and 0.86, while for the upper 50% volumes, it was 0.70 ± 0.05 (range 0.64 - 0.77). The average DSC results between XeCT and Jacobian ventilation distributions were the same while between XeCT and HU they were 0.64 ± 0.05 for the upper 50% ventilation volumes (range 0.60 - 0.70) and 0.79 ± 0.03 for the upper 30% ventilation volumes (range 0.75 - 0.82). High ventilation volumes in ventilation distributions generated from 4DCT data were more accurate compared to low ventilation volumes. Ventilation difference introduced by deformable image registration errors improved with smoothing. The following figure shows the SCC values between the XeCT and the ventilation calculated using the three algorithms versus smoothing.

In conclusion, ventilation distributions generated using ΔV -4DCT and deformable image registration are reasonably accurate and therefore potentially useful in clinical practice. This evaluation study and previous reports support the use of ventilation calculated using 4DCT in clinical applications in areas such as radiation treatment planning and pulmonary function assessment.

SP097.6 - Predicting Survival Outcomes of Post-Treatment Glioma Patients by Quantification of Viable Tumour Volume on CMET/FLT PET and MRI.

Author(s): Christopher Leatherdav¹. Ros Francis². Andrew Campbell¹, Anna Nowak², Laurence Morandeau³, Michael Bynevelt⁴, Nelson Loh², Michael Mccarthy²

¹Medical Engineering And Physics, Royal Perth Hospital, Perth/WA/ AUSTRALIA, 2Wa Pet Service, Sir Charles Gairdner Hospital, Perth/ WA/AUSTRALIA, 3Medical Technology And Physics, Sir Charles Gairdner Hospital, Perth/WA/AUSTRALIA, 4Radiology, Sir Charles Gairdner Hospital, Perth/WA/AUSTRALIA

Aim: To compare the utility of tumour volumes selected using 11C-Methionine (CMET), ¹⁸F-Thymidine (FLT) PET and Gadolinium (Gd) enhanced T1 MRI imaging in prediction of survival outcome in posttreatment glioma patients.

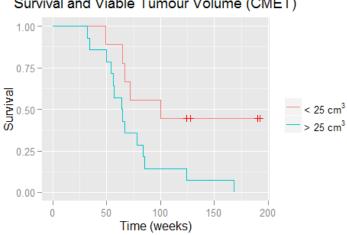

Method: 27 glioma patients (19 m, 8 f, mean age 56, age range 34-77) were given standard clinical treatment at Sir Charles Gairdner Hospital, Perth. After either 2 or 3 chemotherapy cycles, participants underwent PET/CT imaging with both CMET and FLT; the administered dose was adjusted for patient weight. A volumetric Gd enhanced T1 MRI was also acquired. All imaging was completed within 7 davs.

For both PET tracers, background normalisation of the tumour was performed on a voxel-by-voxel basis using the uptake in the contralateral hemisphere. For CMET the tumour to normal (T/N) ratio was used. For FLT, due to low tracer uptake in normal tissues, the absolute difference in standardised uptake values (SUV) was taken.

A modality dependent 'viable tumour volume' was measured for each subject. Voxels with a T/N ratio exceeding 1.5 for CMET images1 and a SUV difference of 0.2 for FLT images were considered viable tumour. For MRI images, viable tumour volume was chosen by manually thresholding the Gd enhanced images.

ROC curve analysis was used to identify the optimal tumour volume threshold above which a subject's survival would be less than the median survival time (78 weeks) of the cohort for each modality. Survival time differences for subjects with volumes below and above the optimal values were examined using a log-rank test.

Results:

Survival and Viable Tumour Volume (CMET)

Fig 1: A Kaplan-Meier survival plot for CMET tumours above and below 25cm³.

The optimal tumour volume thresholds were 25 cm³, 42 cm³ and 20 cm³ for CMET, FLT and Gd-MRI respectively. There was a significant difference in survival time for tumour volumes above and below

these thresholds for CMET-PET (p=0.02), but not for FLT-PET or Gd-MRI.

Conclusion: CMET-PET defined viable tumour volumes may discriminate between high and low survival times in post treatment glioma. FLT-PET or Gd-MRI defined volumes do not appear to be predictive of survival time. Further analysis with more subjects is required to verify the utility of method.

SP097.7 - A Novel Method for Lung's Air Volume Estimation in **Exhalation and Inhalation Phases From CT Imges**

Author(s): Hadi Moghadas Dastjerdi1, Mohammad Reza Ahmadzadeh¹, Elham Karami², Abbas Samani³, Ali Sadeghi-Naini⁴ ¹Electrical And Computer Engineering, Isfahan University of Technology, Isfahan/IRAN, ²Imaging Research Laboratories, Robarts Research Institute, London, ON/CANADA, ³Medical Biophysics, Western University, London/CANADA, 4Medical Biophysics / Radiation Oncology, University of Toronto, Toronto/ON/CANADA

Lung's air volume measurement is of great importance in pulmonary function assessment. CT Image segmentation can be used effectively for lung volume measurement, especially for patients who are not fit for other diagnostic tests, leading to invaluable diagnostic information [1], [2]. Despite that advanced segmentation techniques have been developed over the last decades, thresholding remains effective for various clinical applications if implemented properly [3], [4]. A critical step in this method is finding and fine-tuning the threshold values. The proposed lung's air volume estimation algorithm with CT imaging benefits from the availability of image sequence over the respiration cycle to determine the threshold values based on the lung parenchyma biophysics. The algorithm considers three volumes of lung's air, soft-tissue, and backgroundair. The main concept is that these volumes vary in size and shape in the lung images acquired throughout the respiration cycle. Accordingly, as illustrated in Figure 1, an optimization framework was developed to find the optimal threshold values that minimize a cost function derived based on the principles of tissue incompressibility and air mass conservation throughout the respiration cycle. In general, image intensity of each voxel in a lung CT image is the intensity resultant of tissue and air within the voxel. The probability of having significant tissue fraction in the exhalation phase is higher than in its inhalation counterpart [5], [6]. As such, after determining the threshold values through optimization, the proposed method calculates the air volume by multiplying corresponding voxels number by voxels size and voxels fractional air volume coefficients (FAVCs). Preliminary results obtained from an ex vivo porcine lung study where the amount of inhaled air was recorded in each respiration phase shows that the air volume estimated using the proposed method is significantly more accurate when FAVCs are used in the air volume estimation.

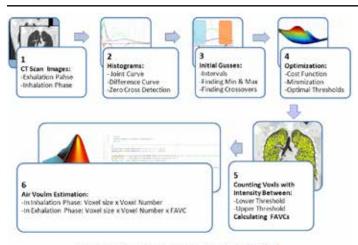

Figure 1: Block diagram of the proposed method.

SP097.8 - High-resolution micro-CT protocol for assessing lung ventilation and perfusion: image subtraction versus multi-energy analysis

Author(s): Pierre Deman¹, Samantha Tan¹, Davood Karimi², John Schipilow³, Rabab Ward², <u>Nancy L. Ford¹</u>

¹Oral Biological And Medical Sciences, University of British Columbia, Vancouver/BC/CANADA, ²Electrical And Computer Engineering, University of British Columbia, Vancouver/BC/CANADA, ³Centre For High-throughput Phenogenomics, University of British Columbia, Vancouver/BC/CANADA

Introduction:

Micro-CT allows full-organ, high-resolution imaging of airways and lung vasculature in rodents when using contrast agents. Advantages include linearity of the measured signal versus the concentration of the contrast agent and co-registration between scans with high resolution leading to a good accuracy. We propose to compare a multi-energy imaging protocol and an image subtraction method to estimate the concentration of two contrast agents at an acceptable x-ray dose level for longitudinal monitoring.

Methods:

Respiratory-gated micro-CT imaging (CT120, Gamma Medica) was performed on 6 rats. Each rat was anaesthetized with isoflurane (1.5-2% in O2), intubated and mechanically ventilated. Low-energy images (50 kV, 63 mA, and 0.1 mm copper filtration) and high-energy images (120 kV, 40 mA, and 0.6 mm copper filtration) were obtained at baseline and post-injection of a vascular contrast agent (Binitio eXIA 160XL, 0.45 mL/ 100g). Rats were euthanized and ventilated with xenon while images were obtained with both the low- and highenergy protocols. The spectrum of each protocol was evaluated using HVL measurements and by simulation with the Spetkr freeware. The dose deposited in air was estimated using a thimble ionization chamber at isocenter of the micro-CT scanner. We performed a histological study (H&E and movat staining) to ensure no damage to the lungs resulted from the x-ray dose received.

Images were reconstructed with 0.05 mm voxel spacing using a FBP algorithm. The concentration of both contrast agents was calculated based on multi-energy equations. To improve the accuracy of the concentration calculations, we tested different denoising methods (on projections and the reconstructed volume).

Results:

The dose of each low- and high-energy scan was estimated to be 96.5 mGy and 91.2 mGy respectively. An example of the concentration of contrast agent map is shown Figure 1. Analysis was performed on the H&E stained histological sections to quantify the percentage of inflamed area over the total area of the lung section and the number of white blood cells present.

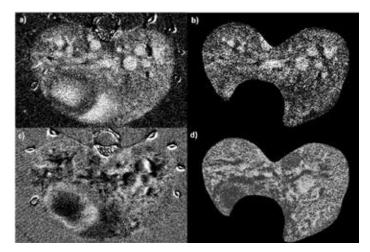

Figure 1: (a) Low-energy subtraction, iodine minus baseline. (b) Multi-energy after iodine injection. (c) Low-energy subtraction (iodine + xenon – iodine). (d) Multi-energy after iodine and xenon injection.

Conclusion:

High-resolution imaging of the vasculature and airways in rodents is achievable at low dose with contrast-enhanced micro-CT using subtraction methods. Because the K-Edges of the two most common CT contrast agents are very close, the multi-energy protocol was more difficult, and would benefit from advanced signal processing and reconstruction algorithms.

SP098 - Biomaterials and Regenerative Medicine

TRACK 02: BIOMATERIALS AND REGENERATIVE MEDICINE

SP098.1 - Finite Element Analysis Of Abdominal Aortic Aneurysms To Predict Risk Of Rupture - The Role Of The Thrombosis Thicknesses. Author(s): <u>Omar Altwijri</u>

Department Of Biomedical Technology, King Saud University, Riyadh/SAUDI ARABIA

Abdominal aortic aneurysm (AAA) is a cardiovascular disease occurring when the aorta becomes weak and develops a balloon expansion in its wall. This balloon diameter can reach sizes up to 4 times the normal aortic diameter, with the diameter enlarging at rates of 0.2–1.0 cm/year. Ruptured aneurysm leads to death in 78% – 94% of diseased aortas [1]

Aneurysm rupture is a biomechanical event that occurs when the mechanical stresses in the wall of the aorta exceed the failure strength of the aortic tissue [2].

In medical practice, when the maximum diameter of AAA exceeds 5 cm it is considered at risk of rupture. Surgical repair is usually not considered until the diameter reaches at least 5 cm. However, It is frequently observed that AAAs with diameters less than 4 cm can rupture which raise the need of finding a more reliable method to assess rupture risk.

The role of the intraluminal thrombus (ILT) which exists in more than 75% of AAA was examined using variable thickness and material properties of the thrombus. The role of the ILT has been experimentally examined in number of studies [4; 5; 6].

ILT with variable thicknesses were used here to examine the effect of ILT on wall stresses compared with AAA without ILT.

SP098.2 - High-Frequency Ultrasonic Measurement of Ischemia and Revascularization in Mice with Ligated Femoral Arteries Author(s): Andrea N. Quiroz¹, Michaelle A. Cadet¹, John A. Chappell², Paul Slezak³, Cyrill Slezak⁴, Timothy E. Doyle⁴ ¹Biology, Utah Valley University, Orem/UT/UNITED STATES OF AMERICA, ²Dentistry, University of Louisville, Louisville/KY/UNITED STATES OF AMERICA, ³Ludwig Boltzmann Institute for Experimental and Clinical Traumatology, Vienna/AUSTRIA, ⁴Physics, Utah Valley University, Orem/UT/UNITED STATES OF AMERICA

High-frequency ultrasound (10-100 MHz) is particularly sensitive to small vascular structures that are close in size to the ultrasound wavelength (15-150 mm). The ability to rapidly determine the degree of vascularization in small animals in vivo would provide a useful characterization tool for regenerative medicine. The objective of this study was to determine if direct ultrasonic measurements in the 10-100 MHz range could be used as a vascularization assay for small animals and tissue specimens. To accomplish this, a study was performed at the Ludwig Boltzmann Institute for Experimental and Clinical Traumatology (Vienna, Austria), where the femoral artery in one hind limb of each of sixteen mice was ligated and tested for eight days. Eight of the ligated limbs were treated with vascular endothelial growth factor (VEGF, "treated") while the remaining eight ligated limbs were not treated ("untreated"). All of the ligated limbs were then allowed to grow ischemic. The unligated limbs were controls. Pitch-catch and pulse-echo measurements were acquired using a 50-MHz immersion transducer (Olympus NDT,

V358-SU), a high-frequency square-wave pulser/receiver (UTEX, UT340), and a 1-GHz digital oscilloscope (Agilent, DSOX3104A). The ultrasonic transducers were coupled to the limbs using glycerol, and triplicate waveforms were acquired from each limb every other day. The ultrasonic parameters analyzed were wave velocity and peak density. Peak density is the number of peaks and valleys in the ultrasonic spectrum between 20-80 MHz, and provides a measure of spectral complexity. In two hospital studies on breast cancer surgical margins, peak density was demonstrated to be sensitive to microstructural changes in tissue due to both benign and malignant processes. The mice were also evaluated with laser Doppler interferometry (LDI), multispectral optoacoustic tomography (MSOT), micro-CT (computed tomography), and histopathology. The results indicated that ultrasonic signals from untreated limbs displayed a steady decrease in wave velocity over the test period as compared to the treated limbs. Peak density displayed no trends for either untreated or treated limbs. The peak density results were consistent with the other evaluation methods, which primarily reveal changes in tissue microstructure and showed no significant differences between the untreated and treated limbs. In contrast, wave velocity is sensitive to the stiffness of the tissue, a material property that is not measured by the other methods. The decrease in wave velocity for the untreated limbs indicates a softening of the muscle tissue, possibly due to inflammation or edema, whereas the decrease and then return to normal for the treated limbs indicates recovery of the tissue. The high-frequency ultrasound may therefore have detected effects due to ischemia and revascularization that were hidden to LDI and histopathology (MSOT and micro-CT data have yet to be analyzed). The study results indicate that high-frequency ultrasound, in particular wave velocity measurements, may provide an added dimension to small animal imaging methods for detecting revascularization. The method is currently being expanded to include highresolution imaging.

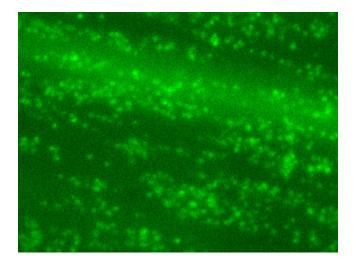

SP098.3 - Prevention of Thrombogenesis with a new Silane Based Adlayer on Commonly used Polymers in Medical Equipment Components

Author(s): <u>Kiril Fedorov</u>, Christophe Blaszykowski, Sonia Sheikh, Michael Thompson

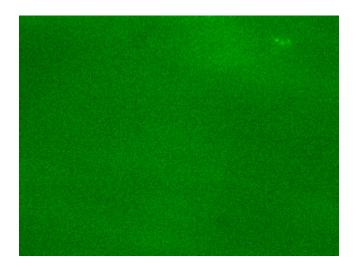

University of Toronto, Toronto/ON/CANADA

In the 21st century the medical field has majority of its equipment coming in contact with blood is manufactured from plastic polymers. This causes a major concern, where exposure may result in undesirable protein-material interactions that can potentially trigger deleterious biological processes such as thrombosis. To address this problem, we have developed an ultrathin antithrombogenic coating based on monoethylene glycol silane surface chemistry. The strategy is exemplified with several polymers including: polycarbonate and poly (vinyl chloride) -plastic polymers increasingly employed in the biomedical industry. The various straightforward steps of surface modification were characterized with X-ray photoelectron spectroscopy supplemented by contact angle goniometry. Antithrombogenicity was assessed after 2,5,10 and 60 min exposure to whole human blood dispensed at a shear rates of 300, 900, 1000 and 1500 s⁻¹. Remarkably, platelet adhesion, aggregation, and thrombus formation on the coated surface was greatly inhibited on all shear rates and both surfaces (>92% decrease in surface coverage) compared to the bare substrate and, most importantly, nearly nonexistent.

Coated Plastic

SP098.4 - Nature's Own "Smart" Biological Material to Inspire Next-Generation Biomaterials

Author(s): Joanna Ng¹, Lauren Kark¹, Renee Whan², Melissa Knothe Tate¹

¹The Graduate School Of Biomedical Engineering, The University of New South Wales, Sydney/AUSTRALIA, ²Biomedical Imaging Facility, The University of New South Wales, Sydney/AUSTRALIA

INTRODUCTION

The periosteal sheath that surrounds all non-articular surfaces of bones exhibits mechano-active and biologically responsive properties, hallmarks of a "smart" material. Due to the intimacy of structure:function relationships in nature, our approach was to capture the periosteum's three-dimensional (3D) spatial relationships. Using high-resolution imaging, we aim to correlate its composition and architecture with its prevailing function.

METHODS

Middiaphyseal transverse sections of the ovine femur, periosteum and surrounding tissue were imaged using a Leica SP5 II inverted multi-photon microscope tuned to 830nm (~100fs pulse). The second harmonic signal of collagen was collected using a 390-440nm band-pass filter and the elastin signal was collected using a 410-490nm emission-filter. A tiled imaged with a 63x1.3NA oil objective was collected at the major and minor centroidal axes (CA) and within the tiled area, a high-resolution z-stack was acquired to quantify the 3D distribution of elastin and collagen.

RESULTS

The architecture of collagen fibers ranged from highly organized and parallel fibers at the periosteum, to loosely woven strands in muscle attachment sites, and then to irregular and thin fibers at the perimysium (Fig. 1). The elastin fibers were spring-like, short, and of irregular architecture and arrangement. Elastin fibers were also primarily abundant in the major centroidal axis, and formed a 3D mesh in the z-stack (Fig. 1).

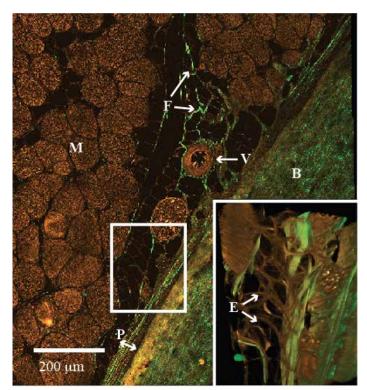

Figure 1. Tiled ROI of major CA showing the periosteum (P) to be illuminated under the collagen signal; elastin (E) abundant between the periosteum and muscle (M) shown in Z-stack insert; vessels (V) elastic and fascia exhibiting both collagen and elastin features.

DISCUSSION

Collagen fibers are mechanically robust, flexible and able to resist tensile loading. The network of fasciae, comprising of mostly wavy collagen fibres branching from the perimysium to the periosteum (Fig. 1), suggest that fascia may be mechanically significant in supporting tissue structures, e.g. preventing distension between the muscle and bone.

Since centroidal axes correlate within 5% of anatomical axes, variations in the arrangement and composition of elastic fibers can be associated with its function. Hence the abundance of elastin in the posterior major CA may be functionally associated with the prevalence of greater muscle bulk in its corresponding anatomical aspect.

CONCLUSIONS

Therefore, by harnessing the "smart" properties of nature's own biological materials and applying a bottom-up approach to engineering novel materials, we aim to facilitate the development and engineering of functional and biomimetic materials. First applications are ongoing for development of novel functional textiles to prevent and treat lymphoedema as well as to provide an optimal interface (liner sleeve) for trans-tibial and femoral prostheses.

ACKNOWLEDGEMENTS

This project has been supported in part through the Paul Trainor and Promobilia Foundations.

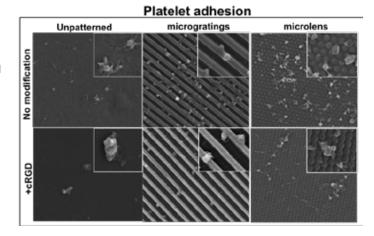

SP098.5 - Vascular endothelial cell adhesion and hemocompatibility of biochemically- and topographicallymodified poly(vinyl alcohol)

Author(s): Marie F. Cutiongco¹, Deirdre E.J. Anderson², Monica T. Hinds², Evelyn K.F. Yim¹

¹Biomedical Engineering, National University of Singapore, Singapore/SINGAPORE, ²Biomedical Engineering, Oregon Health & Science University, Portland/UNITED STATES OF AMERICA

Currently available synthetic small diameter vascular grafts used for bypass or replacement of native arteries fail within the first 10 years. The lack of mechanical properties matching native arteries, thromboresistance and capacity to stimulate in situ endothelialization prevent the long-term application of small diameter vascular grafts. Thus, there is a critical need for new synthetic small diameter vascular grafts that can achieve compliance, hemocompatibility and endothelialization. Poly(vinyl alcohol) hydrogel (PVA) is an excellent candidate for vascular grafts due to its tunable mechanical properties, high water content and high tensile strength. Yet the bio-inertness of PVA must be addressed to improve endothelialization in situ. Both biochemical and topographical modifications have been used to stimulate specific vascular endothelial cell behaviours on synthetic materials by mimicking the physiological cellular niche. Thus, we hypothesize that the modification of PVA with both biochemical and topographical modifications can provide a hemocompatible microenvironment that stimulates endothelialization. PVA modified by the immoblization of fibronectin, RGDS peptide, and cyclic RGD (cRGD) peptide showed slight increase in the adhesion of human umbilical vein endothelial cells (HUVECs) while PVA modified with immobilized heparin showed significant decrease in the endothelial cell adhesion. The cRGD modified PVA did not exhibit any significant change in platelet adhesion, activation and morphology when compared with unmodified PVA in an in vitro hemocompatibility assays using LDH assay, microparticle release percentage and scanning electron microscopy, respectively. Using solvent casting, unmodified and cRGD-modified PVA were incorporated with micro-gratings or microlens topography. Combination of cRGD and micro-gratings or microlens topography on PVA showed significant increase in endothelial cell viability compared with unpatterned and unmodified PVA. Platelet adhesion on all PVA modified with microgratings was comparable with unpatterned and unmodified PVA. PVA with microlens topography significantly increased platelet adhesion, while PVA with both convex and cRGD modification showed no difference with unpatterned and unmodified PVA. Platelets also changed from the fibrous, activated phenotype on PVA with microgratings or microlens to round and less active phenotype on PVA with both cRGD and topography (Figure 1). The in vitro vascular endothelial cell adhesion tests and hemocompatibility tests demonstrated that modification of PVA with both biochemical and topographical cues may serve as an excellent surface for hemocompatible vascular grafts with enhanced endothelialization.

Figure 1. Platelet adhesion on PVA surfaces modified with cRGD and topography.

Interaction between magnetic field and living systems is inevitable; in fact, we are immersed in an ocean of magnetic field due to the magnetic field of the earth and the technology developments. Interaction between magnetic field and living systems is inevitable; in fact, we are immersed in an ocean of magnetic field due to the magnetic field of the earth and the technology developments, this one already have medical applications, currently, the pulsed electromagnetic fields (PEMF) are an alternative option for the treatment of some mental illness as the depression or schizophrenia. In order to have estimation of the side effects from PMF and drugs used for treat this kind of disorders. In this work, it is presented a comparison of the effects of imipramine, a drug for the treatment of depression, and the effects of PMF on cells from the line SHSY5Y, which provide us a representative model of neuronal tissue. The assays were done in both ways, the separately effects and the jointly effects. The imipramine at high dosage for a short period (120 mg/mL, for 20 min) shows cell damage on both, the morphology and the metabolism. Meanwhile, the PMF (50 Hz, 7 mT for 8 h) shows a cell proliferation and a decrease of their metabolism. The jointly assay indicates that the PMF balances the morphological negative effects from imipramine. In the long term these results can impact a therapy that may be more efficient. However, more research is needed in this area

SP012.2 - Porous bio-SiC ceramics from wood: approaching new medical implants

Introduction

Silicon carbide ceramics (SiC) are porous structures derived from different wood sources. The porosity and pore size of such ceramics may repeat the structure and porosity of specific bones in human body. Additional coating of SiC ceramics with hydroxyapatite (HA) and tricalcium phosphate (TCP) using a novel gas-detonation deposition method (GDD) could be advantageous with regard to bone replacement. This work investigates the porosity of SiC ceramics and explores the method to obtain bioactive surfaces.

Methods

Biomorphic porous SiC ceramics were synthesized using forced infiltration with liquid silicon of carbon matrices derived from different hardwood precursors (Hornbeam, Sapele, Tilia and Pear). This process involves impregnation of carbon matrices by silicon and synthesis of SiC ceramics. The porosity of SiC ceramics was analyzed based on 10 images taken using a Carl Zeiss Stereo Discovery.V12 microscope. The HA and TCP coatings were obtained utilizing the GDD method by transporting the powder using a detonation wave at high velocities [1]. The surface morphology of SiC ceramics and deposited coatings was characterized using a scanning electron microscope (SEM).

Results

The GDD method allowed obtaining high-adhesive and structurally perfect bioactive coatings onto SiC ceramics derived from different wood sources (Figure 1). The surface morphology of synthesized SiC ceramics was regular throughout the surface. The smallest pores were observed for SiC ceramics synthesized from Tilia (27.2±10.1 μ m), whereas Sapele-derived ceramics yielded the pores with a mean size of 131.2±41.1 μ m. The calculated highest porosity was inherent to Hornbeam-derived SiC ceramics (45.3±3.4%). Moreover, the porosity was greater for more dense SiC ceramics and was also dependent on mean pore size.

Acknowledgments

The authors acknowledge the exchange program with East European Countries funded by DAAD and are looking for further funding of the project.

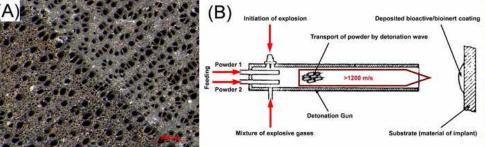

Figure 1. SiC ceramics synthesized from Tilia: surface morphology of ceramics (A) and HA coating (C) obtained by GDD method (B)

Conclusions and outlook

In this study, the bio-SiC ceramics synthesized from different wood precursors were characterized for surface morphology, porosity and pore size distribution; whereas the GDD method was used to generate bioactive HA and TCP coatings. The advantage of these ceramics is that the porosity and pore size can be optimized for different bones by varying the initial wood source. In turn, application of biocompatible and bioactive surfaces onto SiC ceramics could accelerate bone substitution.

SP099 - SPECIAL SESSION: Current situation of dosimetry in radiology and radiation protection

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP099.1 - Current situation of dosimetry in radiology and radiation protection

Author(s): Madan M. Rehani¹, Harry Delis², Pablo Jimenez³, Joanna Izewska⁴

¹Radiology, Harvard Medical School, Massachusetts General Hospital, BOSTON/UNITED STATES OF AMERICA, ²International Atomic Energy Agency, Vienna/AUSTRIA, ³World Health Organization/Pan American Health Organization (PAHO), Washington/UNITED STATES OF AMERICA, ⁴Nuclear Sciences And Applications, International Atomic Energy Agency, Vienna/AUSTRIA

Radiation protection in medicine essentially poses dosimetry issues pertaining to patient dosimetry with some aspects of occupational dosimetry mainly relating to the lens of the eye. Dosimetric measurements in diagnostic radiology are required for the establishment and use of guidance levels, for the assessment of equipment performance and for comparative risk assessment. However, since radiology involves a diverse range of examination types, from simple projection radiography to advanced cross-sectional imaging, several dose quantities have been developed and have been well worked out by IAEA and ICRU. Further, data on the status of patient doses in different radiology procedures enable comparisons with diagnostic reference levels. The reference dose quantities have been well deciphered by the IAEA and ICRU. Some information about patient doses has become available through multi-national studies on patient doses to adults and children in CT, image guided interventional procedures (as relatively high dose procedures), as well as in mammography and conventional radiography of other organ systems. Image quality has been considered in some situations. Important findings include frequent lack of optimization in paediatric CT. There is a need for coordinated actions by different international organizations and professional bodies to improve optimization of protection which requires management of the radiation dose commensurate with the medical purpose. Particular to medical imaging, this equates to the lowest possible dose necessary to acquire diagnostic quality images. Regarding occupational radiation protection, cataract risk is important among staff in interventional suites. Currently there is near absence of monitoring of eye lens doses and actions are needed to develop and implement practical methods for eye lens dosimetry. This issue has attained greater significance granted the drastic reduction of the occupational eye lens dose limit from 150 mSv/year to 20 mSv/year, recommended by the International Commission on Radiological Protection (ICRP) and adopted in the new BSS. The IAEA has been working on promoting and supporting best practices in dosimetry, including traceability of measurements to the International System of Measurement, and strengthening the medical physics capacity throughout the world since the early sixties. As it represents one of the main resources for the medical physicists, and often, especially in developing countries, the only one, work is done in producing guidelines on dosimetry in diagnostic radiology, (Dosimetry code of Practice (TRS-457), Dosimetry for Paediatric Patients (HHS-24), Dosimetry of Wide beam CT (HHR-5)) to support dosimetry in the clinical environment. Therein exists a role for international organizations to promote and support actions on patient and staff dosimetry to improve both patient and occupational safety. This joint session will discuss modalities of cooperation. This joint session will address the current and future activities and areas for cooperation in the field.

SP100 - Dose Optimization: Focus on DRLs

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP100.1 - A Contribution to the Establishment of Diagnostic Reference Levels in Computed Tomography in Brazil Author(s): Lucas D.L. Narciso, <u>Ana M. Marques Da Silva</u>, Nathan W. Lima, Caroline M. Dartora Faculdade De Física, PUCRS, Porto Alegre/BRAZIL

Diagnostic reference level is important to guarantee dose optimization, and can be defined nationally, regionally or locally, using dose descriptors, such as volumetric computed tomography (CT) dose index (CTDIvol, mGy) and dose-length product (DLP, mGy.cm). The aim of this work is to present the local DRL values for a CT department located in Porto Alegre, Brazil, intending to determine, in the future, national and regional DRL. For this purpose, retrospective data have been collected and analyzed, from head, chest and abdomen non-contrasted CT adult (>15 years old) and pediatric (<15 years old) exams. The DRL values have been compared to those described on previous national studies from UK, US, Germany and Switzerland. The results are shown in the following table. These values are similar to the DRLs from Germany, UK, US and Switzerland. The present study is the first of its kind to determine the DRL for scanners operating in the south region of Brazil. Similar studies in other regions of Brazil are necessary in order to establish a National Dose Reference Level.

Table 1 CT service DRLs values for head, chest and abdomen exams by age group.

CT Centre DRLs		
Age group	CTDIvol (mGy)	DLP (mGy.cm)
Head		
0-11	18	290
1-15	30	550
5 - 10	35	670
10-115	44	880
>15	50	950
Chest		
0 - 1	5	64
1 -1 5	7	130
5 - 10	-	-
10-115	-	-
>15	10	350
Abdomen		
0-11	4	110
1 -1 5	5	170
5 - 10	6	220
10-115	-	-
>15	12	380

SP100.2 - Canada's Computed Tomography (CT) Survey: Overview and Moving Toward Establishment of DRLs Author(s): <u>Graeme M. Wardlaw</u>, Narine Martel Consumer And Clinical Radiation Protection Bureau, Health Canada, Ottawa/ON/CANADA

Increasing numbers of Computed Tomography (CT) scanners, examinations and CT's relatively higher patient dose (compared to planar x-ray) have resulted in increased focus on the modality, both in Canada and world-wide. The key pillars of safe imaging, justification and optimization, are becoming especially important to follow. It follows that as CT use increases; protocol optimization (reduction of patient dose while maintaining necessary image quality) is an ever crucial part in reducing patient dose. A widely endorsed and adopted method is the establishment of diagnostic reference levels (DRLs) – typically accepted as the 75th percentile of CTDIvol and/or DLP distributions for a given patient exam type/indication – which help identify protocols that may benefit from further investigation and any necessary dose reduction initiatives.

The establishment of DRLs requires a significant and representative pool of scanning practice data – Canada's National CT Survey collected data from 381 CT units across the country via distributed survey booklets (1 per CT unit) divided into four (4) sections: General CT information (e.g. Vendor/Model), Routine Protocols (as available), Individual Patient data (as applied) and limited CTDIvol measurements. The resultant electronic database includes a large cross-section of general vendor/model data, 2896 routine protocol samples (3494 sequences), 18 985 individual (actual) patient exam samples (24 280 sequences) and some CTDIvol measurements.

Table1: Common CT protocols (anatomical region) polled and clinical indications (not exhaustive) – Adults \geq 19 yrs. and 70±20 kg, Pediatric \leq 13 yrs. and < 50 kg.

Juliana (oo hg.				
EXAM TYPE/ANATOMICAL REGION	CLINICAL INDICATION			
Routine Head [Adult]	Headache, Cerebrovascular Accident (CVA), or Transient Ischemic Attack (TIA)			
Chest [Adult]	Primary cancer, known/suspected me- tastasis or lung nodule follow-up			
Abdomen, Pelvis [Adult]	Primary/metastatic work-up or abscess			
Chest, Abdomen, Pelvis [Adult]	Lymphoma staging, follow-up or Trauma			
Head [Pediatric]	Trauma, including non-accidental injury			
Chest [Pediatric]	Detection of malignancy, Trauma			
Abdomen [Pediatric]	Detection of malignancy, Trauma			

The national survey database covers seven (7) common exam types (Table 1) and is a significant step toward establishment of national DRLs which will help support protocol optimization efforts. Of course, prior to calculation of any reference levels, applied data quality assurance is essential. In our experience, key issues had to be addressed: (i) booklet, patient and sequence numbering mistakes were vetted by an iterative algorithm to verify their accuracy and association (ii) CT vendor/model names were inconsistent, thus a standard convention was applied to facilitate future analysis (iii) incomplete patient mass, potentially limited DRL sample sizes. Implementation of iterative, logical algorithms allowed AP and LAT measurements to act as a surrogate, increasing representative sample numbers (iv) Other, incomplete exam descriptors (contrast/ non, modulated/fixed etc.) presented potential issues, but similar iterative, logic algorithms were also applied to help "complete" samples. E.g. string based search/flag clarification.

Ultimately, the large national sample will provide DRLs, based upon dose metrics for 7 common CT examinations, supporting local optimization efforts and radiation protection of patients across Canada.

SP100.3 - Review UAE Dental Radiology Dosimetry Results for National DRLs Establishment

Author(s): Fatima S. Al Kaabi¹, Jamila S. Alsuwaidi², Jacek Janaczek¹, Alfan S. Al Ameri³, Sara M. Booz³, Wadha M. Alshamsi⁴ ¹Medical Physics Department, Tawam Hospital, Abu Dhabi Health Services (SEHA), Al Ain/UNITED ARAB EMIRATES, ²Department Of Medical Education, Dubai Health Authority (DHA), Dubai/UNITED ARAB EMIRATES, ³Clinical Imaging Department, Mafraq Hospital, Abu Dhabi Health Services (SEHA), Abu Dhabi/UNITED ARAB EMIRATES, ⁴Radiology Department, Al Ain Hospital, Abu Dhabi Health Services (SEHA), Al Ain/UNITED ARAB EMIRATES

Establishment of the Diagnostic Reference Levels (DRLs) is required and essential for all radiology procedures including Dental Radiology. The objective of this study is to investigate pediatric and adult doses in different Dental Radiology modalities. It is also part of technical projects structured by the International Atomic Energy Agency (IAEA) to evaluate and monitor patient radiation doses. In UAE dental centers, 85% of dental radiology units in operation are digital systems. Total number of dental units involved in this survey is 122 Intra-Oral dental units and 16 Panoramic (OPG) dental units.

All of the dental radiology units evaluated in this survey are digital. For Intra-Oral units measurements, Multi-O-Meter electronic dosimeters are used. Quality control tests are applied for all dental units involved in this study. Multi-O-Meter (Dental Unfors) and CT Cylindrical Ionization Chamber are used for OPG measurements. Molar examination which is the longest exposure time used in dental procedures is selected. Patient Entrance Dose, HVL, Exposure time and kVp are measured for adult and pediatric. DRLs in this review study were based on the average and 3rd Quartile dose values. The 3rd Quartile of patient entrance doses of intra oral dental were 0.880 mGy and 0.704 mGy for adult and pediatric, respectively. For OPG, the 3rd Quartile doses were 5.09 mGy and 3.49 mGy for adult and pediatric, respectively.

The results of this review study are cosidered as initial UAE DRLs. These indicate that the dose level within the UAE are comparable to those published in the literature. It is required to expand our study to include further study for Cone Beam Dental CT. The study is in progress for further dose evaluation for digital intraoral and OPG units within the UAE.

SP100.4 - Should restrictions on the patients' behavior during the radiophatmaceuticals incorporation and after 99mTc bone scans be imposed?

Author(s): Josep M. Martí-Climent¹, Verónica Morán¹, Elena Prieto¹, Berta García-García², Lidia Sancho², Benigno Barbés¹, José A. Richter²

¹Radiofísica Y Protección Radiológica, Clínica Universidad de Navarra, Pamplona/SPAIN, ²Nuclear Medicine, Clínica Universidad de Navarra, Pamplona/SPAIN

The dose received by members of the public due to Nuclear Medicine patients is of great interest. However, little information is available on the radiation dose produced by said patients during the input of radiopharmaceuticals in diagnostic procedures. We have evaluated and compared the amount of dose produced by the patient during the radiopharmaceutical incorporation and after the diagnostic procedure.

Methods

After undergoing ^{99m}Tc-HDP bone examinations, 143 patients were studied. Dose rates [H*(10)] were measured from the mid thorax after radiopharmaceutical injection and after bone scan with a Geiger dose-meter at 0.1, 0.5, and 1.0 m. A number of different scenarios were carried out during absorption period and after leaving the Department of Nuclear Medicine. A dose of 1 mSv/year was used upon which restrictions should be imposed. The results were evaluated using the 95th percentile.

Results

The injected activity [median (min-max)] was 744 (370-844) MBq while absorption time and time for imaging procedure were 160 (80-280) and 55 (25-117) minutes.

The median dose rates measured at the three distances were 112.4, 29.8 and 11.5 μ Sv/h after the ^{99m}TC-HDP administration and 29.9, 9.8 and 4.3 μ Sv/h after the image scan.

The absorbed doses were:

Absorbed dose (µSv) (95th percentile) due to patient contact in different scenarios during the 99mTc-HDP incorporation			
Scenario		Delay 0 h	Delay 1 h
The escort	Incorporation time (0,5m)	108.2	
Attending physician	5min @1m + 10min @0.5m + 5 min @0.1m	21.0	18.7
Coffee shop	30min @0.1m	82.5	73.5
Restaurant	1h @1.0m	39.5	35.2

Absorbed dose ($\mu S v$) (95th percentile) for different scenarios and delay of initial contact after leaving the hospital					
Scenario		Delay 0 h	Delay 1 h	Delay 2 h	Delay 3h
Public transport	1h @0.1 m	52.7	47.0	41.8	37.3
Private trans- port	1h @1.0m	7.9	7.5	6.3	5.6
Work place	8h @1.0m		38.9	34.7	30.9
Attending physician	5min @1m)+ 10min @0.5m + 5 min @0.1m	7.6	6.8	6.0	5.4
Coffee shop	30min @0.1m	27.1	24.2	21.5	19.1
Restaurant	1h @1.0m	15.0	13.4	11.9	10.6
Spouse/partner	6h @1m + 8h @0.1m	169.9	150.9	134.5	119.8

During an incorporation interval of 4 hours, the absorbed dose to which a subject could be exposed to due to contact with and injected patient in the waiting room would be 543, 134, and 52 μ Sv at a distance of 0.1, 0.5, and 1.0 m.

Conclusions

The people with higher doses are those who are in close contact with the patient (the escort and the spouse/partner). Nevertheless, the imposition of restrictions is not needed. However depending on the workload of the physicians, some restrictions might be required. Furthermore, the dose received in the waiting room from an injected patient is comparable to a bone scan.

SP101 - Stimulation and Monitoring

SP101.1 - Biological Targets of Seizure Therapy in Major Depressive Disorder using EEG Microstate Analysis

Author(s): <u>Sravya Atluri</u>¹, Willy Wong¹, Daniel M. Blumberger², Zafiris J. Daskalakis², Faranak Farzan²

¹Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA, ²Centre for Addiction and Mental Health, Toronto/CANADA

Introduction: Understanding the exact mechanism of action of electroconvulsive therapy (ECT) can support the optimization of alternative treatments such as magnetic seizure therapy (MST) towards high efficacy and less side effects. Recent evidence suggests that major depressive disorder (MDD) may be associated with impaired brain functional connectivity and that ECT may achieve high efficacy in treatment-resistant MDD by normalizing abnormal neural connectivity. Resting-state EEG microstate analysis is one promising method that classifies global neural activity into discrete and short periods (80-120ms) of guasi-stable functional brain topographic maps (known as microstates) that change over time to represent dynamic states of global functional connectivity. Methods: For this study, pre- and post-treatment 60-channel resting state EEG data of 14 MDD patients (7 responders and 7 nonresponders) receiving ECT and 13 MDD patients (3 responders and 10 non-responders) receiving MST were obtained from the Temerty Centre at the Centre for Addiction and Mental Health. The criterion for treatment response was a minimum of 50% improvement in the Hamilton Depression Rating Scale (HAMD) score. Three main analyses were conducted with the data: (a) Spectral analysis was performed to determine whether previous findings of ECT-induced EEG slowing could be replicated. (b) Microstate analysis was performed to assess seizure therapy-related changes in the dynamic states of global functional connectivity. Four microstate classes were identified and four features were calculated for each class: (i) frequency of occurrence, (ii) transition time between each class, (iii) average duration and (iv) coverage time (fraction of total time covered by a class). (c) Finally, correlation analyses were performed to examine whether baseline microstate and power features could predict response (change in HAMD score) to seizure therapy. Results: (a) Similar to previous findings, frontal delta (0.5-3.5Hz) and midline theta (4-7Hz) were found to be significantly larger in ECT responders than nonresponders. However, this effect was not observed in MST treatment. (b) Also following ECT treatment (but not MST), the frequency of appearance of each microstate class was significantly lower in responders than non-responders (p = 0.03). The transition time between two consecutive microstate classes increased in responders but did not significantly change in non-responders (p = 0.04). The average duration of all four microstate classes were significantly longer for both responders and non-responders (p = 0.001). A change in HAMD score was associated with an increased coverage time of class C (r = 0.56, p = 0.03) and a decreased coverage time of class A (r = -0.62, p = 0.02). (c) Lastly, the frequency of microstate class C pre-treatment was correlated with reduced response to ECT (r = -0.61, p = 0.02) and an increased response to MST (r = 0.54, p = 0.05). Conclusion: Preliminary results suggest that microstate features from resting-state EEG data may provide new and predictive information about the effect of seizure therapy in MDD and should be further explored with larger datasets.

SP101.2 - Magnetic Seizure Therapy for Treatment Resistant Depression: Insights from TMS-EEG Measures Author(s): <u>Yinming Sun</u>¹, Faranak Farzan², Daniel M. Blumberger², Willy Wong¹, Zafiris J. Daskalakis² ¹Ibbme, University of Toronto, Toronto/ON/CANADA, ²Psychiatry, University of Toronto, Toronto/ON/CANADA

Magnetic seizure therapy (MST) is a potential therapeutic option for treatment resistant depression (TRD) that has shown comparable efficacy and less side effects relative to electroconvulsive therapy. Since cortical inhibition is abnormal in TRD patients, measures of inhibition from combined transcranial magnetic stimulation and EEG (TMS-EEG) may further the understanding of MST treatment and provide predictors of its treatment response. Thirty-three TRD patients were recruited in this TMS-EEG study. Before a course of MST treatment, responses from single pulse TMS over the motor cortex and dorsolateral prefrontal cortex (DLPFC) were recorded using EEG. The peak value of the TMS evoked potential near 100 ms (i.e. N100) was computed for each patient and correlated with changes in clinical measures of depression (Hamilton Depression Rating Scale, HDRS-24) and suicidality (Scale of Suicidal Ideation, SSI) collected before and after treatment. For DLPFC stimulation, the N100 value over the frontal electrodes was significantly correlated with a decrease in the HDRS-24 (max at F2, R = -0.51, p = 0.006) and SSI (max at F6, R = -0.61, p = 0.001) values. Moreover, when patients were grouped into responders and non-responders based on SSI change (responder: 50% or more decrease from baseline), the N100 value can predict the label with 80% sensitivity and 89% specificity. These results were not found for motor cortex stimulation. Correlation and classification results suggest that frontal N100 values resulting from TMS stimulation of the DLPFC can be a potential predictor of clinical response to MST treatment for resistant depression.

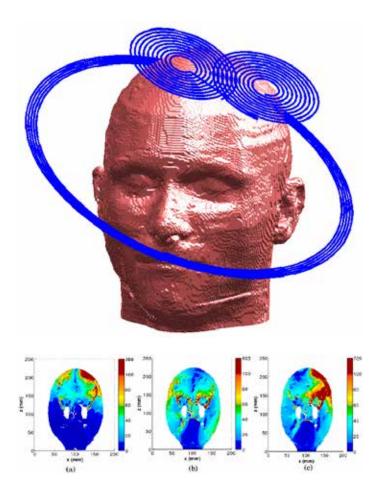

SP101.3 - Deep Transcranial Magnetic Stimulation Using Figure-of-Eight and Halo Coils

Author(s): Mai Lu¹, <u>Shoogo Ueno²</u>

¹Key Lab. Of Opt-electronic Technology And Intelligent Control Of Ministry Of Education, Lanzhou Jiaotong University, Lanzhou/CHI-NA, ²Department Of Applied Quantum Physics, Graduate School Of Engineering, Kyushu University, Fukuoka/JAPAN

Transcranial magnetic stimulation (TMS) is a technique for noninvasive stimulation of the human brain, which has become a major tool in brain research and, potentially, a promising treatment for various neuro-behavioral disorders. Recently, interests in stimulating deeper cortical, subcortical and limbic areas have arisen and have become an active research topic in TMS, because several studies show that activation of deeper prefrontal and limbic regions may increase the antidepressant effect. The Halo coil, a large circular coil being placed around the head was developed for deep transcranial magnetic stimulation(dTMS). It was shown that the Halo coil working with a typical round coil at the top of the head can increase the fields at depth in the brain. The present study was to study the field characteristics of a figure-of-eight coil (Fo8) which was placed at the left dorsolateral prefrontal cortex (DLPFC) working with a Halo coil which was parallelly placed with that of Fo8 coil (Fo8-Halo assembly) as shown in Fig. 1. The same pulse currents with amplitude of I=5 kA and working frequency 2381 Hz was fed into each of the coils. A 3D realistic human head model with 1 mm resolution has been employed in this study. We have calculated the magnetic fields, electric fields and current density in head tissues by using impedance method. Figs. 2(a)-(c) show the variation of induced electric field in the cross section of the head model at 80 mm slice (coronal) for Fo8, Halo and Fo8-Halo assembly coils, respectively. It was observed that the field intensity in deep brain regions have been improved by Fo8-Halo assembly coil. Results suggest that the conventional Fo8 coil can be applied for dTMS by working with a

Halo-coil for DLPFC stimulation.

SP101.4 - Optogenetic Stimulation and Wireless Cortical Recording in Modulating Motor Plasticity and Performance of Free-Moving Rat

Author(s): <u>Chun-Wei Wu</u>, Cho-Han Hsieh, Jia-Jin J. Chen Biomedical Engineering, National Cheng Kung University, Tainan/ TAIWAN

Cortical theta burst stimulation (TBS) could modulate motor plasticity via long-term potentiation/depression (LTP/LTD)-like mechanisms and enhance motor performance, which makes TBS a potential noninvasive therapy for motor deficit diseases such as Parkinson's disease (PD). In our previous rodent study, we had demonstrated that long-term cortical electrical stimulation (CES)-TBS protocols were capable to regulate motor-evoked potentials (MEPs) and enhance motor performance in chronic PD rats. However, the immediate effect of CES-TBS on motor performance in awake, freely moving rat was constrained by wired electrode and stimulators. Since CES excited all types of neurons surrounding the electrode in cortex, it is difficult to differentiate the effect of TBS on specific neural circuit that responses to motor plasticity and performance. It is also known that LTP/LTD occurred dominantly at glutamatergic synapse. The aim of this study is to apply the cell type-specific optogenetic stimulation and wireless recording of local field potentials (LFPs) to reveal the functional roles of glutamatergic neuron in motor plasticity of freely moving rat.

CaMKIIalpha promoter driven channelrhodopsin-2 (CaMKIIalpha-ChR2) was expressed in glutamatergic pyramidal neuron in primary motor cortex (M1). Optogenetic stimulation was achieved using blue laser guided by optical fiber, which was connected by a rotary joint to allow freely rotation. Then the fiber was connected to optical cannula implanted on skull. Optical cannula was homemade of a stainless tube containing a short segment of optical fiber inside. Both ends of the fiber were polished to minimize optical scattering when Laser was emitted into cortex. Stainless tube of the optical cannula was functioned as cerebral electrode to collect electrophysiological signal. Brain biopotentials were then amplified, band-pass filtered and converted to a frequency modulated radio-frequency (RF) signal sent by a small and light (2.7 g) wireless transmitter headstage connected to stainless tube. RF signals were transmitted to the host unit and was demodulated into analog signal and sampled by DAQ card. Optogenetic evoked potentials were analyzed and displayed using average calculation during and after optogenetic TBS treatment.

Our results showed that the local field potentials were recorded in high fidelity and responded well to the optical stimulation. The averaged MEPs amplitude were increased after optogenetic TBS treatment. The observations indicate that motor plasticity was modulated resulting from TBS on glutamatergic neurons in M1. However, there was no significant change in cortical excitability revealed from LFPs. In summary, our results suggested that LTP/LTD-like effects induced by cortical TBS treatment might be located at glutamatergic projections downstream of M1. The modulation of motor plasticity using cell type-specific optogenetic TBS scheme in M1 could be an efficient therapy scheme for neural disorders like PD via targeting specific neural circuit. Ongoing project is working toward the observation of animal behavior during and after optogenetic-TBS treatment of free-moving rat.

SP101.5 - Identification of calf muscles response to functional electrical stimulation as linear models

Author(s): <u>Hossein Rouhani</u>¹, Michael Same², Ya Q. Li², Kei Masani², Milos R. Popovic²

¹Lyndhurst Centre, Toronto Rehabilitation Institute - University Health Network, Toronto/CANADA, ²Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA

Functional electrical stimulation (FES) is used to artificially induce contractions in paralyzed muscles as neuroprosthesis to substitute lost motor functions, in individuals with spinal cord injury or other neuromuscular impairments. The dynamic response of muscles to FES is an integral component of closed-loop controlled neuroprostheses such as neuroprostheses for standing balance. This study aimed at identifying the dynamic response of ankle muscles to FES in a standing posture with FES as an input and the exerted isometric ankle torque as an output using both first-order and criticallydamped second-order models.

Thirteen healthy subjects participated in the experiment. Each subject stood on a standing frame with his/her extended knee and hip mechanically locked. The ankle plantarflexors and dorsiflexors were separately stimulated bilaterally through surface electrodes using a programmable functional electrical stimulator (Compex Motion II, Compex SA, CH). The subject's feet were fixed firmly to the footplates connected to a torque transducer (TS11-200, Durham Instruments, DE) that recorded the exerted isometric ankle torque. The stimulus waveform was rectangular with pulse frequency of 20Hz and pulse duration of 0.3msec. The pulse amplitude was modulated on sinusoids between 20mA and 60mA at frequencies of 0.07, 0.15, 0.3, 0.75, and 1.2Hz. The sinusoids of FES pulse amplitude and fitted to the generated ankle torque curve were considered as input and output, respectively. A Bode diagram was plotted based on the five obtained amplitude gains and phase lags between the input and output. The first-order and critically-damped second-order linear models were fitted to the diagrams and their parameters were estimated for each subject.

Correlation coefficient and RMS error between the experimental and fitted data were calculated to evaluate the fitting. Two-way ANOVA (factor1: first-order or second-order models, factor2: plantarflexors or dorsiflexors) revealed that both models were not significantly different in correlation coefficient and RMS error for both amplitude gain and phase lag (p>0.6) (Table 1). The inter-subject variability was expressed as CV (=100×SD/mean). The CV of the time constants obtained by the second-order model for plantarflexors (18.1%) was significantly smaller than the CV of the time constants obtained by the first-order model (79.9%) (F-test, p<0.001). Therefore, the time constant obtained by the critically-damped second-order model was more consistent among subjects for plantarflexors. This finding should be considered in the design of closed-loop controlled neuroprostheses when immediate torgue generation is expected. In the future, the physiological interpretation and nonlinear components of this modeling should be further investigated.

Table 1.					
ResutIs are pre- sented as mean±SD (standard deviation) over the 13 subjects.					
		Plantar- flexors	Plantar- flexors	Dorsi- flexors	Dorsi- flexors
		1st order	2nd order	1st order	2nd order
Correlation coefficient for fitting	Ampli- tude gain	0.92±0.14	0.90±0.19	0.55±0.40	0.55±0.37
Correlation coefficient for fitting	Phase lag	0.88±0.18	0.89±0.30	0.75±0.38	0.83±0.32
RMS error for fitting	Ampli- tude gain	0.21±0.29	0.20±0.21	0.14±0.14	0.13±0.15
RMS error for fitting	Phase lag	14.6±18.8	16.4±22.7	14.6±16.7	15.3±16.6
Estimated zero- frequency gain		2.90±1.04	2.75±0.98	0.67±0.36	0.64±0.35

SP101.6 - Establishment of Real Human Head Conductivity Model with Ventricular Structure used in TMS Simulation Study Author(s): Chen Zhao, Huanhuan Cheng, Zhipeng Liu, <u>Tao Yin</u> Institute Of Biomedical Engineering, Chinese Academy of Medical Sciences, Tianjin/CHINA

For accurate simulation studies on distribution of electromagnetic field induced by Tran-cranial Magnetic Stimulation, a real human head conductivity model with deep cerebral structure was reconstructed from MRI raw data, by using of MIMICS and ANSYS. This model reflects geometric structural information of Scalp, Skull, Cerebrospinal Fluid (CSF), Gray Matter, White Matter, Cerebellum, Ventricle and Eyeballs. The ventricular structure has relatively higher conductivity, whose effect on induced field could not be neglected. This paper mainly introduces the method to establish the ventricle part of the entire head model, which is used for ANSYS low-frequency magnetic simulation, while the way to generate other parts

is similar and accomplished. On the platform offered here, study on specific individual subject would be easy and practicable. Deep structures will be produced vectorial in the future work.

SP101.7 - Study on electric field in real head model induced by H-coil

Author(s): Huanhuan Cheng, Chen Zhao, Zhipeng Liu, <u>Tao Yin</u> Institute Of Biomedical Engineering, Chinese Academy of Medical Sciences, Tianjin/CHINA

To study the distribution of induced electric field in human brain under the H-coil and to explore the deep character of H-coil, this paper builds a real head model with limbic system inside, and an H-coil model close to the real head model. The electric field distribution in scalp and limbic system induced by H-coil was calculated via finite element method and the results were compared with those of figure-of-eight coil. It is found that the deep field performance of Hcoil was much better than figure-of-eight coil. Although the induced electric field by H-coil is not focusing on scalp, it can concentrate deeply on anterior cingulate cortex, which is an important part of limbic system. It provides a valid evidence for H-coil to stimulate deep brain structures.

SP102 - Clinical Information Systems and Decision Support

TRACK 13: INFORMATICS IN HEALTH CARE and PUBLIC HEALTH

SP102.1 - A Multi-Attribute Decision Theory Approach to Radiation Dose De-escalation in Oropharyngeal Cancer

Author(s): <u>Wade P. Smith</u>¹, Ahmad Aljadaan², John Gennari², Upendra Parvathaneni¹, Mark Phillips¹

¹Radiation Oncology, University of Washington Medical Center, Seattle/WA/UNITED STATES OF AMERICA, ²Biomedical Informatics And Medical Education, University of Washington, Seattle/WA/ UNITED STATES OF AMERICA

BACKGROUND:

Debilitating late normal tissue toxicities such as xerostomia and dysphagia have long been an accepted part of radiotherapy treatment for oropharyngeal cancer. In addition to the physiological changes, both of these health states can induce serious social and emotional burdens. Recently, it has been found that HPV+ populations of oropharyngeal cancer patients survive longer after therapy. Radiation dose de-escalation is being explored as a method to reduce the toxicity for these patients [1].

De-escalation of therapy will result in cure and toxicity rates which are different from the current standard-of-care. This balance between the two is explored implicitly by clinical trials which are explicitly examining de-escalation of therapy. The currently accepted equilibrium did not evolve through a quantifiable methodology, nor do the current trials address the issue of determining the optimal operating point.

Methods:

We developed an outcome model for oropharyngeal cancer which combines cure rates and late toxicity effects into a single quality of life metric. We chose an Influence Diagram to model the decision process because it can incorporate probabilities from previous clinical trials, retrospective analysis, and the beliefs of experienced physicians. We used a Markov model to calculate Quality-Adjusted Life Years (QALYs) for outcomes.

We performed sensitivity analysis to determine the robustness of the model predictions to model parameters, see Fig. 1. In particular, the sensitivity of individual patient preferences was explored in the event that a single standard-of-care approach cannot be taken for this disease site.

RESULTS AND DISCUSSION:

In order to change clinical practice the QALYs for de-escalated therapy must be higher than for standard therapy. We delineated the outcomes of the trials which would and those which would not change clinical practice, within the boundaries of our sensitivity analysis. This type of model has broad applicability to other disease sites in radiotherapy and to clinical trials in medicine in general. Developing the clinical decision model up front could help design a trial that can provide the necessary information for changes in clinical practice.

SP102.2 - Large-scale data of basic patient and treatment characteristics significantly improve predictions for post-radiotherapy dyspnea

Author(s): Timo M. Deist¹, Arthur T.C. Jochems¹, Cary Oberije¹, <u>Andre Dekker</u>¹, Katrien Vandecasteele², Yolande Lievens², Johan Van Soest³, Philippe Lambin¹

¹Department Of Radiation Oncology (maastro Clinic), GROW - School for Oncology and Developmental Biology, Maastricht University Medical Center, Maastricht/NETHERLANDS, ²Radiation Oncology Department, University Hospital Ghent, Ghent/BEL-GIUM, ³Department Of Radiation Oncology (maastro), Maastricht University Medical Centre+, Maastricht/NETHERLANDS

Purpose

Dyspnea is a known side effect of lung radiotherapy. Personalized medicine approaches require reliable models predicting the patient-specific risk. As the number of events is limited, large datasets are needed for model building and these can be obtained by using data from routine clinical practice. This approach limits data to basic patient and treatment features with an increased likelihood for incompleteness and errors. We show that such models for post-treatment dyspnea enhance predictions even if solely based on basic data from clinical practice.

Materials/Methods

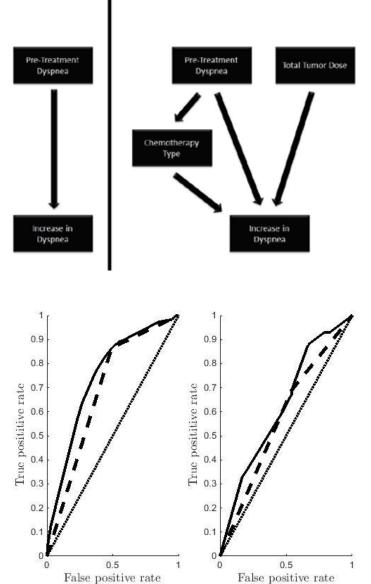

Clinical data were collected retrospectively (2008-2014) from MAASTRO Clinic, the Netherlands, consisting of dyspnea levels before and after radiotherapy, chemotherapy type, and total tumor dose during therapy. 1031 lung cancer patients with a pre-treatment dyspnea score below 2 (according to CTCv.3 or 4) were selected to ensure non-iatrogenic dyspnea did not bias the results. A validation set of 82 patients was provided by Ghent University Hospital, Belgium. A Bayesian Network was learned to predict an increase in the dyspnea score given pre-treatment dyspnea, chemotherapy type, and total planned radiation dose. For comparison, another estimator was constructed solely based on pre-treatment dyspnea which is known to carry high predictive value.

Results

The enhanced model and the estimation only using pre-treatment dyspnea have been cross-validated using 10 folds. The enhanced model outperforms the univariate estimation with an average AUC of 0.7319 versus 0.6852. The additional features yield a significantly different AUC (p-value<0.01, Wilcoxon signed-rank test). These findings are externally validated with the enhanced model increasing the AUC from 0.5740 to 0.6236.

Conclusions

Improvements in the prediction of worsened dyspnea after lung radiotherapy are achieved using only clinical patient and treatment data. This example provides additional evidence for the potential of prediction models based on clinical data to improve patient care and furthering the goal of personalized medicine.

SP102.3 - Substituting human MRI-observed tumor length with automated tumor length calculations for prediction model application

Author(s): Johan Van Soest¹, Jeroen Buijsen¹, Philippe Lambin¹, Vincenzo Valentini², Andre Dekker¹

¹Department Of Radiation Oncology (maastro), Maastricht University Medical Centre+, Maastricht/NETHERLANDS, ²Department Of Radiotherapy, Università Cattolica del Sacro Cuore, Rome/ITALY

Introduction

The development and use of prediction models in radiation oncology is emerging, especially in the context of individualized medicine. Although prediction models can indicate clinical outcomes, automated execution is a problem when information is only available as unstructured text (or missing). For example, van Stiphout et al. (PMID: 21176986) developed 3 prediction models to predict a pathologic complete response (pCR) in rectal cancer patients. In two out of three prediction models, tumor length (determined by radiologists on MRI scans) is used as a model variable, which needs to be manually extracted from free-text radiological reports. In this study, we attempted to find another measurement method for tumor size in already available data, and to measure its influence when applying it to the pre-treatment (clinical) pCR prediction model as a substitute for tumor length measured by a radiologist on MRI.

Methods

We used a dataset of 71 patients having a pre-treatment PET-CT scan and clinical radiotherapy gross tumor volume (cGTV) delineations available. For 41 of these patients the tumor length observed by a radiologist on an MRI was available. We used either this cGTV directly or a semi-automatic PET-threshold based GTV (tGTV) using 40% of the maximum of the standardized uptake value on the PET-CT scan. For both cGTV and tGTV, we calculated the volume, maximum Euclidian and axial distances (transversal perspective). Afterwards, we determined the correlation between MRI-observed tumor length and the computed metrics; using univariate regression analysis. Finally, we substituted the tumor length for the computed metrics in the clinical prediction model, and calculated the area under the receiver operating curve (AUC).

Results

Results of the correlation and substitution are shown in the table below. Based on this table, there is a significant correlation for the Z-axis, determined by a regression coefficient closest to 1 for both cGTV and tGTV. For the cGTV and tGTV, substituting the tumor length along the Z-axis resulted in a reasonable performance comparable to the original model (AUC 0.69 and 0.70), and resulted in a better performance for tGTV volume (AUC 0.78).

N=71	Correlation with MRI tumor length (N=41) Regression Coefficient	Model substitution AUC
	(p-value)	
cGTV Euclidean distance	0.58 (1.75*10-4)	0.57
cGTV absolute max X-axis	0.36 (4.96*10-2)	0.57
cGTV absolute max Y-axis	-0.06 (6.91*10-1)	0.67
cGTV absolute max Z-axis	1.01 (1.55*10-8)	0.69
cGTV volume	0.03 (3.48*10-4)	0.63
tGTV Euclidean distance	0.79 (1.03*10-4)	0.72
tGTV absolute max X-axis	1.23 (1.86*10-4)	0.71
tGTV absolute max Y-axis	0.59 (4.67*10-2)	0.69
tGTV absolute max Z-axis	0.92 (2.68*10-6)	0.70
tGTV volume	0.09 (2.66*10-4)	0.78

Conclusion

We have shown a correlation between the MRI-based tumor length and GTV-based distances; specifically for the Euclidian, Z-axis distance and volume. In general, the semi-automatic tGTV dimensions are better for substitution of the MRI-observed tumor length. Although the results are promising, this dataset is too small (N=71; positive events: 14) to make final conclusions and requires an external validation.

SP102.4 - An Artifact Detection Framework for Clinical Decision Support Systems

Author(s): <u>Shermeen Nizami</u>¹, James R. Green¹, Carolyn Mcgregor² ¹Systems And Computer Engineering, Carleton University, Ottawa/ CANADA, ²University of Ontario Institute of Technology, Oshawa/ CANADA

This research develops a standardized framework to integrate artifact detection (AD) in computerized Clinical Decision Support Systems (CDSS). Review of the state of the art has revealed a number of limitations currently preventing the widespread implementation of AD algorithms within CDSS. To address those limitations, this paper develops a novel component-based AD framework for integration in CDSS. The novelty of this research is the development of a Common Reference Model (CRM) with standard definitions for component interfaces. These definitions include common physiologic data attributes of: (1) type; (2) frequency; (3) length; and (4) Signal Quality Indicator.

SP102.5 - Design and implementation of an IT management system for a Medical Physics Department activity workflows. Author(s): Leonello Servoli¹, <u>Massimiliano Paolucci¹</u>, Bruno Checcucci¹, Roberto Di Lorenzo¹, Mariano Gattafoni², Mario Tiburzi², Alessandro Carnevale²

¹Istituto Nazionale di Fisica Nucleare, Sezione Perugia/ITA-LY, ²BTREE Srl, Foligno/ITALY

The everyday activities of a Medical Physics Department, either in a single Hospital or in a network of Hospital and Medical Institutions, are very complex and the management of the data flow coming from the different tasks, of the scheduled quality controls and mainte-

nance tasks is difficult and time consuming. There are currently no commercial products that tackle in a satisfactory manner the problem.

The aim of this work is to describe the design, implementation and operation of an Enterprise Resource Planning (ERP) and a Database Management System (DBMS) focused on managing the most important workflows of a Medical Physics Department.

The system requirements are based on the application of Italian national radiation protection and quality assurance regulations, guidelines and operating procedures and on the inputs of the Medical Physics Service of the AUSL Umbria 2 (Italy) comprising 8 Hospitals. The systems has been using a 3-tiers architecture, implemented via incremental releases: presentation, middleware and data level with a presentation layer using a user friendly Graphical User Interface (GUI).

The system prototype is capable of recording informations related to all the medical instruments and diagnostic equipments, their relevant characteristics, status and history. Is also capable of recording all the data coming from the quality controls and maintenance activities, digest them and produce the relevant legal and administrative reports.

Furthermore it has a dedicated section for Occupational Exposure to lonizing Radiation, where several parts have been implemented, as radiological surveillance of working environment and individual worker, quality assurance program in diagnostic radiology.

The prototype system has been deployed by the AUSL Umbria 2 Medical Physics Department and used from 2013.

The most relevant results are the increased levels of data security, the optimization of scheduled tasks, implying a more efficient use of manpower, the homogeneity of the approach to the management of many different activies. Furthermore the incremental release model using a 3-tier architecture allows the development of a flexible as well as robust solution.

Therefore it is a system with a high degree of innovation, that could bring significant benefits to the work of medical physics staff and a model for future developments.

SP102.6 - Differential Feature Space in Mean Shift Clustering for Automated Melanoma Assessment

Author(s): <u>Javier Eslava</u>, Christopher Druzgalski Electrical Engineering, California State University Long Beach, Long Beach/CA/UNITED STATES OF AMERICA

Malignant melanoma is one of the most dangerous forms of skin cancer. However, an important aspect of this type of cancer is that, if detected early, it can be successfully treated. This characteristic makes automated early melanoma detection systems clinically desirable. Therefore, a novel technique for melanoma segmentation based in Mean Shift clustering methods along with a complete melanoma detection system were implemented. Mean Shift main benefit over other clustering techniques is that it does not need a known number of clusters, instead, a distance function and bandwidth value are defined affecting the number of clusters that are calculated.

Conducted studies which focused on diagnostic assessment consider two implementations of the Mean Shift algorithm; one that takes the color of the image as the feature space and another that uses the color and texture information to create a two-dimensional feature space. The segmentation algorithm was used with a database of 200 images including unaltered dermatological images and illumination corrected ones in order to study the effects of two widely used illumination correction methods in the segmentation stage.

The first illumination correction technique was developed by making use of morphological operators, specifically the morphological closing. The second illumination correction technique was the algorithm known as Retinex. Performance measurements of the Mean Shift implementations were included with further comparisons of two existing segmentation techniques; image thresholding using Otsu's method and Gradient Vector Flow (GVF) Snakes. The classification results of using two different classifiers are also demonstrated as part of the complete melanoma detection system. The first classifier was based on Support Vector Machines (SVMs). The second classifier used linear discriminant analysis with various discriminant functions: linear, quadratic and mahalanobis distances.

This approach demonstrates enhanced classification capabilities of melanoma detection which can also be extended to other dermato-logic applications.

SP102.7 - Fuzzy-state machine for Triage priority classifier in emergency room

Author(s): Agustin I. Cabrera Llanos¹, María G. Ramírez-Sotelo², <u>Emmanuel S. Sánchez Velarde²</u>, Itzamná O. Rico-Asención², Nayely R. Budar-Alemán², Alejandro A. Sotelo-De Ávila², Rodrigo Sánchez-González²

¹Bioprocesos, Unidad Profesional Interdisciplinaria de Biotecnología - IPN, Distrito Federal/MEXICO, ²Bioprocesos, Unidad Profesional Interdisciplinaria de Biotecnología, Distrito Federal/MEXICO

In this paper, a fuzzy classifier stage of a patient in the emergency room is presented. This classifier is divided into 3 stages: data entry by staff health, the evaluation provided by the software and finally the creation of a report for electronic patient file. A clinical classification system called triage give us the severity and priority of the patient, taking into consideration parameters like consciousness, blood pressure, appearance, temperature, heart rate and respiratory rate, achieving an effective prevaluation . The program is designed for adult patients aged 18 to 40 years.

SP102.8 - An Australian mining boom: development of an Australian radiotherapy datamining network for rapid learning from clinical data to support improved clinical decisions Author(s): <u>David Thwaites</u>¹, Lois Holloway², Michael Bailey³, M Samir Barakat¹, Martin Carolan⁴, Geoff Delaney², Matthew Field¹, Andre Dekker¹, Tim Lustberg¹, Andrew Miller⁴, Johan Van Soest⁵, Shalini Vinod⁶, Sean Walsh¹

¹Institute Of Medical Physics, School Of Physics, University of Sydney, Camperdown, Sydney/AUSTRALIA, ²Department Of Radiation Oncology, Liverpool & Macarthur Cancer Therapy Centres and the Ingham Institute, Liverpool/NSW/AUSTRALIA, ³Medical Physics/ medical Informatics, University of Wollongong, Wollongong/AUS-TRALIA, ⁴Radiation Oncology, Illawarra Cancer Care Centre, Wollongong/AUSTRALIA, ⁵Department Of Radiation Oncology (maastro), Maastricht University Medical Centre+, Maastricht/NETHER-LANDS, ⁶Department Of Radiation Oncology, Liverpool & Macarthur Cancer Therapy Centres, Liverpool/NSW/AUSTRALIA

Objective: Large amounts of data are routinely collected on radiotherapy patients, which can potentially provide additional clinical evidence to inform better clinical decisions. A collaborative project has begun between the MAASTRO clinic and a pilot network of Australian cancer centres, to validate and implement MAASTRO-developed prediction models (PMs) in Australian clinical practice and assess their impact on decisions for future patient treatment. Wider objectives include developing multi-institutional rapid learning, to enable PM evolution by incorporating more centres/data, using a distributed learning approach of transporting the model to the data, rather than data out of the centres, thereby protecting data privacy.

Methods: Two initial stand-alone pilots were conducted: one on datasets for radically-treated Stage I–IIIB non-small cell lung cancer (NSCLC) patients in the Liverpool Hospital Cancer Centre and the second on radically-treated Stage I–IV larynx patient datasets in the Illawarra Cancer Care Centre, both Pinnacle+Mosaiq users. Open-source rapid learning systems, using Semantic Web based tools, were installed, supporting collection of data, from the TPS and OIS databases, relating to the patients, diseases, treatments and recorded outcomes. The MAASTRO PMs were learned (on 'training cohorts') and validated against local datasets ('clinical cohorts'). Further lung studies are currently underway in three other hospitals (Eclipse+Aria and Pinnacle+Mosaiq users).

Results: For the lung patients, of 419 datasets identified meeting the PM criteria, 159 had all required data to be eligible for inclusion in the clinical cohort. Some missing data were imputed using Bayesian methods, increasing eligible datasets to 225. The larynx data were relatively complete; 109/125 datasets identified had all data parameters recorded to be eligible for inclusion. For both pilots, the MAASTRO PMs successfully predicted better and worse prognosis groups, but showing some differences to the models, which reflected differences between the Dutch and Australian patient groups and practice. For example, the PM-predicted good prognosis lung group was differentiated from a combined medium/poor prognosis group (2-year overall survival, 69% vs. 27%, p<0.001) in the Australian data. Stage was less able to identify prognostic groups; most good prognosis patients in this clinical cohort having higher stage disease. For larynx, the proportion of clinical cohort patients in the predicted poor/medium/good prognosis groups were 47%/42%/11%, compared to the training cohort defined as 25%/50%/25%. Thus the larynx model could classify different clinical cohort prognosis groups, but the good prognosis group was smaller, as the clinical cohort was older and had more advanced cancers, nodal spread and non-glottic cancers than the training cohort.

Conclusion: The technical infrastructure and the basic MAAS-TRO prediction models support the prognosis prediction of lung and larynx patients in Australian clinical cohorts, showing promise for support of future personalized treatment decisions, improved treatment quality and potential practice changes. The infrastructure is being extended: for an initial distributed learning pilot between multiple NSW centres; for expansion into more NSW centres, other states and linkage to trials databases; and for model parameters to include radiomics data. Data quality for routine patients is vital when creating a rapid learning infrastructure, to maximize the information's potential.

SP103 - Health Technology Assessment and Cost Effective Technologies for Developing Countries and Usability and Human Factors Engineering for Medical Devices and System Design: Part 2

TRACK 16: CLINICAL ENGINEERING, CLINICAL PHYSICS, AND PATIENT SAFETY

SP103.1 - Novel Medical Device Procurement Tracking Approach

Author(s): <u>Gleb Donin</u>, Ilya Ivlev, Silvie Jeřábková, Jakub Vacek, Peter Kneppo

Department Of Biomedical Technology, Czech Technical University in Prague, Kladno/CZECH REPUBLIC

This paper presents approaches implemented in the medical device procurement tracking system in the Czech Republic. The System was created to enable the monitoring and assessment of procurement efficiency and to provide valid information to different stakeholders during future medical equipment purchases planning. Data collection process was proposed and implemented into practice. Several reports run on the grounds of a multi-criteria comparison based on comprehensive data model, which enable to analyse the procurement data and to formulate hypotheses relative to procurement efficiency. The multi-criteria approach is based on the valuation of the medical equipment procurements upon the set of criteria specified by the user, such as procurement terms and conditions, medical equipment price and technical specifications. The System developed allows users to compare purchase contracts with the purpose of identifying their weaknesses and planning future purchases.

SP103.2 - Influence of shifting patients with off-axis tumor for Tomotherapy

Author(s): <u>Yingjie Xu</u>, Jianrong Dai, Zhihui Hu, Peng Huang, Pan Ma, Kuo Men, Ke Zhang, Minghui Li, Dawei Jin, Wenting Ren Department Of Radiation Oncology, Cancer Institute & Hospital, Chinese Academy of Medical Sciences, Beijing/CHINA

Objectives:

For tomotherapy, it's common practice to set up a patient centrally no matter where a tumor is in his or her body. Here is to evaluate the influence of shifting the patient on plan quality and treatment time if the tumor is off the rotational axis of tomotherapy machine.

Methods:

15 patients with off-axis tumor were chosen for planning in tomotherapy planning system (Accuray Inc.). The off-axis distance ranged from 2 to 12cm. In one group of plans, all patients were shifted in the planning system to make the tumor center coincide to the machine's rotation axis (HiArt) while in the other group, all patients were not shifted. Except center position, all planning settings such as pitch, field width, and modulated factor were the same for two groups. Conformal index, homogeneity index and mean dose of normal tissue were compared in these two groups. So did the treatment time and monitor units.

Results:

The CI, HI and DNTmean were 0.84 ± 0.053 , 1.06 ± 0.023 , and 12.37 (quartile range 5.78)for the first group of plans (the plans with patients shifted), and were 0.84 ± 0.053 , 1.07 ± 0.027 , and 12.4 (quartile range 5.91)for the second group, respectively. There was no significance. But the treatment time was shorter for the first group, and the difference became larger with off-axis distance. So did the MUs. When the distance was more than 6 cm, the treatment time saving was over 10%. These changes were mainly caused by the machine's flattening filter free design.

Conclusion:

For patients with large off-axis tumor, treatment time and MUs can be reduced significantly if the patients are shifted so that the tumor center coincides to the machine's rotational axis.

SP103.3 - Smart pump user interface evaluation

Author(s): <u>Carlos A.B. Viviani</u>¹, Saide Calil² ¹Deb, UNICAMP, Campinas/BRAZIL, ²Department Of Biomedical Engineering, Unicamp, Campinas/BRAZIL

There are at least 73 infusion pump manufacturers registered with the Food and Drugs Administration (FDA).

Many events reported by the FDA occurred due to usability problems of medical devices, which are often related to lack of consistency in the interface. This may induce the user to error and consequently the occurrence of problems during the device operation.

To minimize such events, it is required a careful evaluation of the interface device and also its standardization.

Infusion pumps are always present in ECRI's reports as one of the devices that have the highest probability of risk to the patient.

The objective of this study is to verify the interfaces consistency of four infusion pumps developed by leading manufacturer in world market.

The methodology is structured in two stages. The first stage referred to the development of an appropriate set of criteria for comparing the interfaces of the smart infusion pumps. In the second stage, it was applied the developed criteria to the interfaces using the four pumps as a practical study

Evaluation results showed that there is no standardization for designing medical devices of the same type and cathegory; in this case study the smart pumps. It also suggested that each manufacturer designs a device considering only aesthetic issues and does not maintain any consistency with other manufacturers and even with other models or different version devices.

This preliminary study provides us with evidence that this lack of consistency between the interfaces of these devices can lead to usability problems, and can lead untrained users to error. Additional studies are needed to further investigation and thereby demonstrate qualitatively results.

SP103.4 - Studying the human computer interface of a continuous monitoring software by approaching it from both directions Author(s): <u>Ying Ling Lin</u>¹, Anne-Marie Guerguerian², Patricia Trbovich¹

¹Centre For Global Ehealth Innovation, University Health Network, Toronto/CANADA, ²University of Toronto, Toronto/CANADA

A software to manage the data from continuous monitoring has been implemented in paediatric intensive and cardiac critical care units of a large, tertiary hospital, in Canada, but in its current version has not been integrated in clinicians' work. In this study, we present two components of a proposed four-phase project which each approach the human-computer interface (HCI) from two directions. Established human factors methods will be employed: first, from the computer side using heuristics or "rules of thumb", frequently used in software design, and second, from the human-user side, using cognitive task analysis. These two phases aim to inform an optimized interface design eventually used to study the impact of this software on clinician decision-making within this complex sociotechnical workplace.

Computer Side – Heuristic Analysis

In this phase, the interface was assessed using 14 heuristics, developed by leading experts in interface design and modified for medical devices. Three evaluators assessed the same version of the software for issues and their heuristic violations and severity. The first assessment was performed by a "double-specialist" with novice-level knowledge of both the clinical work and human factors; the second was performed by two domain experts each from clinical nursing and human factors fields.

In total, 68 usability issues were found; 23 were found in the first assessment, 45 were found in the second assessment, and 18 found in both assessments. These were associated with over 200 violations to the heuristics generally, of severity 2 (minor usability problem) or 3 (major usability problem). The most common types of heuristic violations were visibility, match, memory and error.

Human Side - Cognitive Task Analysis

Cognitive task analysis (CTA) is generally referred to as the set of methods used to identify the mental demands and cognitive skills needed to complete a task. Monitoring and decision-making in the technology intense environment of an ICU requires a high degree of staff expertise to carry out these cognitive tasks. A cognitive task analysis was used to understand how different clinicians in the ICU use the information at their disposal to make decisions regarding patient care. Physicians, nurses and respiratory therapists make decisions for a range of tasks required for continuous care. They obtain their information from disparate monitoring technologies and an understanding of their prioritized information sources is key to the design of software interfaces aimed at facilitating their access and integration of this information. We designed four simulated, paper-based, scenarios to aid the CTA.

By using tools from decades of knowledge of software interface design and from structured methods of understanding the work of clinicians, basic usability issues and tasks can be identified. Results from these two directions will inform the next phase of testing, a low-fidelity usability study, using true-to-work tasks and inherent software interface issues.

SP103.5 - Analysis and experimentation of plantar foot segmentation from thermographic digital images for preventive diagnosis of diabetic foot

Author(s): Carolina Rosado¹, Alex E. Dávila², Yahir Pandzic², <u>Luis</u> <u>Vilcahuaman¹</u>, Marko Alpiste²

¹Faculty Of Electronic Engineering, Pontifical Catholic University of Peru, Lima/PERU, ²Pontifical Catholic University of Peru, Lima/PERU

Plantar foot surface temperature is an important feature in type II diabetes as it is an early sign of foot ulcer. We have reviewed the scientific and technical foundations for the use of digital thermography of the sole of the foot as a prevention procedure to avoid foot ulceration. This project has progressed in the implementation of a new segmentation algorithm to analyze plantar foot temperature and its assessment by qualitative judgment. We have processed thermographic images of the feet. To achieve this we first proceeded to capture images from two soles of feet -surrounded or not by a foam block- and then to segment them using two different methods each of which include the iterative closest point (icp) Method: 1) fuzzy clustering modeling (FCM) and 2) growing seeds. Images properly segmented were judged by three observers who have estimated the quality of the contour tracing. Medians and quartile deviations are calculated to estimate the segmentation's quality. As a result, the quality contour tracing was less suitable when there was not a foam block surrounding the sole of foot while imaging was performed. Likewise, the segmentation using FCM was less suitable than the segmentation by growing seeds. Overall, these results suggest the possibility of avoid using foam block by optimizing the software with growing seed method which increase the comfort of patients and asepsis inside hospitals.

SP104 - Phantoms

TRACK 01: IMAGING

SP104.1 - Monte Carlo simulation of interventional cardiac scenarios using a newborn hybrid phantom and MCNPX code Author(s): <u>Fernanda R. Cavalcante</u>¹, Albérico B. Carvalho Júnior², William S. Santos³, Choonsik Lee⁴

¹Departamento De Física, Universidade Federal de Sergipe, São Cristóvão/BRAZIL, ²Departamento De Física, Universidade Federal de Sergipe, Aracaju/BRAZIL, ³Instituto De Pesquisas Energéticas E Nuclears, Comissão Nacional de Energia Nuclear, São Paulo/ BRAZIL, ⁴Division Of Cancer Epidemiology And Genetics, National Cancer Institute, Bethesda/UNITED STATES OF AMERICA

We developed exposure scenarios of pediatric interventional cardiology using a newborn hybrid phantom and the radiation transport code MCNPX. Six angiographic projections (AP, PA, LAO45, RAO45, LAO90 and RAO90) were simulated considering three X-ray energy spectra (60, 70 and 80 kVp), focus-skin distance (FSD) not less than 45 cm and a 7 x 7 cm² field size. Equivalent and effective doses were computed and normalized by kerma-area product (KAP) resulting the conversion coefficients HT/KAP and E/KAP. The results showed highest HT/KAP values in AP projection at 80 kVp. Increasing photon energy, average E/KAP values presented relative differences of 18% (60 to 70 kVp) and 15% (70 to 80 kVp). E/KAP values were compared with those published for mathematical newborn phantom. Results showed relative differences of 14% for AP projection (70 kVp) and 60% for lateral projections (60 kVp).

SP104.2 - Computed tomography of a beating heart: High resolution simulator for the assessment of motion artifacts during CT scan of the heart

Author(s): Yair Zak¹, Vadim Beniagouev¹, Sarah Cohen², <u>Dov Malo-nek¹</u>

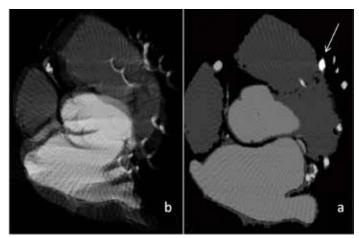

¹Medical Engineering, Ruppin Academic Center, Emek Hefer/IS-RAEL, ²Glocal System, Philips Healthcare, Haifa/ISRAEL

Computerized tomography of internal organs is an important diagnostic tool for the clinician in spite the use of ionizing radiation with the potential for causing harmful deterministic and stochastic effects to the patients. CT angiography, that allows detecting and evaluating coronary heart disease, is a technological challenge as the image acquisition process is done while the heart is moving resulting in information loss. Fast acquisition and precise synchronization to cardiac motion are common techniques to reduce information loss, but they fail when irregular cardiac rhythm is encountered.

We have developed a computerized CT simulator to investigate the effect of irregularities in cardiac cycle during CT scan on the obtained image quality. The CT simulator utilizes high resolution computer phantom mimicking realistic cardiac motion with anatomically realistic heart and associated vasculature. Normal cardiac motion is generated using XCAT/HADES phantom generator with anatomical resolution exceeding 0.25mm. Irregular cardiac rhythm is controlled by a dedicated ECG simulator capable of generating normal and abnormal rhythms. The simulator allows simulation of prospective gating technique ("Step and shoot"). Various reconstruction algorithms have been incorporated in the simulator. Effects of geometry of the scanner, pixel size, gantry rotation speed and other physical parameters on image quality can be studied.

We showed the simulator's capabilities by the introduction of a small calcium block into a coronary artery of the beating heart phantom.

Its detectability was tested while changing the simulated heart rate variability. The calcium block was easily detectable in the reconstructed images when simulating acquisition during normal cardiac rhythm. When heart rate variability was increased to 10%, the coronary artery block was not detected in the reconstructed images.

We suggest that such computerized simulator have the potential be used in future development of CT techniques, to investigate the effects of anatomy and motion on acquisition protocols and to customize imaging protocols for individual patients based on their measured heart rate variability.

SP104.3 - Development of Dynamic Anthropomorphic Heart Phantom for Computed tomography

Author(s): <u>Ali Ursani</u>¹, Murray Rice¹, Shailaja Sajja², Fatima Ursani², Narinder Paul³

¹Medical Engineering, University Health Network, Toronto/ON/CAN-ADA, ²Department Of Medical Imaging, toronto general hospital, toronto/ON/CANADA, ³Medical Imaging, University Health Network, Toronto/CANADA

Background:

Currently available large detector CT scanners with high rotational speed and dual-source have demonstrated good diagnostic accuracy for coronary artery disease. However, the appearance of a coronary stenosis during computed topographic coronary angiography (CTCA) does not always equate the actual blockage in the arteries. This discrepancy is due to calcified plaque can cause bloom artifact or similarly measured density of non-calcified plaque is strongly affected by partial volume artifact from adjacent densities including luminal contrast. Higher or irregular cardiac motions has significant role in producing these artifacts, hence multiple scans are required with different gating techniques. These limitations can be addressed by improvement in image reconstruction algorithms and acquisition techniques.

Method:

This project presents development of a realistic dynamic anthropomorphic heart phantom (DHAP), which can mimic any heart rhythm of patient while waiting in the holding area. The dynamic heart phantom driven in real time from the patient's ECG; then can be scanned in the CT to establish the best gating protocol suitable to current heart rhythms of the patient. Once the protocol is established the patient can be scanned only applying single gating technique; hence significant radiation dose can be reduced for these patients.

The phantom can also support research studies addressing the detection issues due to cardiac motion in space and time domains. Thus phantom can also serve as a useful tool in building new CTCA

reconstruction algorithms for improving image quality.

Specifications:

- Fluid Pump (piston type):

Capacity: 270 ml

HR: 50 to 125 BPM

Piston stroke (max) = 140 ml@120 bpm

 Heart module (Urethane rubber 30A/ 60HU@120kVp; wall thickens = 1cm):

Chambers: Two; LV & RV; 70ml each at relaxed state.

End-diastolic volume [EDV] = up to 130 ml (typical 120 ml)

End systolic volume [ESV] = down to 40 ml (typical 50 ml)

Arterial angular displacement around the axis = up to 2 cm

-Software:

NI LabVIEW Control Design and Simulation Module running on PC with the help of Quanser Q2-USB H.I.L control board. A pressure wave corresponding to the heart chamber movements is simulated and fed into the closed-loop PI position controller to drive the linear shaft of piston-pump.

Results:

Attached figure: Two trans-axial 0.5mm computed tomography images through the basal left ventricle (top right) and apical left ventricle (bottom right) show the presence of non-calcified plaque causing eccentric (top) and central (bottom) luminal stenosis.

Currently following studies are being carried out with the help of DAHP at UHN.

Study.1 -Optimal image reconstruction for detection and characterization of mixed coronary plaque during CTCA.

Study.2 -Influence of X-ray pulse duration on lung nodule sharpness during digital radiography in a dynamic anthropomorphic chest phantom.

SP104.4 - Development of a PET/MR/CT Compatible Tumour Motion Phantom

Author(s): John C. Patrick¹, Mohammad A. Tavallaei², Frank S. Prato³, R T. Thompson³, Maria Drangova³, Stewart Gaede³ ¹Physics And Engineering, London Regional Cancer Program, London/CANADA, ²Imaging Research Laboratories, Robarts Research Institute, London/ON/CANADA, ³Medical Biophysics, Western University Canada, London/ON/CANADA

The development of PET/CT scanners has improved staging for lung cancer, especially for nodal and distant metastatic sites. In the case of chest wall infiltration and mediastinal tumours, MRI is superior to PET/CT. PET and CT are acquired sequentially and thus motion in PET that is acquired over minutes cannot be corrected with the CT, which is acquired over several seconds. Siemens' hybrid PET/MRI acquires both modalities simultaneously, eliminating the impact of respiratory motion due to sequential scanning. This could have a major impact on respiratory-gated lung cancer radiotherapy. Before implementing PET/MRI for lung cancer radiotherapy clinically, the benefits of this novel imaging technique should be validated in an appropriate phantom. Therefore, the goal of this work is to demonstrate a PET/MR/CT compatible respiratory motion phantom that

can be used to understand and validate the impact of tumour motion on hybrid PET/MRI.

The phantom's main torso compartment has internal dimensions of 274.5mm long with an oval profile of 292mm by 240.5mm. The lung compartments have oval profiles with internal dimensions of 89mm by 125.5mm, by 274.5mm long. The spine compartment also has an oval profile with internal dimensions of 32.3mm by 23.6m, by 274.5mm long. The superior-end cap has two fill holes; one to fill the spine compartment and a larger one to fill the torso compartment. The inferior-end cap has two through holes to match the profiles of the lung compartments, which allow a spherical tumour compartment with a stem to be mounted to an MRI-compatible motion stage. This motion stage from Vital Biomedical Technologies can provide user-defined motion profiles to move the tumour (Figure 1A).

The 3.5cm diameter spherical tumour compartment was filled with saline and 17kBq/mL of F18 to mimic tumour uptake of FDG. The torso compartment was filled with saline and 4.27kBq/mL of F18 to mimic normal back ground uptake in a patient body. The motion stage was programmed to produce a repeating 4 second sinusoi-dal cycle of linear motion that was 2cm long in the superior/inferior direction. PET/MR images were acquired on a Siemens Biograph mMR via T1-VIBE sequence with simultaneous list-mode PET acquisition.

Figure 1B shows that the co-registration of the PET and MRI was achieved with no post-processing, despite the presence of motion.

The PET/MR/CT-compatible Tumour Motion Phantom can be used to generate accurate images of known geometries and reproducibly simulate respiration motion or user-defined motion profiles of a tumour.

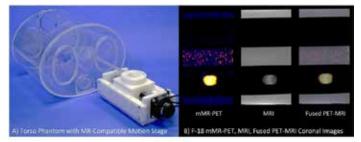

Figure 1. A) Completed Phantom with B) Non-gated images in <u>mMR-PET</u>, T1-VIBE MRI, and Fused PET-MRI of moving chantom filled with saline and F-18.

SP105 - MRI: Novel Approaches and Molecular Imaging & Applications

TRACK 01: IMAGING

SP105.1 - Advancing MRI for Non-invasive Physiological and Cellular Imaging

Author(s): Hai-Ling Margaret Cheng

Institute Of Biomaterials & Biomedical Engineering, University of Toronto, Toronto/ON/CANADA

Magnetic resonance imaging (MRI) is a non-invasive, high-resolution whole-body imaging modality for probing deep tissue structures without requiring exposure to ionizing radiation. The exquisite soft-tissue contrast MRI affords is unparalleled, thus firmly establishing its importance in clinical diagnostic imaging. MRI also has great potential for imaging events at the physiological, cellular, and molecular level. Although most of these efforts currently remain within the domain of pre-clinical research, advancing MRI beyond conventional anatomical imaging is key to opening new avenues for exploration.

In this talk, I will describe the efforts in our laboratory to advance MRI for physiological, cellular, and molecular imaging for eventual translation to humans. Our emphasis is on "quantitation", meaning that we use imaging to "measure" biological events. This focus is critical to improving the way we detect disease, since early changes in cells and tissue function often occur long before physical abnormalities become apparent, and having the ability to detect and measure these changes is crucial to early diagnosis and intervention. It will also enable us to tackle emerging applications, such as tissue engineering, where the ability to track transplanted cells and determine their fate or to monitor tissue development in vivo, can be assessed realistically only inside a living subject. The technical capabilities we are developing will be described alongside their application to guiding tissue-engineering approaches for regeneration and to new concepts for cancer detection (Figure 1) and cardiovascular imaging (Figure 2).

SP105.2 - Detection of Regional Radiation-Induced Lung Injury using Hyperpolarized 129Xe Localized Magnetic Resonance Spectroscopy

Author(s): <u>Brandon Zanette</u>¹, Ozkan Doganay², Elaine Hegarty³, Giles E. Santyr⁴

¹Physiology And Experimental Medicine, The Hospital for Sick Children, Toronto/ON/CANADA, ²Department Of Medical Biophysics, University of Western Ontario, London/ON/CANADA, ³Robarts Research Institute, London/ON/CANADA, ⁴Department Of Medical Biophysics, University of Toronto, Toronto/ON/CANADA

Introduction: Radiation induced lung injury (RILI) remains one of the most important limitations of radiotherapy of the thorax. Magnetic Resonance Spectroscopy (MRS) using hyperpolarized ¹²⁹Xe may be useful for early detection of RILI by quantification of gas exchange between lung air spaces, lung tissue (T), and red blood cells (RBC)¹. Previous work using whole lung irradiation and ¹²⁹Xe MRS has shown detection of inflammatory changes associated with RILI (i.e. pneumonitis) as early as two weeks post-irradiation in rats². This work extends these methods to regional detection of RILI using localized MRS in a rat model involving irradiation of the right versus left lung.

Methods: Sprague Dawley rats were used following Western AUC-approved protocols. One cohort was irradiated with 18 Gy to the right thorax and incubated for two weeks, while the other cohort served as unirradiated controls. Localized ¹²⁹Xe spectra were obtained from an 8x8 matrix in the coronal plane and processed to yield total tissue signal (ST) and total RBC signal (SRBC) for the whole lung as well as each of the left and right lungs, similar to Thind et al.³ For each rat, whole lung and individual lung (right and left) SRBC/ST ratios were calculated, after which ratios of SRBC/ST between right and left lungs (R/L) were calculated. Afterwards, lungs were removed, fixed, sectioned and stained (H&E) for histology.

Results: Eight rats were analyzed (three irradiated, five unirradiated). R/L was significantly different between the two cohorts (p = 0.009) with mean values 0.91 (± 0.08) and 0.69 (± 0.07) for the unirradiated and irradiated cohorts respectively. The difference between SRBC/ST between the cohorts was less significant for the left lung (p = 0.056) compared to the right (p = 0.019), while whole lung comparison was intermediate (p = 0.022).

Discussion: These results confirm that regional RILI differences are detectable at two weeks using hyperpolarized ¹²⁹Xe localized MRS of rat lungs following single-lung irradiation of 18 Gy. The strong

difference between tissue and RBC signal seen in the right lung and left lung of the irradiated cohort suggests that both the tissue and blood pool are affected by the direct effects of radiation. The smaller but significant response of the unirradiated left lung in the irradiated cohort may indicate pneumonitis is present in the left lung with little vascular damage. We hypothesize that the right lung of the irradiated cohort may be exhibiting both pneumonitis (increasing ST) and vascular damage (decreasing SRBC), while the left only exhibits pneumonitis. This agrees with previous studies showing organ-wide pneumonitis to localized irradiation in a similar rat model³. In future, histological analysis may help support this hypothesis. SRBC/ ST may be a useful biomarker for early, regional detection of RILI in humans as the technology becomes available clinically. Early detection of pneumonitis and vascular damage may allow for modification of treatment, mitigating the irreversible effects of RILI.

SP105.3 - Conjugate-Mapped Compressed Sensing: a technique to mitigate the side effects of compressed sensing on MTF

Author(s): <u>Amr A. Heikal</u>¹, Keith Wachowicz², B Gino Fallone³ ¹Medical Physics, Cancer Centre of Southeastern Ontario, Kingston/ CANADA, ²Medical Physics, Cross Cancer Institute, Edmonton/ CANADA, ³Physics, University of Alberta, Edmonton/AB/CANADA

Purpose:

Compressed sensing (CS)¹ in MRI allows images to be generated with a dramatic reduction in acquired k-space data while retaining similar appearance to those conventionally acquired. However, it has been shown that CS can have a detrimental effect on the modulation transfer function (MTF) of chemical shift images.² The aim of this work is to quantitatively illustrate the impact of CS on 2D MRI, and to introduce a modified randomization and reconstruction algorithm (conjugate-mapped compressed sensing (CMaCS)).

Theory:

CMaCS exploits the conjugate symmetry property of the k-space representation of a zero-phased image which allows the unpaired k-space conjugate locations to be estimated prior to reconstruction. The resulting increase in k-space filling should translate to increased resolution of the CS reconstructions.

Materials and Methods:

A phantom with a fan array of alternating 2.9° acrylic wedges and fluid-filled voids was used to measure the MTF. The fans array allows for a square-wave input function (arc profile on fan structure) with continuous variation in spatial frequency (Fig. 1). A 2D T2-weighted turbo spin-echo sequence with a 1×1 mm² nominal resolution was used to scan the phantom on a 3T Philips Intera platform. The resulting k-space data was 3-times sub-sampled in the x-direction (phase-encode) with a randomized 1/r³ probability distribution for CS and CMaCS reconstruction. CS reconstruction was based on the method outlined by Lustig et al.¹, using a 2D wavelet sparsity constraint. The CMaCS modification constrained the 1/r³ randomization to avoid conjugate k-space replicas. Prior to conjugate-mapping, a zero-order phase correction was performed in k-space based on k0,0. After reconstruction, arc profiles over a range of radii on the real, phase-corrected images were used to calculate the MTF in the x-direction at the corresponding spatial frequencies as discussed by Heikal et al.²

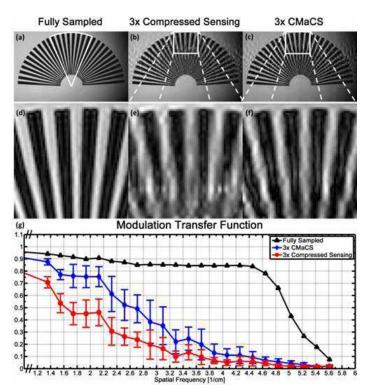

Figure 1: (a) The fully sampled image of the phantom showing the region-of-interest for calculating the MTF (white), (b) 3xCS reconstruction, (c) 3x CMaCS reconstruction, (d) close up of the top of the fully sampled image, (e) close up of the CS image, (f) close up of the CMaCS image, (g) MTFs of the 1 fully sampled image, 10 CS reconstructions and 10 CMaCS reconstructions.

Results and Conclusions:

Similar to results given by Heikal et al.², Fig. 1(g) shows that the spatial frequency response for the CS implementations was markedly lower than the fully sampled acquisition that they are intended to imitate (black plot). CMaCS (blue plot) provided a near two-fold increase in spatial frequency response compared to standard CS. However, due to potential B0 field variations across the FOV, a zeroorder phase correction may prove insufficient for robust CMaCS, requiring more complex phase-handling.

SP105.4 - Gadolinium Labeled Glycosylated Nanomagnetic Particles as Metabolic Contrast Agents in Molecular Magnetic Resonance Imaging

Author(s): Sara -. Heydarnezhadi, <u>Nader Riyahi-Alam</u>, Soheila Haghgoo, Mehdi Khobi, Banafshe Nikfar, Ensieh Gorji, Behrouz Rafiei

Tehran university of Medical Science, tehran/IRAN

Difficulties in the use, preparation, and cost of radioactively-labeled glycosylated compounds led us to this research and development study of a new gadolinium-labeled glucose compounds that do not

have a radioactive half-life or difficulties in its synthesis and utilization. Despite its good resolution, Magnetic Resonance Imaging (MRI) has low sensitivity, therefore, using MRI contrast agents, such as GD-DTPA (Magnevist) will improve tissue discrimination in MRI images.

The purpose of this study is the synthesis and physicochemical characterization of glycosylated gadolinium as metabolic contrast agent for molecular MRI (mMRI). In-vitro T1 relax-ivity measurement and signal intensity of the glycosylated compounds has been also performed in comparison with mag-nevist (GD-DTPA). Based on the structure of the 2-fluoro-2-deoxy-D-glucose molecule (FDG), first compound consisting of D-glucose con-jugated to a well-known chelator, diethylenetriamine penta-acetic acid (DTPA), was syntheside, labeled with Gd to achieve Gd-DTPA-DG, another comound consisting of gado-linium oxide-based nanoparticle coating of diethyleneglycol conjugated with D-glucose via N,N-carbonyldiimidazole (CDI) mediate reaction, to achieve Gd-DEG-DG, and characterized by various analytical technique, utilizes dynamic light scattering (DLS) to determine the size distribution. The nanoparticle size and morphology were using high resolution transmission electron microscopy (HTEM). In our study, the Gd-DTPA-DG were well defined nanoparticle with size 40 nm in diameter TEM images. While Gd-DEG-DG were 10 nm. The mean hydrodynamic diameter of nanoparticles, as measured by DLS, were 300 nm and 70 nm for GD-DTPA-DG and GD-DEG-DG, respectively. The synthesized GD-DTPA-DG and GD-DEG-DG were shown higher relaxometery rates in vitro relative to magne-vist. GD-DEG-DG and GD-DTPA-DG demonstrated shorter T1 than GD-DTPA at the same conectration.

SP105.5 - Hyperpolarized 129Xe Magnetic Resonance Imaging of a Rat Model of Radiation-Induced Lung Injury Involving Single-Lung Radiation Therapy

Author(s): Ozkan Doganay¹, Elaine Hegarty², Rolf F. Schulte³, Charles Mckenzie⁴, Giles E. Santyr¹

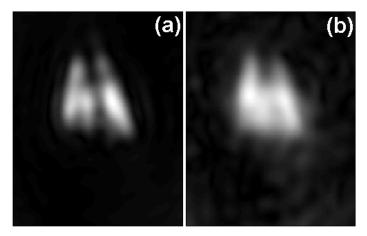

¹Medical Biophysics, Western University, London/CANADA, ²The Hospital for Sick Children, Toronto/ON/CANADA, ³GE Global Research, Munich/GERMANY, ⁴Robarts Research Institute, London/ ON/CANADA

Radiation therapy is a common treatment for lung cancer, but is limited by radiation-induced lung injury (RILI)[1]. It has been previously shown that Magnetic Resonance Imaging (MRI) with hyperpolarized ¹²⁹Xe can detect changes in both lung tissue signal as well as exchange between gas and tissue (ie. pneumonitis) as early as two weeks following whole thorax irradiation in rats[2]. In this study, a novel MRI approach is developed for imaging of hyperpolarized ¹²⁹Xe both in the gas phase and dissolved in lung tissue. The method is applied to a rat model of RILI involving single-lung irradiation.

The right thorax of three Sprague Dawley rats were irradiated with a cobalt-60 irradiatior (18Gy), following previously described methods[2]. Three rats served as non-irradiated controls. 2D coronal spiral IDEAL[3] images were acquired using a repetition time (TR) of 300ms. Following three wash-in breaths of hyperpolarized ¹²⁹Xe, IDEAL gas images and tissue images were acquired from the lungs within a breath-hold time of 6 seconds. Signal-to-noise ratios (SNR) of the averaged IDEAL gas images and the lung tissue images, for both the left lung (SGL, STL) and the right lung (SGR, STR) of both cohorts were calculated. To account for potential differences in ventilation and polarization, the lung tissue SNR values were normalized by respective gas SNR values for both left and right lungs (STL/ SGL and STR/SGR). Following imaging, lungs were removed for histological examination.

Fig.1 shows coronal IDEAL gas (a) and tissue (b) images from a representative non-irradiated rat. STL/SGL and STR/SGR was strongly correlated with tissue area measured by histology (R=0.75), with a Pearson coefficient P-value=0.005 at p<0.01.

This study shows that MRI of hyperpolarized ¹²⁹Xe in the gas space and in the lung tissue is feasible, and can be used to detect increases in tissue signal in the lungs of irradiated rats as early as two weeks post-irradiation. An increase of approximately 50% in tissue signal was observed in the right lungs of the irradiated cohort compared to the unirradiated cohort corresponding to increases in tissue area (ie. pneumonitis) measured using histology. These methods should be readily translatable to human subjects given the growing availability of hyperpolarized gas technology in the clinic. Early detection of pneumonitis may allow adjustment to the radiotherapy plan and/or the application of alternate therapies to mitigate RILI.

SP105.6 - Ultra-short Echo Time (UTE) Magnetic Resonance Imaging of Cortical Bone: An Undersampled Acquisition Study Author(s): <u>Yanchun Zhu</u>¹, Qun He², Jiang Du², Yaoqin Xie¹ ¹Institution Of Biomedical And Health Engineering, Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shenzhen/CHINA, ²Department Of Radiology, University of California, San Diego/UNITED STATES OF AMERICA

Purpose: Ultra-short echo time (UTE) sequences have shown great utility in visualizing short T2 tissues like cortical bone which shows little or no signal with conventional clinical magnetic resonance imaging (MRI) techniques. Several short T2 contrast mechanisms have been developed to enhance bone contrast by suppressing signals from surrounding long T2 tissues including muscle and fat. These contrast mechanisms may significantly prolong the acquisition times.

Methods: A series of UTE pulse sequences were implemented on a 3-T Signa TwinSpeed scanner (GE Healthcare Technologies, Milwaukee, WI, USA) with a maximum gradient performance of 40 mT/m and slew rate of 150 mT/m/ms. In this paper, UTE, dual echo UTE (dUTE), adiabatic inversion recovery prepared UTE (IR-UTE) and adiabatic inversion recovery prepared dual echo UTE (IR-dUTE) with different undersampling acquisition ratios were compared by measuring signal-to-noise ratios (SNRs), contrast-to-noise ratios (CNRs), signal distortion, contrast, image sharpness and streak artifact power. The feasibility of using undersampling acquisition in UTE approaches was demonstrated by imaging cortical bone in vitro and in vivo using the clinical 3T scanner.

Results: Results showed that UTE, dUTE, IR-UTE and IR-dUTE data acquisitions can be highly undersampled to save scan time, while providing images with limited undersampling artifact especially for IR-UTE and IR-dUTE acquisitions. Figure 1 shows the dUTE

undersampling images of distal tibia.

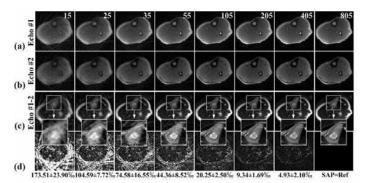

Figure 1: dUTE undersampling study of in-vivo distal tibia. dUTE images of a volunteer's distal tibia with different number of projections (15, 25, 35, 55, 105, 205, 405 and 805) are shown in the first row (a) for the first echo images and the second row (b) for the second echo images. Subtraction images between these two echoes are shown in the third row (c). Residual images in the fourth row (d) are used to show streak artifacts in subtraction images.

Conclusion: This study has shown that UTE imaging of cortical bone with highly undersampling acquisition (accelerating factor up to 23) is feasible when surrounding long T2 tissues are efficiently suppressed.

SP105.7 - Brain activation associated with working memory maintenance under anxiety-provoking distracter in patients with obsessive compulsive disorder

Author(s): Gwang-Won Kim¹, Jong-Chul Yang², <u>Gwang-Woo Jeong¹</u> ¹Radiology & Biomedical Engineering, Chonnam National University Medical School, Gwang-Ju/KOREA, ²Psychiatry, Chonnbook National University, Jeonju/KOREA

The purpose of this study was to discriminate the brain activation patterns associated with the anxiety-provoking distracter during the working memory (WM) maintenance for the human faces between patients with obsessive compulsive disorder (OCD) and healthy controls by using a function magnetic resonance imaging (fMRI).

Twelve patients with OCD (mean age = 31.3 ± 7.4 years) and 12 healthy controls (mean age = 33.3 ± 7.8 years) underwent the functional MRI on a 3.0 Tesla MR Scanner (Siemens Medical Solutions, Germany). The activation paradigm consisted of a string of "encoding - WM maintenance - distracter - retrieval." In the encoding task, three different human faces sequentially appeared once on a quartile coordinate of a screen monitor. During the delay time following the encoding, the subjects were asked to maintain the WM for the encoded faces. Then, distracters were given to the subjects while maintaining the WM of the encoding step, in which the distracters consisted of an anxiety-provoking picture and a neutral picture. In the retrieval task, either of the face presented in the encoding task or a new face was presented. The brain activation mapping and the resulting qualification were processed by SPM8.

The average scores of perceived anxious emotion for anxietyprovoking picture were 7.8 \pm 1.4 and 7.7 \pm 1.4 in patients with OCD and healthy controls, respectively. The scores for the face recognition task with anxiety-provoking distracters were 67.8 \pm 9.1% and 68.3 \pm 11.9% in patients and healthy controls, respectively, while the scores for neutral distracters were 62.1 \pm 15.7% and 70.0 \pm 12.1%, respectively. The patients with OCD showed significantly decreased activities in the ventrolateral prefrontal cortex, superior parietal gyrus, middle temporal gyrus, and fusiform gyrus during the WM maintenance with the anxiety-provoking distracters as contrast to healthy controls, whereas the patients with OCD significantly increased activities in the inferior temporal gyrus and median cingulate gyrus (p<0.001).

It is concluded that our findings provide an evidence for the differential brain activation patterns associated with anxiety-provoking distracter between patients with OCD and healthy controls during the delay interval of the WM task. This finding will be helpful to understand the neural mechanism related to general impairment of emotional function in patient with OCD.

SP105.8 - Fractioanal Anisotropy, Voxel Wise Morphometry and Resting State in Patients with Lateral Amyotrophic Sclerosis Author(s): <u>Maria M. Lopez-Titla</u>, Salvador Gsrcía, Lourdes M. Martínez

Imágenes Cerebrales, Instituto Nacional de Psiquiatría, México/ MEXICO

Introduction:

The Amyotrophic Lateral Sclerosis (ALS) is a degenerative disease that is characterized by the damage of the Upper Motor Neurons (UMN) and the Lower Motor Neurons (LMN). Many studies have found that motor areas are affected by this disease, being the main affected areas the corticospinal tract, the posterior limb of the internal capsule and the anterior and medial parts of the corpus callosum; other studies have also found a general decrement of the gray matter in all the brain. The ALS has a difficult prognosis because the symptoms can be misleading; therefore it is really important to find biomarkers that help us in the diagnosis of this disease and in improving its medical treatment.

The Magnetic Resonance Imaging (MRI) is a non invasive neuroimage method that offers information in vivo of the brain structures. This method counts with different advanced techniques which evaluates many parameters that could be used as biomarkers to identify distinct diseases or disorders.

Among the MRI advanced techniques are: a) The diffusion tensor imaging that can provide the Fractional Anisotropy (FA) index which takes values between 0 and 1 and it is used to evaluate the integrity of the white matter; b) The Voxel-wise morphometry that helps to quantify the volume and the amount of gray and white matter in the brain; c) The functional Magnetic Resonance Imaging (fMRI) based on the Blood Oxygen Level Dependent (BOLD), that is used to identify different brain areas that are activated during specific tasks and to infer the connectivity between different brain regions that may be interconnected, as it is shown in the resting state connectivity.

Methods:

A total of 16 voluntary subjects participated in this study, 8 patients with ALS (age 18-54) and 8 control subjects, age matched, without antecedents of neurologic or psychiatric disease. The images were acquired with a Philips magnetic resonance scanner, Ingenia 3.0 T with a 32 channel head coil. We acquired sagittal T13D-weighted images with spatial resolution of 1x1x1mm³, axial diffusion tensor images with 33 independent directions of diffusion and b of 1000 s /mm². Axial fMRI based on BOLD with echo planar images (EPI) technique, TR=2s and 150 dynamics. Axial T2FLAIR-weighted images were also acquired to identify intra cortical and supra cortical lesions. The software FSL v.2.0 was used for the analysis of the data.

Results:

The FA is decreased in the corticospinal tract in bilateral form and in the posterior limb of the internal capsule. The Voxel-wise Morphometry analysis shows a decrement of the volume of all the brain in patients with ALS. The motor network obtained by the resting state images is affected in cerebellum in patients with ALS. In this study we tried to correlate these tree different techniques of MRI to find biomarkers for a better diagnosis of the ALS even though it is important to mark that results are very dependent on the analysis method used, for that reason is very important to assure good reproducibility in the results.

SP106 - PR: Proton Therapy

TRACK 04: RADIATION ONCOLOGY

SP106.1 - Proton therapy – close to becoming mainstream Author(s): Thomas Bortfeld

Massachusetts General Hospital and Harvard Medical School, Boston/UNITED STATES OF AMERICA

The number of patients treated with proton therapy is now well over 100,000. The field of proton therapy is growing at a remarkable and stable growth rate: the numbers double every ten years. To make this growth rate sustainable, and for proton therapy to become mainstream, we argue that two goals must be achieved: First, proton therapy must become cheaper and more compact. Secondly, we must be able to fully exploit the physical potential of proton therapy.

Many developments are underway to help with the first goal. Single room solutions and "compact" proton machines are becoming increasingly available. We will give an overview of the available options and report on our own experience with proton therapy retrofitted in a conventional treatment area. The biggest proton therapy component and one of the most expensive ones is the gantry. Based on an analysis of almost 5,000 patients treated with gantries in our center, we find that the vast majority of them could have been treated without the gantry. Developments of robotic patient positioning and immobilization, advanced in-room imaging solutions, as well as advances in pencil beam scanning delivery, will further reduce the need for a gantry.

The second goal requires the precise localization of the end of range of the proton beam in the patient. There are a number of developments underway to reduce range uncertainties. We will report on advances of measuring the proton range through the prompt gamma radiation produced by the proton beam in the patient. This will allow one to determine the proton range with millimeter precision in realtime.

SP106.2 - Monte Carlo-based Inverse Treatment Plan Optimization for Intensity Modulated Proton Therapy

Author(s): <u>Yongbao Li</u>¹, Zhen Tian², Ting Song², Zhaoxia Wu¹, Yaqiang Liu¹, Steve B. Jiang², Xun Jia²

¹Department Of Engineering Physics, Tsinghua University, Beijing/ CHINA, ²Department Of Radiation Oncology, University of Texas Southwestern Medical Center, Dallas/UNITED STATES OF AMERICA

Intensity-modulated proton therapy (IMPT) can achieve a better dose distribution than passive scattering or uniform scanning. For IMPT optimization, Monte Carlo (MC) is desired for spots dose calculations because of the high accuracy in heterogeneous cases. Due to its capability of computing linear energy transfer (LET), MCbased IMPT planning is preferred in biological optimization scheme. However, MC simulation is too slow to be used for this purpose. Although GPU-based MC engine has been developed, the achieved efficiency is still not ideal. The purpose of this work is to develop a new scheme to include GPU-based MC into IMPT. The conventional approach for this purpose is simply using MC repeatedly for each spot dose calculations. However, this is not the optimal approach, because of the unnecessary computations on spots that turned out to have very small weights after IMPT optimization. Memory writing conflict also poses a challenge, if one sequentially compute dose at each spot. To solve these problems, we have developed a new MC-based IMPT plan optimization framework that iteratively

performs MC dose calculations and plan optimization. At each dose calculation step, the particles are sampled from different spots based on previously optimized spots intensity map with Metropolis sampling method. Simultaneous handling multiple spots also solves the memory writing conflict problem. We validated the proposed MC-based optimization schemes in one prostate case. It took 5-6 min of total computation time including both spots dose calculation and optimization with only one GPU card for the proposed method, whereas a conventional method naively using MC for spot dose calculations would be ~2-3 times slower.

SP106.3 - FoCa: a protontherapy treatment planning system written in object-oriented MATLAB

Author(s): <u>Daniel Sanchez-Parcerisa</u>, Alejandro Carabe Radiation Oncology, Hospital of the University of Pennsylvania, Phialdelphia/UNITED STATES OF AMERICA

Purpose: Monte Carlo transport codes are useful in protontherapy research as they provide accurate calculations, but at the cost of long calculation times. On the other hand, commercial treatment planning systems provide fast dose calculation but with limited access to the calculation engine behind them. To address these issues, we developed FoCa, an in-house treatment planning system, developed entirely in object-oriented MATLAB, which includes forward dose and LET calculation of proton radiotherapy plans in both active and passive modalities as well as a generic optimization suite for inverse treatment planning. Methods: Our approach was to provide the user with a set of classes dealing with the different aspects of a treatment planning system (CT importing, structure sets, dose kernel calculation, et cetera). We chose MATLAB for its fast prototyping capabilities, its speed at matrix calculations and its extensive geometry libraries. FoCa implements the proton-convolution-superposition algorithm for dose calculation and a similar pencil beam algorithm for analytical LET calculation. We included a user-friendly GUI for basic user interaction, as well as scripting capabilities for advanced operations. The inverse treatment planning framework is presented with an open architecture, not specific to any treatment mode or optimization algorithm, which allows researchers to work on their own optimization methods or therapy modalities. Results: We developed and tested the FoCa code. The validation results show a good agreement with the commissioning data, the 3D dose distributions based on patient-specific CT data calculated by a commercial treatment planning system, and 3D Monte Carlo calculations of dose and LET performed with Geant4. Finally, the inverse treatment planning suite was used to produce the first prototype of intensity-modulated, passive-scattered proton therapy, using 13 passive scattering proton fields and multi-leaf modulation to produce a concave dose distribution on a cylindrical solid water phantom without any field-specific compensator. Conclusions: We have demonstrated the validity and capabilities of the FoCa TPS in a wide range of setups. Its current and potential uses range from the fast calculation of any physical, radiobiological or clinical quantity in a patient CT geometry, to the development of new treatment modalities not yet available in commercial treatment planning systems. FoCa is currently available within our institution to a selected number of test users and it will be made available to the research community after all the necessary testing has been completed.

SP106.4 - Assessment of the limitations of the dose calculation algorithm of a commercially-available treatment planning system for proton pencil beam scanning

Author(s): <u>Jessica E. Scholey</u>, Liyong Lin, Christopher G. Ainsley Department Of Radiation Oncology, The University of Pennsylvania, Philadelphia/PA/UNITED STATES OF AMERICA

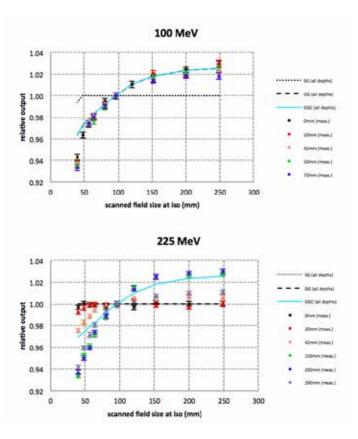

This study evaluates the accuracy and limitations of a commer-

cially-available treatment planning system's (TPS) dose calculation algorithm for proton pencil-beam scanning (PBS) and quantifies the sensitivity of the accuracy to the proton beam source modeling.

In-air fluence profiles of PBS spots were modeled in the TPS alternately as single- (SG) and double-Gaussian (DG) functions, based on fits to commissioning data. Uniform-fluence, single-energy-layer square fields of various sizes and energies were calculated with both beam models and delivered to water. Dose was measured at several depths (Figure 1). For lower energies (100-150 MeV), the DG model fits the measurements well at all depths, while the SG model does not. For higher energies (150-225MeV), both the SG and DG models fit the measurements well at shallow depths (< 4 cm), but not deeper, where dose contributions from proton-nuclear interactions become important, suggesting a limitation of the algorithm. The possibility of using, instead, a third model, based on double-Gaussian functions with parameters contrived to offset this inadequacy (DGC) was therefore investigated.

Eleven cuboid-dose-distribution-shaped fields with varying range/ modulation and field size were subsequently generated in the TPS, using each of the three beam models described, and delivered to water. Dose was measured at the middle of the spread-out Bragg peak. Percent differences between calculated and measured doses (Table 1) were greatest for the SG model, increasing the smaller the field. The DG model showed improvements for all field sizes in shorter range beams, though the percent differences for smaller fields persisted in longer range beams. The DGC model was, however, able to predict the measurements to within 2% for all beams.

It can be concluded that while neither SG nor DG models, employed as intended, are ideally suited for routine clinical use, the TPS's DG model can be tuned judiciously to yield acceptable results.

SP106.5 - Impact of the microdosimetric spread on cell survival data analysis

Author(s): Gloria Bäckström¹, Fernanda Villegas-Navarro², <u>Shirin A.</u> Enger¹, Anders Ahnesjö²

¹McGill University, Montreal/CANADA, ²Uppsala University, Uppsala/SWEDEN

Purpose/Objective

The microscopic uncertainty of the energy imparted (microdosimetric spread, MDS) at the cellular/cell nuclei level due to the stochastic nature of ionizing radiation is normally not explicitly considered during parameterization of experimental survival fraction data. The magnitude of the MDS is higher for protons than for photons because of the known differences in track structures. The aim of this work is to present a method to quantify the impact of MDS on the biological radiation response. We estimate the effect on the α and β parameters of the linear quadratic (LQ) model used to describe experimentally obtained cell survival curves in different volumes sizes for various radiation qualities.

Materials and Methods

The Monte Carlo transport code LlonTrack was used to simulate event-by-event proton tracks in liquid water for the energies 0.91, 1.4, 1.72, 3.18, 3.59, and 4.97 MeV·u⁻¹, as well as for a ⁶⁰Co source. The frequency distribution of specific energy for one track f1(z) and the dose dependent frequency distribution of specific energy f(z,D)were calculated with in-house analysis codes for a range of spherical volume sizes typical of cell nuclei. Experimentally obtained survival curves intrinsically account for the MDS. When the specific energy z given by f(z,D) is weighted with the LQ equation, exp[-($\alpha z+\beta z^2$)], the α and β values based on D instead of z exclude the MDS variations and can be determined by fitting α and β to survival curves calculated from published aexp and Bexp values. The RBE10 at 10% survival with 60Co as the reference radiation for the dexp and Bexp was also factorized into a factor equal to the RBE for the fitted α and β values (RBEinh), and a factor representing effects of the MDS (RBEMDS). RBEMDS for a tissue with variable cell nuclei sizes was calculated by weighting f(z,D) with the size distributions presented by Poole et al [Submitted to Med. Phys. 2015] for healthy and tumor tissues.

Results

The f(z,D) can be quite well represented by a narrow normal distribution for the lowest LET radiation (⁶⁰Co) even at small volumes, becoming wider and skewed towards lower specific energies with increasing particle LET. The relative MDS increases with decreasing dose and decreasing volume. The RBEMDS factor decreases with increase in LET and volume thereby reducing the RBEinh. For a heterogeneous size sample, the RBEMDS for healthy tissue reduces the RBEinh the most when compared to the tumor tissue.

Conclusions

Our data suggests that the MDS in experimental data smears out the higher efficiency of the inherent RBE. The MDS component in a clinical scenario with an irradiated volume that consists of cells with different sizes might be smaller for tumor tissues than for healthy tissues due to the higher number of larger nucleus sizes in tumor tissues.

SP106.6 - Magnetically scanned-beam proton radiography using Micromegas detectors

Author(s): <u>Derek Dolney</u>¹, Godwin Mayers², Mitch Newcomer², Douglas Bollinger¹, Niral Desai², Robert Lustig¹, Kevin Teo¹, Richard Maughan¹, Timothy D. Solberg¹, Robert Hollebeek² ¹Radiation Oncology, University of Pennsylvania, Philadelphia/PA/ UNITED STATES OF AMERICA, ²Physics And Astronomy, University of Pennsylvania, Philadelpha/PA/UNITED STATES OF AMERICA

Purpose: While the energy of therapeutic proton beams can be adjusted to penetrate to any given depth in water, range uncertainties arise in patients due in part to imprecise knowledge of the stopping power of protons in human tissues. Proton radiography is one approach to reduce the beam range uncertainty, thereby allowing for a reduction in treatment margins and dose escalation.

Methods: The authors have adapted a novel detector technology based on Micromesh Gaseous Structure ("Micromegas") for proton therapy beams and have demonstrated fine spatial and time resolution of magnetically scanned proton pencil beams, as well as wide dynamic range for dosimetry. In this work, proton radiographs were obtained using Micromegas 2D planes positioned downstream of solid water assemblies. The position-sensitive monitor chambers in the IBA proton delivery nozzle provide the beam entrance position.

Results: Radiography with Micromegas detectors and actively scanned beams provide spatial resolution of up to 300 μ m and water-equivalent thickness (WET) resolution as good as 0.02% (60 μ m out of 31 cm total thickness). Dose delivered to the patient by the proton radiography technique would be 2 cGy. The spatial resolution as a function of sample rate and number of delivered protons is found to be near the theoretical Cramer-Rao lower bound. Using the CR bound, we argue that the imaging

dose could be further lowered to 1 mGy, and still achieve sub-mm spatial resolution, by relatively simple instrumentation and beam delivery modifications.

Conclusion: For proton radiography, high spatial and WET resolution can be achieved, with minimal additional dose to patient, by using magnetically scanned proton pencil beams and Micromegas detectors.

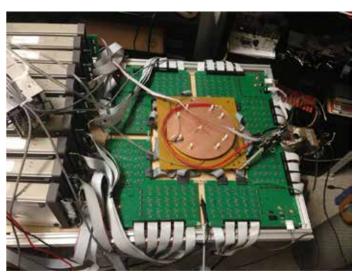

Figure 1: Prototype Micromegas-based system for proton radiography.

SP107 - Beam Delivery

TRACK 04: RADIATION ONCOLOGY

SP107.1 - A Quantitative Analysis of Teletherapy in Low Resource Settings: Cobalt or Linac?

Author(s): <u>Rachel Mccarroll</u>¹, Bassem Youssef¹, Beth Beadle¹, Maureen Bojador², Rex Cardan³, David Followill¹, Geoffrey Ibbott¹, Anuja Jhingran¹, Christoph Trauernicht⁴, Peter Balter¹, Laurence Court¹ ¹University of Texas MD Anderson Cancer Center, Houston/UNITED STATES OF AMERICA, ²University of St. Tomas Hospital, Manila/ PHILIPPINES, ³University of Alabama Birmingham, Birmingham/ UNITED STATES OF AMERICA, ⁴Groote Schuur Hospital and University of Cape Town, Cape Town/SOUTH AFRICA

Purpose: There exists a deficit of more than 6,500 megavoltage teletherapy units worldwide, many in low resource-settings. Medical linear accelerators and cobalt units would address this need, and the tradeoffs between them have been compared qualitatively in the literature. Often discussed are dose rate, power infrastructure, and machine downtime all of which affect machine availability and treatment time. We have quantitatively addressed these topics and their effect on patient throughput (treatments/day).

Methods: Patient treatment time was calculated as the sum of patient set-up, beam-on, and mechanical motion time, with input data from clinical observation and electronic records (1000+ patients). The following treatment techniques were considered: linacs (conformal with MLC, Step-and-Shoot IMRT, Dynamic IMRT, and VMAT), and cobalt units (conformal therapy with and without MLC). Power data from The World Bank for 44 African countries were divided into three power scenarios based on frequency of outages. We assumed that cobalt units remain operable during outages using a backup generator. Machine downtime data was acquired from in-house records (linacs) or experienced users (cobalt).

Results: Low dose rates associated with cobalt units increase conformal treatment beam-on time between 0.6 and 2 minutes. depending on source activity. This represents between 14% and 28% of the total treatment time. Advanced modalities increase treatment time, particularly step-and-shoot IMRT which requires the most mechanical motion time, an average of 2.6 minutes (28% of total treatment time). VMAT and Dynamic IMRT treatments have shorter mechanical motion time (0.5 and 1 minutes, respectively) but longer beam on time (2 and 1.9 minutes, respectively). Patient throughput, under each of the seven treatment techniques and three outage scenarios, is shown below. In scenarios of "fewer" or "fewest" outages, the two machines are comparable when linac delivers conformal or VMAT treatments. If linac downtime is increased to account for availability of service parts and personnel, throughput is decreased by 6%, but conclusions remain unchanged. If a cobalt unit uses blocks instead of MLCs, throughput is reduced by 14-24% (1-3 block changes per fraction). Additionally, effects of machine utilization, IGRT usage, geographically specific cancer incidences (IARC data), fractionation schemes, and palliative or curative treatment goals were investigated.

		Most Number of Outages	Fewer Number of Outages	Fewest Number of Outages	
Mean Power (Dutage per 10 hour day (hrs)	5.9	1.6	0.2	
	Cobalt Conformal Year 1	Baseline	Baseline	Baseline	
	Cobalt Conformal Year 5	87%	87%	87%	
Treatment	Cobalt Conformal Year 8	76%	76%	76%	
Delivery	Linac Conformal	48%	879	113%	
Technique	Linac VMAT	38%	78%	91%	
[Linac Dynamic	36%	74%	86%	
	Linac Step and Shoot	32%	66%	77%	

Daily throughput relative to cobait treatments during year 1, expressed as a percentage. These data assume 10 hour working days, linac downtime of approximately 1.7%, and cobait downtime of 1%. **Discussion:** While additional aspects, including cost comparisons, dosimetric advantages, and personnel requirements remain to be addressed, this work establishes a framework for teletherapy implementation in low resources settings, and identifies power as the predominant influence on patient throughput.

SP107.2 - The study of Total Marrow Irradiation Based on Rotational Intensity-modulated techniques

Author(s): <u>Shouping Xu</u>¹, Chuanbin Xie², Baolin Qu², Wei Yu², Wei Xu², Xiaohu Cong², Xiangkun Dai²

¹Key Laboratory Of Particle & Radiation Imaging, Tsinghua University, Ministry of Education, Beijing/CHINA, ²Radiation Oncology, PLA General Hospital, Beijing/CHINA

Total body irradiation (TBI) is a special form of radiotherapy, generally as part of bone marrow conditioning regimens. Conventional TBI is difficult to achieve dose uniformity because of using the large field of simple technique. In recent years, tomotherapy technique has been used for TBI, due to delivering highly conformal and uniform target dose, and providing better normal structure avoidance. But this kind of technique isn't widely used for its expensive cost. Volumetric-modulated arc therapy (VMAT) could achieve rotational intensity modulation based on the traditional accelerator and may obtain the efficient and accurate treatment with the imaging-guided device. The purpose of this study is to compare the dosimetric characteristics and efficiency of RapidArc and Tomotherapy in total marrow irradiation (TMI) for hematologic malignancies in order to get the reference data for the choice of clinical application. Eight patient plans were retrospectively designed and analyzed for RapidArc and Tomotherapy. Total bone morrow was contoured as clinical target volume excluding the cubitus and hand part, then plus a 3.0mm margin as planning target volume. The prescription was 12Gy in 10 fractions. ArcCHECK system was used for dose verification, and the safety and accuracy of clinical delivery would be evaluated. The results of this study showed that the two techniques could well achieve the target coverage. The conformity indexes of RapidArc and Tomotherapy were 0.54±0.05 vs 0.52±0.07 (p=0.45), but Tomotherapy plans have a visible advantage over RapidArc plans in the dose uniformity of target. The homogeneity indexes were 0.19±0.02 vs 0.13±0.02 (p=0.00). Tomotherapy plans showed better in sparing of the critical organs apart from the whole brain, oral, parotid gland, the small intestine, rectum, and the maximum dose of lens of Tomotherapy plans was reduced by 41% comparing to RapidArc plans. The MUs and treatment delivery time of RapidArc and Tomotherapy were 2608MU/560s vs 12842MU/891s. The γ-analysis passing rates for head-neck, chest-abdomen, pelvic were 98.9%±1.9%, 98.4%±1.8%, 97.4%±2.1% for RapidArc and 94.3%±1.5%, 96.5±1.2%, 94.1%±1.9% for Tomotherapy plans. This study shows that the two methods using RapidArc and Tomotherapy could achieve the acceptable dose of TMI, and the delivery efficiency of RapidArc was better than Tomotherapy. Two kinds of techniques are promising and can solve the clinic implementation of TMI.

SP107.3 - IMRT and VMAT comparison for a case of bilateral breast carcinoma

Author(s): <u>Erick O. Montenegro</u>¹, Juan F. Lucero¹, Rafael E. Lengua¹, Luis A. Linares¹, Milton E. Ixquiac², Ricardo Contreras² ¹Medical Phisics, HOPE International Radiotherapy Center, Guatemala/GUATEMALA, ²Phisics, Universidad de San Carlos De Guatemala, Guatemala/GUATEMALA

Introduction: A comparison was made between IMRT and RapidArc (VMAT) plans for a patient with bilateral breast carcinoma involving supraclavicular lymph nodes and skin. The prescription dose is 50Gy (25 fractions, 2Gy each), one of our goals was to maintain the organs at risk (OAR's) as low as possible.

Objectives:

 \cdot Select the best suited treatment modality for the this case, taking into account the coverage to the PTV, the OAR's irradiation and the treatment delivery time.

 \cdot Evaluate the dosimetric parameters such as homogeneity, conformity index and monitor units.

Methodology: Four different treatment plans were created; three IMRT plans using 10, 11 and 16 fields and two full rotations VMAT.

All plans were optimized Eclipse (Ver.10.0) from Varian Medical Systems Inc. and delivered in a ClinacIX with Millenium Multileaf Collimator (120 MLC). The gamma evaluation was performed using the EPID AS500 and the ArcCheck from SunNuclear Corporation.

Results:

	IMRT 10	IMRT 11	IMRT 16	VMAT
DMinPTV	71.60%	74.60%	75.00%	83.80%
V20GyLung (L)	35.91%	31.12%	14.05%	16.60%
V20GyLung (R)	49.60%	43.00%	27.28%	16.72%
DMeanHeart	23.16 Gy	20.31 Gy	19.61 Gy	9.49 Gy
DMaxSpinal Cord	29.00 Gy	28.85 Gy	24.92 Gy	23.04 Gy
Homogeneity(D5% - D95%)	11.94	10.79	12.74	5.77
Conformity Index (V95% / VPTV)	1.04	1.04	1.01	1.04
Time(min)	14:55	16:05	22:30	3:57
Gamma Evaluation $\gamma < 1$ (EPID) $\Delta D=2\%$, DTA=2mm	95.71%	93.49%	93.09%	90.70%
Gamma Evaluation γ<1 (ArcCheck)	81.85%	83.30%	64.60%	83.00%

1: Comparison of dose distributions.

Conclusions:

It was decided to treat the patient with the VMAT plan. It is observed that it presents better PTV coverage, but more importantly the OAR's receive less dose and it reduces drastically the treatment delivery time and the monitor units.

According to the gamma evaluation, all plans are equally reproducible.

SP107.4 - Measuring the Location and Dynamics of the Beam Spot and Field Centre on a Therapy Linear Accelerator in X-Ray Mode

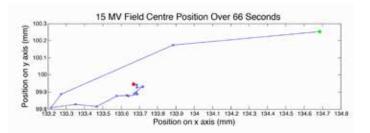

Author(s): Victoria C. Foss¹, Tyler S. Meyer², <u>David P. Spencer²</u> ¹Physics And Astronomy, University of Calgary, Calgary/CANA-DA, ²Medical Physics, Tom Baker Cancer Centre, Calgary/AB/ CANADA

Introduction: On radiation therapy linacs the X-Ray source location, or beam spot, is critical to accurate treatment. Yet it is not measured. Instead, we accept that the vendors adjust symmetry and radiation-light field agreement. The beam spot will, therefore, be different for different photon energies. We set out to measure the location of the beam spot on a machine where the rad-light agreement was different for the 6 MV and 15 MV energies. We used images of the X-Ray projections of BBs at different source-to-object distances and 180° collimator rotations. We discovered that the beam spot actually moved during beam delivery. We believe this is due to the dynamic beam steering attempting to adjust beam parameters such as flatness and symmetry.

Methods: We mounted two 4 mm diameter Tungsten balls just off-axis on plastic trays in the upper wedge slot and in the cutout location of an electron cone. We took images at about 5 second intervals on a Varian Trilogy[™] using an output rate of 100 MU/min in Service Mode on the linac and AM Maintenance High Quality mode on the aSi-1000 portal imager with a 4x4 cm field for both 90° and 270° collimator angles. We do not think the use of Service mode invalidated the use of our data for Clinical mode. Only the Collimator and Accessory interlocks were overridden. The images are analyzed using Doselab[™].

Results: We observed that for 15X the field centre moved as much as 1.5 mm at the isocentre over the first 30 seconds of beam (see Figure), while our 6X beam moved about 1 mm. We also tested a stereotactic cone which showed field motion up to 0.3 mm at 6X and 0.6 mm at 15X. This motion made it difficult to measure the location of the beam spot, since two separate images were required to determine its location. Assuming that sequential runs showed the same pattern, we paired the images to show that the beam spot moved about 0.15 mm for 6X, settling about 0.14 mm from the rotational axis. For 15X it moved 0.4 mm, settling about 0.12 mm from the rotational axis.

Conclusions: This means that beam spot size measurements assuming the beam is static may be incorrect. SRS delivery may be affected. Field symmetry and location will be time-dependent, so the QC time-scale should reflect clinical use. Investigations will continue on our other 8 linacs.

SP107.5 - Monte Carlo based optimization of flattening filters for a cobalt-60 total body irradiation unit

Author(s): Ingrid H. Lai¹, Chandra P. Joshi², Ling B. Xu³, L John Schreiner²

¹Department Of Physics, Engineering Physics & Astronomy, Queen's University, Kingston/ON/CANADA, ²Medical Physics Department, Cancer Centre of Southeastern Ontario, Kingston/ON/CANA-DA, ³Engineering, Best Theratronics, Ottawa/ON/CANADA

Introduction:

A dedicated total body irradiation (TBI) unit (GammaBeam 500, designated here as the GB-500) is being developed by Best Theratronics (Kanata, ON). It uses a cobalt-60 source with a fixed rectangular collimator and brass flattening filters to produce clinically useful fields at a source to treatment axis distance (SAD) of ~220cm. Different filters are required to maintain an appropriate constant dose rate (within 5% of ~20MU/min over the treatment length) as source decays and to accommodate local treatment protocols. The calculation of filter shapes using simple ray-tracing approximations is complicated by the large source size and broad beam geometry. In this work we compare measured beam profiles to Monte Carlo (MC) calculated profiles for the open beam and beams flattened by two prototype/testing filters. The validated MC simulations are then used to design alternate filters. The goal is to provide a design tool so that filters required for various clinical implementations of the GB-500 can be designed rigorously and not by trial and error.

Materials and Methods:

The dose profiles along the two axes of an open and two filtered fields (filter A, and a thicker filter B) of the GB-500 were measured with a Standard Imaging (Middleton, WI) A12 ion chamber at 10cm depth in the centre of a $30 \times 30 \times 27$ cm³ (small) solid water phantom placed at various positions. These profiles were then calculated using the EGSnrc MC code (National Research Council, Canada) set to the conditions of the GB-500. Doses were calculated at 10cm depth in a continuous $360 \times 120 \times 27$ cm³ (large) water phantom and in the same small phantom as used in measurements. Over 60 billion histories were run on a CPU cluster to achieve an estimated dose uncertainty of <0.8% in the clinically useful field.

Results and Conclusions:

Measured and MC calculated longitudinal profiles are shown in Figure 1. For both filters, the beam flatness over 200cm treatment length for measured doses is approximately 3%. The beam flatness for MC calculated doses is slightly better for filter B (5%) than for filter A (6%). MC calculated doses (in both the small and large phantom) differ from the measured doses (in the small phantom) by a maximum and average of around 4% and 1% respectively, for all open and flattened fields. The agreement shows that the MC simulation faithfully models the GB500. Additional results showing prediction for new filter designs will be presented.

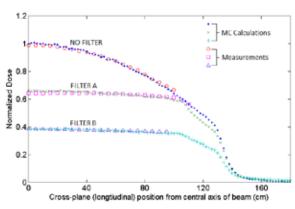

Figure 1: A comparison of MC calculated and measured dose profiles at 10 cm depth in water at SAD = 220 cm for open and filtered beams of the GB-500 TBI unit.

SP107.6 - Monte Carlo study for the design of a novel Gamma-Tomo SBRT system

Author(s): <u>Grisel M. Mora</u>¹, Omar Chibani², Ahmed Eldib², Jinseng Li², C.M Ma²

¹Institute Of Biophysics And Biomedical Engineering, University of Lisbon, Lisbon/PORTUGAL, ²Radiation Oncology, Fox Chase Cancer Center, Philadelphia/UNITED STATES OF AMERICA

Introduction: The 60Co beam emerging from the Gamma-Tomo source assembly was simulated in a previous study [1] and the authors reported the spectra of particles reaching the plane immediately (1mm) before the collimation system entrance. In the present work, we simulate the 60Co beam emerging from a novel Gamma-Tomo SBRT collimation system and calculate the output factors and dose rates for different source configurations and collimator sizes.

Methods: A Gamma Tomo system includes 13 60Co source capsules, source housing, a primary collimator and 4 different changeable collimators. The sources (6.22 mm of diameter) are located in 2 rows with different angles and distances to the longitudinal axis and the beams can be collimated to obtain four different circular field sizes at the isocenter (35 mm, 16 mm, 7mm, and 3.5mm). The BEAM-Monte Carlo [2] code is used to realistically model the collimation system geometry, including primary collimator and 4 different changeable collimators. The previously calculated phase space file [1] is used to transport particles throughout the collimation system to the patient plane for all of the changeable collimators of the Gama-Tomo System, and the respective phase space files of particles are stored at isocenter for each of the circular fields to be used as input of the GEPTS [3] to perform dose calculations. A newly designed geometry module is used to determine the dose distributions in a spherical polystyrene phantom with an 8cm radius centered at the isocenter.

Results: The characteristics of the particle spectra emerging from the collimation assembly are determined and the effect of the source-collimator position on the spectra reaching the isocenter found to be dependent on field size. We observed differences up to 5% between the energy spectra and fluence distributions calculated for different configurations of the source-collimator assembly. The effect of the source-collimator position is observed (up to 6%) on dose distributions calculated at isocenter and is dependent upon the size of the circular field.

Conclusions: The resulting data from the present study supports the machine design process and is valuable in building a well-represented source model for all sources to perform the dose calculations for all of the changeable collimators for this novel Gamma-Tomo system.

SP107.7 - A dosimetric evaluation of flattening filter-free volumetric modulated arc therapy for postoperative treatment of cervical cancer

Author(s): Fuli Zhang

Radiation Oncology Department, The Military General Hospital of Beijing PLA, Beijing/CHINA

AIMS: To compare flattening filter free (FFF) beams and conventional flattening filter (FF) beams in volumetric modulated arc therapy (VMAT) of cervical cancer after surgery through a retrospective planning study. MATERIALS AND Methods: For a cohort of 15 patients, VMAT plans of FFF beams and normal flattened (FF) beams were designed. The prescribed dose was 45Gy/1.8Gy/25f, 95% of the planning target volume received this dose. Doses were computed with a commercially available TPS using Monte Carlo (MC) algorithm. Plans were compared according to dose-volume histogram (DVH) analysis in terms of PTV homogeneity and conformity indices (HI and CI) as well as OARs dose and volume parameters. Results: FFF-VMAT was similar as FF-VMAT in terms of CI, but inferior to the latter for HI. No statistically significant differences were observed between FFF-VMAT and FF-VMAT in terms of pelvic bone marrow, small bowel, bladder and rectum. Conclusions: For patients with cervical cancer after hysterectomy, the FFF beam achieved similar target and OARs dose distribution as the FF beam. Reduction of BOT in cerval cancer is beneficial.

SP108 - Patient and Occupational Dose Assessment

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP108.1 - Radiation dose to patients from cardiac interventions performed using image intensifier, flat detector and novel flat detector systems

Author(s): Roshan S. Livingstone¹, Anna Varghese¹, Paul V. George² ¹Radiology, Christian Medical College, Vellore/INDIA, ²Cardiology, Christian Medical College, Vellore/INDIA

Background: Radiation dose to patients from interventional cardiology are of concern whether it is being performed using image intensifier (II) or flat detectors (FD). There are very few reports on achieving reduced doses using novel FD systems with advanced real-time image noise reduction algorithms and optimized acquisition chain. This study intends to compare radiation doses from cardiac interventions performed using II, FD and novel FD systems.

Design and Methods: Coronary angiography (CA) and single stent percutaneous transluminal coronary angioplasty (PTCA) were performed using Philips Integris H5000 II, Philips Xper FD10 and Philips Allura ClarityFD10 mono plane systems (Philips Healthcare, Netherlands). The novel FD - Allura clarityFD10 was equipped with real-time noise reduction algorithms and optimized acquisition chain for dose reduction. Dose area product (DAP) was measured using DAP meter available in all systems. During interventions, low dose protocol with 0.4mm Cu filter for fluoroscopy and 0.1mm Cu for cine runs were selected in all systems.

Results: Tables 1 and 2 show dose related information for CA and PTCA performed in II, FD and novel FD systems. During fluoroscopic screening, DAP values were similar in all systems. However, during cine runs, a reduction of the order of 60% and 30% in DAP was observed in novel FD when compared to II and FD respectively. A 20 – 50% reduction in the overall doses could be achieved with the use of novel FD systems during CA procedures following standard imaging protocol.

Conclusion: Though all systems utilised stringent dose reduction strategies involving heavy filtration; significant dose reduction without compromising diagnostic image quality was observed using novel FD systems involving real time image noise reduction algorithm.

SP108.2 - First National Occupational Radiation Dose Registry in Ministry of Health and its Validation: An Oman Experience Author(s): <u>Arun Kumar L S</u>, Rashid Al-Hajri, K Jaseer, Saeed Al-Kalbani

Medical Physics, Ministry of Health, Muscat/OMAN

In Ministry of Health (MOH), Oman; radiation is used for diagnosis, radiation therapy, bio-medical research and for the irradiation of blood & blood products. As per the IAEA Basic Safety Standards (2014), it is the responsibility of the employer to make arrangements for the assessment & recording of occupational exposures and for the workers' health surveillance. Not only that, the records of occupational exposure for each worker must be maintained during and after the worker's employment, at least until the worker attains the age of 75 years, and for not less than 30 years after cessation of the work. However, the current national radiation protection legislation

of Sultanate of Oman does not mandate the recording of occupational doses or a national dose registry. To overcome this problem in MOH, Oman; we developed the first National Occupational Radiation Dose Registry (NORDR) for its workers.

This in-house developed NORDR - Centralised Dose Recording System (CDRS) - for the management of personal monitoring of radiation workers, is having about 1500 radiation workers in about 145 health facilities. Each one of them is monitored by issuing a Thermo Luminescent Dosimeter (TLD) every month through the CDRS by tagging the serial number of each TL dosimeter with the unique MOH staff number of each worker by post for a wear period of one month. Some of the above locations are very remote - few thousand kilometers away from the capital city, Muscat. End of every month, the TLD's are collected back and processed for Hp(10) and Hp(3). Upon estimation and recording of doses, individual and institutional dose reports are sent to the health facilities. The cumulative annual dose report of each worker is also dispatched from the NORDR facility to each worker.

CDRS also records age, sex, category of staff, section and department of staff, duration of work with radiation, dose received prior to joining MOH, any episode of an overexposure or any suspected over exposure, annual and cumulative radiation dose of each radiation worker etc. If a worker uses more than one TL dosimeter such as for forehead, lens, ring right, ring left etc; each will be accounted and accordingly dose will be estimated according to the type & the corresponding dose report will be generated. Also, the same software will handle the individual dose(s) of each worker on a monthly, quarterly, half-yearly, yearly basis and the dose history for the entire period of radiation job. CDRS will also perform the dose analysis of an individual worker, a group of workers in an institution and all the radiation workers available in CDRS as a whole. If a worker exceeds the annual dose limit or investigation level, the CDRS will alert accordingly. The details of our in-house national occupational radiation dose registry - CDRS - will be further discussed during presentation. This dose registry can be emulated by other countries those who do not have a national dose registry for their radiation workers especially for those who are having relatively smaller number of radiation workers.

SP108.3 - Assessment of Patient and Staff Doses in Interventional Cerebral Angiography Using OSL Author(s): <u>Chryzel Angelica B. Gonzales</u>

Center For Device Regulation, Radiation Health, And Research (cdrrhr), Department of Health (DOH) - Food and Drug Administration (FDA) Philippines, Manila City/PHILIPPINES

Assessment of Patient and Staff Doses in Interventional Cerebral Angiography Using OSL

²Center for Device Regulation, Radiation Health and Research, Food and Drug Administration, Department of Health, Manila, Philippines

Abstract— In interventional radiology (IR) procedures, radiation doses received by both patient and staff are relatively high. The objectives of the study are: (1) determine/measure entrance surface dose (ESD) to patient using nanoDot optically stimulated luminescence (OSL) dosimeter, (2) verify that patient doses do not exceed established international guidance levels set by IAEA and ICRP Report 103, as stated in the BSS, applied in the Philippines, (3) estimate the effective dose E to operator and using InLight OSL dosimeters, (4) estimate the annual effective dose E for the operator and staff performing interventional cerebral angiography procedure, (5) determine who among the staff have training in radiation protection in interventional radiology/cardiology, and if so, if such training is applied in practice, and (6) verify that staff doses do not exceed established dose limits set by the IAEA and ICRP Report 103, as stated in the BSS, applied in the Philippines.

Clinical data and technical factors were gathered from interventional cerebral angiography procedures (4-vessel angiogram/6-vessel angiogram) performed at the University of Santo Tomas Hospital (USTH). It was found that none of the ESD values approach the dose thresholds for induced skin injuries (erythema or epilation). The estimated weighted annual dose for all the interventional medical workers is 5.9 mSv which is lower than the dose limit given by the IAEA and ICRP Report 103, as stated in the BSS. However, the primary operator has exceeded the investigation level of 30% of the annual dose limit of 20 mSv (13.44 mSv in the case of research badge #3). The computation of the annual dose for this study was based on a survey for the maximum number of IR procedures performed per year.

SP108.4 - A wireless personal dosimeter for Interventional Radiology medical personnel.

A personal wireless active dosimeter prototype has been developed to be weared by medical staff during Interventional Radiology procedures to obtain real-time measurement of the dose-rate.

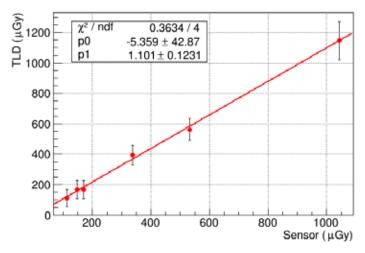

It has been tested both on phantom and during several different medical procedures. It is battery powered with an autonomy up to 8 hours.

The dose-rate measurement is performed at a frequency of 5 Hz, and transmitted to the receiving station with no dead time and a packet error rate less than 1%. Even this small information loss could be recovered with simple data handling strategies, transmitting the integrated dose at the end of each procedure.

The dose-rate measurement capability, using a certified X-ray beam facility, is linear up to 400 microGy/s, higher than the rate diffused by the most demanding procedures, while there is virtually no upper limit on the dose measurement linearity, as long as the battery is working, because the sensor element is reset after each measurement (> 1.5 Gy/h).

The sensitivity to diffused photon energy is below 10 keV.

The linearity of the response to an absorbed dose during medical procedures is shown in the following picture, where on the horizontal axis are reported the dose measured by the prototype and on the vertical axis the dose measured by the control dosimeter system (TLDs). Both systems have been calibrated simultaneously on the same certified X-ray beam.

A measurement precision between 5 and 10%, compared to reference dosimeters and dominated by their measurement uncertainty, has been obtained either on phantom than during actual medical procedures.

SP109 - Micro- and Nano-Dosimetry

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP109.1 - Development of a Thick Gas Electron Multiplier Based Multi-element Microdosimetric Detector

Author(s): <u>Zahra Anjomani</u>¹, Andrei R. Hanu², Sahar Darvish-Molla¹, William V. Prestwich¹, Soo H. Byun¹

¹Medical Physics And Applied Radiation Sciences, McMaster University, Hamilton/CANADA, ²NASA Goddard Space Flight Center, Greenbelt/UNITED STATES OF AMERICA

A prototype multi-element gaseous microdosimetric detector using Thick Gas Electron Multipliers (THGEM) has been designed and constructed for monitoring mixed neutron-gamma radiation fields1. The multi-element design was employed to increase the neutron detection efficiency²⁻³, particularly for weak radiation fields commonly encountered in radiation protection applications. Owing to the absence of wire electrodes, the THGEM multi-element detector offers flexible and convenient fabrication⁴. The prototype THGEM multielement detector consists of alternating layers of tissue-equivalent plastic hexagons and each layer houses an array of cylindrical gas cavity elements with equal height and diameter. The fundamental signal and stability performance of the THGEM detector was tested using a ²⁴⁴Cm alpha source and the detector responses to various neutron fields are currently under comprehensive investigation using the ⁷Li(p,n) neutron source at the McMaster Tandetron accelerator. A preliminary result on the neutron microdosimetric and absorbed dose responses of the prototype detector will be presented in contrast to the responses of a commercial detector.

SP109.2 - Development of a 2-D THGEM Microdosimetric Detector

Author(s): <u>Sahar Darvish-Molla</u>¹, Andrei R. Hanu², Zahra Anjomani¹, William V. Prestwich¹, Soo H. Byun¹

¹Medical Physics And Applied Radiation Sciences, McMaster University, Hamilton/CANADA, ²NASA Goddard Space Flight Center, Greenbelt/UNITED STATES OF AMERICA

Inspired by our prototype THick Gas Electron Multiplier (THGEM) detector [1,2], an advanced two-dimensional microdosimetric detector is currently under development at McMaster University. This detector aims to measure the spatial distributions of high and low linear energy transfer radiation doses simultaneously in mixed radiation fields, which will enable us to overcome the operational limitation of the classical tissue-equivalent proportional counters (TEPCs), particularly for high dose rate fields. Compared to the traditional TEPCs, wire electrodes were replaced by THGEM, which not only enhances the gas multiplication gain but also offers a flexible and convenient fabrication process for building two-dimensional detectors.

A prototype detector consists of an array of 3×3 gas cavities, equivalent to 9 TEPCs, each of which has a dimension of 5 mm diameter and length. By filling its sensitive volume with propane based tissue equivalent gas, at a pressure of 167 torr, each detector simulates a spherical soft tissue of 2 µm in diameter. To process nine detector signals simultaneously, taking the overall cost, size and flexibility into account, we developed a multi-input digital pulse processing system using a modern microcontroller interfaced with an ADS807 12-bit sampling ADC with a sampling rate of 42 Msps. The proto-type signal processor was tested using a Nal(TI) detector and the test results have proven that it is faster than a traditional analogue system and a commercial digital system. Using the McMaster Tandetron ⁷Li(p,n) accelerator neutron source, both signal performance as well as neutron dosimetric response of the detector have been extensively investigated. A preliminary test result will be presented.

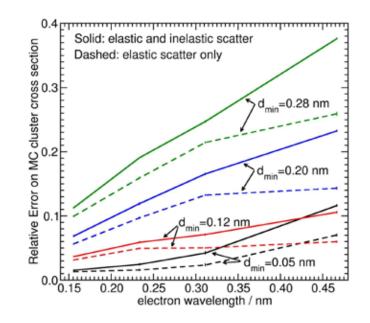

SP109.3 - Quantum versus classical trajectory Monte Carlo simulations of low energy electron transport in condensed media

Author(s): Rowan Thomson¹, Iwan Kawrakow² ¹Physics, Carleton University, Ottawa/CANADA, ²ViewRay Inc, Cleveland/UNITED STATES OF AMERICA

Widely-used Monte Carlo simulations of electron transport neglect the quantum wave nature of electrons; however, quantum effects have the potential to be non-negligible at sub-1 keV energies. Low energy simulations are increasingly employed across medical physics and beyond to model the interactions of radiation with matter on sub-micron scales, *e.g.*, interactions of electrons with DNA. This work compares quantum mechanical (QM) and classical trajectory Monte Carlo (MC) simulations for low energy electron transport.

A simplified model of electron scattering in small volumes (nanometre droplets) of condensed media, e.g. water, consisting of > 10^3 point scatterers (molecules) is developed. Adjustable model parameters include the number of scatterers, average and minimum distances between scatterers (*dav, dmin*), cross sections for elastic and inelastic scattering, and droplet size and shape. QM calculations involve numerically solving ~ 10^3 coupled equations for the electron wavefield incident on each scatterer in a droplet. Results are averaged over > 10^4 droplets, each having different scatterer positions but with the same parameters. Average QM water droplet incoherent cross sections and scattering event densities are compared with MC results. A relative error (RE) on MC results is computed.

RE is highly sensitive to electron wavelength (energy), scatterer density, droplet shape and structure, and the presence of inelastic scatter. The figure shows the RE on droplet incoherent cross section plotted as a function of electron wavelength for water droplets (radius and length of 2.124 nm) with the realistic average scatterer spacing of dav=0.311 nm for varying levels of structure (dmin) as well as with and without inelastic scatter (always with elastic scatter). As shown in the figure, it is generally found that RE increases considerably with increasing *dmin*, corresponding to more structured water (representative of water in the human body). Further, introducing inelastic scatter while maintaining the same elastic scattering cross section increases RE, suggesting that electron mean free path is a relevant length scale. It is also found that droplet cross section and relative error on MC results are sensitive to droplet size and shape, with considerable errors observed in changing droplet size and shape.

In condensed media, the quantum wave nature of electrons may be non-negligible for simulation of sub-1 keV transport. These results within a simplified model of electron transport in condensed media suggest that electron transport is strongly affected by the structure of the medium and that inelastic scatter does not necessarily improve agreement between QM and MC simulations.

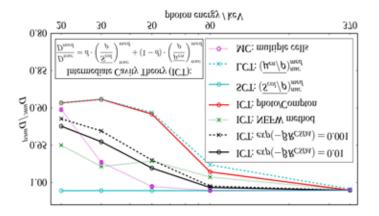

SP109.4 - Investigation of the relations between absorbed dose to cellular targets and to bulk tissue for kilovoltage radiation using Monte Carlo simulations and cavity theory Author(s): <u>Patricia Oliver</u>, Rowan Thomson Physics, Carleton University, Ottawa/CANADA

Relationships between macroscopic (~1 mm) and microscopic (cellular) dose descriptors for incident photon energies between 20 and 370 keV are investigated using Monte Carlo (MC) simulations and cavity theory.

MC simulations of clusters of cells, single cells, and single nuclear cavities embedded in phantoms are carried out for various normal and cancerous tissues; cell (nucleus) radii range from 5 to 10 microns (2 to 9 microns). Results are compared to cavity theory predictions for the dose to a cavity of nuclear size and elemental composition embedded in a bulk tissue phantom (Dnuc), relative to the dose to the corresponding average bulk medium (Dmed). Large (LCT), small (SCT), and various intermediate (ICT) cavity theory approaches are investigated. The ICT approach (see figure) is a weighted sum of SCT and LCT contributions (stopping power and energy absorption coefficient ratios, respectively). Approaches for computing the weighting parameter *d* include MC simulations determining the fraction of cavity dose due to electrons set in motion by photons interacting in the surrounding medium (ICT: NEFW method') and others involving Burlin's approach (1969) where $d = (1 - exp(-\beta L))/\beta L$, with β given by $exp(-\beta L)$ $\beta RCSDA$)=0.01 or exp(- $\beta RCSDA$)=0.001 and L is the cavity's mean chord length, taking RCSDA as the CSDA range corresponding to the most energetic electron or using a weighted sum of photoelectron and Compton electron components ('ICT:photo/Compton').

The ratio *Dnuc/Dmed* varies considerably with tissue type, cell and nucleus size and elemental composition, and source energy. ICT predictions for *Dnuc/Dmed* are highly sensitive to the method used to estimate the parameter *d*. The figure provides example results for

the dose ratio *Dnuc/Dmed* for one cell model (cell and nucleus radii of 7.35 and 5 microns, respectively) in melanoma tissue; MC results give dose to the nucleus of the central cell in a multiple cell model. At low energies, LCT qualitatively predicts nuclear doses, whereas at energies above 50 keV, SCT predictions are reasonable. In general, over the range of energies and simulation geometries (tissues, cell types) considered, ICT with Burlin's approach ('ICT: exp(- $\beta RCSDA$)=0.01') provides the best estimate of *Dnuc/Dmed*, resulting in an average discrepancy of 4%. However, no cavity theory method accurately predicts MC results over the entire range of energies and simulation geometries; thus, there is no general conversion method to obtain dose to the cellular nucleus from macroscopic dose descriptors. Further, neither dose to water nor dose to medium provides an accurate estimate of nuclear dose.

SP109.5 - Development of transmitted alpha particle microdosimetry using Timepix: Investigation of A549 lung carcinoma cells exposed to alpha particles irradiated from Ra-223 Author(s): <u>Ruqaya Al Darwish</u>¹, Alexander H. Staudacher², Eva Bezak¹

¹Department Of Medical Physics, Royal Adelaide Hospital, Adelaide/ AUSTRALIA, ²Centre For Cancer Biology, Translational Oncology Laboratory, Adelaide/SA/AUSTRALIA

Aim

To investigate the survival of A549 human lung carcinoma cells when irradiated with α -particles.

To correlate the number of DNA double-strand breaks (DSBs) per cell with the number of transmitted α -particles from Ra-223.

Materials and Methods

A549 cells were seeded at 15,000 cells on transwell inserts (0.14 cm²). The transwell system consists of two compartments: a larger well containing an evaporated Ra-223 source and an insert with a 10 μ m thick polycarbonate membrane to which cells adhere.

The Timepix detector, Amsterdam Scientific Instruments, is a hybrid semiconductor pixel radiation detector. It consists of a pixelated silicon layer of 256 x 256 pixels (55 μ m² each) bump-bonded to a CMOS pixel readout chip. Experiment setup is shown in figure 1 (A). Transmitted α-particles were detected and imaged with respect to seeded cells (figure 1 (B)). The quantitative correlation between the distribution of α-particle hits and cell damage was investigated for 1-5 hours irradiation times.

To assess the cell radiation damage, unirradiated (controls) and irradiated cell monoloayers were stained with the DNA DSB marker γ -H2AX (green staining) and cell nuclei were counterstained with DAPI (blue staining). The number of DNA DSBs per cells after irra-

diation as well as the total damaged cell count were determined.

Results

 γ H2AX staining showed that the number of DNA DSBs was six-fold higher for 5 hour irradiated cells compared to controls. The incidence of 6 and more DSBs in an irradiated cell was 22 times higher compared to control cells. These numbers correspond to more than 5000 transmitted a-particles.

Conclusion

Timepix can be used effectively as a transmitted microdosimetry detector, providing high resolution images and excellent spatial resolution of detected α -particles. The relationship between the number of transmitted α -particles and the number of the DNA DSBs is being evaluated for us in targeted alpha therapy.

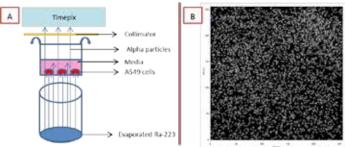

Figure 1: A) Experimental setup: Timepix chip was mounted above the A549 monolayer with an evaporated Ra-223 α -source underneath. B) Detection of transmitted α -particles using Timepix.

SP110 - Surgical Navigation: Part 2

TRACK 07: SURGERY, COMPUTER AIDED SURGERY, MINIMAL INVASIVE INTERVENTIONS, ENDOSCOPY AND IMAGE-GUIDED THERAPY, MODELLING AND SIMULATION

SP110.1 - Optical Navigation in Functional Neurosurgery Author(s): <u>Karin Wårdell</u>

Department of Biomedical Engineering, Linköping University, Linköping/SWEDEN

Learning objectives:

Understand the basic principle of blue-light fluorescence microscopy

Be able to present two different fluorescence methods used in neurosurgery

Give examples of intraoperative navigation options used during DBS-implantations

Optical Navigation in Functional Neurosurgery

During the last decade, the use of optical techniques for navigation during neurosurgery has increased. Neurosurgical microscopes, introduced already in the 1950^s, are today available with video recording and fluorescence imaging. Among these the blue-light setting is designed for visualization of malignant tumours by means of 5-aminolevulinic acid (ALA) [1]. In order to also quantify the fluorescence during tumour surgery, we have developed a handheld optical probe adapted to the requirements of the operating room [2]. The performance of the probe-system has been compared with fluorescence microscopy and biopsies and the results show that it is superior in detecting weak fluorescence when using the recommended microscopy-dose of ALA (20mg/kg). By combing the blue-light microscope and the hand-held probe both an overview of the operational field as well as the point specific fluorescence can be visualized.

Laser Doppler perfusion monitoring (LDPM) and imaging (LDPI), and diffuse reflectance spectroscopy (DRS) are other optical techniques currently under assessment as navigation support during neurosurgery. DRS allows for extraction of information from tissue chromophores and thus makes estimations of for instance saturation tissue of oxygenation possible [3].

With LDPI the cortical blood perfusion can be visualized whereas high resolution detection of differences in blood flow and tissue greyness can be achieved by LDPM. This dual function has been applied as an intra-operative navigation tool in relation to stereotactic deep brain stimulation (DBS) implantation. Its performance has now been evaluated in more than 110 lead implantations, and typical "bar codes" for optical trajectories have been defined towards two common DBS-targets the subthalamic nucleus (STN) and the ventral intermediate nucleus (Vim) [4]. In addition, the forward-looking LDPM-probe has shown as a potential to prohibit bleedings, by indicating blood flow peaks at a 0.5mm resolution along pre-planned trajectories.

Optical techniques have already proven to be useful as navigation tools in neurosurgery. However, continuation of technical and methodological evaluations based on the clinical needs is necessary in parallel to translation into the neurosurgical demands and environments, both as stand-alone techniques, and methods based on multiparametric approaches for improving intraoperative navigation.

SP110.2 - Endoscopic Electrospray: A minimal invasive tool for physical targeted gene delivery

Author(s): <u>David Hradetzky</u>¹, Stephan Boehringer¹, Paulius Ruzgys², Prosper A. Fiave³, Karin F. Blaser¹, Thomas Geiser², Amiq Gazdhar³ ¹Institute For Medical And Analytical Technologies, University of Applied Sciences and Arts Northwestern Switzerland (FHNW), School of Life Sciences, Muttenz/SWITZERLAND, ²Department For Pulmonary Medicine, University Hospital Bern, Bern/SWITZER-LAND, ³Department Of Clinical Research, University of Bern, Bern/ SWITZERLAND

Targeted gene or chemotherapeutic drug delivery offers a great potential for various diseases. In comparison to systemic delivery, side effects can be reduced and the quantity of delivered agent may increase. Also physical delivery is expected to reduce inflammatory and immunological reactions which often accompany targeted delivery utilizing viral vectors [1].

Physical localized delivery based on electrospray process, utilizes the bombardment of accelerated droplets containing the therapeutic molecule on targeted tissue, facilitating the entrance of the molecule into the cells. Electrospray process is based on Coulomb repulsion of charged particles, and to generate and accelerate the aerosol high electrical potential difference between a capillary and a counter electrode is required.

To transfer this method into clinical application single-port access instruments are needed providing the accelerating power and the fluid to the intraluminal region. The electrical field is applied by connecting the targeted tissue with ground potential, at the tip of the devices thus acting as counter electrode, while the high voltage is connected to the capillary axially placed within a working chamber. This configuration assures a predefined working distance and provides repeatable conditions of application.

Based on described concepts, different instruments were designed and realized (Figure 1). First standalone devices (Ø10mm, adjustable working distance 0-10mm, rigid, fabricated with additive manufacturing) for endoscope assisted application and second miniaturized

systems (Ø2-3mm, flexible, fabricated from Polydimethylsiloxane) applicable through the working channel of a bronchoscope.

To check the feasibility of the electrospray devices for physical targeted gene delivery, the rigid device was tested in vitro (A549) for transfection of enhanced green fluorescent plasmid (eGFP, 50-500µg/ml), at different applied potentials (2.5-4.5kV, distance 3mm). The rigid and flexible devices were also tested in an ex-vivo scenario (cultivate explanted rat lung tissue). The fluorescence signal of eGFP was detected after 24hrs incubation at 37°C using fluorescence imaging. GFP after electrospray expression indicates the successful transfection.

Both, the rigid and the miniaturized flexible electrospray instrument successfully transfected the plasmid into the cells, proving the suitability of electrospray for physical targeted delivery and providing a feasible concept of rigid and flexible electrospray instruments for gene therapy in clinical application.

This work was supported by the School of Life Sciences of the University of Applied Sciences and Arts Northwestern Switzerland, the Department for Pulmonary Medicine at University Hospital of Bern and the Scientific Exchange Program NMS.CH.

SP110.3 - Cone-Beam CT-Guided Fluorescence Tomography for Intraoperative 3D Imaging

Author(s): <u>Michael Daly</u>, Nidal Muhanna, Harley Chan, Brian C. Wilson, Jonathon Irish, David Jaffray Princess Margaret Cancer Centre, Toronto/CANADA

A multi-modality intraoperative imaging system has been developed for hybrid cone-beam computed tomography (CBCT) and fluorescence diffuse optical tomography (FDOT). This translational research system is under investigation for clinical applications in head and neck surgery including oral cavity tumour resection, lymph node mapping, and free-flap perforator assessment. The fluorescence imaging system is configured for use with indocyanine green (ICG) using a collimated 760 nm laser diode and a 14-bit near infrared (NIR) camera. Freehand image collection in a non-contact geometry is achieved using a stereoscopic optical camera for real-time localization of the laser source and camera. Intraoperative CBCT images with sub-mm spatial resolution are acquired with a flat-panel C-Arm. FDOT is implemented using a finite element method for diffuse tissue optics (NIRFAST), with structural information from CBCT used directly in the optical reconstruction algorithm using Laplacian-type regularization ("soft priors"). The light rays from the laser source and camera pixels are geometrically projected onto the boundary elements of the tissue mesh using algorithms for ray-triangle intersection and camera lens distortion. Registration errors between real and projected boundary points are <2 mm for typical acquisition geometries. Surface flux is converted from CCD photon counts using free-space radiometry models and camera photon transport calibrations (e.g., filter transmittance, camera quantum gain, sensor noise). Pre-clinical studies using tissue phantoms and small animals are presented to characterize 3D imaging performance as a function of sub-surface fluorophore size, depth, and concentration. Experiments with ICG inclusions embedded in liquid phantoms demonstrate that the use of CBCT spatial priors improves the quantitative performance (<15% error, a reduction of 50% relative to no priors) in the tomographic reconstruction of fluorescence yield at depths <2 cm.

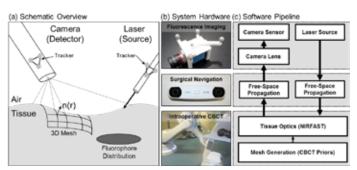

Figure 1. (a) Schematic of a surgical navigation system for CBCTguided fluorescence tomography. Volumetric mesh segmentations are generated from intraoperative CBCT images. Laser source and camera detector positions relative to the tissue surface are obtained in real-time from an optical tracking system. (b) System hardware components include a NIR CCD camera (PCO Pixelfly USB) and lens (Edmund Optics), a stereoscopic optical tracking system (NDI Polaris Vicra), and a flat-panel cone-beam CT C-Arm (Siemens Zeego). (c) Software pipeline for non-contact fluorescence tomography. Registered fluorescence CCD images are used in a finite element diffuse optics model to generate 3D reconstructions of sub-surface fluorescence inclusions (e.g., tumours, lymph nodes, blood vessels) that are fused with intraoperative CBCT.

SP110.4 - An Optimal Motion Profile for a Wireless Endoscopic Capsule Robot

Author(s): Sina Mahmoudzadeh, Hamed Mojallali Faculty Of Engineering, University of Guilan, Rasht/IRAN

Purpose: The inner parts of the GI track such as the small intestine are inaccessible using conventional methods. We propose an optimal model of motion profile for a wireless endoscopic capsule robot (capsubot) for obtaining diagnostic data from the GI track. Critical criteria such as the size and smoothness of the movement of the capsubot are taken into consideration for the optimization process, making it possible to fabricate the capsubot smaller in size, making it easier for the patient to swallow, and causing less discomfort during the procedure.

Methods: The legless capsubot model used in this work mainly consists of two parts: the inner mass and the capsule body which would contain the diagnosing equipment. The inner mass can move back and forth inside the capsule body. By applying a force to the inner mass in the proper direction, the capsule body can be moved forward or backward. An optimization model was developed for the motion of the capsubot which takes into account the limitations on the capsule body, such as shape, length and weight. The optimization model, uses non-linear optimization to minimize the power consumption and maximize the traversing distance given a limited battery source. Finally, a sensitivity analysis was performed to test the robustness of the proposed model to fabrication errors.

Results: The results showed 82% reduction in battery consumption for the movement of the capsubot compared to the other work in the literature, which allows the capsubot to be smaller than those in the literature. The results for simulation of the trajectory and the speed of the capsubot showed a smooth movement of the capsubot without any backward movement. Under the same conditions (same duration and available power for moving the capsubot) the capsubot moved a distance 89% longer than the best result of other work in the literature with the same power consumption. The sensitivity analysis results showed very low variability among the quality of movement of capsubot and distance traversed under small variations in different parameters of the capsubot such as size and length of the capsule body.

Conclusions: The results for the proposed model showed significant improvement in the motion of the capsubot and the required power. Since the dimensions of the battery could be decreased due the reduced required power, the model can be used to fabricate a potentially smaller capsubot. This allows fabrication of a smaller capsubot that could be swallowed more easily by the patient causing less discomfort, or a better use of the capsule space for adding additional features such as drug delivery and biopsy equipment.

SP110.6 - Orthogonal IR System for Instrumental tracking in Minimally Invasive Spine Procedures for training using Wiimote Technology

Author(s): Juana E. Martínez, Daniel Lorias, Arturo Minor Electrónica, CINVESTAV, México, D.F./MEXICO

In this paper we present a system for track the movements of the training instrumental in 3D space, using two infrared Cameras from two Nintendo Wii Remotes in order to evaluate the progress surgeons during the learning phase for making incisions and placement of screws in the spine throw minimally invasive procedures. The cameras are positioned orthogonally, and they detect the position of IR markers that are placed in the training instrumental.

SP110.7 - Use of a Patient-Specific Ventriculostomy Surgical Simulator to Develop a Model for Preoperative Risk Assessment Based on Measures of Anatomical Variation Author(s): Ryan Armstrong, Roy Eagleson, Sandrine De Ribaupierre University of Western Ontario, London/CANADA

Insertion of a ventricular catheter –an external ventricular drain – is a common neurosurgical procedure. Though considered a simple procedure and often performed by residents, catheters are inserted blindly, most often without image guidance, relying on the surgeon's spatial abilities and anatomical landmarking. The relatively high malplacement rates reported by some institutions reflect the difficulty. We used a virtual reality surgical simulator with patient-specific scenarios to examine the anatomical factors that influence user performance. Using objective metrics to quantify user performance and anatomical variations, we developed a model to predict malplacement risk based on measures of anatomical variation.

A diverse set of patient scenarios were created by segmenting the lateral and third ventricles from MR and CT images and incorporating the geometries into a custom ventriculostomy module within the NeuroTouch simulator. The simulator consists of a mannequin head with a pointing tool. Users are tasked to select a burr hole location and indicate the trajectory into the lateral ventricle. Metrics to evaluate user performance were devised to reflect clinical outcome using a single aggregate score. A model was constructed to estimate the difficulty of a given case based on the mean and variance of user performance. To examine the role of anatomical variations, we examined measures thought to influence performance, including ventricle volume, midline shift, Evan's ratio and maximal width of the anterior horn. One neurosurgical expert and seven residents were recruited for a user study and each performed the surgical task of burr hole and trajectory selection a number of times on various cases. We found that anatomical variation in the simulator had a significant impact on user performance. Correlation with performance was seen for all anatomical measures, although the strongest predictors of performance were ventricle volume, midline shift and anterior horn maximal width. By determining the difficulty of each case based on user performance, we were able to produce a model to predict risk of malplacement (based on targeting accuracy) using an optimized weighting of each anatomical variant measure considered.

Results provide the foundation for an objective model to predict surgical risk based on measures of anatomical variation. While image-guidance systems exist for such procedures, they are usually not used as they are often deemed impractical by the bed-side due to immobility and increased setup time. Determining the inherent risk of each case allows us to set guidelines for the use of guidance systems where there is a high chance of malplacement, which often results in complications. Additionally, identifying high-risk cases can help determine when use of simulated rehearsal using patientspecific simulators is an appropriate component of the preoperative process. This knowledge can also aid in the selection of appropriate training scenarios in development of a simulation curriculum. Ultimately, we aim to provide trainees with the knowledge and the tools to guide the preoperative planning process, improving patient outcomes.

SP111 - Cardiovascular

TRACK 12: MEDICAL DEVICES

SP111.1 - Ultrasound-induced heart rate decrease: Role of age in female rats

Author(s): Olivia C. Coiado, William D. O'Brien Jr.

Bioacoustics Research Laboratory - Department Of Electrical And Computer Engineering, University of Illinois at Urbana-Champaign, Urbana/UNITED STATES OF AMERICA

Objective:

Use of ultrasound in therapy has been increasing and new techniques have been developed as, for instance, in cardiac diseases. Animal models for cardiovascular disease support the hypothesis that female sex and/or the sex hormone estrogen may contribute to the sexual dimorphism in the heart and to a better outcome of cardiac diseases in females. Aging is associated with reduced responsiveness of many hormone receptors. The goal was to investigate the age-dependent changes in the cardiac system in female rats exposed to pulsed ultrasound that may benefit therapeutically with heart rhythm abnormalities.

Methods:

Transthoracic ultrasonic exposure experiments were divided into two female Sprague-Dawley rat groups (n=5 ea): Group 1: Five 3-mo-old 200-250-g rats and Group 2: Five 24-mo-old 250-400g rats. The ultrasonic exposure protocol was the same for both groups: 3.5 MHz pulses of 2.0 MPa peak rarefactional pressure amplitude (equivalent to spatial peak intensities of 133 W/cm²), variable pulse repetition frequencies (6, 5, 4, 5, 6 Hz), 10-s each sequence (0.5% duty factor), see Figure. Cardiac conditions were evaluated before (at baseline) and at 3 and 15 min after ultrasonic exposure ceased (3 and 15 min results normalized to each rat's baseline values).

Results:

Group 1: at 3 and 15 min, respectively, the heart rate decreased 12% and 15%, and the cardiac output decreased 16% and 14%. Group 2: at 3 and 15 min, respectively, the heart rate decreased 12% and 15%, and the cardiac output increased 14% and 15%. There was no significant difference between the younger and older rats for the heart rate or for the cardiac output.

Conclusions:

Pulsed ultrasonic exposure caused similar decreases in the heart rate and cardiac output in the two rat-age groups, that is, there were no age-dependent differences in the cardiac system of young and old female rats stimulated by pulsed ultrasound. The results are promising for therapeutic application in cardiology as treatment for heart rhythm abnormalities in women of different ages. This work was supported by NIH R37EB002641.

Basal heart rate acquired immediately before ultrasound initiation (baseline value). 3 min after ultrasound ceased.

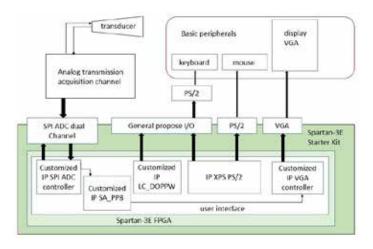

SP111.2 - Low cost pulsed wave Doppler ultrasound system for vascular studies

Author(s): Isabel Arnaiz

Cebio, High Polytechnic Institute "José A. Echeverría", Havana/ CUBA

Recently reports made by World Health Organization establish that vascular diseases are the leading cause of death by non-communicable diseases around the world. In Cuba, it is the second one. Doppler ultrasound technique is the main method for non-invasive high risk vascular diagnosis which convergent to cardiovascular diseases. Nowadays, commercialized Doppler ultrasound systems are expensive and overbroad to more than one technique. As possible solution for Cuba's Health Service, it is designed a spectral Doppler pulsed wave ultrasound system with user interface for visualizing the blood flow profile relative to Doppler shift spectrum. Data visualization occurs by RGB mode with 9 bits color depth, 8 bits for velocity resolution and 7.5 ms of time resolution. The visualization of the sonogram is at 130 frames/s. Digital processing and user interface are implemented on a Xilinx Spartan-3E FPGA. This low cost alternative for diagnosing vascular pathologies on superficial vessels helps to prevent and assist the high number of cases affected by vascular diseases in Cuba.

Keywords- vascular diseases, ultrasound, FPGA, low cost.

SP111.3 - Real-Time Three Degree-of-Freedom Measurement of Catheter Motion for Input to a Robotic Catheter Navigation System

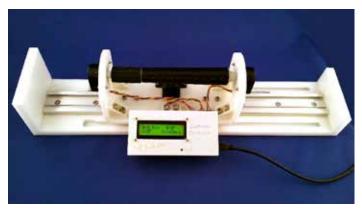

Author(s): <u>Daniel Gelman</u>, Michael K. Lavdas, Maria Drangova Robarts Research Institute, Western University, London/ON/CANADA

BACKGROUND: Commercial robotic catheter navigation systems (RCNS), used for many types of cardiac ablation therapy, enable the interventionalist to remotely manipulate a catheter's position. Typically, the interventionalist operates the robotic systems unnaturally with a provided user interface that is not instinctive, often including a joystick-based controller. Specialized training is required to operate these systems, which may lead to future dependence on this technology. An intuitive solution was previously developed to facilitate translation form conventional to robotic intervention [1]. This device detects axial and rotational changes of a master-side catheter and although inherent to the interventionalist, its use in contemporary RCNSs is limited because modern interventional catheters are steerable, permitting catheter tip deflection. To address this, we have developed a master-side input device that detects motion changes in all three positional degrees-of-freedom.

Methods: The input device enables direct manipulation of an ergonomic master-side catheter handle. A shell of a recycled steerable

catheter handle is rigidly attached to 3D-printed concentric inserts. Incremental optical rotary encoders are coupled to extended shafts of the inserts to detect motion changes in the rotational and tip deflection degrees-of-freedom. The catheter handle assembly is then mounted on a custom linear motion stage whereby a rack and pinion mechanism coupled to another encoder detects axial motion. A dedicated electronic system with a powerful microcontroller provides quadrature encoding and robotic motion scaling to enable higher levels of precision. A wireless module provides position streaming to a slave robot. The design of the input device provides a calculated axial resolution of 13 µm and both rotational and deflection resolution of 0.18°. The accuracy of the input device was evaluated using an optical tracking system. Five 30-second motion profiles were manually imposed on each degree-of-freedom. Position data provided by the embedded system and the tracking system, were then compared for their mean error.

Results: The input device, depicted in the image below, shown to have an absolute mean error in the axial direction to be 0.44 ± 0.33 mm, rotary direction to be $0.41 \pm 0.15^{\circ}$, and tip deflection to be $0.54 \pm 0.43^{\circ}$. The on-board embedded system enables reliable, high-speed data transmission for optimal master-slave robotic control and permits selectable motion scaling.

Conclusion: We have developed and evaluated an instinctive master-side input device that can be used with an RCNS to fully manipulate a slave-side steerable interventional catheter with high precision and dexterity.

SP111.4 - Pulse Wave Velocity as a Function of Cuff Pressure – Extra Information About the Cardiovascular System Author(s): <u>Akos Jobbagy</u>, Peter Nagy

Measurement And Information Systems, Budapest University of Technology and Economics, Budapest/HUNGARY

High blood pressure (BP) is one of the biggest global health risks. Non-invasive methods determine only the momentary value of systolic- and diastolic BP. Knowing arterial rigidity would provide cardiologists with invaluable extra information.

A Home Health Monitoring Device, HHMD, was developed at the Dept. Measurement and Information Systems, Budapest University of Technology and Economics. HHMD inflates and deflates the cuff slowly (6 mmHg/s) and records also ECG and photoplethysmographic signal (PPG) at both index fingertips. Among other parameters the pulse wave transit time, PWTT is calculated. Measured from a healthy senior person, Figure 1 shows a typical PWTT – cuff pressure (CP) curve. Occlusion with the cuff causes temporary alteration in the dynamic properties of the brachial artery. The alteration can be characterized by the change of PWTT. Fig. 1.

The slope of the PWTT – CP curve is characteristic for the cardiovascular system. We determined the CP belonging to the steepest change. During inflation it is denoted by *dup*. PWTT was averaged for 8 s with CP=0 before (PWTTbefore) and after (PWT-Tafter) inflation and deflation. The ratio of the two PWTT values is Δ TRatio=PWTTbefore/PWTTafter.

170 were selected and analyzed from more than 1500 recordings taken from patients who underwent open-chest cardiac surgery and also from young- and senior healthy control persons. The results confirm that the PWTT – CP function provides extra information about the state of the brachial artery. Based on our research we suggest three parameters to quantify this information.

The difference between dup and DBP: For all the three tested group dup correlates with DBP. The difference is smallest for the young healthy group. Values for the senior healthy persons and for the patients are similar.

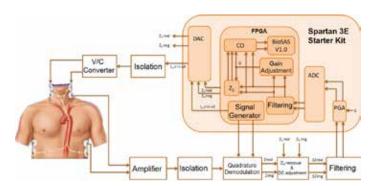

The change of PWTT: In most cases PWTT is greater after than before occlusion, thus ΔT Ratio < 1. It can be interpreted that occlusion temporarily increases the elasticity of the brachial artery. For patients ΔT Ratio can exceed 1. The value of ΔT Ratio is an indicator of arterial rigidity; it correlates neither with SBP nor with DBP.

Slope of increase of PWTT during inflation: There is almost no difference among tested persons regarding the slope of increase of PWTT during inflation when CP exceeds dup. However, there are two patients who sometimes produced much higher values than the maximum of all other tests (6 s/mmHg). This indicates momentary increased rigidity of the arterial wall.

SP111.5 - Cardiac Output estimation through Impedance Cardiography using reconfigurable hardware. Author(s): Leidy M. Alvero González

Bioingeneering Department, High Polytechnic Institute Jose Antonio Echevarría, Havana/CUBA

Impedance Cardiography allows the noninvasive determination of cardiac output quickly and continuously. Cardiac output provides vital information for evaluating and analyzing the hemodynamic information in patients who are in critical medical conditions. A distribution of current-injection electrodes is used to sense changes to pulsed voltage changes that are proportional to the thorax bioimpedance.. The acquired signal combines basal impedance component with dynamic tissue components. It is the resulting product of an amplitude modulation with frequency components located on either side of the frequency component of the injection signal. A quadrature demodulation stage is used for translation to baseband of the signal in order to preserve amplitude and phase information. Digital signal processing is implemented on FPGA, allowing high flexibility during the research process.

SP111.6 - Microfluorimetry System Instrumentation for Ca2+-

Associated Fluorescence Imaging of Cardiomyocytes in Response to High Electric Fields

Author(s): <u>Marcelo Zoccoler</u>¹, Pedro X. Oliveira² ¹Faculty Of Electrical And Computing Engineering, University of Campinas, Campinas/BRAZIL, ²Center of Biomedical Engineering, University of Campinas, Campinas/BRAZIL

The defibrillation is the only effective therapy against ventricular fibrillation. Although a common clinical procedure, this technique also harms healthy cells by means of electroporation, possibly reintroducing arrhythmias. In order to study how myocytes respond to high electric fields (E), scientists commonly use fluorescent dyes in sophisticated and expensive microscopes. These devices produce high quality data, but they are sometimes financially unreachable. We have developed an artisanal microfluorimetry system employing some pieces from deactivated medical equipments. The system proved successful as we could generate quality fluorescence images of isolated adult rat cardiac myocytes loaded with Ca2+associated fluorescent dye Fluo-3 and subjected to monophasic high intensity E. Cells with major axis parallel to E direction were selected. Using regions of interest (ROIs) analysis, we verified that fluorescence variations in ROIs facing the electrodes are bigger and asymmetric, with higher variations at the side towards the anode.

SP111.7 - A practical device to warn on impending syncopal episodes

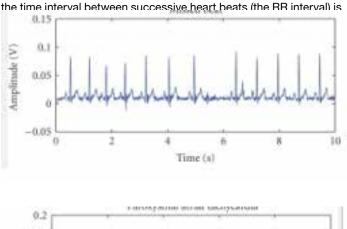

Author(s): Michael Cheng¹, Venkatesh Thiruganasambandamoorthy², Hilmi R. Dajani³, Miodrag Bolic⁴

¹Biomedical Engineer, ottawa/ON/CANADA, ²Emergency Physician, Ottawa Hospital, ottawa/CANADA, ³School Of Electrical Engineering And Computer Science, University of Ottawa, Ottawa/ON/ CANADA, ⁴School Of Electrical Engineering And Computer Science, University of Ottawa, N/CANADA

Syncope (fainting) can lead not only to serious personal injury but also can endanger public health such as when the sufferer is driving a car. An electronic monitoring device can help to minimize syncopal events due to cardiac rhythm changes. This kind of devices will greatly enhance the ability of the patient to take immediate action to safeguard personal and public health.

On the current consumer market, there are numerous heart rate monitoring devices catering for sports use with sophisticated software support; however such devices are not specific to individual patient's needs. On the other hand, ample devices are available to monitor and record various patient data to be analyzed by proprietary clinical software catered for physician use; but such devices are relatively expensive, sold only to physicians, and the data are interpreted "off line" (by the physician).

This paper proposes a simple device to be worn by sufferers of cardiac arrhythmia to provide online (instant) warning signals directly to the wearer on impending fainting. The sufferer could act immediately to stop physical activities, sit, lie down, or stop the car etc. and so help prevent potential injury to the sufferer or to others. The device concept is based on physiological findings that when

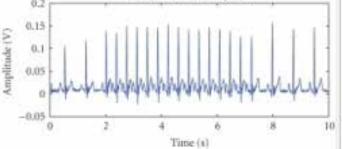

Fig 1 sample ECG strips on cardiac arrhythmia. The interval between consecutive QRS complex is the RR interval

Thus, the device measures each inter-heart beat intervals in real-time; then compare this interval with pre-set values (say 0.4, 2 seconds). If the RR interval is lower or greater than the set values, the device will immediately issue an alarm warning (audio/visual). The person should then stop any activity, sit or lie down to reduce the demand on body blood circulation and avoid a serious syncopal episode.

This device will resemble a watch to be worn on the wrist with electronic sensors. Initially, simple electronic circuitry and software are sufficient. If desired later, more sophisticated, intelligent software algorithm can be incorporated for a variety analyses such as blood pressure changes and types of cardiac arrhythmia.

SP111.8 - Robust Blood Pressure Monitoring in Atrial Fibrillation Patients

Author(s): Saif Ahmad¹, Izmail Batkin¹, Miodrag Bolic¹, Hilmi R. Dajani¹, Voicu Z. Groza¹, <u>Sanjeev Chander²</u> ¹University of Ottawa, Ottawa/CANADA, ²Ottawa Cardiovascular Centre, Ottawa/CANADA

Background Blood pressure (BP) is an important vital sign characterizing cardiovascular health. Therefore, hypertension/hypotension diagnosis and management through accurate monitoring is critical for reducing risk of life-threatening conditions like stroke. Automated non-invasive BP (NIBP) devices are increasingly recommended in clinical practice. However, these devices tend to be unreliable in patients with chronic conditions like atrial fibrillation (AF) and obesity [1] – resulting in inefficient BP management and hence increased risk [2]. Unreliability arises because NIBP monitors estimate BP by analyzing arterial pulses alone and these patients may present weak, erratic, and/or unpredictable arterial pulses. **Method/ Results** Health Parametrics Inc. (HPI), a University of Ottawa spinoff, is investigating novel technology for increasing the accuracy of automatic NIBP estimation. Briefly, we have developed a novel yet simple method for simultaneous acquisition of electrocardiogram

(ECG) and arterial pulse wave data within the automatic NIBP monitoring paradigm [3]. Algorithms analyze arterial pulses with the assistance of ECG data, which tends to be less affected by the above conditions, to improve BP estimation accuracy [4-5]. We recently conducted a pilot clinical investigation in which 13 patients with chronic conditions including AF and obesity were recruited. For each patient, in about 30 minutes, 6 BP measurements taken by our prototype were compared with 6 BP measurements taken by BpTRU, a commonly used clinical NIBP monitor (78 measurements/ device for N=13). The average systolic and diastolic BP measured by our prototype and BpTRU were not significantly different (Studentys t-test, p>0.05). Moreover, standard deviation of systolic and diastolic BP measured by our prototype was lower than that of BpTRU in 10/13 (77%) and 9/13 (69%) of the patients respectively (Figure 1). Conclusion These initial results suggest that our technology has the potential to improve the accuracy and reliability of NIBP estimation in patients with chronic conditions - leading to improved BP monitoring/management and therefore reduced risk. Ahmad et al., "Electrocardiogram-Assisted Blood Pressure Estimation," IEEE Trans. Biomed. Eng., 59, 2012.

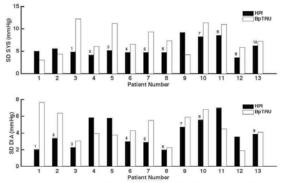

Figure 1: Standard deviation (SD) of systolic pressure (top panel) and diastolic pressure (bottom panel) for each patient as measured by HPI's prototype (black bars) and the BpTRU monitor (white bars). The numbers on top of the black bars indicate the number of patients for whom the SD of BP measured by HPI's prototype was lower than that of BpTRU – 10/13 (77%) patients for systolic and 9/13 (69%) patients for diastolic pressure.

SP112 - Instrumentation

TRACK 12: MEDICAL DEVICES

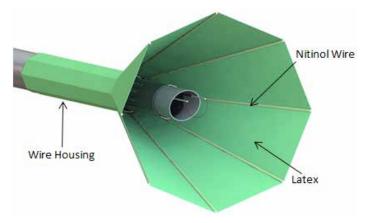

SP112.1 - Adaptation of Surgical Instruments for the Removal of Bladder Tumours

Author(s): <u>Spencer C. Barnes</u>¹, Duncan E.T. Shepherd¹, Daniel M. Espino¹, Richard Viney², Prashant Patel², Richard T. Bryan² ¹Mechanical Engineering, University of Birmingham, Birmingham/ UNITED KINGDOM, ²School Of Cancer Sciences, University of Birmingham, Birmingham/UNITED KINGDOM

Background: Transurethral resection of bladder tumour (TURBT) is the gold standard in non-muscle invasive bladder cancer removal. The tumours are removed piecemeal and this is thought to be a key reason for the high recurrence rate of up to 78% at 5 years.

Aims: A novel device has been designed to facilitate a decrease in this high recurrence rate by creating a sealed environment in which the surgeon can resect a tumour. This device aims to arrest the spread of cancer cells to the rest of the bladder wall.

Methods: Shape memory metal (Nitinol), 3D printing and latex have been used to create an actuating cone which can press against the bladder wall, surrounding the tumour. This design, in the open state, can be seen in figure 1 around a resectoscope, the device currently used for removing bladder tumours. Shape memory alloys (SMAs) such as Nitinol exhibit the property of solid phase change when heated and as such are able to move to a pre-trained shape. Nitinol wires were 'trained' at 550 °C in a steel jig at 30°. These wires were then sequentially placed in a 3D printed housing and soldered together in a series configuration. Subsequently, liquid latex was painted onto the wires using a mould, and allowed to dry. After being initially deformed to a closed state the device was then able to open when heated.

Testing: The device was actuated successfully using a 2.6 ampere 10 volt supply in liquid environments at 37 °C using custom made testing apparatus. Despite the extra heat loss due to the liquid environment the device was still able to open. The ability of the device to seal was also successfully tested with blue dye.

SP112.2 - A compact gantry based on pulse powered magnets for a laser-based proton radiotherapy

Author(s): Leonhard Karsch¹, Thomas Hermannsdörfer², Florian Kroll², Umar Masood¹, Michael Schürer¹, Jörg Pawelke¹ ¹TU Dresden - OncoRay, Dresden/GERMANY, ²Helmholtz-Zentrum Dresden - Rossendorf, Dresden/GERMANY

Purpose: The new approach of particle acceleration by high intensity lasers may provide size and cost reduction for proton facilities. However, laser-driven proton beams are characterized by intense and short (few picoseconds) pulses with low repetition rates, high energy spread and large beam divergence. In addition to more compact accelerators due to the short acceleration length of few micrometers, also more compact beam transport systems are possible. The beam pulse structure enables more compact gantries by the use of pulse powered magnets without iron core, but much higher magnetic field strengths. Using pulsed magnets, the magnetic field is only generated for a short time period but still sufficient long for the transport of a proton pulse.

Method: First, a gantry was designed regarding laser accelerator specific requirements like a proton capturing element and an energy selection system. Secondly, prototypes for every type of pulsed magnets necessary for the gantry - solenoid, dipole and quadrupole - were designed and realized. Thirdly, these prototypes were experimentally characterized at a pulsed 10 MeV proton beam of a tandem accelerator. This beam is well defined in energy and intensity, the pulse duration is arbitrary adjustable down to 1 microsecond which is still longer than the pulse duration of laser driven beams. Therefore, it allows to test the ion optical behavior at low electrical risks, i.e. at reduced magnet current.

Result: A gantry for laser driven proton therapy was designed being much smaller than existing devices. A radius of 2.5 m and a length of 3 m is achieved by deploying high magnetic fields of up to 40 T inside the solenoid, up to 10 T inside the dipole and a magnetic field gradient of up to 300 T/m in the quadrupole. The achieved magnetic pulse durations with these prototypes are approximately 1 ms. The duration during which the field is constant is about 100 microseconds. Each of the individual magnets, as well as their combination to a pulsed beamline, show the expected ion optical properties like focussing and bending.

Outlook: After an adaption of the setup, further experiments at clinical relevant proton beam energies (up to 230 MeV) will follow. For this purpose, the proton beam from the conventional cyclotron at a facility in Dresden recently put into patient treatment, has been adapted to deliver pulsed beams to an experimental bunker. The work is supported by the german government BMBF (no. 03Z1N511).

SP112.3 - Developing a pH Responsive Mesh as a Smart Skin Wafer in Ostomy Appliances

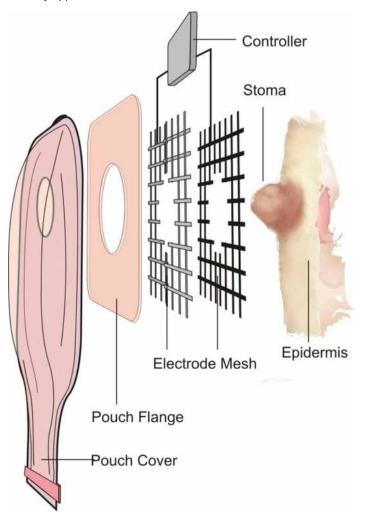

Author(s): Anna Mclister, James Davis

Nibec - Computing & Engineering, Ulster University, Newtownabbey/UNITED KINGDOM

Despite notable advancements in the management and treatment of ostomies over the past number of years, one problem still persists; peristomal skin complications (PSCs). The erosion of the skin directly underneath the skin wafer as a consequence of exposure to stoma fluid can lead to debilitating irritation and ulceration and is one of the most common post surgical complications. In the US alone, it is estimated that over one million patients deal with the routine of ostomy care, the majority of which will have, at some point, suffered from a PSC. Despite requisite pre and post-operative education for new patients, PSCs continue to be a perennial issue with incident rates ranging from 10-70%.

The present communication outlines progress towards the design of a smart wafer system that can actively monitor the skin condition

and respond accordingly to minimize the onset of irritation dermatitis. A conductive, mechanically flexible mesh incorporating poly-Ltryptophan is detailed and its modification to yield a pH sensitive diagnostic layer is outlined. The system has been characterized and its potential integration and application in stoma appliances is critically appraised.

SP112.4 - Development of a smart needle integrated with a micro-structured impedance sensor for the detection of breast cancer

Author(s): <u>Niall T.P. Savage</u>¹, Brian D. O'Donnell², Martin J. O'Sullivan³, Eric J. Moore¹

¹Life Science Interface, Tyndall National Institute, Cork/IRE-LAND, ²Department Of Anesthesia, Cork University Hospital, Cork/ IRELAND, ³Department Of Surgery, Cork University Hospital, Cork/ IRELAND

The aim of this research is to develop a novel medical device for the detection of breast cancer within the clinical setting. Breast cancer is the second most common cancer in women worldwide and the use of population-based screening programmes has increased the demand for more sensitive and specific detection tools to limit the number of patients being misdiagnosed or over-treated. This research will focus on the development of a minimally invasive diagnostic probe for the determination and localisation of cancerous tissue within the structure of the breast. Gold microelectrodes fabricated on a silicon substrate were developed in Tyndall National Institute and used to obtain electrical impedance recordings from *ex vivo* tissue samples of both animal and human origin. Functional prototype devices have been produced using both photolithogra-

phy and metal deposition processes to pattern the dual-electrode structures. The probes have been characterised using a series of techniques including CV and EIS. The prototype probes have been shown to be reproducibly manufactured and the electrochemical response of the electrodes has been very positive to date. A study of the electrical impedance response of animal tissues (beef, lamb and pork) has shown that a variety of tissues (fat, muscle and liver) can be discriminated using the prototype gold electrodes for the detection of discrete electrical responses. There are a number of potential uses for this device including improved biopsy localisation, cancer-free border determination during lumpectomy and the possibility of DCIS determination without invasive surgery. It is envisaged that this novel device would be used primarily as an adjunct to the gold-standard of x-ray mammography detection of breast cancer tumours during the routine screening process.

SP112.5 - Towards development of a wearable, miniaturized, bioartificial lung

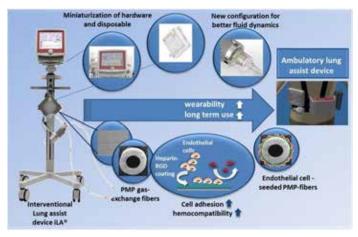

Author(s): Esther C. Novosel¹, Joerg Schneider², Fabian Metzger², Annika Wenz³, Kirsten Borchers³, Markus Schandar³, Petra Kluger³, Brigitte Vollmar⁴, Peter Lelkes⁵, Georg Matheis² ¹Business Development, Novalung GmbH, Heilbronn/GER-MANY, ²Novalung GmbH, Heilbronn/GERMANY, ³Cell Systems, Fraunhofer IGB, Stuttgart/GERMANY, ⁴Experimental Surgery, University of Rostock, Rostock/GERMANY, ⁵Bioengineering, Temple University, Philadelphia/PA/UNITED STATES OF AMERICA

Introduction

Chronic obstructive pulmonary disease is the 4th leading cause of death worldwide. Extracorporal lung assist devices that promote oxygenation and /or CO2 removal, like the Novalung interventional lung assist device (iLA®), can improve lung protection and increase quality of life [1]. As a drawback these systems limit patient mobility. In addition, longterm use is frequently accompanied by thromboembolic complications and device fouling due to inappropriate material characteristics of the blood contacting surfaces. Our goal is to develop the first wearable miniaturized lung assist device with improved surface properties [2].

Methods

We developed prototypes of new miniaturized hard- and software components, as well as a suitable carrying system. We also designed a new, diposable gasexchange unit with optimized geometry to minimize hemolysis and thrombogenicity. Hemolysis and gas exchange performance tests were carried out in vitro and validated in a porcine model.

```
Fig1: transformation of the iLA® to a longterm ambulatory lung assist device.
```

To improve the hemocomaptiblity of the gas exchange material Polymethlypentene (PMP), we seeded human dermal endothelial cells onto PMP hollow fibers, either coated with heparin/albumin, or covalently functionalized with heparin/RGD. Seeding efficiency and cell coverage were analyzed microscopally using live/dead stainging and staining for van Willebrand factor.

Results

We successfully miniaturized all hardware components and developed a new design of the gas exchanger to improve blood distribution, while maintaining adequate gas exchange *in vitro* and *in vivo*. Following seeding of stacked PMP fiber mats, the endothelial cells formed a confluent monolayer on the fibers, which was preferentially retained for 5 days on the heparin/RGD coated fibers under both static and dynamic *in vitro* testing conditions in a new bioreactor system.

Conclusion

We successfully designed and implemented a miniaturized wearable lung assist device, which is currently being tested in a porcine model. Importantly the gas exchange property of the miniaturized device are adequate to provide significant respiratory support. Future studies will test these devices in a first in man trial.

SP112.6 - Development of a Low Cost Spectrometer for Studies of Diffuse Reflectance with Dermatological Science and Applications

Author(s): <u>Gerardo S. Romo-Cardenas</u>, Sydney Dominguez-Dominguez, Rusbel Dominguez-Dominguez

School Of Engineering, Montemorelos University, Montemorelos/ MEXICO

From an optical perspective, skin with all its layers and surfaces are made from different tissues that have different or unique pattern of reflectance, which could help to differentiate normal or healthy tissues from those with a presence of any type of injury or pathology. The application of optical tool for the characterization of bio- tissues have gained importance due to its noninvasive nature.

In this work it is proposed to conduct a study to develop an inexpensive spectrometer and a light source of broad spectrum; as well as the protocol that would allow the exploration of diffuse reflectance of colloids with the intention of develop a tool that could be used to identify any type of pathology. In this paper, the preliminary results of the study, involving the development of the light source, a low-cost spectrometer and the measurement and analysis protocol to explore the feasibility of implementation in areas of biomedical science areas are discussed.

Beside the development of the system, agar and dyed gelatin tis-

sue phantoms were used in order to study the performance of the system.

Results show a good consistency in the performance of the developed spectrometer, in its capability to acquire the diffuse reflectance from the tissue samples. As well, as in accordance to the irradiated wavelength and the amount of dispersion induced in the tissue phantom. Still, results cannot be conclusive in order to determine significate differences that could lead to the application of this technology in health applications, it is expected to obtain a better specificity with future work.

SP112.7 - Correctness of bioimpedance data for body composition obtained by BIA approach in various external conditions Author(s): Jan Hlubik¹, Lenka Lhotská¹, Jan Kříž²

¹Cybernetics, Czech Technical University, Prague/CZECH RE-PUBLIC, ²Department Of Physics, Faculty of Science University of Hradec Kralove, Hradec Kralove/CZECH REPUBLIC

This paper presents our ongoing research in a field of body composition obtained by body impedance analysis. In this work we were focused on changes in bioimpedance in dependence on change of measurement external conditions. This paper also deals with question if data obtained from this method are enough informative with ought any information about the performed measurement. We discovered that it is crucial to have information about the whole measurement procedure and that operator that is performing such measurement should know exact type of device that is used for measurements. Influence of specific conditions did not statistically changed results of calculated values. However in directly measured values resistance and reactance at high frequencies (250 kHz and 500 kHz) were found statistically significant changes (P=0,05) for highly conductive gel. Overall was concluded that external conditions that can be normally encountered at laboratories do not have effect on obtained values. However it is important to know which device was used so the set of used equations are comparable.

SP113 - Information Technologies in Healthcare Delivery and Management: Part 1

TRACK 14: INFORMATION TECHNOLOGIES IN HEALTHCARE DELIVERY AND MANAGEMENT

SP113.1 - Technologies for Patient Self-Care of Chronic Illness: Development and Evidence.

Author(s): Joseph A. Cafazzo

Centre For Global Ehealth Innovation, University Health Network, Toronto/CANADA

The global plight of chronic illness has affected healthcare systems around the world. The delivery of care for those who need it most is not sustainable without a re-evaluation of enabling patients and their informal caregivers with the ability to perform self-care. Technological innovation in this area is showing great promise with the advent of mobile devices and wearables, but is not without the challenges of design, implementation, and a lack of clinical evidence. The keynote will outline addressing these challenges and the emerging evidence that shows the untapped potential of patients when given the opportunity for self-care facilitated through technology.

SP113.2 - A mobile monitoring tool for the automatic activity recognition and its application for Parkinson's disease rehabilitation

Author(s): Jorge Cancela, Matteo Pastorino, Eugenio Moreno, Maria T. Arredondo Waldmeyer

Life Supporting Technologies, Universidad Politecnica de Madrid, Madrid/SPAIN

In order to perform a continuous monitoring of patients in their daily lives, it is the need to contextualize the collected data coming from the patients. In this sense, the identification of the Activities of the Daily Life (ADL) carried out by the subjects is essential to understand and to put in context other data linked to the monitoring disease itself. This work was aimed at using the accelerometers integrated in most of the current available smartphones to build an automatic activity recognizer based on the signal coming from this sort of sensors. The validation carried out showed the impact of the frequency sampling in the classifier performance as well as the impact in the battery usage. Finally, it suggested that the use of one second as sampling period is a fair trade-off between accuracy in the classification and power saving.

SP113.3 - My Patient: An Electronic Patient Information Management System

Author(s): <u>Satish Jaywant</u>¹, Qaiser Muhammad² ¹Uhn International Program, Princess Margaret Cancer Center/ University Health Network, Kuwait City/KUWAIT, ²University Health Network, Toronto,Canada, Kuwait/KUWAIT

Princess Margaret Cancer Center/University Health Network (UHN), Toronto, was approached to improve cancer services over a period of five years at the Kuwait Cancer Control Center (KCCC), Kuwait. As an integral component of this project, a computerized appointment scheduling system was implemented to reduce patient wait times, improve patient satisfaction and efficiency. It also provided an opportunity for data collection, tracking and management of resources. For this purpose, an electronic patient management system called "My Patient" was developed that will allow users to become familiar with the basic steps and processes of creating, accessing and updating patient records. UHN Kuwait Information Management/Information Technology teams performed the gap analysis and requirements for the KCCC outpatient department workflows. It then worked closely with KCCC clinicians to finalize the clinical engagement, project governance and implementation plan. An in-house outpatient department scheduling module for KCCC was built. The pilot was launched May 2014 for 2 months in the gastro-intestinal site and has now been implemented for Radiation Oncology.

The tasks and functions in My Patient cover four distinct areas: *Registration*: Staff within the Medical Records Department has access to register patients, create new patient files and modify patient demographic information. Other users must contact Medical Records to have these functions performed.

Scheduling: This functionality is available within the outpatient departments to staff with appointment booking access. Any other My Patient users can only view schedules whereas booking, updating and cancelling appointments is limited to scheduling users only. *Laboratory Ordering*: The cytology laboratory staff has access to the laboratory management tool for laboratory order entry, specimen number generation and specimen label printing.

Administrative: The supervisory staff within each department has administrative access to correct entry errors within their department.

Various safety and patient confidentiality features are in place in this tool. As an example, every staff member accessing My Patient for clinical or administrative purposes has a unique user name and password.

This presentation highlights the application of My Patient to Radiation Oncology.

SP113.4 - Hom-e-call – An enhanced fall detection system based on accelerometer and optical sensors applicable in domestic environment

Author(s): Daniel Wohlrab¹, Markus Heß², André Apitzsch², Mandy Langklotz³, Andreas Schwarzenberger¹, Sebastian Bilda², Henry Schulz³, Gangolf Hirtz², Jan Mehner¹

¹Professorship Of Microsystems And Biomedical Engineering, Technische Universität Chemnitz, Chemnitz/GERMANY, ²Professorship Of Digital Signal Processing And Circuit Technology, Technische Universität Chemnitz, Chemnitz/GERMANY, ³Professorship Of Sport Medicine And Sport Biology, Technische Universität Chemnitz, Chemnitz/GERMANY

A reliable detection of falls is an important challenge for applications of ambient assisted living. Especially for elderly people living autonomously at their home, such a system would help to treat possible injuries faster. Most of the currently used systems are only based on the analysis of the movement data recorded by a wearable device. In this study an automatic fall detection system is developed that can be installed in domestic environment. Based on an accelerometer fixed to the body and optical sensors mounted on the wall, the fusion unit analyses the actual posture of the patient and detects fall events. By means of simulated fall scenarios performed by young athletes, the overall system performance is tested. To identify the false alarm rate of the fall detection system elderly people have performed activities of daily living in a furnished test flat. The combined system approach can be used to improve conventional fall detection algorithms. SP113.5 - An Algorithm Based on Voice Description of Meal for Insulin Dose Calculation to Compensate Food Intake Author(s): <u>Piotr Foltynski</u>¹, Piotr Ladyzynski¹, Ewa Pankowska², Karolina Mazurczak², Karolina Migalska-Musial¹ ¹Nalecz Institute of Biocybernetics and Biomedical Engineering, Polish Academy of Sciences, Warsaw/POLAND, ²Department of Pediatrics, The Institute of Mother and Child, Warsaw/POLAND

Diabetes may lead to serious complications when blood glucose levels are not maintained in save ranges. Proper insulin dosing is crucial in good metabolic control, however it is not easy for all patients. There are some computer applications supporting insulin bolus calculation based on the meal composition, but they may be difficult to use for some patients. Our team decided to developed a voice-driven system helping patients in calculation of the proper insulin dose for food intake compensation. The system consists of several software applications (on smartphone and MS Windows server) working with developed language dictionaries and with nutrient database. The speech recognition software was trained with sets of words from meal descriptions. The algorithm for transition from the text description is based on language dictionaries with variety of food item descriptions related to one product in nutrient database. The system calculates the number of insulin units for patients using insulin pen or delivery time and number of insulin units for patients with insulin pump. The algorithm for insulin dosage works not only on the basis of the amount of carbohydrates, but also takes into consideration protein and fat content in the meal. The system was successfully tested on the group of 34 subjects achieving 92.3% of correctly recognized food descriptions in the first try. The overall percentage of fails in recognition was 1.5%.

SP113.6 - Building neuroscientific evidence and best practices in active and healthy aging

Author(s): <u>Panagiotis D. Bamidis</u> Medicine, Lab Of Medical Physics, Aristotle University of Thessaloniki, Thessaloniki/GREECE

Supporting the elderly by means of technology has recently taken the form of monitoring the elderly in an unobtrusive way. The latter is linked with the task of installing various devices inside the home as well as requesting the elders to wear specific garments (e.g. watches, bracelets etc) or being trained by means of cognitive and physical exercise games (serious gaming; exergaming). The latter forms a contemporary trend within the field of Active and Healthy Aging (AHA). Serious games for elderly healthcare provide a promising and novel way to promote the well-being of senior citizens. However, to fully understand the underlying mechanisms as well as to accumulate scientific evidence for such approaches, we argue that one needs carefully designed neuroscientific experiments, along the usual batteries of neuropsychological tests and subjective measures like quality of life questionnaires.

In the past 6 years we have been using a comprehensive protocol of EEG recordings pre- and post any game enriched intervention. This allows for a much stronger analysis of the effects but also a deeper understanding of the underlying neuroplasticity mechanisms. In this paper, we demonstrate how functional neuroimaging analysis of these dense EEG measurements can reveal brain sources/ areas responsible for the de-noising of the elderly brain after the intervention. What is more, functional connectivity network analysis can reveal a reorganisation of the default mode network due to combined physical and cognitive training. Our results refer to a wide pilot deployment involving more than 150 senior subjects over an intensive training protocol of 2 months.

Besides this, recent emergence of motion capture technology has enabled acceptable unobtrusiveness as well as other features of making the game challenging and seniors being motivated. A key step towards this direction would require using emotional queues in the midst of the game-flow and within the gaming environment, so as to allow for suitable embodiment of real-time mental (cognitive and emotional), and physical data. To properly study the above, one needs ecologically valid but yet controlled set-up, in the form of home-like environments. We have designed and implemented such an Active and Healthy Aging Living Lab/e-home within our Assistive Technologies and Silver Science Lab to facilitate such simulation as well as experiments and recordings with real elderly users. A vast amount of "daily-living" data is therefore created. These are then analysed with intelligent methods enabling early symptom identification and allowing decision support for early disease diagnosis. Emphasis is given on interlinking robust scientific methods and tools of studying emotions, as well as, age-related cognitive decline within the gaming environment and in-game metrics.

SP113.7 - Intelligent System for Identification of patients in Healthcare

Author(s): Alexandra Vasquez¹, Monica Huerta¹, Roger Clotet¹, Ricardo Gonzalez¹, <u>Giovanni Sagbay²</u>, David Rivas³, Jose Pirrone Puma⁴

¹Networks And Applied Telematics Group, Universidad Simon Bolivar, Caracas/VENEZUELA, ²Electrónica, Universidad Politécnica Salesiana, cuenca/ECUADOR, ³Electronic, Universidad de las Fuerzas Armadas, Latacunga/ECUADOR, ⁴Esc. Ingenieria En Telecomunicaciones, Universidad Catolica Andres Bello (UCAB), Caracas/ VENEZUELA

The Inadequate identification of patients in health care centers remains as a common problem that has brought incidents and adverse event to this kind of facilities. This work present a system design to deal with this situation. To develop this proposal different identification systems and patient monitoring systems in health centers was studied, and a comparative study was conducted between existing technologies to develop this proposal. The NFC technology was chosen to develop a system solution because of its availability in mobile phones, its feature of information security, speed, low cost and simplicity in data exchange. Confidentiality of the patient information is guaranteed through authentication profiles for system access and data security through SSL and HTTPS protocols. The purpose of the proposed system is to provide correct information transfer, keeping track on patients and facilitate control of them by the health care center staff, in order to minimize accidents and mistakes of identification and to improve the healthcare facilities' quality.

SP114 - Dosimetry and Radiation Protection

PRESIDENTS CALL

SP114.1 - Development of Object Simulator for Evaluation Periapical Radiographs

Author(s): Jadna M.S. Mendes¹, Elias S. Sales Junior², Cinthia M.M. Paschoal³, Cledison J. Cunha⁴, Lourdes M. Brasil⁵, <u>Fernanda C.L.</u> <u>Ferreira¹</u>

¹Federal University of South and Southeast of Pará,, Marabá/BRA-ZIL, ²Phsysics, Federal University of South and Southeast of Pará, Maraba/BRAZIL, ³Civil Engineering, State University of Vale do Acarau, Sobral/BRAZIL, ⁴Phsysics, Federal University of Sergipe, São Cristovão/BRAZIL, ⁵University of Brasilia, Brasília/BRAZIL

This study aimed to develop a dental phantom with cysts for evaluation of periapical radiographs that was tested in private dental offices in the city of Maraba, northern Brazil. Through some tests with the object simulator (phantom) were obtained 12 periapical radiographs (one in each of the offices visited) that waking up to the standards of Ordinance Nº. 453 were visually evaluated by observing the physical parameters of exposure (kVp and mA), time revelation of the radiographic film, later the other radiographs were visually compared with C6 ray set as the default. Among the results, it was found that only two of the twelve rays cysts could not be viewed and, therefore, these two images were deemed unsuitable for accurate diagnosis in the 10 images the cysts could be displayed. however according the images have different qualities comparisons. In addition, it can be concluded that the performance of the phantom was highly satisfactory showing to be efficient for use in quality control testing of dental X-rays, the quality control of radiographs and continuing education of dental professionals for a price much more accessible.

SP114.2 - Impact Created by Medical Physicist from Regulatory Quality Assurance Controls in Developing Country Author(a): Samba Diabard Ndii, Simo Augustia?

Author(s): <u>Samba Richard Ndi</u>¹, Simo Augustin² ¹Control And Inspection, National Radiation Protection Agency, Yaounde/CAMEROON, ²Directorat General, National Radiation Protection Agency, Yaounde/CAMEROON

Background: The use of lonizing Radiation in medicine has been increasing rapidly over the years in Countries in general and Cameroon in particular. Individual occupational exposure and patient safety varies widely among those involved in medical care. There are certain medical procedures that might give substantial doses to medical staff, normal tissues of patients and the education of medical professionals in radiation protection and quality control issues are continuing problems. Regulatory bodies are mandated through laws and regulations to regulate all ionizing radiation sources as well as the protection of people and environment against ionizing radiation to hazards.

Objectives: Improvement of regulatory framework by Medical Physics Quality Assurance Controls.

Methodology: National Radiation Protection Agency (NRPA) of Cameroon activities started with inventory program in 2009, which was completed in July 2010. Over 500 occupationally exposed workers were recorded with about 12 % being monitored 5% of quality assurance undertaken. There was no national dosimetry service provider, all were monitored from abroad. Regulatory Technical control started in 2011. A medical physicist was employed by NRPA in 2010 to coordinate Quality Control and dosimetry activities as regulatory aspect. There were a lot of discrepancies recorded at the level of occupational monitoring and state of equipment to produce quality images. NRPA acquired dosimetric monitoring and quality control kits in 2010 and 2011 respectively. These are widely used in quality control, radiation protection and safety, offer a number of potential advantages for medical applications (diagnostic and radiation therapy).

Results:As of 2014, remarkable improvement has been noticed in the dose reduction of workers, patients and the quality of the machines used in then controlled medical facilities. In this, the results of occupational exposure from 2011 to 2014 is shown and the results of the quality control executed from 2011 and 2014 compared are illustrated in tables.

Recommendation: Recommendations are ditched out to competent authorities at various levels for the continuous improvement of quality assurance programme and occupational monitoring to safeguards radiation protection/safety culture.

Conclusions:Radiation Principles are being applied by using national and international standards for the benefits of both patients and workers in radiological practices. This can never be sustainable without the creation of the awareness of Medical Physicist policy and roles in developing countries.

SP114.3 - Evaluation of Dental X-rays equipment in Sobral-CE, Brazil

Author(s): F L. Meneses¹, <u>Fernanda C.L. Ferreira</u>², Cinthia M.M. Paschoal¹

¹Civil Engineering, State University of Vale do Acarau, Sobral/BRA-ZIL, ²Federal University of South and Southeast of Pará,, Marabá/ BRAZIL

The ionizing radiation has important application in dental diagnosis. In Brazil, the National Ordinance No. 453/1998 of the Ministry of Health regulates the operation of medical and odontological diagnostic radiology services. However, the inspection of periapical dental X-ray equipment is not carried out by some Sanitary Surveillances. This study intended to determine the suitability to the ordinance of the dental offices of Sobral-CE, Northeast of Brazil, and to compare the results with literature data for other cities of Brazil. It was performed tests of radiation field and image guality, and it was applied questionnaires to the professionals. For the image guality test, it was used a dental phantom and the processing of the films was performed in the clinics and at the laboratory (standard). The questionnaire assessed physical parameters that interfere on the radiation protection and on the quality of images. The results show that the ordinance is not being properly followed and that it is necessary to inspect the periapical X-ray equipments. Moreover, in general, it is observed that dental professionals should have better training on ionizing radiation and on radiation protection.

SP114.4 - Effect of static magnetic field exposure on human blood electrolyte levels in vitro

Author(s): <u>Pankaj Parashar</u>¹, Kishore K. Deepak², Sneh Anand³, Ashok K. Mukhopadhyay⁴, Sudip K. Datta⁴, Jitendar K. Sharma⁵, Jyoti Kumar⁶, Raoji S. Shinde⁷, Mithilesh K. Pal⁸, Prabhat Arora⁵ ¹Centre For Biomedical Engineering, Indian Institute of Technology Delhi, New Delhi/INDIA, ²Physiology, All India Institute of Medical Sciences Delhi, New Delhi/INDIA, ³Centre For Biomedical Engineering, Indian Institute of Technology, New Delhi/INDIA, ⁴Laboratory Medicine, All India Institute of Medical Sciences Delhi, New Delhi/ INDIA, ⁵Healthcare Technology Division, and WHO Collaborating Center, National Health Systems Resource Center, Ministry of Health and Family Welfare, Government of India, New Delhi/IN-DIA, ⁶Instrument Design And Development Centre, Indian Institute of Technology, New Delhi/INDIA, ⁷Accelerator Magnes Technology Division, Raja Ramanna Center for Advanced Technology, Indore/ INDIA, ⁸Biomedical Engineering Unit, All India Institute of Medical Sciences Delhi, New Delhi/INDIA

This proposed paper presents a study of effect of strong static magnetic field (SMF) exposure on electrolytes in human blood in-vitro. There have been major concerns of safety from magnetic fields (static and dynamic magnetic fields) to life and their effects on physiology. It is noteworthy that magnetic fields are listed as 'Potentially carcinogenic' by W.H.O. There are evidences of SMF causing special sensations in humans and animals like bizarre behavior and magnetophosphenes, these are probably attributed to cell membrane property changes.

Magnetic therapy is a treatment modality being used since ages, the claimed mechanism of action being the presence of iron in the blood and the alteration in blood viscosity, which is mostly doubted by the modern science.

Here, the effect of SMF exposure on blood electrolytes was studied. A Case - Control study was carried out, collecting blood samples from healthy young volunteers. The samples were divided into 6 equal parts in 3 pairs of Case and Control, and exposed in vitro for 20 minutes to SMF strengths of 500 Gauss (G), 5000 Gauss and 1 Tesla respectively one after the other. Here case sample was exposed to 500G SMF generated by a coil electromagnet between 2 soft iron cores and the control samples shielded by placing in an iron box. After 20 minutes of exposure and shielding, both samples were estimated for electrolytes: K⁺, Ca⁺⁺ (ionic), Na⁺, Cl⁻ and pH by indirect Ion Selective Electrodes method on a Combiline [®] blood gas analyzer machine. The process was repeated for the other pairs of samples with cases on 5000G and 1 Tesla (1 Tesla = 10000 Gauss) SMF one after the other and shielding controls to match the effects of the time lapse. The data acquired was analyzed by applying paired T test on the case and control samples for each ion parameter at each SMF strengths exposed, the P value was taken to be significant at p<0.05. Here, no statistically significant changes in the ionic concentrations of the case and control samples were found. The results indicate that the SMF of 500 Gauss, 5000 Gauss and 1 Tesla did not result in any significant change in the electrolyte concentration in the samples, possibly inferring to no significant change in leakiness of the red blood cell (RBC) membrane

This study suggests that very strong SMF of up to 1 Tesla, as used in this experiment, do not affect the electrolytes and possibly the leakiness of the RBC membrane in vitro. In this study it was also found that the SMF of around 500 Gauss, the strength of the magneto-therapy magnets also did not show any change in electrolyte concentration, hence no change in membrane leakiness of the RBCs. This study, hence points towards the safety of the magnetic field exposure on the red blood cell membrane leakiness.

SP115 - CT Image Quality and Dose Optimization

TRACK 01: IMAGING

SP115.1 - Towards Image Quality Analysis of Small and Full Field of View Dental Cone Beam CT Systems

Author(s): Elias Cantarelli Hoffmann¹, <u>Ana Maria Marques Da Silva</u>², Dario F.G. Azevedo³

¹Núcleo De Pesquisa Em Imagens Médicas, PUCRS, Porto Alegre/ BRAZIL, ²Faculdade De Física, PUCRS, PORTO ALEGRE/BRA-ZIL, ³Faculdade De Engenharia, PUCRS, PORTO ALEGRE/BRAZIL

Cone-beam CT (CBCT) systems have been used for dentomaxillofacial surgery applications. Different dental CBCT devices are being developed and released, with a wide variability of exposure parameters and fields of view. Although they have sufficient diagnostic quality, a quantitative analysis of image quality and radiation dose is required to enable their optimal use. The aim of this study was to develop and implement a feasible methodology for image quality analysis for different dental CBCT devices. The methodology was based on conventional CT quality control procedures and adapted to overcome the limitations of dental CBCT. A prototype phantom was specially designed to allow the acquisition of image guality parameters relevant to dental imaging. Equipments were divided into categories, related to their field of view: Small Field of View (SFOV) and Full Field of View (FFOV). The following image quality parameters were evaluated: uniformity, noise, contrast-to-noise ratio, CT number accuracy, artifacts, spatial resolution and geometric distortion. Applicability of the methodology was assessed using one SFOV and four FFOV CBCT devices. Results from preliminary analyses of the prototype phantom showed its potential for routine quality assurance on dental CBCT. Large differences in image quality performance were seen between the devices.

SP115.2 - Rapid non-invasive spatially varying HVL measurements for CT sources

Author(s): <u>Matthew Randazzo</u>, Mauro Tambasco Physics, San Diego State, San Diego/CA/UNITED STATES OF AMERICA

Purpose: A method is presented generate spatially varying half value layers (HVLs) that can be used to construct of computed to-mography (CT) x-ray source models for CT dose computations.

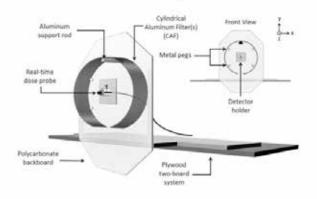

Methods: To measure the spatially varying HVLs, we combined a cylindrical HVL measurement technique with the characterization of bowtie filter relative attenuation (COBRA) geometry. An apparatus (HVL-Jig) was fabricated to position a real-time dosimeter off-iso-center while surrounded by concentric cylindrical aluminum filters (CAFs). Data was acquired using axial CT protocols filters to inves-tigate the energies of 80, 100, and 120 kVp on a single CT scanner (GE Optima CT580). In this geometry, each projection of the rotating x-ray tube is filtered by an identical amount of high-purity aluminum while the stationary detector records an air kerma rate versus time waveform. The CAFs were progressively nested to acquire exposure data at increasing filtrations to calculate the HVL. Using dose waveforms and scanner geometry, each timestamp was related to its corresponding fan angle. These measurements were validated against the more laborious conventional step-and-shoot approach.

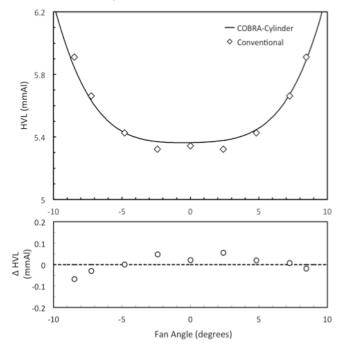

Results: At each energy, HVL data from the COBRA-cylinder technique was fit to a trendline and compared with the conventional approach. The average relative difference in HVL between the two

techniques was 1.3%. A systematic overestimation in HVL was observed due to scatter contamination, but by applying a 1% downward shift to all measurements, all differences lie within a 0.2 mm Al threshold needed to generate spectra for accurate Monte Carlo CT dose computations.

Conclusion: The rapid, accurate, and non-invasive approach described allows one to acquire the spatially varying fluence and HVL data using a single experimental setup and three scans. These measurements can be used to characterize the CT beam fluence and energy spectra along the BT filter direction, which can serve as input for CT dose computations.

80 kVp Off-Axis HVL Measurements

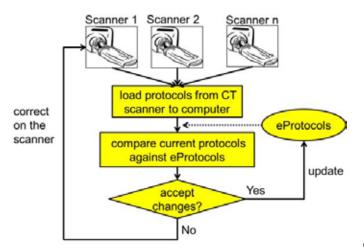

SP115.3 - Development of a CT protocol management system for automated review of CT scanner protocols Author(s): Josh Grimes, Shuai Leng, Yi Zhang, Cynthia Mccollough Mavo Clinic. Rochester/MN/UNITED STATES OF AMERICA

Protocol review is mandatory in some states and for ACR CT accreditation. The benefits of protocol review include a decreased risk of patient injury and increased consistency in CT image quality. There can be many CT protocols loaded on a scanner and continual protocol customization and optimization can make manual review of these protocols labor intensive, error prone and costly. The objective of this work was to develop software for automatic protocol review to help ensure the accuracy of protocols loaded on CT scanners.

The protocol management software was developed in MATLAB. The general workflow of the software is as follows. First, protocol files are copied from the CT scanner. Next, the scanner protocol files are compared to the corresponding eProtocols, which are the set of instructions that the technologists at our institution follow for CT examinations. All CT scanners of a given model are compared simultaneously with the eProtocols for that particular scanner type. Differences between the scanner protocol files and the eProtocols are flagged and this comparison is summarized in an excel spreadsheet. A lead technologist reviews the spreadsheet and decides whether the flagged protocol parameters are correct in the eProtocols or on the scanner. A list of these decisions is automatically created. Using this list, the technologist must update the eProtocol or correct the protocol on the scanner.

The software can be configured to run completely automatically by loading the protocol files off of the scanner and running the protocol monitoring software according to a predetermined schedule (e.g. daily or weekly). In this case, alerts can be automatically sent each time a discrepancy is found between the scanner protocol file and the eProtocol. Another useful application of the software is to run the program each time the scanner protocols are modified. This provides the user with immediate feedback about whether or not the protocols were set appropriately on the scanner.

An automated CT protocol management system is essential to ensure protocol accuracy and consistency. The protocol management software developed in this work can be applied to a wide range of practices with negligible impact on workflow.

SP115.4 - Evaluation of automatic exposure control systems in computed tomography

Author(s): <u>Paulo R. Costa</u>, Thamiris R. Reina, Denise Y. Nersissian Nuclear Physics, Radiation Dosimetry and Medical Physics Group, Physics Institute, São Paulo/BRAZIL

Introduction: The greatest and relatively new advance in CT to lower the patient dose is the automatic exposure control (AEC) systems [1]. These systems modulate the dose distribution along the patient taking into account their size and tissue densities [2]. AEC-systems are complex and their functioning is not fully understood [3]. This work aims to evaluate the performance and susceptibilities of AEC-systems.

Methods: The approach was the extraction of tube current modulation (TCM) data from DICOM image sequences and analysis of the image noise of those images [4]. The TCM of each CT scanner provides the performance of the AEC-system. Dose measurements with the AEC-system ON and OFF were made to verify if the tube current was consistent regarding the dose distribution behavior.

Results and Discussion: Figure 1 shows the TCM, and the corresponding noise for a Philips Brilliance 16 longitudinal AEC mode, Z-DOM, and the longitudinal AEC mode with the DoseRight ACS option ON. This example shows that this option causes a great increase on tube current, with a lower image noise and it doubles the dose compared to Z-DOM with this option OFF and the image noise decreases about 25%.

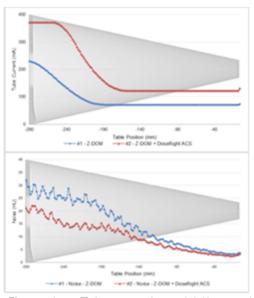

Figure 1 - Tube current modulation and correspondig image noise for the longitudinal AEC mode, Z-DOM, and the longitudinal AEC mode with the DoseRight AEC option ON. The blue line represents the Z-DOM and the red line represents the Z-DOM with DoseRight ACS option ON.

Conclusions: The results attained give rise to optimizations on the AEC-systems applications and, by consequence, decreases the patient dose without compromising the diagnostic image quality.

Acknowledgments: The authors thank FAPESP (project 2010/12237-7) and CNPq/FAPESP INCT Radiation Metrology in Medicine.

SP115.5 - Development of a Software for Image Quality Assessment in Computed Tomography using the Catphan500[®] Phantom

Author(s): Daniel V. Vieira, <u>Paulo R. Costa</u>, Denise Y. Nersissian Departamento De Física Nuclear, Instituto de Física da Universidade de São Paulo, São Paulo/BRAZIL

Introduction: A software for image quality assessment in computed tomography (CT) was written using MatLab[®] language. This software intends to improve CT scanners quality control programs, evaluating quantitatively the Catphan500[®] images. The software can identify the images from each section of the phantom and calculate the physical quantities of interest in these images. This process is performed with minimal direct user interference.

Methods: The software was written in modules. The MTF module uses images of the beads of the Catphan section CTP528 and subtracts the background, obtaining the PSF. The MTF is calculated from the resulting PSF. Due to the system symmetry, the two-dimensional MTF can be averaged over the azimuthal angle to obtain a radial MTF, MTFrad, in function of the spatial frequency fr. The uncertainty is also evaluated by averaging the MTFrad of multiple bead images.

The noise module uses images acquired from the section CTP486, and evaluates the noise and the NPS of the CT system. Noise is calculated taking the pixel mean and standard deviation in a central region of interest (ROI) and other four peripheral ROI's, as recommended by the Catphan user manual[i]. The two-dimensional NPS, NPS2D, in function of the spatial frequencies fx and fy is calculated by the method proposed by the ICRU Report n° 87[ii]. The NPS2D of multiple image pairs are then averaged to lower the uncertainty.

Results: Figure 1 illustrates the mean NPS2D and MTFrad calculated by the software, using 49 noise image pairs and 82 bead images respectively, selected from a set of 868 images in total. The images were acquired in a GE Discovery 690 PET/CT scanner. These results are consistent with previous qualitative results obtained from the quality control program implemented in the same equipment.

Figure 1: NPS2D (left) and radial MTFrad (right) of the GE Discovery scanner.

Conclusions: The preliminary results from the software agree with the expected from previous works. Without such software, the calculations of NPS and MTF is not always done, as it takes many hours; this software greatly reduces this time. Also it makes the analysis less subjective, more quantitative, and improves reproductibility.

SP115.6 - Performance of attenuation-based dynamic CT beam-shaping filtration for elliptical subject geometries in dependence of fan- and projection-angle

Author(s): <u>Stella Veloza</u>¹, Hans-Ulrich Kauczor², Wolfram Stiller² ¹Department Of Physics, Universidad Nacional de Colombia, Bogota, D.C./COLOMBIA, ²Department Of Diagnostic And Interventional Radiology (dir), University Hospital Heidelberg, Heidelberg/ GERMANY

Purpose: The computed tomography (CT) beam-shaping filter, also called bowtie filter, modulates X-ray beam intensity across the fan beam, compensating for decreasing absorption due to shorter X-ray path lengths through patient body periphery compared to its center. The effect of replacing static beam-shaping filter geometry currently used in commercially available CT systems by a novel filter geometry dynamically adapted to the attenuation of objects of elliptic cross-section during the image acquisition has been evaluated with regard to its potential for signal homogenization and radiation exposure reduction.

Methods and Materials: A theoretical model of a beam-shaping filter that dynamically adapts its attenuation profile to subjects of elliptic cross-section as a function of fan- and projection-angle has been developed. To achieve comparison, an accurate empirical model of a static large bowtie filter has been determined from Compton spectroscopy measurements of the X-ray spectra at different angular distance (0°-21°) from the central ray of the fan beam of a CT system for a tube potential of 120kVp by using a low energy Germanium detector. In order to calculate relative radiation exposure reduction achievable by replacing static with dynamic bowtie filtration in CT, spatial dose distributions in a homogeneous elliptical water phantom with a major axis of 32 cm and a minor axis of 25 cm were Monte-Carlo simulated with Geant4 for projections a.p. to lateral in steps of 15° (20 million of photons per projection) and exploiting phantom symmetry, total dose maps were calculated.

Results: Regarding signal homogenization the performance of dynamic adaptive beam-shapingfiltration fully lives up to expectation in as much as the attenuation becomes constant throughout the complete FOV, i.e. independent of fan angle, for all projection angles. Compared to a CT acquisition with the static beam-shaping filter, a significant additional radiation exposure reduction of 15% can be achieved by using dynamically adapted beam-shaping filtration. Replacing static by dynamic filtration allows relative patient skin dose reductions of around 23% in the antero-posterior (a.p.) projection and 40% in the lateral projection.

Conclusions: The new dynamic adaptive beam-shaping filter concept allows to homogenize absorbed radiation dose distribution and has potential for saving additional absorbed radiation dose compared to static beam-shaping filtration currently used in CT. The results suggest that static beam-shaping filter geometry should be reevaluated in favor of a dynamic adaptive beam-shaping filtration concept such as developed and evaluated here in order to reduce patients' (skin) dose.

SP115.7 - A software tool for automated artifact detection in scans of the CT daily water phantom

Author(s): Josh Grimes, Shuai Leng, Lifeng Yu, Cynthia Mccollough Mayo Clinic, Rochester/MN/UNITED STATES OF AMERICA

Purpose: The objective of this work was to develop a software tool for automated artifact detection in scans of the daily CT water phantom.

Methods: The artifact detection algorithm developed in this work uses a uniformity map created from convolution of the water phantom image with a small region of interest (ROI). Non-uniformities in the image are detected by looking for connected objects with CT numbers outside of an acceptable range inside the uniformity map. A pilot study was conducted to test the artifact detection algorithm on water phantom images acquired on a Siemens Sensation 64. This pilot study was split into two phases. First, a training dataset consisting of one month of daily water phantom images was collected for tuning the parameters of the artifact detection algorithm. Parameters to tune included the size of the ROI used in the convolution to generate the uniformity map, an acceptable CT number range in an artifact free image, and the minimum size of a connected region to count as a non-uniformity. Histograms summarizing how often connected objects of varving sizes occur for different CT number ranges were used to tune the parameters of interest. In the second phase, the software was used to monitor daily water phantom images for five more months.

Results: The training dataset revealed several important characteristics of the water phantom images. These characteristics included: a normal image (artifact-free) might not be uniform, there can be variation in "normal" non-uniformities between slices, and there are fluctuations in mean CT numbers from day-to-day as well as drift in average CT number over time. The artifact detection algorithm was modified to deal with these characteristics as follows. First, a normal image acquired on a previous date and known to be artifact-free is subtracted from the current water phantom image under investigation. This subtraction is performed slice-by-slice to deal with the variation observed between slices. Second, the average CT number of each water phantom image is subtracted from each pixel in the image to address the fluctuation in CT numbers from day-to-day. The histograms that were plotted to show the frequency of connected objects of various sizes with different settings for the acceptable CT number range demonstrated that a reasonable set of parameters for detecting artifacts was to classify a connected object as an artifact if it was larger than 200 pixels in size and had a CT number greater than +2 HU or less than -2 HU. Using these parameters for the second phase of the study, no artifacts were detected by the software over the five month period. No artifacts were reported by a technologist during this same period. When the software was used to analyze water phantom images with known artifacts from other scanners, these artifacts were correctly identified.

Conclusion: A general method for detecting non-uniformities in water phantom images was developed. This software should not be used to replace the human observer, but can serve as an added daily check for scanner issues.

SP115.8 - Monte Carlo Simulation of X-ray Spectra in Computed Tomography Scanner using GATE

Author(s): <u>Mohammad Reza Ay</u>, Samira Nezhaddehghani, Saeed Sarkar

Department Of Medical Physics & Biomedical Engineering, Tehran University of Medical Sciences, Tehran/IRAN

Introduction: X-ray spectrum modeling has an important role in medical imaging and many of researchers are still trying to find a simple and accurate method for simulation of x-ray spectrum. Monte Carlo simulation is a powerful tool in prediction of the x-ray spec-

trum. In this study, the x-ray spectra of the computed tomography system simulated using GATE Monet Carlo code. After validation the effect of the anode angle, tube voltage and thickness of filter on x-ray spectrum was investigated by using of Monte Carlo (MC) simulation. The simulated results were compared with MCNP4C MC simulated x-ray spectra and the spectra calculated by IPEM report No.78.

Materials and Methods: The GATE and NCNP4C MC packages were used for accurate modeling of the x-ray tube. The geometry of the x-ray tube in both codes was implemented precisely the same. The tungsten target with 7 degree and focal spot size 1.2×1.2 mm² was simulated. The x-ray spectra simulated using various tube voltages and different anode and variable thickness of Cupper filter. The IPEM report No.78 was used as a reference to compare with the results from simulation codes.

Results: The changes in quality and quantity of the spectrum for four different tube voltages 60, 80, 100, and 120 kVp were investigated and the results indicated that by increasing the voltage, the average of spectrum reached to the higher energy level. The x-ray spectra simulated for 4 different anode angle 7, 9, 11, and 13 degree. The simulated spectrum by using GATE was compared with two spectra from MCNP4C and IPEM report No.78 and in general there was good agreement between the results.

Conclusion: The effect of different variables on the spectrum was investigated. Good agreement between the simulated spectra by using GATE, MCNP4C and IPEM report No.78 were observed, al-though there are systematic differences between the simulated and reference spectra especially in the K-characteristic x-rays intensity. The results indicate that the GATE MC package is a useful tool for generating x-ray spectra of CT.

SP116 - Image Processing and Visualization: Part 2

TRACK 01: IMAGING

SP116.1 - Automated segmentation of whole-slide histology for vessel morphology comparison

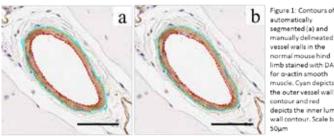

Author(s): <u>Yiwen Xu</u>¹, J Geoffrey Pickering², Zengxuan Nong², Aaron D. Ward¹

¹Medical Biophysics, The University of Western Ontario, London/ ON/CANADA, ²Robarts Reseach Institutue, London/ON/CANADA

Introduction: Characteristics of microvasculature can be revealed by immunohistochemical tissue staining, but manual guantification of these characteristics on whole-slide images containing potentially hundreds of vessels on each is tedious and subject to operator variability. Conventionally, manual quantification is performed for selected regions of the whole tissue section where the regions may not be representative of the pathology. Major challenges to automated segmentation include the irregularity of staining of vessel walls and artefactual appearance of DAB stain on structures other than vessel walls. Our objective was to develop and validate a fully automated segmentation of the vascular smooth muscle layer on whole-section histology of normal and regenerated post-ischemia mouse hind limb microvasculature, stained for smooth muscle using 3,3-diaminobenzidine (DAB) immunostain.

Methods: Our approach accounts for irregularity of vessel wall staining using colour deconvolution to isolate the DAB stain, and joining the morphological skeletons of the vessel wall fragments disjointed by inconsistent staining. Artefactual fragments were removed based on incoherence of neighbouring tissue in an accurate 3D histology reconstruction (Y Xu, SPIE Medical Imaging 2014). The vessel wall thickness, vessel density, area, and perimeter were quantified.

Results/Discussion: For segmentation validation, vessels were manually delineated and compared to the automated segmentation approach on a normal mouse, resulting in a Dice similarity coefficient of 0.84 (Figure 1). Differences in the vessel measurements observed between the normal and ischemic mice were concordant with the known effects of regeneration of vasculature in ischemic mice (p < 0.05, Table 1). Fully automatic and accurate measures of the vascular morphology are feasible with the automated segmentation of the vascular smooth muscle. With refinement and validation of this method on a larger data set, we aim to provide a valuable tool for scientists requiring high-throughput vascular segmentations and morphological measures for the analysis of vasculature for disease state comparisons.

SP116.2 - Using Gamma Maps of Anatomy to Highlight Changes in Anatomy During Image-Guided Adaptive Radiotherapy: Head and neck example

Author(s): Jeff Kempe¹, David Palma², Bryan Schaly¹, Jerry J. Battista²

¹Physics And Engineering, London Health Sciences Centre, London/ ON/CANADA, 2Department Of Medical Biophysics, Western Universtiy, London/CANADA

In recent years, technology has allowed radiation therapy of increasing complexity to be delivered to cancer patients, with the goal of improving tumour control and reducing toxicity. In adaptive radiotherapy (ART), imaging information acquired during treatment is used to adjust the treatment plan if necessary. During treatment of head and neck cancer, anatomical changes (e.g., weight loss) may occur and patients are flagged for re-CT simulation if the changes are substantial. But, how do we know when to flag patients for treatment replanning? The goal of this abstract is to demonstrate a graphic tool to aid in assessing changes in patient anatomy using the gamma comparison.

In the past, gamma function calculations have been used for quality assurance of the dose delivered to phantoms by the treatment machine compared with the planned computed dose. We propose using this function to highlight changes in patient anatomy, instead of dose, as a tool (an alarm) to aid the therapist and oncologist in deciding whether to flag the patient for re-CT simulation. Implementing this function in 3-D is computationally intensive; but, recent advances in graphics processing units (GPUs), and associated software, have greatly accelerated this calculation. With GPU hardware (costing under \$1,000) the gamma function comparing two full-size 3-D CT data sets (512x512x60) can be calculated in one minute. This result could be displayed at the treatment console to determine if a treatment adjustment merits consideration. We will demonstrate a sample application of this approach to head and neck cancer.

Figure 1: Gamma function on pairs of CBCT data sets of the head and neck region. AHU: 30 (absolute) Ar: 5 mm

SP116.3 - Improvement of Ventricle Volumetric Calculation and Visualization in Cardiac MRI

Author(s): Yarish Brijmohan¹, Naren Ramchander², Stanley Mneney¹, William I.D. Rae³

¹Electronic Engineering, University of Kwa-Zulu Natal, Durban/ SOUTH AFRICA, ²Electronic Engineering, eThekwini Municipality, Durban/SOUTH AFRICA, ³Medical Physics, University of the Free State, Bloemfontein/SOUTH AFRICA

Magnetic resonance imaging (MRI) is widely used in medical care services to perform visualisation of the human heart in order to assist in the diagnosis of several cardiovascular diseases. The severity of these disease states is often diagnosed and evaluated by analysing the blood volumes and flow rates within the ventricles. An accurate segmentation of the left and right ventricle from MRIs, at the end diastolic and end systolic cardiac phases, is the first step required for the volumetric calculations. Simpson's rule for measuring volumes is currently the most commonly used method in the literature, in which the volume at a particular cardiac phase is obtained by multiplying the segmented area by the slice thickness per slice and performing a summation over all slices. This method results in volumetric errors for imaging performed with large (non-isotropic) slice thickness. In this paper, methods of surface modelling are introduced to interpolate the volume between slices, providing a smooth surface visualisation of the ventricles. Furthermore, by using segmentation information from three orthogonal MRI views, improvements in the visualisation and volume calculation is formulated.

SP116.4 - Inter-operator variability of 3D prostate magnetic resonance image segmentation using manual and semiautomatic approaches

Author(s): <u>Maysam Shahedi</u>¹, Derek W. Cool², Cesare Romagnoli², Glenn Bauman³, Matthew Bastian-Jordan², Eli Gibson⁴, George Rodrigues¹, Belal Ahmad³, Michael Lock¹, Aaron Fenster⁵, Aaron D. Ward⁶

¹London Regional Cancer Program, London/ON/CANADA, ²Department Of Medical Imaging, The University of Western Ontario, London/ON/CANADA, ³Department Of Oncology, The University of Western Ontario, London/ON/CANADA, ⁴Graduate Program In Biomedical Engineering, The University of Western Ontario, London/ ON/CANADA, ⁵Imaging Research Laboratories, Robarts Research Institute, London/CANADA, ⁶Department Of Medical Biophysics, The University of Western Ontario, London/CANADA

Purpose: To measure accuracy and inter-operator variability of a semi-automatic prostate segmentation method for T2-weighted endorectal magnetic resonance (MR) imaging.

Materials and Methods: MR images from 42 prostate cancer patients were acquired. Manual border delineation was performed by one observer on all the images and by two other observers on a subset of 10 images. Simultaneous truth and performance level estimation (STAPLE) segmentation was calculated from all three segmentations. Our algorithm calculated inter-subject prostate shape and local boundary appearance similarity during its training phase. To initiate the segmentation, the operator indicated the anteroposterior prostate orientation and selected the prostate centre on the most-superior, mid-gland, and the most-inferior slices. These inputs were used to identify candidate prostate boundary points using learned appearance characteristics, which were regularized according to learned prostate shape information to produce the final segmentation. On all subjects, we evaluated our method against the manual reference segmentations using complementary boundary-, region- and volume-based metrics: mean absolute distance (MAD), Dice similarity coefficient (DSC), recall rate, precision rate, and volume difference (ΔV). On 10 cases, we measured the interoperator variability of manual segmentation by comparing the reference segmentations to the STAPLE segmentation, and conducted a multi-operator study to measure inter-operator variability of the semi-automatic algorithm.

Results: Table 1 shows our results on our 42 subjects with a single operator. Table 2 compares the consistency of manual and semi-automatic segmentations on 10 cases. The variability of all of the metrics resulting from the semi-automatic segmentation was reduced, compared to the manual segmentation.

Conclusions: We observed substantial inter-operator variability in manual segmentation and reduced variability in semi-automatic segmentation. In studies evaluating prostate segmentation algorithm accuracy using a single-operator reference standard, it is important to consider the measured errors in the context of inter-operator manual segmentation variability. Table 1: Accuracy and variability for semiautomatic segmentation: mean \pm standard deviation of MAD, DSC, recall, precision, and ΔV for different regions of interest.

Region of interest	MAD (mm)	DSC (%)	Recall (%)	Precision (%)	ΔV (cm 3)		
Whole gland	2.0±0.5	82±4	77±9	88±6	-4.6±7.2		
Mid-gland (1/3)	1.6±0.5	90±3	90±7	91±6	-0.1±2.0		
Apex (1/3)	2.0±0.7	79±6	82±14	80±13	0.1±3.3		
Base (1/3)	2.6±0.8	73±10	61±14	93±6	-4.5±3.7		

Table 2: Consistency of manual and semi-automatic segmentation: average of means (average of standard deviations) of the metrics across three manual and three semi-automatic segmentations by three expert operators. (N: number of images, reference: STAPLE segmentation).

Segmentation Method	Ν	Region of interest	MAD (mm)	DSC(%)	Recall(%)	Precision(%)	ΔV(cm 3)
Manual	10	Whole gland	1.3(1.6)	90(11)	88(19)	94(6)	3.9(10.1)
		Mid-gland	0.8(0.9)	95(5)	93(10)	97(2)	0.8(2.1)

SP116.5 - Derivation of Residual Noise of Filtered Poisson and Gaussian Series

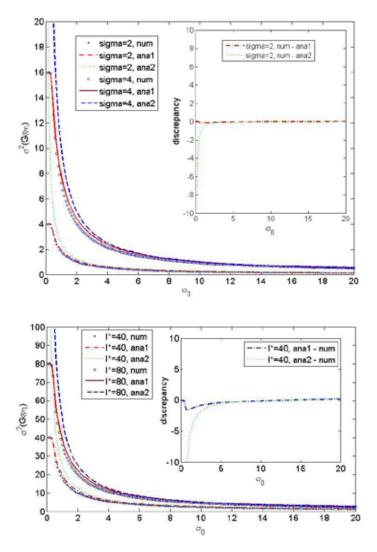

Author(s): Weiguang Yao¹, Jonathan B. Farr²

¹St. Jude Children's Research Hospital, Memphis/UNITED STATES OF AMERICA, ²St. Jude Children's Research Hospital, Memphis/ TN/UNITED STATES OF AMERICA

Residual noise analysis is useful in designing optimal filters for noise reduction. To begin we derived the variance of residual noise σr^2 , from Poisson and Gaussian series after filtered by a Gaussian filter. For Poisson series, we have $\sigma r^2 = \sqrt{(2\pi)} l^* / (4\sigma 0)$, and for Gaussian series, $\sigma r^2 = \sqrt{(2\pi)} \sigma^2 / (4\sigma 0)$, where l* is the noiseless signal in the Poisson series, σ and $\sigma 0$ are the standard deviations of the Gaussian series and the Gaussian filter, respectively.

The figures below compare the analytically derived or 2 , noted as «ana2» in the legends, with the numerically simulated ones, noted as «num». The first figure is for Gaussian noise sequences η , with standard deviations 2 and 4, respectively, and the second figure is for Poisson noise sequences $I^* + \eta$ with noiseless $I^*=40$ and 80 respectively. The discrepancy is mainly due to pixelation of the Gaussian filter. For example, when $4\sigma0$ / $\surd(2\pi)$ <1, the shape of the pixelated filter used in numerical simulations is very different from the bell shape Gaussian. If one uses the shape of the pixelated filter in the analytical derivation, the results, noted by "ana1" were much improved.

By utilizing these results, we designed an optimal filter with the aim of minimizing the local noise-to-signal ratio in a Poisson series with $I^* = 40 + A \sin(kx)$, which can represent the change of contrast and resolution of an image with *A* and *k*, respectively. Given *A* and *k*, the optimal standard deviation in the Gaussian filter was analytically obtained, and excellently agreed with that from numerical simulations. See our full paper for the details, Thus the analytical form of the variance of residual noise can be utilized to design filters and determine the optimal values of the filter parameters.

SP116.6 - Fast Registration of Intraoperative Ultrasound and Preoperative MR Images Based on Calibrations of 2D and 3D Ultrasound Probes

Author(s): <u>Fang Chen</u>, Ruizhi Liao, Hongen Liao Biomedical Engineering, School of Medicine,Tsinghua University,China, Beijing/CHINA

During the intraoperative-ultrasound-guided intervention, ultrasound (US) is often registered with other highquality preoperative images like computed tomography (CT) or magnetic resonance (MR) to improve the navigation accuracy. However, real-time registration is difficult to achieve due to the difference of image modality and dimensionality. To solve this problem, we apply preoperative 3D US image collected with a 3D calibrated probe to simplify 2D US and 3D MR image registration into two easy-achieved steps: 2D-3D US intra-modal registration and 3D US 3D MR pre-operative registration. To achieve fast intraoperative 2D US and preoperative 3D US registration, we take advantage of effective 2D and 3D US probes' calibration results and get a near optimal registration transform. Then intraoperatively we just need to do an automatic local adjustment, which will make real-time registration become possible. To achieve effective calibrations, we design an improved calibration phantom and propose a warm-start iterative closest points (ICP) method.

SP116.7 - Development of digital subtraction angiography for coronary artery without motion artifacts enabling read-time processing

Author(s): Megumi Yamamoto, Yasuhiko Okura

Clinical Radiology, Hiroshima International University, Higashihiroshima/JAPAN

Purpose: The purpose of this study is to develop a new method of digital subtraction angiography (DSA) for coronary artery reducing motion artifacts caused by heart beat and by the periodic motion in the lung field.

Methods: In this study, the mask image is produced by the density difference image. That is made by subtracting plain mask image from contrast-enhanced live image. Our approach employed fluctuation of pixel value at the same position. First, the pixel value for the mask image is selected from the plain mask image, when the density difference value is larger than a threshold level. The search area for the maximum pixel value was selected from two volume areas using the value of the standard deviation (SD) for each pixel from the previous 14image frames. Next, when the SD value in the 14 frames was greater than a threshold level, the search area of the maximum value was set 1 pixel x 1 pixel x 14 frames. Otherwise, 32 pixels x 32 pixels x 7 frames was selected as the search area mentioned above. Finally, the pixel value in mask image was selected from either volume area. To evaluate images obtained by our method, we used standard deviation of total pixel values in subtraction image sequences as an objective evaluation method. In addition, subjective evaluation was carried out. Cardiologists evaluated the degree of motion artifacts using score (1 to 5: 1 is the most deteriorated by artifacts). Twenty coronary arteriograms with various occlusion severities in vessels were used. We employed the PC (CPU: 2.4GHz, 4 GB memory) to produce DSA image process by our method.

Results: As results of objective evaluation, standard deviations of total pixel value of subtraction images were 33% lower than that of normal DSA, in 20 cases of coronary arteriogram. In subjective evaluation, average score of motion artifacts was 4.2 whereas 2.6 for normal DSA images. These results showed that the motion artifacts were extremely decreased by our method. Coronary artery and carotid artery and vein were clearly enhanced. The calculation time to product one subtraction image by our method was 0.085 sec/image. This result shows this method will be able to use in a real-time in the clinical situation.

Conclusions: In conclusion, we proposed this new method where using standard deviation of pixel value and searching the highest value in the volume area. The results showed that the motion artifacts were extremely decreased and will be able to use in a real-time. Coronary artery, carotid artery and vein were clearly enhanced. This method would be very helpful for the diagnosis of angiography with motion.

SP116.8 - Real-time measurement of cardiomyocyte contraction and calcium transients using fast image processing algorithms

Author(s): Vratislav Čmiel, Jan Odstrčilík, Marina Ronzhina, <u>Ivo</u> Provazník

International Clinical Research Center - Center Of Biomedical Engineering, St. Anne's University Hospital Brno, Brno/CZECH REPUB-LIC

An improved technique for recording of contraction of heart cells simultaneously with recording of calcium transients by fluorescence method is introduced. The technique aims to quantify contractions under conditions including low image quality caused by reduced transmitted light. The proposed methods allow more accurate detection, lower error rate using the up-to-date image processing, and automation of the process comparing to recent approaches. The technique is compared with direct optical measurement method using processing of two-dimensional digital images of the cardiac cell. The technique is improved to be fast enough to be included in the system for real-time measurements.

SP117 - Treatment Planning - Knowledge Based

TRACK 04: RADIATION ONCOLOGY

SP117.1 - Next Generation Radiotherapy Treatment Planning: Current Status and Future Prospects Author(s): Steve Jiang

Radiation Oncology, University of Texas Southwestern Medical Center, Dallas/TX/UNITED STATES OF AMERICA

Treatment planning is one of the most important links on the chain of cancer radiotherapy. The current treatment planning systems have the following issues.

First, there exists a large variation in plan quality, depending on who develops the plan, for which attending radiation oncologist, at which institution, and using what planning system, etc. This is particularly a big problem for resource-limited regions and institutions.

Second, the current treatment planning procedure is very inefficient, usually taking one week or longer, partially due to the iterations between the planner and the radiation oncologist that are often required to reach the acceptable plan quality. There is an urgent need to greatly improve the treatment planning efficiency and thus to reduce the waiting time for patients with cancer, - a frightening disease, from both clinical and psychological points of view.

Third, the current treatment planning practice is costly, not only due to the wasting of the clinical staff's, especially radiation oncologists', costly time, but also due to the expenses associated with the purchase, installation, commissioning, maintenance, and upgrade of the planning workstations, as well as with the setting up and maintenance of the dedicated data centers for patient data storage.

Forth, the current distributed treatment planning practice makes it difficult for cross institution collaboration, experience sharing, data sharing and mining and multi-institution clinical trials.

All these problems need to be resolved during the development of the next generation treatment planning systems. In this presentation, we will review and discuss various technologies that have been or are being developed for various aspects of next generation treatment planning, including automatic segmentation, knowledgebased automatic plan optimization, interactive plan tuning, personalized plan quality control, and efficient plan quality assurance, etc.

SP117.2 - Overlap-Guided Fixed-Patient Support Positioning for Cranial SRT

Author(s): <u>Robert L. Macdonald</u>¹, Christopher G. Thomas² ¹Physics And Atmospheric Sciences, Dalhousie University, Halifax/ NS/CANADA, ²Medical Physics, Nova Scotia Cancer Centre, Halifax/CANADA

Purpose: To investigate potential dosimetric improvements by optimizing fixed-couch rotation position for cranial stereotactic radiotherapy (SRT)

Methods: The current convention at the Nova Scotia Cancer Centre (NSCC) for planning of cranial stereotactic radiotherapy (SRT) with volumetric modulated arc therapy (VMAT) is a fixed-couch approach in which each individual arc is at a static patient treatment couch position. Three to four arcs are typically used in a plan, and for each of these arcs, the couch is positioned 45° apart, with one arc at

couch rotation 0°. In some cranial SRT cases, the planning target volume (PTV) is in very close proximity to vital organs-at-risk (OARs), and these cases require additional modification of patient treatment couch position due to this anatomical arrangement. Using six previously delivered cranial stereotactic radiotherapy plans for acoustic neuromas treated at the NSCC, we have redesigned the treatment arrangement to find the optimal couch rotation position based on the reduction of overlap between OARs and PTV. Maintaining the arc lengths from the delivered treatment, the couch position was determined based on a cost function analysis of accumulation of overlap score from an equation developed by Yang *et al*[2] and refined by MacDonald *et al*[1]. The algorithm incorporates factors for depth of OARs and PTV volumes and radiation dose sensitivities of each OAR.

Results: In a six patient population with application of this optimization technique, maximum and mean doses to the OARs were reduced by approximately $35.48\% \pm 5.38\%$ and $36.60\% \pm 4.68\%$ respectively, as compared to the original delivered plans. In addition, PTV coverage was maintained during optimization. The average homogeneity index [3] was 7.53 ± 1.46 for conventional plans and 4.89 ± 0.38 . The conformity number [4] was 0.76 ± 0.05 for conventional plans.

Conclusion: The reduction in OAR doses is a substantial improvement in plan quality. The modification of the existing delivery technique with guidance from a PTV-OAR overlap cost-function analysis technique can yield significant dosimetric improvements with no increase to delivery or planning time. This technology is immediately implementable on any linear accelerator capable of basic stereotactic radiotherapy.

SP117.3 - Automated Dose Map Prediction Through Radiomics and Regression on the Patient Manifold Author(s): Chris Mcintosh, Thomas G. Purdie

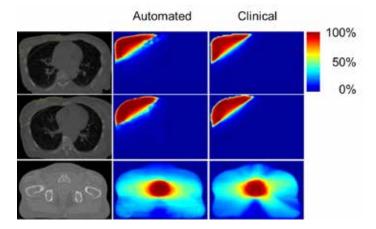

Princess Margaret Cancer Centre, Toronto/CANADA

Technical innovations in RT have improved the quality of RT plans at the cost of increased complexity. Therefore, automated planning methods have been suggested to improve the highly manual, iterative and complex RT planning process. To date, treatment planning has focused on optimizing volume-based objectives (e.g. <30% of the right lung volume should receive <50% of the prescribed radiation dose) which are derived from a template and manually adjusted at each planning iteration or selected from a database in the case of automated planning approaches. These objectives neglect fundamental spatial information and only represent surrogates of the actual clinical treatment intent with the resulting RT plans limited in their capacity to tailor dose for each patient. We propose a paradigm shift in automated RT planning. By explicitly modelling the relationship between patient anatomy and radiation dose, this research is the first to generate automated RT plans that directly specify the spatial distribution of the radiation dose to the patient.

Our method uses a novel machine learning (i.e. customized regression) algorithm based on thousands of previous RT plans deemed to be of high quality, to learn relationships and patterns in the data (i.e. how radiomic features describing patient organ/target appearance and geometry correlate with radiation dose to ensure a clinically acceptable RT plan). For a new patient, the algorithm computes relevant radiomic features, to be correlated with features in the database. Machine learning uses the radiomic features to predict a probabilistic dose for each voxel in the image, based on features at both the voxel and whole image level.

Our preliminary results have focused on three distinct RT treatment sites using intensity modulated RT (IMRT) and volumetric modulated arc therapy (VMAT): whole breast (tangent IMRT), breast cavity (non-coplanar IMRT), and prostate bed (VMAT). We used 336 training patients, 143 testing patients, and measured automated planning accuracy via Gamma analysis comparison with each patient's clinically delivered treatment plan. Our overall accuracy rates were 88.2%, 74.9%, and 86.1% respectively, with 50.6%, 20.0%, and 25.7% having a Gamma over 90%. An example image is shown below with fully automated planning results from two breast cavity, and one prostate bed plan.

Our method will enhance the existing RT process by reducing RT planning times, promoting simplification and standardization, and improving the quality of personalized RT. The research will realize a novel clinically implementable framework and provide a training knowledge base for RT.

SP117.5 - Models for Predicting Objective Function Weights in Prostate Cancer IMRT

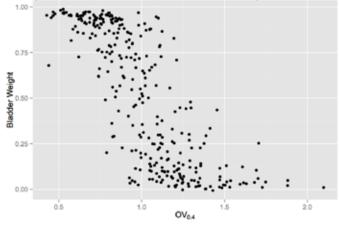

Author(s): Justin J. Boutilier¹, Taewoo Lee¹, Tim Craig², Michael B. Sharpe², Timothy C.Y. Chan¹

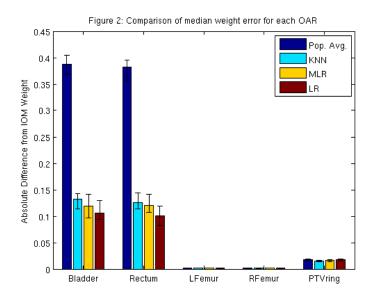

¹Mechanical And Industrial Engineering, University of Toronto, Toronto/CANADA, ²The Princess Margaret Cancer Centre, Toronto/ CANADA

Purpose: To develop and evaluate the clinical applicability of advanced machine learning models that simultaneously predict multiple optimization objective function weights from patient geometry for intensity-modulated radiation therapy (IMRT) of prostate cancer. **Methods:** A previously developed inverse optimization method (IOM) was applied retrospectively to determine optimal objective function weights for 315 treated patients. We used

an overlap volume ratio (OV) of bladder and rectum for different PTV expansions and overlap volume histogram slopes as explanatory variables that quantify patient geometry. Using the optimal weights as ground truth, we trained and applied three prediction models: logistic regression (LR), multinomial logistic regression (MLR), and weighted K-nearest neighbor (KNN). The population average of the optimal objective function weights was also calculated. Results: The OV at 0.4 cm feature was found to be the most predictive of the objective function weights (Figure 1). We observed comparable performance (i.e., no statistically significant difference) between LR, MLR, and KNN methodologies, with LR appearing to perform the best. All three machine learning models outperformed the population average by a statistically significant amount over a range of clinical metrics including bladder/rectum V53Gy, bladder/ rectum V70Gy, and dose to the bladder, rectum, CTV, and PTV. When comparing the weights directly, the LR model predicted bladder and rectum weights that had, on average, a 73% and 74% relative improvement over the population average weights, respectively (Figure 2). The treatment plans resulting from the LR weights had, on average, a rectum V70Gy that was 35% closer to the clinical plan and a bladder V70Gy that was 29% closer, compared to the population average weights. Conclusion: We demonstrated that the KNN and MLR weight prediction methodologies perform comparably to the LR model and can produce clinical quality treatment plans by simultaneously predicting multiple weights that capture tradeoffs associated with sparing multiple OARs.

SP118 - Diagnostic Radiology: Dosimetry and Quality Control

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP118.1 - Measuring absorbed-dose to cardiac implantable electronic device using OSL.

Author(s): Étienne Létourneau

Radio-oncologie, Centre intégré de cancérologie de Laval, Laval/ CANADA

Purpose/Objectives

The American Association of Physicists in Medicine (AAPM) Task Group 34 and more recently 203 raised the issue about the management of radiation oncology patients with a cardiac pacemaker or an implantable cardioverter-defibrillator (ICD). Clear guidance about dose limits are given in these reference works. However, most dose levels reported in the literature and used clinically to evaluate the absorbed-dose are based on calculated values and not on direct measurements. In this study, direct measurements using optically stimulated luminescent (OSL) detectors placed directly inside a pacemaker were performed for planning CT scan, positioning CBCT scan and external beam radiation therapy treatment in order to compare with the planned dose.

Materials/Methods

Output measurements of the CT scan at 140 kVp and of the CBCT X-ray tube were performed at 100 kVp and 120 kVp. Measurements were based on the AAPM Task Group 61 protocol using a Farmertype ionization chamber calibrated for the corresponding beam quality. Once the outputs were determined at the reference point, the correlation between OSL's number of counts and the resultant dose was achieved for both imaging methods. Then, an OSL dosimeter was placed inside a Biotronik pacemaker in the electronic section. Several measurements were performed placing the pacemaker recovered with bolus on an anthropomorphic phantom. Using different scanning parameters and protocols, a clinically relevant overview could be achieved.

Results

Direct exposition of the pacemaker could give a maximum reading of 4 cGy for a CT scan acquisition and 3 cGy for a CBCT scan acquisition with our in-house protocols.

Conclusions

Knowing the measured absorded-dose to the cardiac implantable electronic device (CIED) from our different planning and positioning imaging protocols, adequate classification of risk group of patients with (CIED) could be done. Therefore, dosimetric decisions regarding the planning can be performed under a sounder basis.

SP118.2 - Organ dose estimation in computed tomography based on Monte Carlo simulation

Author(s): <u>Camille Adrien</u>¹, Cindy Le Loirec¹, Juan Carlos Garcia-Hernandez¹, Serge Dreuil², Jean-Marc Bordy¹ ¹Dm2i, CEA, List, Gif-sur-Yvette/FRANCE, ²Service De Physique Médicale, Gustave Roussy, Villejuif/FRANCE

Due to the significant rise of computed tomography (CT) exams in the past few years and the increase of the collective dose due to medical exams, dose estimation in CT imaging has become a major public health issue. However, in clinical practice, dose is still estimated by empirical index such as CT air kerma indices and air kerma-length product. Protocols can hardly be optimised with such information. On this basis, we decided to develop an organ dose estimator providing dosimetric information for DICOM patient images and/or numerical standard phantoms. In this paper, developments and validations of the Monte Carlo (MC) dose simulator are mainly discussed. A MC tool, based on the 2006 release of the PENELOPE code, has been adapted to enable CT exams simulations in a voxelized numerical phantom mimicking the human anatomy.

For that purpose, the GE Lightspeed VCT 64 CT tube was modelled by adapting the method proposed by Turner et al (Med. Phys. 36: 2154-2164). First of all, equivalent spectra were determined for 100 kVp and 120 kVp by using experimental half-value layers (HVL). Measurements were performed is static mode with a CdTe detector associated with a method developed by the French national laboratory of metrology for ionizing radiations (LNHB) to achieve experimental spectra (X-ray Spectrometry 43(5): 298-304) and validate the tube model. Equivalent bowtie filter shapes were then established by using dosimetric profiles. Furthermore, axial and helical rotations of the X-ray tube were implemented in the MC tool. To improve the efficiency of the simulation, two variance reduction techniques were used: a circular and a translational splitting. The splitting algorithms allow a uniform particle distribution along the gantry path to simulate the continuous gantry motion in a discrete way. To validate the calculation, simulated sinograms are compared with the expected ones and the particle distribution along the gantry path is checked.

First validations were then performed in homogeneous conditions using a home-made phantom and the well-known CTDI phantoms. Comparisons between measured and simulated values are in good agreement with less than 10% deviation for several cases. Then, validations were performed in CIRS ATOM anthropomorphic phantoms using both optically stimulated luminescence dosimeters for point doses and XR-QA Gafchromic[®] films for relative dose maps. Last results are very encouraging with less than 20% deviation for punctual doses.

Organ Doses for several acquisition parameters into the ICRP male and female phantoms (ICRP, 2009. Adult Reference Computational Phantoms. ICRP Publication 110. Ann. ICRP 39 (2)) should soon be provided by the simulator in order to build a dosimetric data base which could be used in clinical practice.

SP118.3 - Comparative study of Average Glandular Doses of three different digital mammography units in three Ministry of Health Hospitals in Oman: An analysis

Author(s): <u>Arun Kumar L S</u>, Rashid Al-Hajri, Saeed Al-Kalbani Medical Physics, Ministry of Health, Muscat/OMAN

Breast cancer accounts about 12% of all new cancers worldwide (WHO, World Cancer Report 2014) and this is about 25 % in the Sultanate of Oman (2013) which is also the highest among all cancers in Oman. Breast screening by mammography can reduce mortality by about 25% and hence we follow a comprehensive radiation acceptance & quality assurance protocol for the testing of mammographic units installed in ministry of health (MOH), before handing over for routine patient care work. Of the many radiation parameters measured, the average glandular doses (AGD) of three different digital mammographic units from three manufacturers installed in three different hospitals was analysed in this study so as to make sure that the mammographic units meet WHO/IAEA standards as the Sultanate does not have currently a national protocol for acceptance of mammographic units.

The Average Glandular Dose (AGD) of three different digital mammo units was estimated by using a 4.5 cm polymethyl methacrylate (PMMA) phantom along with a calibrated 3.0 cc mammo ion

chamber. Of the three mammo units, the first two had identical x-ray spectral features - W/Rh, Mo/Mo & Mo/Rh where as the third unit had W/Rh & W/Ag spectrum. The phantom used is assumed to have a glandularity of 50:50. The Entrance Surface Air Kerma (ESAK) and half value layer (HVL) of the beam was measured by the mammo chamber. The paddle is made in contact with the ion chamber and arranged the phantom & chamber side by side such that ESAK is measured without backscatter. From the measured ESAK and HVL values, AGD was estimated as per the European Guidelines (2003) by the formalism of Dance et. al. (2000 and 2009). i.e., AGD = Kgcs where K - is the ESAK without backscatter and g, c & s are correction factors. The phantom was compressed to the same breast thickness in all the three hospitals so that compressed breast thickness remained the same. ESAK and HVL for all available spectral gualities were measured in the three units and AGD's were estimated for each spectral quality.

Also, AGD's were estimated for phantom thicknesses of 3cm, 6cm and 8cm in the three units for the above spectral qualities. The results showed that AGD's increased with the increase in thickness as expected. The system/mammo unit estimated/displayed entrance surface dose & organ dose (AGD) were noted and compared with the measured values of ESAK & the estimated values of AGD of the corresponding setting. Of the three hospitals, the estimated AGD's were quite comparable in two hospitals where as the third hospital shown a variation of about 18% from the other two. However, in all the three hospitals, AGD's were within the recommended value of 3 mGy for each projection.

Surveys shown that mammo units operating at optimal parameters have increased detection rates for smaller lesions with optimal dose to the breast. A well performed QA programme in mammography will yield good quality mammograms which in turn delivers an optimal dose to the patients undergoing mammographic investigations.

SP118.4 - First Data on Quality Control Test done in Diagnostic X-ray facility at Major Public Hospitals in Kathmandu Valley, Nepal.

Author(s): Kanchan P. Adhikari, Navagan Ghimire, Prakash D. Gautam, Tirthraj Adhikari

Department Of Clinical Oncology, National Academy of Medical Sciences, Bir Hospital, Kathmandu/NEPAL

One of the most important goals of good medical practice in the use of X-ray is to diagnose the disease and its extent to minimize an adverse effect. During any action taken in diagnostic X-ray, there is an important issue of quality of the image and dose to the patient. Hence, regular practice of quality control in diagnostic X-ray is essential to provide a good quality images and less hazard to the patients and its checking on regular basis enhances the appropriate diagnosis with minimum side effects.

The quality control tests were carried out at thirteen X-ray units at seven different government hospitals in Kathmandu valley. The parameter like kV, kVp, dose, dose rate, HVL and mAs were measured with the acceptance limits. In this study, beam alignment test, radiation leakage test and focal spot test were also done.

During the study, we found that there is not any established proper method for the installment of diagnostic X-ray equipment and acceptance testing procedure in Nepal. Actions were not taken to improve the old X-ray machine and for restoring it to a proper working condition. The study shows that the need for quality assurance of diagnostic X-ray to be taken to avert detrimental effects to patients and staffs. Radiographers should provide sufficient training to ensure proper condition of X-ray machine. Radiation regulation now is essential for such programs to be introduced. Any program to manage patient dose in radiology should provide a high priority in the country like Nepal. Dose given in diagnostic X-ray should be compared with standard reference level on regular basis to identify the condition of the X-ray. Institute must introduce a mandatory system for acceptance test of X-ray when installed and regular quality control program.

Keywords— X-ray, acceptance test, quality control, radiation regulation

SP118.5 - Estimation of dose distributions in mammography into a tissue equivalent phantom

Author(s): <u>Josilene C. Santos</u>¹, Alessandra Tomal², Tania A.C. Furquim¹, Paulo R. Costa¹

¹Radiation Dosimetry And Medical Physics Group, Physics Institute, University of São Paulo, São Paulo/BRAZIL, ²Physics Institute Gleb Wataghin, State University of Campinas, Campinas/BRAZIL

Mammography is the most important method to detect premature breast cancer. However, there is a risk of inducing cancer by the exposure to radiation in this kind of examination. In this way, it is important to know the dose distribution in typical techniques used in mammography procedures. The aim of this work was to estimate the dose distributions in different positions parallel to the image plan and different depths of a tissue equivalent phantom using LiF thermoluminescent dosimeters (TLD).

LiF TLDs pellets were positioned at 5 positions on the *xy* plan (Figure 1) on a BR12 phantom (CIRS, model E14) at different depths. The set was irradiated in a GE Senographe DS System for a maximum field size. The dosimeters were irradiated using Mo/Mo anode/filter combination, 100 mAs, and different X-ray tube voltages (25, 28, 30 and 32 kVp). A fixed X-ray tube voltage (28 kVp), 100 mAs, was also used with different anode/filter combinations (Mo/Mo, Mo/Rh and Rh/Rh). A similar set of TL dosimeters were calibrated using mammographic X-ray beam qualities RQR-M 2 and RQR-M 4 in an accredited SSDL. The TL signal was read on a TL/OSL reader (Ris ϕ , model DA-20). Dose distributions in different *xy* positions and depths of the phantom were estimated.

Dose variation in the y direction was more significant than in the x direction. It were observed variations up to 8% and 28.2% in x and y directions respectively. For the tube voltage 28 kVp, the maximum dose in the phantom surface in the y-axis was 16(1) mGy for Mo/Mo, and 15.0 (9) mGy for Mo/Rh and 12.8(6) for Rh/Rh.

The dose variation obtained is probably due to the non-uniformity of the field. The maximum dose value calculated corresponds to a position that is next to the chest wall in a compressed breast. This occurs due to the Heel effect.

Figure 1: – TLDs positioning scheme in a phantom BR12 for irradiation in a GE mammography system

SP118.7 - Radiation Dose Assessment for Retrospectively ECG-Gated Coronary Computed Tomography Angiography (CCTA) Examination

Author(s): T S Tuan Muda¹, <u>C H Yeong</u>¹, Sock Keow Tan¹, Kwan Hoong Ng¹, Yang Faridah Abdul Aziz¹, Zhonghua Sun² ¹Biomedical Imaging Department, University of Malaya, Kuala Lumpur/MALAYSIA, ²Discipline Of Medical Imaging,department Of Imaging And Applied Physics, Curtin University of Technology, Perth/AUSTRALIA

Purpose:

Coronary computed tomography angiography (CCTA) has been recognised as a reliable diagnostic technique for the assessment of coronary artery disease since the introduction of 64-slice CT. However the radiation dose received by the patients from CCTA is still high compared to other examinations, thus raising concerns in the medical field. This study aimed to assess the entrance skin dose (ESD) and organ absorbed dose measured in both patients and phantom during retrospectively ECG-gated CCTA examination.

Methods:

ESD for 30 patients (15 males, 15 females, 58±10 year-old) who underwent CCTA using a dual-source CT scanner (Siemens Definition DS, Germany) were measured at selected radiosensitive organ regions (eye lens, thyroid, breast, heart and reproductive system) using optically stimulated luminescence dosimeters (OSLD). The measurement was extended to organ absorbed dose in an anthropomorphic phantom (Atom702G, CIRS, Virginia) with OSLD placed within the respective organs. Effective dose was then calculated using the CT Expo V2.3.1 software (Hannover, Germany).

Results:

The ESD measured on both male and female patients are presented in Figure 1. Figure 2 shows the absorbed dose measured within the selected organs of the ATOM phantom. The effective doses calculated from the CT Expo software showed that female patients received significantly higher effective dose than the male patients (14.70 \pm 4.35 vs. 10.40 \pm 5.94 mSv; p<0.05). The ESD of the breasts was about 8-9 times higher than the ESD reported from a typical mammogram of a breast of 5 cm compressed thickness.

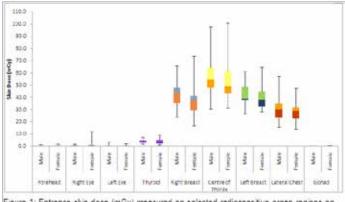

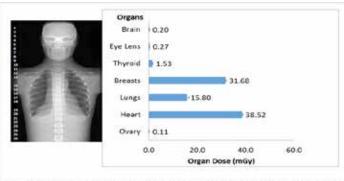

Figure 1: Entrance skin dose (mGy) measured on selected radiosensitive organ regions on the mole and female patients.

Conclusion:

Due to the high radiation dose delivered to the patients, serious attention should be given to CCTA examination for dose reduction. Optimisation of the CCTA protocols should be carried out to minimise radiation dose to the patients.

SP119 - Dose Surveys in CT and Interventional Radiology

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP119.1 - CT Dose Optimization: First Results from a Province-Wide Program in Quebec

Author(s): <u>Manon Rouleau</u>¹, Moulay Ali Nassiri¹, Philippe Després² ¹Centre d'expertise clinique en radioprotection (CECR), CHUS, Sherbrooke/CANADA, ²Département De Physique, De Génie Physique Et D'optique, Université Laval, Québec/QC/CANADA

Purpose: Many studies have shown a statistically significant increase of life-time risk of radiation-induced cancer from CT examinations. In this context, the province of Quebec has created and mandated the Center for clinical expertise in radiation safety (CECR) to proceed with a province-wide tour of CT installations in order to: i) evaluate the technical and functional performances of CT devices, ii) initiate a dose optimization process in CT scanning protocols and iii) support and guide the local team of technologists, radiologists and managers with regards to dose reduction strategies in CT.

Methods: To achieve these objectives, the CECR coordinates a tour of the province's 180 CT installations. The tour consists in two-day visits to CT centers by a team of medical physicists and technologists in medical imaging (TIMs). The first day of the visit is dedicated to CT performance evaluation by medical physicists and to clinical CT image inspection by TIMs. The former includes tests related to HU numbers, collimator aperture and CTDI accuracy while the later verifies scan range compliance with protocols and dose levels for recent studies of the head, chest and abdomen. On the second day, observations by the CECR experts are presented to the local team along with recommendations on radiation safety good practices and potential improvements of CT protocols with regards to the dose. Upon consent from a local radiologist, optimized CT protocols were used for patients scheduled on day two. Prompt feedback on optimized images by the radiologist allowed fine-tuning of the protocols with the experts on site. Then, in the next month, images acquired with optimized protocols were scored with a qualification form and sent back to CECR for compilation.

Results: Since 2011, the CECR has evaluated 110 CT devices, 60% of which are 64-slice scanners. Local protocols were modified in 64%, 80% and 70% of the time for adult head, thorax and abdomen-pelvis respectively. The average dose reduction obtained with these optimized protocols was 18%, 24% and 20% for adult head, thorax and abdomen-pelvis respectively. The general recommendations often made by the CECR experts were: 1) the implementation of low-dose protocols for the follow-up of pulmonary nodules and for renal calculi, 2) the compliance to the prescribed scan range as defined by local practice guides, 3) the adequate positioning of patients, and 4) the use of bismuth shielding to reduce the dose to superficial radiosensitive organs, such as the breast, lens of the eye, and thyroid.

Conclusion: The approach used by CECR to optimize CT protocols takes into account the performances of CT devices as well as current modulation and iterative reconstruction when available. It is based on the active participation of all stakeholders in the process: radiologists, biomedical engineers, TIMs and managers. The clinical requirements as expressed by radiologists remain at the core of the optimization process. This approach, based on support and guidance as oppose to formal inspection, is very well accepted and led to significant dose reductions. SP119.2 - CT overexposure as a consequence of scan length Author(s): <u>Mohamed K. Badawy</u>¹, Michael Galea², Kam S. Mong¹, Paul L. U¹

¹Medical Physics, Austin Health, Heidelberg/AUSTRALIA, ²Radiology, Austin Health, Heidelberg/AUSTRALIA

Background

The diagnostic benefits of CT scans with appropriate clinical reasoning far outweigh the potential radiation risks and this has seen an increased number of CTs ordered yearly in Australia. In saying that, effort must be made to lower radiation dose to the patients to ensure that the risk is kept as low as reasonably achievable.

A simple method of dose optimization is ensuring the correct scan length is chosen for the corresponding scan type, i.e. imaging only the anatomy that is required and nothing more. Initially, a scout image is obtained to ensure the patient is set up correctly for their scan. Adjustments to scan lengths based on anatomical landmarks and radiologist protocol should be made on the scout image before executing the CT scan on the patient.

Aim

This study aims to quantify the increased effective dose as scan length were chosen that deviated from standard protocol.

Methods

This study was performed using Monte Carlo software and a mathematical phantom to represent real patient data. The software package used in this study was CT-Expo V2.2. The software was validated by comparing the calculated CTDIvol and DLP to the CT-DIvol and DLP given on the CT scanner.

A reference scan was obtained for each scan protocol and the scan parameters, including kV, mA, rotation time, collimation width, table feed and slice thickness, were entered into CT-Expo to calculate the effective dose. The reference scan was acquired using CTU-41 CT Torso Phantom and the correct scan length for each simulation was based on the anatomical landmarks suggested by ARPANSA in the National DRL survey user guide.

The scanned region was then increased by 0.5 cm either side of the standard protocol and the effective dose increase was recorded.

Results

The results of this study show that for scans with a high CTDIvol the patient is exposed to an extra 1 mSv within 6 cm of overscan. Protocols that investigated large scan areas may not see a significant relative dose reduction, however radiation exposure should be kept as low as reasonably achievable

Conclusions

The main emphasis of CT dose optimisation has been focused on new scanner technologies, however the operator can still play a key role in reducing patient dose. Ensuring the correct scan length is chosen by the radiologist and selected by the radiographer can potentially reduce the effective dose of each scan by up to 2 mSv. High dose protocols, such as head and spine, can benefit significantly in dose reduction with more stringent adherence to the anatomical region to be imaged.

SP119.3 - Regional survey of pediatric patient doses from CT examinations in Tehran, Iran

Author(s): <u>Hamid R. Khosravi</u>¹, D Chettle¹, Leila Sadri², Saeed Setayeshi², Khadijeh Asnaashari³, Hossein Khosravi⁴, Mehran Midia⁵ ¹Medical Physics, McMaster University, Hamilton/ON/CANA-DA, ²Nuclear Engineering, Amir Kabir university of Technology, Tehran/IRAN, ³Allied Medicine, Tehran University of Medical Sciences, Tehran/IRAN, ⁴Medical Physics, Tarbiat Modares University, Tehran/ IRAN, ⁵McMaster University, Hamilton/ON/CANADA

Objectives: To establish regional diagnostic reference levels (RDRLs) for typical paediatric CT examinations in Tehran, Iran and compare them with established international data. In addition, the aim was to develop a method of analyzing local scan parameters for further optimization.

Methods: The dose assessment was performed in terms of weighted CT dose index (CTDIw) and dose length product (DLP) for head, sinus, chest, abdomen and pelvis CT examinations using standard methods. CTDI were measured in a polymethyl methacrylate (PMMA) Head and Body phantoms. RDRLs were derived from mean survey values for different age categories in 19 CT facilities in Tehran, Iran.

Results: The mean range of CTDlw for all age categories were 41.77-53.04,24.37-26.55, 12.45-13.48 and 13.18-18.25 for Brain, Sinus, Chest and Abdomen-pelvis, respectively. Related DLPs were 325.5-495, 181.5-222.7, 143.2-250.6 and 198.5-488.4, respectively.

Conclusion: Many hospitals were incorporating adult scanning parameters for children, resulting in very high effective doses. The great variations of CTDIw and DLP observed among hospitals and relatively high values of DLP in some centers are evidence that radiation doses of Paediatric patients from CT examinations need to be optimized.

SP119.4 - Dose Reduction Efforts in PET/CT: the Quebec Experience

Author(s): Moulay Ali Nassiri¹, <u>Manon Rouleau¹</u>, Philippe Després² ¹Centre d'expertise clinique en radioprotection (CECR), CHUS, Sherbrooke/CANADA, ²Département De Physique, De Génie Physique Et D'optique, Université Laval, Québec/QC/CANADA

Problematic and objective: The province of Quebec (Canada) has 15 publicly funded PET/CT center for a population of 8.2 million. This relatively large per capita ratio makes PET an accessible technology that significantly contributes to the collective radiation dose of medical origin in the province. In this context, the province of Quebec has created and mandated the Center for clinical expertise in radiation safety (CECR) to proceed with a province-wide tour of PET/CT installations with the objective of establishing good radiation protection practices for patients and caregivers.

Methods: The CECR first conducted a province-wide survey to establish a snapshot of the current practice in 2014. This survey was followed by on-site visits by a team composed of a medical physicist, a nuclear medicine technologist and a CT imaging technologist. The 2-day visit consisted, on day 1, in 1) quality controls and performance evaluation of the CT, PET and dose calibrator, 2) verification that the procedures used to perform the PET/CT studies (preparation and execution) are defined and observed. Furthermore, 15 whole-body and 4 high-resolution (fine CT slice thickness) head and neck 18F-FDG PET/CT studies were analyzed. Specifically, the signal to noise ratio (SNR) for both PET and CT images were obtained for the liver (whole-body studies) while the CTDI, the DLP, the injected activity and the injection/acquisition interval were retrieved from images or their DICOM header. The team also verified all aspects of radiation protection practices in the visited center. On day 2, the team presented their observations to the local team of technologists, physicians and managers and made recommendations for improving the radiation protection practices. For adult studies, the amount of 18F-FDG recommended was based on both EANM guidelines for tumor imaging and on the Japanese guidelines. The measured performance of the PET system was also taken into account for the determination of the optimal injected dose. With the approval of local physicians, PET/CT studies scheduled for the second day were performed using the proposed protocols. Prompt feedback from the physician on image quality allowed the CECR expert to fine-tune the protocol parameters in order to reach optimal quality with the minimal dose.

Results: Survey results showed that PET examinations vary considerably across centers, with dose varying from 8 to 30 mSv for 18F-FDG whole-body protocols, which account for 99% of all PET studies. Recurring visit recommendations for adult protocols include: 1) using automatic tube current modulation for CT, resulting typically in 20% dose savings, 2) reducing the tube current by 20% for high-resolution head and neck CT protocols, 3) reducing by 30% the amount of injected activity, 4) complying with the prescribed injection/acquisition interval.

Conclusion: The approach used by CECR to optimize PET/CT protocols takes into account the performances of devices and EANM/ Japanese guidelines. It is based on the active participation of all stakeholders in the process: nuclear medicine physicians, biomedical engineers, technologists and managers. This approach, based on support and guidance as oppose to formal inspection, is very well accepted and led to significant dose reductions.

SP119.5 - Assessment of high cumulative patient doses of repetitive CT examinations

Author(s): <u>Cecile R. Jeukens</u>, Roald S. Schnerr, Sandra Niesen, Joachim E. Wildberger, Marco Das

Maastricht University Medical Centre+, Maastricht/NETHERLANDS

Purpose

In daily routine patients often undergo multiple CT examinations within a short time frame, which may lead to a high radiation exposure. Our purpose was to evaluate patients who received a cumulative effective dose of more than 100 mSv within one year with repeat CT examinations.

Methods and Materials

15,000 consecutive CT examinations were systematically analyzed using dedicated dosemonitoring software (RadimetricsTM, Bayer Healthcare) within the time period 08/2013-08/2014. The effective dose (according to ICRP 103) is calculated from the technical and dose related parameters retrieved from the CT scanners, using an incorporated Monte Carlo module. All patients with a cumulative effective dose above 100 mSv were identified. Besides patient specific parameters (sex, age, weight), patients were analyzed with respect to cumulative effective dose, number of CT scans and scan series, dose per CT scan, time interval of the scans, clinical scan indications and anatomical scan regions.

Results

A small fraction (0.27%) of forty-one patients were identified (63% male, mean age 62, range 24-83, mean weight 82 kg). These patients received 347 CTs in total. The median of the received number of CTs was 7.0 (range 3-20) with 3.5 series per scan within a time frame of 166 days (median; range 8-320). Median cumulative effective dose was 117 mSv (range 100-301). A positive correlation was found between the number of CTs and the received effective dose (Figure 1). Most frequent scan indications were: oncology, abdomi-

nal imaging for abscess and drainage as well as complications after surgery. The most frequently selected scan region was the abdomen (n=150) with a median effective dose of 11 mSv (range 2.5-49), followed by combined thorax/abdomen protocols (n=39, median 17 mSv, range 6.4-57).

Conclusion:

Very high cumulative doses (>100mSv) only occur in a fraction of patients..As clinical indications justify each examination and the average radiation dose per scan was acceptable, these cumulative doses may represent common clinical practice in severely ill patients.

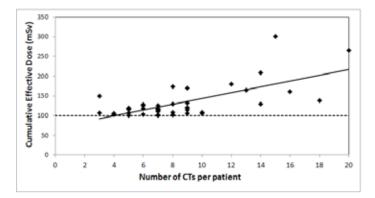

Figure 1 The cumulative effective dose per patient as a function of the number of CTs a patient received. The solid line indicates a linear fit ($R^2 = 0.46$), the dashed line the 100 mSv inclusion criterium.

SP119.6 - IAEA survey of pediatric computed tomography practice in Pakistan procedures and protocols (2005-2015) Author(s): Areesha Zaman

Medical Physics, institution of nuclear medicine and oncology lahore INMOL, LAHORE/PAKISTAN

TITLE IAEA survey of pediatric computed tomography practice in Pakistan procedures and protocols.(2005-2015)

Objective: To survey procedures and protocols in pediatric computed tomography (CT) in Pakistan.2005-2015

Methods: Under a project of the International Atomic Energy Agency, 45 CT facilities throughout the country responded to a survey of CT technology, exposure parameters, CT protocols and doses.

Results: Modern MDCT systems are available in 70 % of the facilities surveyed, dedicated pediatric CT protocols available in 90%. However Specific CT protocols for certain age groups were unavailable in around 50 % of the facilities. Indication-based protocols were used in 40 % of facilities. Estimates of radiation dose using CTDI or DLP from standard CT protocols demonstrated wide variation up to a factor of 100. CTDIvol values for the head and chest were between two and five times those for an adult at some sites. Sedation was frequently reported and use of shielding and immobilization was not in routine use. Records of exposure factors were kept at 10 % of sites.

Conclusion: This survey demonstrates significant potential for improvement in CT practice and protocol use for children in less resourced sites .Dose estimates for young children varied widely. it provides critical baseline data for ongoing quality improvement efforts by the IAEA.and PNRA Pakistan regulatory authority for reduction in pediatric doses.

SP119.7 - Occupational Dose Measurement in an Interventional Radiology Facility in Jakarta

Author(s): Lukmanda Evan Lubis, Nur Aida, Nurdina G. Pratiwi, Kristina Tri Wigati, Supriyanto Ardjo Pawiro, Djarwani Soeharso Soejoko

Department Of Physics, Faculty Of Mathematics And Natural Sciences, University of Indonesia, Depok/INDONESIA

The increasing use of ionizing radiation for diagnostic aims increases the alert on radiation protection. Whereas high standard and awareness are typically possessed by workers on Diagnostic Radiology facilities, personnel of Interventional Radiology departments are of higher need of attention. The works in Interventional Radiology the procedures are done with a long time fluoroscopy and the personnel being inside the imaging room. Two studies were performed on occupational dose measurement in Cardiac Interventional Radiology. The first study was done by measuring exposure levels on working staffs during a single interventional procedure, with the efficacy of available shielding being evaluated also. Second study was carried on by measuring scattered dose levels in various positions during a range of varied cardiac interventional procedures. On the whole, resulting remarks served as an input for the workers on the feasibility of their equipment, and scattered radiation during Cardiac Interventional Radiology procedures.

SP119.8 - Evaluation of the Comparative Effectiveness of Various Jurisdictional Computed Tomography Radiation Dose Reduction Models

Background: High reliance on computed tomography (CT) worldwide results in high levels of radiation exposure to patients, which translates into increased cancer risks. Efforts to manage radiation dose are progressing, but the approach has not been standardized. It was, therefore, the aim of this study to systematically assess and compare jurisdictional policies that have been developed to optimize CT radiation dose.

Methods: Six jurisdictions (British Columbia, Ontario, Texas, California, Germany, Ireland) that contain institutions with dose tracking systems were selected to account for several possible approaches to radiation dose management. Each policy was reviewed and indexed for recurring themes. Five themes (technical requirements, operating requirements, radiation safety committee/quality assurance programs, radiation dose reporting, diagnostic reference levels) emerged. An assessment instrument was formulated by identifying 3 domains of related constructs (executability, comprehensiveness, rigor) that would negate common knowledge translation barriers. Two reviewers performed independent policy evaluations using the assessment framework until inter-rater reliability was judged to be sufficient (ĸ <0.75). Inter-rater reliability was calculated using Weighted Cohen's kappa. Final scores were achieved through consensus once κ was satisfactory. Statistical analyses were performed using Pearson correlations.

Results: Two rounds of independent evaluations were necessary to achieve sufficient inter-rater reliability. Inter-rater reliability was high (κ =0.830) for the assessments after discussion occurred to clarify the definition and application of the domains. Final domain and theme scores for each jurisdiction are presented in Table 1. There was strong positive correlation for the domains, but not themes.

Conclusions: The assessment instrument may be useful for relative comparisons of knowledge translation potential in regulatory policies. Positive correlations between the domains suggest that carryover effects may be present if policymakers focus intensively on developing any one domain. The evaluations revealed that precise accreditation standards (such as those in British Columbia and California) exhibited the most executable, comprehensive and rigorous model for managing radiation dose. California's efforts in mandating CT facility accreditation and dose reporting achieved the highest score overall (51 out of 72). Ireland and Germany achieved comparable scores, despite developing different interpretations of the same regulatory framework (Euratom's Directive 97/43) that resulted in varying approaches to dose management. The framework can be further enhanced to account for these critical differences. Our goal is to improve patient safety globally, by encouraging translatable jurisdictional models for radiation dose management. Further evaluations will need to validate the relationship between jurisdictional policies and radiation dose reduction over time.

Table 1: Final Domain and theme scores for each jurisdiction						
Domain	British Columbia	Ontario	California	Texas	Germany	Ireland
Exeuctability	15	5	17	11	11	10

SP120 - Biomedical Diagnosis & Prediction

TRACK 09: BIOSIGNAL PROCESSING

SP120.1 - Desaturation event characteristics and mortality risk in severe sleep apnea

Author(s): <u>Antti Kulkas</u>¹, Anu Muraja-Murro², Timo Leppänen², Peka Tiihonen², Esa Mervaala³, Juha Töyräs²

¹Clinical Neurophysiology, Seinäjoki Central Hospital, Seinäjoki/ FINLAND, ²Clinical Neurophysiology, Kuopio University Hospital, Kuopio/FINLAND, ³Institute Of Clinical Medicine, Faculty Of Health Sciences, University of Eastern Finland, Kuopio/FINLAND

Obstructive sleep apnea (OSA) is a public health problem with severe health consequences. The current OSA severity estimation is based on the average number of breathing cessation and desaturation events per hour of sleep, neglecting the individual event characteristics. The aim of the current study was to evaluate desaturation event morphology in deceased and matched control patients with severe OSA.

12 deceased and 12 AHI, age, BMI and follow-up time matched alive control patients with severe OSA were analyzed. Desaturation event durations, depths, and areas of the deceased and alive control patients were compared. Also the effect of different baseline level selection in the desaturation depth analysis was investigated.

Patient demographics, apnea-hypopnea-index (AHI) and oxygendesaturation-index (ODI) did not differ statistically significantly between the groups. The average oxygen saturation levels were statistically significantly lower 89.8% vs. 93.2% (p=0.002) in the deceased patients compared to the alive controls. The median desaturation event duration 31.8s vs. 25.9s (p=0.017), depth 15.0% vs. 9.5% (p=0.006) and area 349.9s% vs. 201.4s% (p<0.001) were statistically significantly greater in the deceased patients compared to the alive control patients when using 100% saturation as baseline level for desaturation events. When the first point before desaturation onset was used as baseline no statistically significant differences (p=0.089) were found between the deceased and alive control patients in desaturation depths. Based on quantitative inspection of the distributions of individual desaturation event characteristics the desaturation events were more severe in the deceased group.

Patients with similar AHI and ODI can have different individual desaturation event characteristics. Selection of the baseline for desaturation event depth analysis can affect the estimation of the event severity. The analysis of the individual desaturation event characteristics can provide supplementary information on the severity estimation of OSA and support the individual mortality risk estimation in severe OSA patients.

SP120.2 - Static Posturography of Elderly Fallers and Non-Fallers with Eyes Open and Closed

Author(s): <u>Jennifer Howcroft</u>¹, Jonathan Kofman², Edward D. Lemaire³, William E. Mcilroy⁴

¹Department Of Systems Design Engineering, University of Waterloo, Waterloo/ON/CANADA, ²Systems Design Engineering, University of Waterloo, Waterloo/ON/CANADA, ³Crrd, The Ottawa Hospital Research Institute, Ottawa/CANADA, ⁴Department Of Kinesiology, University of Waterloo, Waterloo/ON/CANADA

Static posturography can be used to assess postural balance, which is important for activities of daily living. For older adults, poor postural balance can indicate increased fall risk. This study investigated eyes open and eyes closed static posturography assessments of 100 elderly participants (≥ 65 years) in two-feet stance. Twenty-four of these people had fallen in the previous six months. Range in anterior-posterior (AP) and medial-lateral (ML) motion; center of pressure (CoP) root mean square distance from mean; AP, ML, and resultant CoP velocity; and percent body weight on left and right feet were calculated from Wii Balance Board vertical force data. All AP measures and resultant CoP velocity were significantly greater with eyes closed than eyes open for fallers and non-fallers. ML CoP velocity was significantly greater with eyes closed than open for fallers. The largest percent increase from eyes open to eyes closed was for AP velocity, followed by 2D velocity for both fallers and non-fallers. Therefore, AP-based center of pressure-derived posturography measures appear to be sensitive to changes in postural control due to elimination of visual input. Significant differences were not found between fallers and non-fallers.

SP120.3 - Quantitative analysis of ventricular ectopic beats evaluated from short-term recordings of heart rate variability before imminent tachyarrhythmia

Author(s): <u>Marisol Martinez-Alanis</u>, Claudia Lerma Departamento De Instrumentación Electromecánica, Instituto Nacional de Cardiología Ignacio Chávez, Mexico City/MEXICO

Background: Several analysis of heart rate variability (HRV) data recorded with implantable cardioverter defibrillators (ICDs) have been proposed as predictors of ventricular tachyarrhythmia (tachycardia VT, or fibrillation VF). Most analysis are based on normal-to-normal sinus beat (NN) intervals or the effect of premature ventricular complexes (PVCs) upon the sinus rate. This work is based on the analysis of PVCs features in relation to NN intervals (called heartprint), which has several risk markers of fatal or near-fatal arrhythmias obtained from long-term recordings (over 70,000 beats).

Objective: The aim was to compare PVCs characteristics with the heartprint before a sustained tachyarrhythmia (VT/VF) versus control in time series from short-term HRV recordings (about 1,000 beats).

Methods: Data was obtained from the Spontaneous Ventricular Tachyarrhythmia Database (http://www.physionet.org/physiobank/ database/mvtdb/), which contains 135 pairs of short-term RR interval time series recorded by ICDs in 78 subjects. RR intervals from PVCs were identified with an adaptive filtering algorithm (available: http://tocsy.agnld.uni-potsdam.de/). Heartprint indexes included the coupling interval (CI, the RR interval between each PVC and its preceding sinus beat) and the number of intervening sinus beats between two PVCs (NIB). Mean and standard deviation (SD) of NN intervals and CI were estimated for each time series, as well as the most frequent value of NIB (NIB score), which quantifies the prevalence of repeating forms of PVCs. According to the mean heart rate (HR) during the last minute before VT/VF, the recordings were classified into two groups depending on whether the HR was faster or slower than 90 beats per minute (bpm). Since most indexes had no normal distribution, median values were compared using Wilcoxon signed-rank test (VT/VF versus control) or Mann-Whitney U-test (HR≥90 bpm versus HR<90 bmp).

Results: Table 1 shows that for the group with accelerated HR (HR \ge 90 bpm), several indexes were different before VT/VF (faster HR, more ectopy, shorter and more fixed CI) versus control. In contrast, the group with HR<90 bpm had similar indexes before VT/VF versus control. Although the group with HR<90 bpm was characterized with faster HR and shorter CI than the group with HR \ge 90 bpm, both groups had similar ectopy.

Conclusions: Several quantitative characteristics of PVCs evaluated with the heartprint method in short-time HRV series obtained from ICDs are potential markers of imminent tachyarrhythmia (VT/ VF). The interaction between accelerated HR and high ectopy (previously known risk factors of tachyarrhythmia) should be considered in future evaluation of CI indexes as risk indicators for VT/VF.

SP120.4 - An evaluation of Arterial Stiffness Index in Relation to the State of the Cardiovascular System

Author(s): Jan Havlík¹, Jakub David², Jan Dvořák³, Lenka Lhotská⁴ ¹Faculty Of Electrical Engineering, Czech Technical University in Prague, Prague /CZECH REPUBLIC, ²Faculty Of Electrical Engineering, Czech Technical University in Prague, Prague /CZECH REPUB-LIC, ³Faculty Of Electrical Engineering, Czech Technical University in Prague, Prague/CZECH REPUBLIC, ⁴Cybernetics, Czech Technical University, Prague/CZECH REPUBLIC

The study deals with an evaluation of correlation between an Arterial Stiffness Index and a state of the cardiovascular system. The main goal of the research is to show whether the ASI is an appropriate parameter for CVS state classification. The statistical evaluation of the dependency of the ASI on the CVS state and other parameters has been done using the linear regression analysis and the t-test of mean values. The ASI has been correlated with the age of the patient, the blood pressure (low/normal/high), the mean arterial pressure and the presence both of the cardiovascular diseases and diabetes mellitus. For the evaluation the signal database which consists of signals from more than 90 persons in wide age range (from 20 to 94 years) has been used. It has been proved that the ASI depends on the age of the patient, on the MAP and on the presence both of the cardiovascular diseases and diabetes mellitus in the study. Only the correlation between the ASI and blood pressure (low/normal/high) has not been directly proved. Although the results are statistically significant, the study shows the limitations of ASI as a CVS status marker. The ASI is a suitable parameter for primary screening, but it should be complemented by additional parameters for increased reliability.

SP120.5 - Investigating a Novel Non-invasive Measure to Assess the Upper Airway Narrowing during Sleep Author(s): Ving Xuan Zhil, Elma Zola² Milos Popovin³ Azadel

Author(s): <u>Ying Xuan Zhi</u>¹, Elma Zola², Milos Popovic³, Azadeh Yadollahi¹

¹Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA, ²Ryerson University, Toronto/CAN-ADA, ³Toronto Rehabilitation Institute, University Health Network, Toronto/CANADA

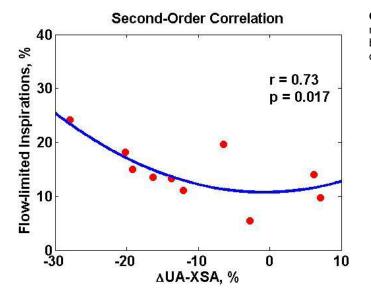

Introduction: Previous studies from our team have shown that upper airway (UA) narrowing during sleep could increase its resistance. Increased UA resistance and the associated inspiratory flow limitation are important means of assessing both the cause and the consequences of breathing disorders during sleep. While gold standard assessment of the UA resistance requires invasive measurement of pharyngeal pressure, previous studies have shown that the contour of nasal airflow could be used as a non-invasive technique to detect increased UA resistance during sleep. However, these studies have not investigated whether the non-invasive estimation of the UA resistance is associated with physiological variations such as the narrowing in UA cross-sectional area (UA-XSA). The objective of this study is to evaluate the sensitivity of the non-invasive measures of the UA resistance to estimate the changes in the UA-XSA during sleep.

Methods: Subjects attended a regular sleep study in our sleep laboratory. The nasal airflow was collected non-invasively using a nasal cannula. The sleep apnea severity was assessed by the apnea-hypopnea index (AHI). Before and after sleep, UA-XSA was measured by acoustic pharyngometry. For each inspiration, different temporal features such as the number and location of peaks and the plateau in the airflow contour were extracted. Those features were used to manually annotate the inspirations, which correspond to severe flow limitation in the UA and increased UA resistance. The correlation between changes in UA-XSA due to sleep and the percentage of the flow-limited breaths were examined.

Results: 10 non-obese men, age 31.8 ± 26.7 years and AHI of 41.4 ± 12 completed the protocol. After sleep, UA narrowed by -11.87±10.38% (P<0.001). From each subjects, 244 ± 80 episodes of inspiratory airflow signal were randomly selected from their stage 2 of sleep, and annotated by two experts with consistent agreement. We found that there was a second-order significant correlation between the narrowing in UA-XSA and the percentage of flow-limited inspirations (r=0.73, p=0.017).

Conclusions: Our results show that non-invasive assessment of the UA resistance, obtained by measuring the contour of nasal airflow, can be used as a sensitive measure to assess the severity of UA narrowing during sleep.

SP120.6 - Establishing a New Biomarker to Determine Patients at Increased Risk of Developing Obstructive Sleep Apnea Due To Fluid Overloading

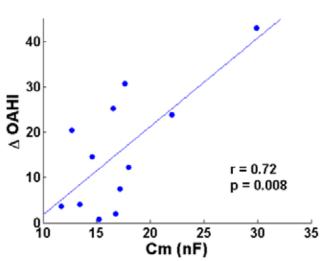

Author(s): Milos R. Popovic, <u>Bojan Gavrilovic</u>, Azadeh Yadollahi Toronto Rehabilitation Institute - University Health Network, Toronto/ ON/CANADA

Introduction: Obstructive sleep apnea (OSA) is common in 10% of adults and is characterized by repetitive collapse of the pharynx. OSA prevalence increases in fluid retaining patients such as those with heart or renal failure. It is shown that OSA severity worsens with overnight fluid accumulation in the neck. The objective of this study is to develop a new biomarker to assess fluid accumulation in the neck which can be used to determine patients at high risk of developing OSA due to fluid overload.

Methods: This study was part of a double cross-over study to investigate the effects of experimentally induced fluid overloading during sleep on OSA severity. During the control arm saline was infused at a minimal rate to keep the vein open, while during the intervention approximately 2L of saline was infused intravenously during sleep. OSA severity was assessed using polysomnography to estimate obstructive apnea-hypopnea index (OAHI). Before and after sleep, neck fluid volume was measured using bioelectrical impedance at 50kHz. For each subject, resistance and reactance was extracted from the impedance measurements. Neck impedance can be modeled as a resistor (extracellular fluid, RE) in parallel with a capacitor (cell membrane, Cm) and resistor (intracellular fluid, Ri). Increase in intracellular fluid could swell the cell and increase Cm. The recorded reactance and resistance from bioimpedance measurements can be expressed in terms of Ri, RE, Cm, $\omega(2\pi f)$ and τ (Cm[Ri+Ro]). Assuming that $\omega^2 \times \tau^2 \ll 1$, the recorded resistance and reactance can be simplified to R = Ro, and $Xc = -\omega CmRo^2$, respectively. Using these relations, the bioimpedance recording of neck can be used to estimate Cm, which could represent the intracellular fluid of the neck.

Results: Subjects who had an increase in OAHI from the control to saline infusion arm were investigated. 12 non-obese men, age 44 ± 13 , with OAHI 18 ± 23 were included. Our results show that subjects with a larger Cm before sleep during the control arm had a larger increase in OAHI from control to intervention (P=0.008). This indicates that those with a larger estimated capacitance and intracellular fluid were more susceptible to the adverse effects of fluid overload on OSA severity.

Conclusion: These promising results demonstrate that non-invasive measurements of bioimpedance can be used to develop a novel biomarker to assess patients at high risk of fluid overloading and developing OSA.

SP121 - Deep Brain Stimulation

TRACK 11: NEUROENGINEERING, NEURAL SYSTEMS

SP121.1 - A 16-bit High-Voltage Digital Charge-Control Electrical Stimulator

Author(s): Soheil Mottaghi¹, Richard Pinnell¹, <u>Ulrich G. Hofmann²</u> ¹Neuro Surgery, Neuro Electronics Systems, University Hospital Freiburg, Freiburg/GERMANY, ²Neuro Surgery, neuro Electronic Systems, University Hospital Freiburg, Freiburg/GERMANY

Research on the effects of electrical stimulation, needs an accurate system able to generate any arbitrary waveforms with different frequencies and interphase delays. Some applications such as Deep Brain Stimulation (DBS) turn to smaller electrodes resulting in higher impedances, causing obstacles to deploy the same amount of charge to the tissue. In this paper a 16-bit digital charge-control current stimulator is presented which can produce up to -/+ 35V output swing voltages. Platinum flexible electrodes have been used to compare the performance of the developed with two commercial stimulators.

SP121.2 - A method for side effect analysis based on electric field simulations for intraoperative test stimulation in deep brain stimulation surgery

Author(s): Daniela Pison¹, Fabiola Alonso², Karin Wårdell², Ashesh Shah¹, Jérôme Coste³, Jean-Jacques Lemaire³, Erik Schkommodau¹, <u>Simone Hemm-Ode¹</u>

¹Institute For Medical And Analytical Technologies, School of Life Sciences, Muttenz/SWITZERLAND, ²Department Of Biomedical Engineering, Linköping University,, Linköping/SWEDEN, ³Imageguided Clinical Neurosciences And Connectomics (ea 7282, Centre Hospitalier Universitaire de Clermont-Ferrand, Clermont-Ferrand/ FRANCE

Despite an increasing use of deep brain stimulation (DBS) the fundamental mechanisms underlying therapeutic and adverse effects remain largely unknown. The simulations of electric entities are increasingly used to evaluate stimulation effects. So far no group has considered such simulations combined with a side effect analysis of data obtained during intraoperative test stimulations. The aim of the present paper is to introduce a method allowing patient-specific electric field simulations for stimulation amplitudes inducing side effects during DBS-surgery.

Two female patients presenting essential tremor, both bilaterally implanted in the ventral intermediate nucleus (VIM) region (Clermont-Ferrand University Hospital, France) were included in the study. Intraoperative test stimulations were performed on central and posterior trajectories in each hemisphere. At each position, in addition to the evaluation of the therapeutic effects, side effects such as pyramidal symptoms and paresthesia without localization indicator or paresthesia with localization indicated by the patient (in the hand or in the fingers) were noted. The anatomical structures such as VIM and its neighbors were preoperatively manually outlined using the iPlan software (Brainlab, Feldkirchen, Germany) according to spontaneous MRI contrasts [1]. The so identified structures were exported via a specifically designed interface (VVLink, Brainlab, Feldkirchen, Germany). Whenever side effects occurred the inducing stimulation amplitude was chosen for electric field simulations. A finite element method [2] was applied to calculate the electric field distribution. Conductivity values were deduced from the patient's T1 weighted MRI. An isofield level of 0.2V/mm was chosen and the

points of the isosurface were exported. They were visualized together with the extracted anatomical structures and the trajectories. The different structures presented inside the volume defined by the isofield level and their appearances were determined. Combinations of structures always appearing together for a specific side effect were identified.

For both patients, eight electric field simulations were performed. A first analysis showed that pyramidal effects appear when parts of the ventro-oral nucleus (VO) and the VIM were present inside the isosurface. The ventrocaudal lateral nucleus (VCL), the ventrocaudal medial nucleus (VCM) and the VIM were among the identified structures in hand paresthesia (VCL, VIM), finger paresthesia (VCL, VCM, VIM) and paresthesia with location not formally identified by the patient (VCM, VIM).

The application of our method to two patients has shown its feasibility. Our results are consistent with anatomical knowledge that stimulation of VCL and VCM induce paraesthesia in the body and the face respectively. Nevertheless, more patient data have to be analysed to draw any conclusions. The present method will allow an optimised data exploration compared to existing methods only taking into account the anatomical position of the center of the measurement electrode.

SP121.3 - Comparison of Three Deep Brain Stimulation Lead Designs under Voltage and Current Modes

Author(s): <u>Fabiola Alonso</u>, Malcolm A. Latorre, Karin Wårdell Department Of Biomedical Engineering, Linköping University, Linköping/SWEDEN

Since the introduction of deep brain stimulation (DBS) the technique has been dominated by Medtronic systems. In recent years, new DBS systems have become available for patients, and some are in clinical trials. The present study aims to evaluate three DBS leads operated in either voltage or current mode. 3D finite element method (FEM) models were built in combination with a neuron model for this purpose. The axon diameter was set to D = 5 μ m and simulations performed in both voltage (0.5-5 V) and current (0.5-5 mA) mode. The evaluation was achieved based on the distance from the lead for neural activation and the electric field (EF) extension at 0.1 V/mm. The results showed that the neural activation distance agrees well between the leads with an activation distance difference less than 0.5 mm. The shape of the field at the 0.1 V/mm isopotential surface in 3D is mostly spherical in shape around the activated section of the steering lead.

SP121.4 - Effect of closed-loop and open-loop deep brain stimulation on chronic seizures control

Author(s): <u>Muhammad T. Salam</u>¹, Roman Genov², Jose Luis Perez Velazquez³

¹Electrical Engineering, University of Toronto, Toronto/CANA-DA, ²Electrical Engineering, University of Toronto, Toronto/ON/ CANADA, ³Neuroscience & Mental Health Programme And Division Of Neurology, Hospital for Sick Children, Toronto/ON/CANADA

Objective: To investigate the effects of closed-loop and open-loop neurostimulation of the hippocampus on the suppression of spontaneous seizures in a rodent model of epilepsy. Method: Chronic seizures in ten rats were induced by intraperitoneal kainic acid injection. Two bipolar electrodes were implanted into the CA1 regions of both hippocampi. The electrodes were connected to the custombuilt programmable therapeutic neuromodulation device that can trigger an electrical stimulation either in a periodic manner or upon detection of the intracerebral electroencephalographic (icEEE) seizure onset. This device has a microchip consisting of a 265-channel icEEG recording system and a 64-channel stimulator, and a programmable seizure detector built in a field-programmable gate array (FPGA). This device was used to evaluate seizure suppression efficacy in the epileptic rats for 240 days (5760 hours). For this purpose, all rats were randomly divided into two groups: the nonstimulation and the stimulation group. The non-stimulation group did not receive stimulation; whereas the treatment group received closed-loop stimulation and later, open-loop stimulation. Result: The non-stimulation and stimulation groups had a similar seizure frequency baseline, average 5 seizures per day, but the closed-loop stimulation reduced seizure frequency by 90% and the open loop stimulation reduced by 17% in the stimulation group. Significance: In this study, this closed-loop stimulation strategy proved superior to the open-loop stimulation in the seizure suppression using the optimal number of stimulations. Therefore, an effective alternative to the open-loop neurostimulator is the closed-loop neurostimulator. in which the involvement of the deep brain stimulation is minimal. Such a system would be able to sense the upcoming seizure in real time, and deliver the proper stimulation. The new era of deep brain stimulation strategies based on closed-loop paradigms may be able to target different pathological aspects of brain activity for the treatment of various neurological disorders.

SP121.5 - Clinical validation of a precise tremor assessment system to aid deep brain stimulation parameter optimisation Author(s): <u>Thushara Perera</u>¹, Shivanthan A.C. Yohanandan², Mary Jones³, Richard Peppard³, Wesley Thevathasan¹, Andrew H. Evans⁴, Joy L. Tan¹, Colette M. Mckay¹, Hugh J. Mcdermott¹ ¹Neurobionics, Bionics Institute, East Melbourne/AUSTRALIA, ²Electrical And Electronic Engineering, The University of Melbourne, Melbourne/AUSTRALIA, ³Department Of Neurology, St Vincent's Hospital, Melbourne/AUSTRALIA, ⁴Department Of Neurology, The Royal Melbourne Hospital, Melbourne/AUSTRALIA

Introduction

Deep brain stimulation (DBS) is an established therapy for Parkinson's disease and Essential Tremor. Yet finding the most efficacious stimulation amplitude, pulse duration and frequency is difficult due to the numerous parameter permutations. The therapeutic outcomes are measured using a variety of clinical assessments including subjective rating scales. These measures lack sufficient sensitivity to inform DBS parameter optimisation, thus justifying our aim to develop a more precise and objective measure.

Methods

The Tremor Biomechanics Analysis Laboratory (TREMBAL) system, developed at the Bionics Institute, provides real-time tremor severity measurements for clinicians using an electromagnetic motion tracker (Ascension, Vermont, US) to acquire absolute displacements and rotations of the tremulous body part. TREMBAL automatically computes tremor amplitude, velocity, peak frequency and peak power spectral density (PSD) for both translational and rotational components of motion.

We placed two sensors on each hand at the proximal phalanges of the middle fingers and approximately 5 cm above the olecranon of the elbows to measure proximal and distal tremors of nine participants with existing DBS therapy. Four trials were performed where DBS level was systematically reduced from 100% (clinically optimal level) to 75%, 50% and finally 0% (DBS off). In each trial, after waiting 12 minutes for adaptation, the participant held their hands outstretched for 10 seconds and performed the finger-nose exercise. These were video recorded and presented to three blinded experts (W.T., A.H.E., J.L.T.) for clinical rating using the Bain Tremor Rating Scale. Linear regression analysis between the average expert tremor ratings and computed tremor metrics were used to validate TREMBAL. Pearson's correlations were also performed to confirm any associations.

Results

Sixty-four clinical ratings were included in the analysis. One patient was excluded because they presented with dystonia. Results were deemed significant if p < 0.0063 (Bonferroni correction for multiple comparisons). Objective measures of translational amplitude and velocity had the strongest ability to predict clinical ratings (table 1).

Motion Type	Metric	R ²	SE	r	р
Translation	Amplitude	0.81	0.53	0.90	<0.001
	Velocity	0.81	8.34	0.90	<0.001
	Frequency	0.32	0.09	0.56	<0.001
	PSD	0.71	0.22	0.84	<0.001
Rotation	Amplitude	0.34	0.27	0.59	<0.001
	Velocity	0.34	5.15	0.58	<0.001
	Frequency	0.20	0.09	0.45	<0.001
	PSD	0.20	0.01	0.44	<0.001

Table 1. The coefficient of determination (*R2*) and standard error (SE) indicated the goodness-of-fit of the linear regression between clinical ratings and TREMBAL metrics for distal tremor of the worst affected hand. Pearson's correlations indicated strength (r) and statistical significance (p) of the association. PSD = Power Spectral Density.

Discussion

Tremor frequency and PSD in addition to all angular measures showed weaker agreement with clinical ratings. We believe that clinicians rely mostly on displacement and speed to assess tremor severity thus accounting for the high concordance with translational TREMBAL data. Further work will aim to determine the test-retest reliability of the system and the optimal combination of metrics to reduce TREMBAL's output to a single measure based on machine learning algorithms.

SP121.6 - The Role of Microelectrode Recording (MER) in STN DBS Electrode Implantation

Author(s): <u>Venkateshwarla R. Raju</u>¹, Rukmini M. Kandadai² ¹Biomedical Eng & Neurology & Neurosurgery And, Nizam's Inst of Medical Sciences (NIMS) University & Hospital, HYDERABAD/ INDIA, ²Neurology, Nizam's Inst of Medical Sciences, Hyderabad/ INDIA

The purpose of this paper is to study the correlation of microelectrode recording with the final tract chosen during bilateral STN DBS performed at a specialized centre in South India. Deep brain stimulation (DBS) of bilateral subthalamic nuclei (STN) is an efficient method of rehabilitation in subjects (diseased conditions-patients) with advanced idiopathic Parkinson disease (PD). Accurate targeting of STN neurons and placement of microelectrodes are paramount importance for optimal results after STN-DBS. Stereo tactic assessment, intra-operative microelectrode recording and intra-operative stimulation effects have all been used in targeting, albeit the individual role of each modality is still not known. Microelectrode recordings (MER) of STN were detected in a mean of 3.5 ± 1.1 channels on right hemisphere and 3.6 ± 1.04 on left hemisphere. Final channel selected were most commonly central seen in 42.3% followed by anterior in 33.7%. Concordance of final tract with the channel having the highest recording was 58.7%, with the channel showing maximum depth of recording was 48% and with either was 64%. Absence of any recording in the final tract chosen was seen in 6.52%, in these subjects the tract was chosen based on stimulation results. The depths of microelectrodes were detected by MER in 75.6%. Thus, MER is useful to detect-confirm the tract in which DBS electrodes are placed and is most useful in determining the depth of electrodes placement but has to be taken in consideration with effects seen on macro-stimulation.

SP121.7 - Effectiveness of Micro-Electrode-Recording(MER) in Determining Subthalamic-Nuclei Deep Brain Stimulation (STN-DBS) Lead Position in PD Conditions

Author(s): <u>Venkateshwarla R. Raju</u>, Praveen P. Ankathi Biomedical Eng & Neurology & Neurosurgery And, Nizam's Inst of Medical Sciences (NIMS) University & Hospital, HYDERABAD/INDIA

Objectives: To study the effectiveness of microelectrode-recording in determining final tract for placing DBS-electrode during bilateral-STN-DBS

Background: Deep-brain-stimulation of bilateral subthalamicnuclei is an effective mode-of-therapy in subjects with idiopathic Parkinson's-diseased-conditions(PDpatients). Accurate targeting and placement of microelectrodes are paramount importance for optimal results after STN-DBS. Stereotactic-assessment, intraoperative microelectrode-recording and intra-operative stimulation effects have all been used in targeting, though the individual role of each modality is still unknown.

Methods: 52PDsubjects were included in the study. Subjects with advanced PD of >5 years with good response to levodopa and H and Y score of <4 with normal cognition were eligible for surgery. Functional_Surgery was planned using a CRW frame with an MRI protocol using Framelink software with5channels. Microelectrode recording was performed in all subjects extending from 10mm above target to 10mm below STN. Final target-selection was based on the effects and side effects of macrostimulation and confirmed by post op MRI.

Results: 52PDsubjects with_their mean_age_of58.1 \pm 9.1years, mean_disease_duration of8.8 \pm 3.64years were included. Prior to implantation, mean-UPDRS-score in 'off' state was52.7 \pm 10.6and in 'on' state was 13.4 \pm 5.0. STN microelectrode recordings were detected in a mean of 3.5 \pm 1.1 channels on right-hemisphere and3.6 \pm 1.04on left-hemisphere. Final channel selected were most com-

monly central seen in42.3% followed by anterior in33.7%. Concordance of final track with the channel having highest recording was58.7%, with the channel showing maximum-depth-of-recording was48% and with either was64%. Absence-of-any-recording in the final tract chosen was seen in6.52%, in these subjects the tract was chosen based on stimulation results. The depth of microelectrodes was identified by microelectrode recording in75.6%.

Conclusion: Microelectrode-recording(MER) is useful to identify and confirm the tract in which DBS electrodes are placed and is most-useful in determining depth-of-electrodes placement but has to be taken in consideration with-effects seen on macrostimulation.

SP122 - Bioinformatics

TRACK 15: BIOINFORMATICS

SP122.1 - Machine learning for bioinformatics in the face of class imbalance Author(s):

Many pattern classification challenges of interest to bioinformatics involve the prediction of rare events. Examples include prediction of true protein-protein interactions among the millions of potential protein pairs within the human proteome, differentiating the few thousand true microRNAs from the millions of pseudo-miRNA sequences in the human genome, and identifying rare post-translational modification sites characterized only by degenerate sequence motifs. To create effective bioinformatics classifiers in the presence of severe class imbalance requires careful application of appropriate techniques during both the training and evaluation phases of system development. This talk will discuss a number of these techniques and include illustrative examples from recent studies conducted in our lab.

SP122.2 - Bioinformatics-based identification of osteoarthritis-associated genes in synovial tissues

Author(s): Yi-Jiang Song¹, Guiling Li², Li Yang¹

¹Key Laboratory Of Biorheological Science And Technology, Ministry Of Education, Bioengineering College, Chongqing University, Chongqing/CHINA, ²Institute Of Genomic Medicine, Wenzhou Medical University, Wenzhou/CHINA

Objective

Osteoarthritis (OA) is a highly prevalent chronic degenerative joint disease. Piling evidence has shown that primary OA is closely associated with aberrant genetic components. The current study aims to identify genes that are associated with OA in synovial tissues, and to further predict the biological pathways in which they may be involved, as well as their expressional microRNA (miRNA) regulators.

Table 1: miRNA regulators and GO functional annotation of five putative osteoarthritis-associated genes

Methods

We applied both data mining and microarray analysis in this study to identify genes that differentially express (fold-change > 2, p-value < 0.05) in synovial tissues between OA and the control patients. To further study the biological roles of these differentially expressed genes (DEGs), they were analyzed using DAVID. In addition, TargetScan was used to predict the conserved miRNAs that target the interested genes.

Results

The microarray data series were first downloaded from GEO, and then analyzed to obtain OA-related gene expression profile. We have identified 2,602 and 1,556 DEGs from series GSE29746 and GSE55235, respectively. The subsequent gene function annotation revealed that a number of pathways in which the DEGs may be involved, including cytokine-cytokine receptor interaction, MAPK signaling pathway, Hematopoietic cell lineage and cell adhesion molecules, might be associated with OA pathogenesis. Among them, 5 DEGs may be the potential molecular targets of OA (Table 1). MiRNAs have been reported to regulate genes expression in joint disease. So conserved miRNAs that target these genes were also predicted. However, the biological functions of these genes in OA, as well as their regulation by miRNAs, need further elucidation.

Conclusion

We have studied the expression of genes between OA and healthy controls, and identified a number of DEGs that may be putative molecular signatures of OA. miRNA regulators of five distinct DEGs were also predicted. *TIPARP* may be targeted by miR-221/222. And we found that *TIPARP* expression was significantly reduced in OA patients. Taken together with the fact that miR-221/222 is significantly over-expressed in rheumatoid arthritis synovial fibroblasts, *TIPARP* may play a role in OA pathogenesis via negative regulation by miR-221/222. The newly identified dysregulated genes and their miRNA regulators in OA may act as genetic markers for OA diagnosis and treatment in the future.

SP122.3 - Dynamic Epistasis Analysis Author(s): <u>Aseel Awdeh</u>, Theodore Perkins University of Ottawa, Ottawa/CANADA

Identifying regulatory relationships between genes is a central and challenging problem in the field of genetics. One classical approach is epistasis analysis (Avery & Wasserman, Trends in Genetics, 1992). Broadly speaking, epistasis between a pair of genes in a pathway, X and Y, happens when the phenotypic consequence of deleting genes X and Y is "unexpected" based on the results of deleting each gene individually. By following the rules of epistasis, one can sometimes infer which of X or Y is upstream of the other, and whether the relationship between them is activating or repressing. However, different pathway structures can result in identical phenotypes upon gene deletion. Thus, it is not always possible to infer the relationship between X and Y.

We propose *dynamic epistasis analysis*, which extends the classical approach by assuming that we can drive the pathway with a time-varying input signal. Intuitively, the time-varying input may help us discriminate between alternative pathway structures that are otherwise indiscriminable—for instance, because of how quickly the signal propagates to the phenotypic output, or because of transient changes in the output. Moreover, the approach is feasible in practice, because robotic flow cytometry and microfluidics devices make it relatively easy to interrogate cells with time-varying signals such as drug dosages or nutrient concentrations. Here, however, we report on a theoretical investigation of the limits and benefits of dynamic epistasis analysis.

First, we computationally enumerated all possible acyclic network topologies on two genes X and Y, which regulate the state of a third "output" gene Z, and which are themselves influenced by an "input" signal S. (Epistasis analysis is generally restricted to studying feedforward pathways, hence the limitation to acyclic networks. However, we impose no other limitations.) We adopted a discretetime Boolean model for all variables, S, X, Y and Z. When there is a regulatory link between a pair of variables, we assumed it can be activating or repressing. When a variable takes input from more than one other variable, we assume it adopts either the AND or the OR of its inputs (or their negations, in the case of repressive links). We found a total of 4608 possible networks that differ either by structure or regulatory functions. We then studied how many of those could be uniquely identified based on classic epistasis analysis, which looks at Z under different knockout conditions and static signal states S=0 or S=1, and dynamic epistasis analysis, which looks at Z under different knockout conditions and arbitrary time-varying S. We found that no network had unique patterns of phenotype Z in the classical approach, whereas 7.3% do under dynamic epistasis. If we allow gene knock-ins, which force X or Y to be on, classical epistasis can still only identify 0.7% of pathways, whereas dynamic epistasis identifies 19.4%. Thus, we conclude that dynamic information is potentially a very powerful addition to epistasis analysis.

SP122.4 - Transcription factor binding in an expanded epigenetic alphabet

Author(s): Coby Viner¹, James Johnson², Charles E. Grant³, William S. Noble⁴, Timothy L. Bailey², <u>Michael M. Hoffman⁵</u> ¹Department Of Computer Science, University of Toronto, Toronto/ ON/CANADA, ²Institute For Molecular Bioscience, University of Queensland, Brisbane/QLD/AUSTRALIA, ³Department Of Genome Sciences, University of Washington, Seattle/WA/UNITED STATES OF AMERICA, ⁴Department Of Genome Sciences, University of Washington, Seattle/UNITED STATES OF AMERICA, ⁵Princess Margaret Cancer Centre, Toronto/ON/CANADA

Many transcription factors (TFs) initiate transcription only in specific sequence contexts, providing the means for sequence specificity

of transcriptional control. A four-letter DNA alphabet only partially describes the possible diversity of nucleobases a TF might encounter. Cytosine is often present in the modified forms 5-methylcytosine (5mC), 5-hydroxymethylcytosine (5hmC), 5-formylcytosine (5fC), and 5-carboxylcytosine (5caC). TFs have been shown to distinguish unmodified from modified bases. Modification-sensitive TFs provide a mechanism by which widespread changes in DNA methylation and hydroxymethylation found in many cancers can dramatically shift active gene expression programs.

To understand the effect of modified nucleobases on gene regulation, we developed methods to discover motifs and identify TF binding sites in DNA with covalent modifications. Our models expand the standard A/C/G/T alphabet, adding m (5mC), h (5hmC), f (5fC), and c (5caC). We adapted the well-established position weight matrix (PWM) formulation of TF binding affinity to this expanded alphabet.

We engineered several tools for expanded-alphabet sequence and PWMs. We developed a program, Cytomod, to create the sequence using data from bisulfite sequencing. Cytomod decides between multiple modifications at a single position using a configurable evidence model. We also developed new versions of MEME (Multiple EM for Motif Elicitation) and FIMO (Find Individual Motif Occurrences) that enable de novo discovery of modification-sensitive motifs and identification of modification-sensitive binding sites.

We created an expanded-alphabet genome sequence using mouse embryonic stem cell data, and identified cis-regulatory modules that we believe are active only in the presence of cytosine modifications. We found new binding sites for known methylation-sensitive TFs, such as Klf4 and the c-Jun/c-Fos heterodimer. Using ChIP-seq data on TF binding locations, we discovered novel expanded-alphabet motifs.

SP122.5 - Identification of Molecular Phenotypes in Lung Cancer by Integrating Radiomics and Genomics

Author(s): <u>Patrick Grossmann</u>¹, Olya Grove², Nehme El-Hachem³, Chintan Parmar¹, Emmanuel Rios-Velazquez¹, Ralph T.H. Leijenaar⁴, Benjamin Haibe-Kains⁵, Philippe Lambin⁶, Robert J. Gillies², Hugo J.W.L. Aerts⁷

¹Radiation Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston/UNITED STATES OF AMERICA, ²Cancer Imaging And Metabolism, H. Lee Moffitt Cancer Center and Research Institute, Tampa/UNITED STATES OF AMERICA, ³Institut de recherches cliniques de Montreal, Montreal/CANADA, ⁴Radiation Oncology (maasro), Research Institute GROW, Maastricht/NETH-ERLANDS, ⁵Princess Margaret Cancer Centre, University Health Network, Toronto/CANADA, ⁶MAASTRO Clinic, Maastricht/NETH-ERLANDS, ⁷Radiology, Brigham and Women's Hospital, Harvard Medical School, Boston/UNITED STATES OF AMERICA

Medical imaging can visualize phenotypic characteristics of human cancers non-invasively. Radiomics is the process of converting images to mineable data and can provide a comprehensive quantification of tumor phenotype non-invasively by applying image feature extraction algorithms. Radiomic data have been suggested to be associated with clinical outcomes, however the biological basis of these associations is unknown. We therefore analyzed two independent lung cancer cohorts (one North American discovery cohort and one European validation cohort) totaling 351 patients, for whom diagnostic computed tomography (CT) scans, gene-expression microarrays, and clinical data were available. The tumor phenotype was characterized based on 636 radiomic features describing tumor intensity, texture, shape and size (Figure 1). We performed an integrative analysis by developing association modules of coherently expressed radiomic features and molecular pathways. We identified thirteen independently validated radiomic-pathway association modules (P < 0.05), the most prominent of which were associated

with the immune system, p53 pathway, and other pathways involved in cell cycle regulation (Figure 2A). Eleven modules were significantly associated with clinical factors (P < 0.05, Figure 2B). We further observed strong predictive power for pathway activation status; the areas under the receiver operating characteristic curves (AUCs) of the strongest predictions of every module ranged from 0.62 (P = 0.03) to 0.72 (P < 1E-6). In addition, combining radiomic data with clinical factors and genomic information resulted in consistent increases in power to predict overall survival in the validation dataset (concordance index max 0.73, P < 1E-9). In conclusion, we show that radiomic approaches permit a non-invasive assessment of molecular and clinical characteristics of tumors, and therefore have the potential to support clinical decision-making and advance therapeutic strategies using routinely acquired, standard-of-care imaging data.

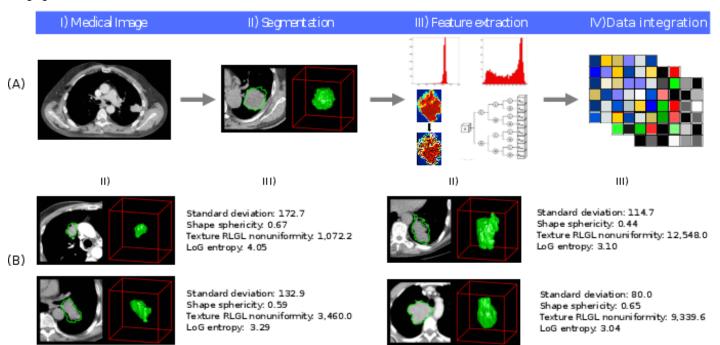

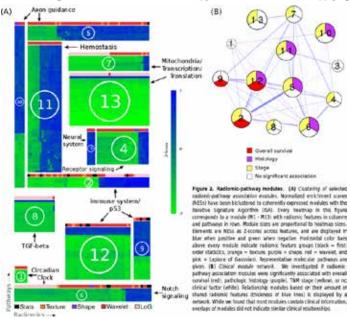

Figure 1. Radiomic strategy. (A) Workflow of extracting radiomic features: I) A lung tumor is scanned in multiple slices. II) Next, the tumor is delineated in every slice and validated by an experienced oncologist. This allows to create a 3D representation of the tumor outlining strong phenotypic differences in tumors of different patients. III) Radiomic featuresare extracted from these 3D images, and IV) integrated with genomic and clinical data. (B) Representative examples of lung cancer tumors. Visual differences in tumor shape and texture between patients can be objectively defined by radiomically defined features such as standard deviation of voxel intensity values ("How dispersed are the intensities"), sphericity of the tumor ("How compact is the tumor?"), non-uniformity of texture run-length gray-levels (RLGL) ("How heterogeneous is the tumor?"), and entropy of voxel intensities after applying a Laplacian of Gaussian (LoG) filter ("How uncertain are the intensities?").

SP122.6 - A machine learning method to build multi-SNP predictive models of clinical radiosensitivity

Author(s): Jung Hun Oh¹, Sarah Kerns², Harry Ostrer³, Barry Rosenstein⁴, Joseph O. Deasy¹

¹Memorial Sloan Kettering Cancer Center, New York/NY/UNITED STATES OF AMERICA, ²University of Rochester Medical Center, Rochester/NY/UNITED STATES OF AMERICA, ³Albert Einstein College of Medicine, New York/NY/UNITED STATES OF AMER-ICA, ⁴Mount Sinai School of Medicine, New York/NY/UNITED STATES OF AMERICA

Purpose: Genome-wide association studies (GWAS) have become a vital method to identify single nucleotide polymorphisms (SNPs) associated with common complex diseases. Many current GWAS analyses have used single-SNP models by individual association test. However, these methods suffer from multiple-testing correction due to a large number of SNPs being evaluated, which may cause some potentially important SNPs to fail to achieve genome-wide significance. Moreover, single-SNP models do not take into account correlations or interactions among significant SNPs.

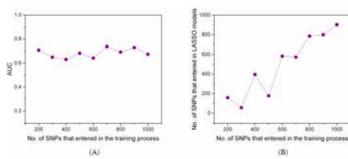

Materials/Methods: To overcome these weaknesses of the single-SNP approaches, we propose a machine learning-based multi-SNP model for predicting radiation-induced late rectal bleeding toxicity in prostate cancer patients. Our method consists of the supervised principal component analysis (SPCA) and least absolute shrinkage and selection operator (LASSO). Using SPCA, many irrelevant SNPs are filtered out and redundant SNPs are further removed via sparse regression models in the LASSO process.

In this radiosensitivity study, 365 prostate cancer patients who received radiotherapy were analyzed. For these patients, germline DNA extracted from lymphocytes was genotyped using the Affymetrix genome wide array (v6.0). To build a predictive model, we coded the status of rectal bleeding as 0 (grade 0 or 1; n=291) or 1 (grade 2+; n=74) using the Radiation Therapy Oncology Group (RTOG) late radiation morbidity scoring schema.

For an unbiased assessment, the dataset was split once and for all into two groups: a training dataset (2/3 of samples) and a validation dataset (1/3 of samples). In the modelling process, only the training dataset was used and the validation dataset was used to validate final predictive models.

Results: With the training dataset, univariate analysis was performed using Chi-square test. Based on the p-value, with an increasing number of top ranked SNPs (from 200 to 1000 SNPs), the model building process was conducted. Figure (A) shows the best AUC results obtained using the validation dataset with a different number of SNPs that were fed into the model building process. Figure (B) shows the number of SNPs that entered into the LASSO models after irrelevant and redundant SNPs were removed. When 700 SNPs were input into the model, an AUC of 0.74 was obtained with 573 SNPs that entered into the LASSO models.

Conclusions: Our proposed machine learning-based method was used to build a predictive model of late rectal bleeding toxicity for prostate cancer patients. We demonstrated that the proposed method has the potential to improve the prediction power in GWAS.

SP122.7 - Updated Free Energy Parameters Increase MicroRNA Prediction Performance

Author(s): <u>Robert J. Peace</u>¹, James R. Green² ¹Systems And Computer Engineering, Carleton University, Ottawa/ CANADA, ²Department Of Systems & Computer Engineering, Carleton University, Ottawa ON/CANADA

Most *de novo* microRNA prediction tools rely on RNA structure prediction as a pre-screening step – only those sequences that exhibit miRNA-like hairpin structures are considered as putative miRNAs. However, little attention has been paid to the quality of this prescreening step. This prescreening may unduly limit the sensitivity of the miRNA prediction method. We here demonstrate that leveraging recent advances in RNA structure prediction results in significant increases in overall miRNA prediction recall and precision.

SP123 - Patient Safety, Medical Errors and Adverse Events Prevention Related to Health Technologies

TRACK 16: CLINICAL ENGINEERING, CLINICAL PHYSICS, AND PATIENT SAFETY

SP123.1 - Incident reporting and learning systems improving quality and safety in radiation oncology Author(s): <u>Mary Coffey</u>

Radiation Therapy, Trinity College Dublin, Dublin/IRELAND

The publication of a number of fatal incidents in radiotherapy globally has led to an increased emphasis on openness and transparency and underpins the importance of reporting and learning from minor incidents and near misses in the prevention of further major incidents. Incidents and near incidents are a fact of life and cannot be eliminated completely, what is important is to learn from these and to share that learning with the wider radiotherapy community.

Reporting as part of the cycle of investigation, analysis, feedback and learning is one method of improving the safety of radiotherapy. Reporting can be mandatory or voluntary, internal or external depending on the requirements of the individual country. In the last decades a number of initiatives at country or professional organization level have resulted in the development of comprehensive reporting systems. One of the most recent systems to be put in place, the RO-ILS, was launched at ASTRO in 2014. Canada are currently piloting a national system, the ASN in France, the United Kingdom and The Netherlands have well established national systems and two voluntary international systems are in place: the Radiation Oncology Safety Information System (ROSIS) and the International Atomic Energy System: Safety in Radiation Oncology (SAFRON).

The Radiation Oncology Safety Information System (ROSIS) was established in 2001 and went live online in 2004. The IAEA Safety in Radiation Oncology (SAFRON) went live in December 2012. ROSIS and SAFRON share information with each other and SAFRON is currently developing further links with other national systems. In 2013/14 as part of a project supported by Varian and Elekta the taxonomy of ROSIS was revised to be consistent, as far as possible, with SAFRON, the AAPM system and RO-ILS.

The European Society for Radiotherapy and Oncology has established a Risk Management Committee with reporting and learning in the context of the recent European legislation a key focus.

SP123.2 - Applying an Evidence-based Approach to Managing Alarm Safety: A University Health Network Case Study Author(s): Anne Li¹, Dave Gretzinger²

¹Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/ON/CANADA, ²Department Of Medical Engineering, University Health Network and Mount Sinai Hospital, Toronto/ ON/CANADA

Background: High reliance on medical technologies to perform a myriad of tasks, ranging from surveillance to delivery of therapies, in modern medicine has resulted in excessive number of alarms on clinical units. This translates into an increased risk of alarm fatigue amongst caregivers, lowered quality of care and interrupted patient recovery. Technologies (such as alarm communication management systems and smart algorithms) have been developed to address alarm safety, but there are inherent limitations to every technology. It was, therefore, the aim of this case study to develop an evidence-

based approach to alarm safety management that can be applied across clinical units.

Methodology: Two intensive care units, a Level 3 (Medical Surgical Neurological Intensive Care Unit (MSNICU)) and a Level 2, at the Toronto Western Hospital were investigated. A recommended alarms management program by the ECRI Institute was modified to include only steps that were applicable to the investigational units and their associated workplace cultures. A multi-disciplinary team consisting of clinical engineers, nursing educators, and allied health professionals assembled bi-weekly to steer the direction of this initiative. Observations in the clinical units, nursing alarm surveys for MSNICU staff and review of incident reports from April 2012 to September 2014 were used to determine the areas of greatest vulnerability and establish priorities. Recurring themes in the textual data were indexed and refined.

Discussion: Thematic analysis revealed that alarm safety concerns centered around three themes of related constructs (alarm noise, alarm desensitization and alarm workflow). However, the relative contribution of each theme to alarm concerns varied due to differences in workflow and patient population. A universal management option, therefore, does not exist. The negative impact of continuous noise on patient recovery was unanimous amongst the surveyed nurses. High number of false positive and/or clinically irrelevant alarms resulted in caregiver apathy and desensitization, which caused true monitor events to be neglected. Non-standardized workflows (such as procedure for coverage of breaks and physiological parameter adjustments) also contributed to alarm safety issues.

Conclusions: Observations revealed that institution-wide procedural changes, such as mandatory physiological patient parameter adjustments and implementation of a standardized procedure to temporarily pause alarms when continuous monitoring is not required, may reduce excessive noise and false positive alarms. Frustrations often arose due to incomplete knowledge of the medical technologies. Information sessions and easily accessible answers to frequently asked questions (FAQ) could lessen this aspect of concern. Cultural changes are anticipated to provide a good first step to alarm safety management, however, gualitative data alone is insufficient to drive alarm safety initiatives. Since there is no "one size fits all" solution, future studies will require analysis of alarm data (number per bed, type and duration) to identify high-priority areas per clinical unit. Alarm data collection systems provide a safe process to monitor and evaluate the effectiveness of interventions. Sustainable improvements in alarm safety will require long-term commitment from all levels of institution.

SP123.3 - Using infusion pump logs to recreate a patient safety event: considerations for smart pump improvement Author(s): <u>Andrew lbey</u>¹, Derek Andrews², Barb Ferreira³ ¹Biomedical Engineering, Providence Healthcare, Vancouver/CAN-ADA, ²Pharmacy, Vancouver Coastal Health, Vancouver/BC/CANA-DA, ³Acute & Chronic Health, Vancouver Coastal Health, Vancouver/ BC/CANADA

The authors describe the reconstruction of a unique event involving a nurse's response to an error with an infusion pump in a critical care environment, and subsequent learning opportunity. The authors propose further considerations for smart pump improvement.

A 75-year-old male patient presented in July 2013 to a major teaching hospital with a massive gastrointestinal bleed and myocardial infarction, and was admitted to the intensive care unit. Although in tenuous health, the patient's condition stabilized with multiple infusion lines providing life-sustaining medication. At some point during the patient's care, the pump alarmed a "Communication Error" message. The nurse attempted to clear the alarm but the pump appeared unresponsive. She disconnected the module to reprogram the pump, causing an interruption in the DOPamine infusion. This caused the patient's blood pressure to plunge, resulting in a cardiac arrest. The pump was subsequently quarantined and sent to Biomedical Engineering for analysis.

The smart pump was a modular infusion pump with one central PC unit (PCU) and up to four large volume pump modules. Pump logs and the server database were mined and discovered that three PCUs and eight modules were connected to the patient at the time of the error. All equipment was functional and operated within the manufacturer's specification. The inter-unit interface connecting the PCU and module infusing DOPamine had corrosion and white "fluff" on the contacts, which is believed to be the cause of the "communication error".

During the investigation, the manufacturer explained that the pump's fail safe mechanism is to continue to infuse the drug at the prescribed rate during a "communication error" message. The pump gave no explicit instructions to resolve the issue, and resolution was not intuitive. Learning yielded a nursing practice alert to clarify how a nurse should resolve a "communication error".

The authors believe that infusion pump logs are not designed with any forethought as to how they will be used in an incident investigation. Pump logs are awkward and the data extracted is often heavily coded and not easily interpretable in plain English. Vendor software lacks meaningful tools to easily analyze the data, leaving the investigator to make sense of raw data.

Modern smart pump technology does not operate as a patient focused system. Instead, each PCU operates independently, lacking the ability to allow soft warnings or hard stops for a combination of contraindicated drugs (e.g. additive, potentiation or antagonistic) in the drug library that are infusing on separate channels of a PCU. Similarly, if 2 or more PCUs are connected to the patient, none of the PCUs know what is being infused on the other PCU channels. Pumps should be able to be daisy chained together so that they can communicate and record information as a cohesive system *per patient*.

Smart pumps have succeeded mitigating bedside medication errors. Secondary uses for incident investigations and multiple pumps to operate as a cohesive system on a patient should be considered for future enhancements.

SP123.4 - Developing an information retrieval engine for medical devices' vigilance reports

Author(s): Charalampos Tsirmpas¹, Athanasios Anastasiou¹, Maria Haritou², Dimitrios Koutsouris¹, <u>Nicolas Pallikarakis³</u> ¹School Of Electrical & Computer Eng., National Technical University of Athens, ATHENS/GREECE, ²Biomedical Engineering Lab., Institute of Communication and Computer Systems, ZOGRAFOU, ATHENS/GREECE, ³Biomedical Engineering Unit, University of Patras, Rio-Patras/GREECE

Objectives: Patient safety is a fundamental cornerstone of care and a critical component of healthcare systems. To create a safer environment, it is necessary to provide effective and efficient medical device (MD) vigilance information. The traditional approach, based only on user reports of adverse incidents, has been proven inadequate today.

Approach: In this work we describe our experience on the development of the EIPAS NLP engine, an information retrieval module in the context of the EIPAS project aiming at developing an innovative cross validation vigilance platform for medical devices. EIPAS NLP engine is mainly focused on retrieving information from direct sources such as vigilance reporting databases (VRDs). In other words, it is constructed with the goal of providing structured data related to medical devices' adverse events, by extracting the appropriate information from semi-structured vigilance reports. Although the input data (vigilance reports) is raw, we considered it as semi-structured as it follows the structure defined by the definition of the report. More specifically the vigilance reports contain sections of descriptions related to medical devices malfunctions, as well as detailed information of the recalling process.

Method: The proposed engine is organized in three basic phases: the phase of preprocessing and parsing, the phase of entity extraction and the phase of ontology population. The phase of *preprocessing and parsing* is responsible for recognizing and separating the interesting section of the vigilance report related to the medical devices. The phase of *entity extraction* is the core process of our approach. During this stage, the entities of interest from each vigilance report are extracted. In our case, terms of interest among others include the manufacturer, model, serial number, etc. The phase of *entology population* includes the mapping of the previous phase outputs into ontology individuals.

Results & **Conclusion:** For evaluating purposes we fed the NLP engine with 30 reports (in html format) from FDA which were also manually annotated. In order to test our NLP engine we examine two aspects. Firstly, we assess the efficiency of preprocessing and parsing and its capacity to dissociate the areas of the report which are related to product description (PD), code description (CD), reason description (RD) and recalling firm description (RFD). The second examined aspect is the ability to extract the entities Manufacturer, Model, Serial, Product Metric (PM) and Product Amount (PA) from the respective sections.

Based on the results, it is expected that the proposed engine through the design, development and implementation of modern ICT tools, will create a prototype system, which will provide critical, on time and customized information to health care institutions with regard to MD adverse events.

Acknowledgements: The presented work was carried out in the framework of the project "EIPAS", funded under the THALES programme, co-financed by the European Union (European Social Fund-ESF) and Greek national funds through the Ministry of Education, Lifelong Learning and Religious Affairs and the Operational Program "Education and Lifelong Learning" of the National Strategic Reference Framework (NSRF).

SP123.5 - Efficient, all-in-one, Monte Carlo simulations of transit EPID cine-mode dose distributions for patient-specific VMAT quality assurance

Author(s): <u>Shiqin Su</u>¹, Parmveer Atwal¹, Julio Lobo², I Antoniu Popescu¹

¹Medical Physics, British Columbia Cancer Agency, Vancouver/ CANADA, ²Electrical And Computer Engineering, The University of British Columbia, Vancouver/CANADA

Introduction: The purpose of this study is to present a novel tool within the BEAMnrc/DOSXYZnrc environment for Monte Carlo (MC) simulations of transit EPID dose. During a standard DOSXYZnrc simulation, each particle history is tracked using a randomly sampled time-like variable (i.e. MU index ranging from 0 to 1), but the temporal information is discarded during dose deposition, producing a cumulative distribution. This means that if we wish to determine dose distribution as a function of time, separate simulations would have to be run for each interval of interest. Consequently, it is clinically unfeasible to perform MC simulations of transit EPID cine-mode acquisition for a VMAT plan delivered to a patient. To overcome this limitation we developed a method capable of providing these transit EPID distributions, per control point, or over any user-defined time interval, in a single simulation.

Methods: We modified DOSXYZnrc (version V4-2.4.0) to optionally output a 4D IAEA phase space during a source 20 simulation, in order to collect particles exiting the patient during a VMAT treatment. This phase space can be used for further synchronized simulations of EPID dose using the MU index associated with each particle. We have also modified DOSXYZnrc to output a new file in which this time-like variable is binned in a user-defined manner (e.g. consistent with the EPID cine-mode acquisition), and associated with each bin is the amount and location of energy deposited by particles whose MU indices fall within that bin.

Results: Evaluation of the new technique was done with an anthropomorphic phantom for a 2-arc head-and-neck VMAT plan. Comparison of the EPID cine-mode images with the corresponding MC calculated distributions, via the Gamma metric (3%, 3mm), showed greater than 96% agreement (see Figure). Total simulation times were not increased and the time-integrated dose was identical to that from a standard 3ddose file.

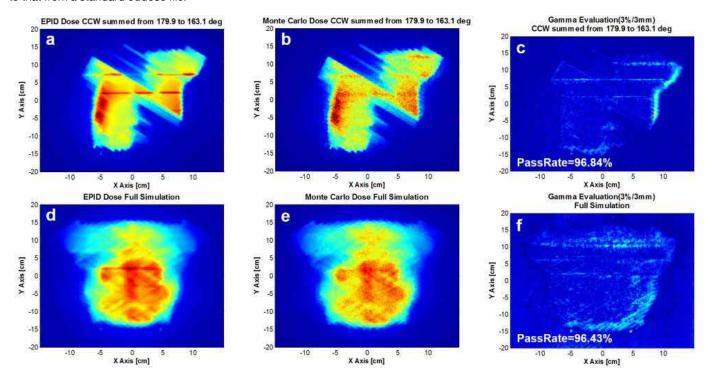

Figure. EPID dose images (a, d) compared with MC distributions (b, e), using 3%/3mm Gamma metric (c, f). Upper row corresponds to a segment of one arc; bottom row corresponds to full treatment (2 arcs).

Conclusions: Our method allows for comparisons of the 4D MC phase space EPID prediction with the actual EPID data acquired with the patient on treatment. This technique also allows for creation of a dose rate map within a phantom or patient. We demonstrated the feasibility of including transit EPID cine-mode MC simulations as part of a comprehensive patient-specific VMAT quality assurance process.

SP123.6 - Development of an interactive training tool to help reduce error rate associated with shared infusion volume management tasks

Author(s): Kyle Tsang¹, <u>Patricia Trbovich</u>², Sonia Pinkney³ ¹Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA, ²Humanera, University Health Network, Toronto/ON/CANADA, ³Centre For Global Ehealth Innovation, University Health Network, Toronto/CANADA

Background Medication administration errors in a hospital pose a serious threat to patients. Several types of medical technologies (e.g. smart pumps, alarms) have been introduced into the hospital environment, yet despite their numerous benefits, preventable medication administration errors still exist. Analysis reveals that inadequate training is a primary reason for these preventable errors. In the context of intravenous (IV) infusion systems, a clinician's training is mainly associated with the specifics of "how" to use certain equipment, but a fundamental understanding regarding IV infusion principles (e.g. hydrostatic pressure) is often missing. In particular, the concept of shared infusion volume, which refers to the common volume shared by 2 or more infusions in the IV tubing between the patient's vein and the point of medication delivery, is often incorrectly accounted for, which can result in unpredictable and hard to detect medication errors (e.g. delays in therapy, medication incompatibilities). Nurses often do not understand nor consider the presence of shared infusion volume in their practice and there are currently no explicit training methods to address this issue. This research aims to design and test an interactive training tool (ITT), in the form of a computer based e-learning module, to help improve a clinician's ability to deal with shared infusion volume management.

Objective The purpose of this research is to understand the different mental processes (e.g. decision making) associated with shared infusion volume using a cognitive task analysis method. Once a critical decision model is formed, the knowledge gained will be applied to the refinement of an ITT. This ITT will help train nurses to better understand multiple IV infusions by supporting the cognitive processes required and removing identified barriers associated with shared infusion volume.

Design A cognitive task analysis method consisting of semi-structured interviews with experienced clinicians will help determine the cognitive processes (e.g. specific critical cues) required to successfully manage the problem of shared infusion volume. Based on the processes discovered, an ITT will be refined, which will focus on improving the performance of IV infusion tasks. An experimental study using nurse participants from intensive care units will then be conducted. The number of errors in the high-fidelity simulated critical care environment will help assess the effectiveness of the newly developed ITT compared to a baseline condition of no training.

Conclusions It is expected that the use of an ITT can help reduce the error rate related to medication administration when dealing with multiple IV infusions. When designing an ITT for a complex task (e.g. shared infusion volume management), it is important to perform a suitable cognitive task analysis method to better understand the mental processes associated with the procedure. It is expected that a well-designed ITT that encompasses a proper knowledge framework can better train critical care nurses to effectively tackle complex medication administration tasks by making the invisible features of shared infusion volume visible. Improving patient safety by reducing the number of preventable human-related errors through ITTs may potentially reduce the number of preventable adverse events related to IV infusions.

SP124 - Medical Physics in Developing Countries

TRACK 17: EDUCATIONAL AND PROFESSIONAL ACTIVITIES

SP124.1 - Medical Physics Training Resources for Developing Countries

Author(s): Muthana Al-Ghazi

Radiation Oncology, University of California, Irvine, Orange/UNITED STATES OF AMERICA

Purpose: To outline resources available to developing countries for the training of medical physicists

Background: Cancer incidence in developing countries is rising with dearth of resources to combat it. In recent years, there has been a concerted effort on the part of national and international organizations (e.g. IAEA) to provide a framework and resources including complex radiotherapy technologies to address the problem. An important component of this effort is provision of trained personnel. Medical physicists play a leading role in the safe implementation of modern radiation treatment planning and delivery technologies and establishment of cancer care programs.

Methods: The advent of the World Wide Web, internet and social media make possible the use of these media to devise training resources aimed at developing educational and training programs for medical physicists in developing countries with little or no cost. The information is already available. What is required is guidance to colleagues in developing countries to harness these resources in a structured manner. The resources include, by way of example:

American Association of Physicists in Medicine (AAPM) resources such as task group reports, medical physics graduate and residency program structures, standards of practice, international educational portal and partner-in-physics (PIP) membership category

International atomic Energy Agency (IAEA) web-based resources

These do not require special access requirements and are globally available. There are many others based on UK, Canada, European medical physics organizations.

A key component is guidance by an experienced physicist based in a developed country who is specifically interested in education and development of the profession in developing countries to establish contact with a counterpart(s) in developing countries and work with them to tailor the available resources to their specific needs. This will generate interest in the country(ies) concerned and initiate awareness amongst authorities once the advantages of the effort are realized. This communication will develop and lead to the establishment of national medical organizations in developing countries which can then become IOMP members and access the full advantages of IOMP membership.

Results: Based on the author's experience, the approach described above led to the promotion and establishment of several national medical physics organizations in developing countries. All started from a single encounter.

Summary: Modern communication methods based on the availability of the internet can assist in promoting the field of medical physics and the training of medical physicists in developing countries who will contribute to the safe implementation of radiation treatment planning and delivery. This contributes positively to the global effort of combating cancer.

SP124.2 - Medical Physics in Indonesia: Current Status and Plans

Author(s): Djarwani Soeharso Soejoko, <u>Supriyanto Ardjo Pawiro</u>, Lukmanda Evan Lubis

Department Of Physics, Faculty Of Mathematics And Natural Sciences, University of Indonesia, Depok/INDONESIA

Since the nation-wide introduction of medical physics profession in 1980s, Indonesia continuously seeks a way to improve physics services in clinical environments in response to the rapidly-enhancing devices coming into use. It begun with efforts to primarily enhance educational aspect, to be followed by the work of making equipment and legal instruments available. Major hold-back is caused by inadequate number of master-degree holders in medical physics due to limited number of universities offering relevant degrees. Physics Department, Faculty of Mathematics and Natural Sciences, University of Indonesia has started to contribute on Medical Physics enhancement since 1998. Since then, nation-wide developments and changes has taken place involving our department, with more efforts to approach international standard still in place. This paper serves to share Indonesia's Medical Physics status and plans of enhancements.

SP124.3 - Surveying Trends in Radiation Oncology Medical Physics in the Asia Pacific Region

Author(s): Tomas Kron¹, Kwan Hong Ng²

¹Physical Sciences, Peter MacCallum Cancer Center, Melbourne/ AUSTRALIA, ²Department Of Biomedical Imaging, University of Malaya, Kuala Lumpur/MALAYSIA

Aim

Medical Physicists are important contributors to patient care in radiation oncology. However, their work is often less visible than that of clinicians or allied health staff which could affect their status as members of the health care team. It is the objective of our study to assess and track the work load, working conditions and professional recognition of radiation oncology medical physicists (ROMPs) in the Asia Pacific Region over time.

Methods

Since 2008 we have been conducting surveys on profession and practice of ROMPs in the Asia Pacific Region. A structured questionnaire was mailed in 2008, 2011 and 2014 to approximately 20 senior medical physicists representing 23 countries. The questionnaire covers 7 themes: 1. Education and training, 2. Staffing, 3. Typical tasks, 4. Professional organisations, 5. Resources, 6. Research and teaching, and 7. Job satisfaction.

Results

Across all three surveys the response rate was >90% with the replies representing practice affecting more than half of the world's population. The expectation of ROMP qualifications has not changed much over the years and typically requires a master degree and between 1 and 3 years of clinical experience. This is in line with the policy documents of IOMP; however, formal professional certification is only available in a small number of countries. Compared to 2008, the number of medical physicists in many countries has doubled. However, the number of experienced ROMPs compared to the overall workforce is still small in particular in low and middle income countries. The increase in staff is matched by a similar increase in the number of treatment units over the years. Furthermore, the number of countries using complex techniques (IMRT, IGRT) or installing high end equipment (tomotherapy, robotic linear accelerators) is increasing.

A trend towards increasing quality assurance activities over treat-

ment planning can be observed and most ROMPs are required to work overtime, usually not fully remunerated. The number of ROMPs who find time for research is still small and typically only 10% or less of the workforce have academic appointments, even if more are required to teach other professions. Resource availability has only improved marginally; however, better opportunities exist now than 6 years ago as nearly all medical physicists have access to the internet. Overall, ROMPs still feel generally overworked and the professional recognition, while varying widely, appears to be improving slightly.

Conclusion

Radiation Oncology Medical Physics practice has not changed significantly over the last 6 years in the Asia Pacific Region. However, both the number of physicists and the number and complexity of treatment techniques and technologies have increased dramatically. It is important to increase our effort now to improve the quality of the workforce and its professional recognition.

Acknowledgement: We would like to acknowledge the support of our colleagues in the Asia Pacific Region.

SP124.4 - The Status of Medical Physics in Iraq Author(s): Muthana Al-Ghazi

Radiation Oncology, University of California, Irvine, Orange/UNITED STATES OF AMERICA

Purpose: To provide an overview of the status of medical physics in Iraq

Background: Iraq is a Middle Eastern country with a population of approximately 30 million It has a history of excellent educational and healthcare systems in the Middle East. In the past three decades these suffered greatly due to wars, sanctions and civil strife. Despite these challenges, steps are being taken to advance the field of medical physics concurrent with developments in cancer care and attention that is being directed towards establishment of modern radiotherapy facilities where medical physicists play a critical role.

Medical Physics Practice: Most medical physicists are graduates of main stream academic physics programs and receive on the job training upon employment. There is one university that offers graduate medical physics studies at M.Sc./Ph.D. levels. Courses in radiation dosimetry, medical imaging, anatomy and physiology, radiobiology and radiation safety are included in the curriculum. This program has been re-structured recently to follow modern recommendations (e.g. AAPM report #197). This development is a result of improved communication between educators in Iraq and their counterparts in the West.

Professional Activities and Organization: The Iraqi Medical Physics Society (IMPS) was established in 2010. It has the usual structure (constitution and officers). It is a member organization of IOMP through the Middle East Federation of Organizations of Medical Physics (MEFOMP), the latter being the regional chapter of IOMP. IMPS has 40 members.

The majority of IMPS members are employed in cancer hospitals. There are three such hospitals in the capital and one each in 6 of the major provinces. The physicists' main responsibilities are in radiotherapy physics. Some collaborate with biomedical engineers in diagnostic imaging departments. There is a national radiation protection agency that monitors radiation safety in the country. The major cancer hospital in Baghdad has 70 oncology beds and serves as the Oncology teaching hospital for the University of Baghdad. This hospital takes advantage of the radiotherapy quality assurance program offered by the IAEA through the latter's TLD service for monitoring linear accelerators' output. Discussion: There are 11 megavoltage units, 9 treatment planning systems, 9 CT-simulators and one Gammaknife, with another 10 linear accelerators planned, along with associated imaging and treatment planning systems. In the past 7 years, radiotherapy practice has advanced to include 3DCRT. One center has started using IMRT, with others expecting to follow. While these are encouraging developments, recent surveys indicate that only one third of the population has access to cancer care. This is because of shortage of centers within reach of majority of the population and travel challenges in a war zone.

Cancer incidence in the country is higher than that in developed countries and most patients present with advanced disease making their outcome poorer than their counterparts in the developed world.

Summary: Medical physics in Iraq is developing in the right direction by establishing a medical physics society, modernizing educational programs and acquiring new technologies to establish imaging and cancer treatment programs befitting modern clinical practices. Detailed numerical data will be presented.

SP124.5 - Evaluation and Adaptation of Medical Physics Practicum for Nicaraguan Students at a Canadian Cancer Centre Author(s): Sarah Quirk¹, Jose E. Villarreal-Barajas², Coline Dirkse³, <u>Alana Hudson¹</u>

¹Medical Physics, Tom Baker Cancer Centre, Calgary/CANA-DA, ²Physics And Astronomy, University of Calgary, Calgary/AB/ CANADA, ³Oncology, Tom Baker Cancer Centre, Calgary/AB/ CANADA

On-the-job training is paramount to success in any career and must be particularly rigorous in medical professions. Unfortunately, practicum or residency-type clinical opportunities for medical physicists from low-income countries are in short supply, often requiring new graduates to transition to clinical work without the necessary knowledge, exposure, and experience. Inadequate training programs can lead to sub-optimal and even unsafe treatment conditions. This is especially true in cases where countries are preparing to transition to more modern radiation therapy technologies, and local knowledge from more senior medical physicists is limited. In order to help bridge this gap in practical training, our cancer centre in Canada hosted two medical physics students from Nicaragua in a three-month practicum towards the end of their studies. The practicum had students rotate through clinical and QA areas including simulation, treatment planning, treatment delivery, HDR brachytherapy, radiation safety, and nuclear medicine. The primary goal of this practicum was to provide fundamental medical physics knowledge and hands-on experience for treatment techniques currently used in Nicaragua (simulator, Cobalt RT, simple treatment planning and delivery). The other major goal was to provide exposure to linacbased treatments in preparation for the purchase of a new linac in the Nicaraguan clinic in the upcoming years.

Benchmarking [Brown et al., 2014, IAEA, 2007] has been previously highlighted as a top priority for implementing new technologies in low-income countries. A similar concept was applied to this practicum. Upon arrival, the students were asked to give presentations on their educational background, and their expectations for the practicum, and details about cancer treatment in Nicaragua. A short written survey was also implemented to assess these factors and their basic medical physics knowledge. These written and oral evaluations allowed us to evaluate both the level of education and previous training, and English language proficiency. The evaluations were crucial in personalizing the training to meet their specific needs. Benchmarking surveys/quizzes were given before each rotation. Based on the student responses, appropriate learning objectives were then set. Students were re-evaluated again after each rotation to determine if the learning objectives were met. Any shortcomings were noted and added to the schedule. At the end of each rotation, the students were given feedback evaluations in order to address both individual concerns and interests that could be added to the final month of the schedule. Ideally, the practicum would get a final evaluation in one year once the students have spent time practicing medical physics in Nicaragua.

We are using this practicum hosting experience as a guide to determine 'what works best' and the feasibility of hosting more students in the future at our centre, and at other Canadian centres.

In addition to evaluating the practicum on a functional level, we also looked at it from a staffing and resource level by tracking the amount of dedicated time spent with the Nicaraguan students by medical physicists and clinical staff. In this way we can provide detailed information to other institutions interested in supporting this type of program.

SP124.6 - Coordination of AAPM Educational Courses for Developing Countries with Major International and Regional Organizations of Medical Physicists

Author(s): Eugene P. Lief Radiation Oncology, White Plains Hospital, Pelham/NY/UNITED STATES OF AMERICA

American Association of Physicists in Medicine (AAPM) has had an active program of arranging two educational courses a year in developing countries since 1992. Typically, AAPM reimburses travel expenses for five AAPM members who volunteer their time for teaching practical topics in diagnostic and therapy medical physics for physicists from developing countries.

As a result of joint meetings of AAPM, IOMP, and EFOMP officials in 2013, these educational courses are now organized in close collaboration with International Organization for Medical Physics (IOMP), International Atomic Energy Agency (IAEA), and regional Medical Physics organizations, such as EFOMP, ALFIM, and others.

While choosing a place, time, and topic of such an education event, it is extremely important to avoid duplication of efforts by excluding regions that recently had a benefit of a similar educational course conducted by IAEA, IOMP, EFOMP, ESTRO, ALFIM, or some other international or regional organization.

A recent example was a course in Radiation Therapy organized in Estonia last year. The course was developed in the framework of AAPM International Scientific Exchange Programs Committee (ISEP) and IOMP on 16-20th of June 2014 in the capital of Estonia-Tallinn. The course was endorsed by EFOMP and IAEA. These agencies also provided financial assistance and sponsored some participants and speakers bringing the total number of lecturers to 10.

The meeting was attended by 62 clinical physicists and 10 company representatives. Third of participants were from the Baltic States (Estonia, Latvia, Lithuania), another third from the former Commonwealth of Independent States countries (Russia, Ukraine, Belarus, Azerbaijan, Kazakhstan), and the remaining third - from other Eastern European countries (Poland, Romania, Serbia, Montenegro, Croatia, Czech Republic, Slovenia, Bulgaria, etc.). Altogether, the participants represented 25 countries. By all measures, the course was a success and was highly evaluated by the attendees.

Conclusion: To be really efficient, future educational efforts in developing countries should be organized in close coordination and collaboration with the major international and regional organizations.

SP125 - Technology Enhanced Education

TRACK 17: EDUCATIONAL AND PROFESSIONAL ACTIVITIES

SP125.1 - e-Learning in Medical Physics – pioneering and future trends

Author(s): Slavik Tabakov

Medical Engineering And Physics, King's College London, London/ UNITED KINGDOM

Medical Physics was one of the first professions in the world to develop its own original e-learning materials. The projects EMERALD and EMIT (1994-2004) developed extensive e-Learning materials – training tasks, image databases (including 4000+ images), simulations, and one of the first e-learning web sites (www.emerald2. eu). Further, the project EMITEL (2005-2013) developed the first e-Encyclopaedia of Medical Physics (3100+ articles) with Multilingual Dictionary of terms (translated in 29 languages) – both major reference materials for the profession (www.emitel2.eu). These materials are used by thousands of colleagues all over the world. The success and impact of Medical Physics e-learning through these projects was recognised with the first educational award of the European Union – the Leonardo da Vinci Award.

The projects, initially including specialists from UK, Sweden, Italy, Portugal, Ireland, France, Czech Republic and Bulgaria, expanded rapidly through EFOMP and IOMP to include more than 320 senior colleagues from 36 countries. The unique experience of the profession led to further expansion through other e-Learning projects and web sites delivering quick educational and professional information to the whole medical physics community.

This development was extremely useful for a dynamic profession like medical physics, characterised by constant development of new methods/equipment and their implementation in medicine. Our experience and surveys showed strong involvement in e-learning development of all different sub-fields of the profession. At the same time we noticed an increased ratio of the time of development to the time of use of e-learning simulations, (mainly due to change of software versions). The web sites above (emerald2 and emitel2) were specifically coded for the purpose, what assures their long uninterrupted life. Their platforms are now available to be used for additional e-learning materials and IOMP is now forming Task Groups to update and expand the existing ones.

In parallel with the above development, we are witnessing expansion of Virtual Learning Environment (VLE) platforms in all Universities – a cost-effective way to supply students with lecture notes and Power Point handouts, as well as handling assessments. These platforms (especially useful for distance education) could further deliver specific "taylor-made" e-learning content, what will increase the effectiveness of the learning process.

In our opinion medical physics, one of the first professions to pioneer e-learning, should concentrate on rapid development of specific e-learning materials, synchronised with the introduction of new methods and equipment. IOMP and its large Regional Organisations include highly experienced specialists, who have all capacity to do this. Such development will significantly increase the speed of delivery of new information to the users. The new IOMP Journal Medical Physics International could facilitate this dissemination. The development of e-learning and its current trends will be described in the presentation (available also in an e-book to be launched at the Congress).

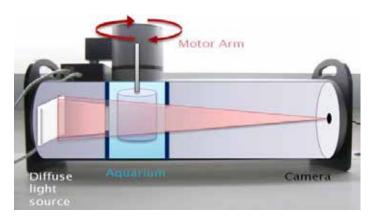

SP125.2 - A Desk-Top Optical Scanner for Teaching the Principles of Computed Tomography (CT)

Author(s): Jerry J. Battista¹, <u>Linada Kaci²</u>, Kurtis H. Dekker¹, Arvand Barghi², Colin Versnick², Michael Peng², John Miller³, Jennifer Dietrich³, Kevin J. Jordan²

¹Department Of Medical Biophysics, Western University, London/ CANADA, ²Physics And Engineering, London Regional Cancer Program, London/ON/CANADA, ³Modus Medical Devices, London, Ontario/ON/CANADA

Medical imaging is widely used for diagnostic and treatment guidance purposes. Students are often faced with difficulties in understanding the concepts of computed tomography (CT) image reconstruction because of the lack of practical demonstrations while learning these concepts. DeskCAT[™] is an optical CT system (http:// www.deskcat.com/) that has been introduced at 40 universities as a very effective tool for teaching the principles of CT. It is a safe device for classroom or lab demos since it uses visible light instead of xrays, allowing interactive real-time teaching.

The system offers a dozen lab exercises that introduce different concepts such as: exploring 3D medical imaging by localizing fiducial markers, measuring linearity by scanning materials with known optical attenuation coefficients, assessing spatial resolution by plotting the contrast profiles of line pairs in a phantom, exploring Fourier methods to calculate the Modulation Transfer Function (MTF) and learning the importance of contrast-to-noise ratio in the context of low-dose imaging. More advanced labs also explore artifacts caused by incorrect, incomplete, or inconsistent projections and cone-beam scattering effects, emission CT (SPECT) with attenuation corrections, and Dual Energy CT to discriminate structures according to their absorption at different imaging energies. Artifacts occurring due to organ motion or beam hardening are also observed. Iterative reconstruction is tested as a means of dose and artifact reduction. This presentation will highlight the learning objectives of several of these labs and show sample images and plotted results obtained by DeskCAT[™] students.

SP125.3 - Medical Physics e-Encyclopaedia and Multilingual Dictionary – Upgrade and New Developments

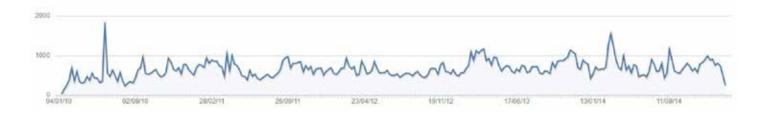

Author(s): <u>Slavik Tabakov</u>¹, Perry Sprawls², Franco Milano³, Sven-Erik Strand⁴, Cornelius Lewis⁵, Magdalena Stoeva⁶, Asen Cvetkov⁶, Vassilka Tabakova¹, John Damilakis⁷

¹Medical Engineering And Physics, King's College London, London/UNITED KINGDOM, ²IOMP, Atlanta/UNITED STATES OF AMERICA, ³Medical Physics, University of Florence, Florence/ ITALY, ⁴Medical Physics, University of Lund, Lund/SWEDEN, ⁵Medical Eng And Physics, King's College Hospital, London/UNITED KINGDOM, ⁶Medical Imaging Dept., Medical University - Plovdiv, Plovdiv/BULGARIA, ⁷Department Of Medical Physics, University of Crete, Heraklion/GREECE Since its launch at the World Congress in Munich (2009) the EMITEL on-line Encyclopaedia of Medical Physics and Multilingual Dictionary of terms established itself as a very useful reference source for the profession. About 5.3 million searches have been made for its 5 years of existence with approximately of 800 unique users per week. Two more languages were added during this period, thus making the Dictionary with 29 languages in total. The image below shows the number of unique EMITEL users per week for the last 5 years

EMITEL (www.emitel2.eu) includes about 3100 articles with over 2000 illustrations (with volume about 2100 pages). All these were developed by 7 teams working in parallel (Diagnostic Radiology; Magnetic Resonance; Nuclear Medicine; Radiation Protection; Radiotherapy; Ultrasound; General terms). The overall number of colleagues working on the Encyclopaedia included more than 120 senior specialists, while the 29 groups of translators included another 200+ colleagues). During 2013 it was published on paper by CRC Press. On the next year the EMITEL was prepared to go under IOMP – the largest international medical physics organisation, who will care for its future updates.

A Group was formed under the IOMP Education and Training Committee to deal with the first upgrade including Gerard Boyle, Paola Bregant, Asen Cvetkov, John Damilakis, Mario De Denaro, Charles Deehan, Antonio De Stefano, Peter Dunscombe, Geoffrey Ibbott, Lefteris Livieratos, Renata Longo, Renato Padovani, Magdalena Stoeva, Vassilka Tabakova, Sameer Tipins, Slavik Tabakov.

The first task of the group will be to expand the Thesaurus with new terms (methods, equipment, etc). After this, in parallel with the development of the encyclopaedic entries, the Dictionary will be updated. In fact the Dictionary updates were already initiated. The upgrading process uses the existing EMITEL guides, thus providing all new additions similar to the existing materials. Before upload all new materials will be reviewed by members of the EMITEL Editorial Team (S.Tabakov, P.Sprawls, M.Lewis, A.Simmons, S.Keevil, F.Stahlberg, S-E.Strand, B-A.Jonson, M.Peterson, C.Lewis, P.Smith, J.Thurston, F.Milano, I-L.Lamm, C.Deehan, J.Chick, D.Goss, T.Janson, G.Taylor, W.Hendee). The Upgrade Group will continue to expand aiming to have the first updates ready by the WC2015.

SP125.4 - Physics for Medical Students: Technology Enhanced Teaching from the Dipole to the Vectorcardiogram Author(s): Robert Arnold, <u>Ernst Hofer</u>

Institute Of Biophysics, Medical University Graz, Graz/AUSTRIA

Teaching Biophysics of the electrocardiogram (ECG) to first-year medical students is challenging. In research, the origin of cardiac field potentials has been explored in detail with computer simulation programs. Such programs allow ECGs to be computed at any given site of the body with almost arbitrary resolution and complexity. However, in the first year, medical students cannot take advantage of such detailed knowledge as they lack the necessary background in physics, physiology and cardiology. Therefore, the goal of our first semester course is to establish the relevant fundamental laws of physics, apply them in simple qualitative and semi-quantitative models, and explain the origin of the ECG and vectorcardiogram (VCG).

Our course follows a sequence of teaching steps and themes, leading from the electrical dipole to the VCG. Starting with Coulomb's law, we consider the electric field and potential caused by electric dipoles. We then demonstrate the projection of a dipole vector on to given axes and its reconstruction by back-projection. We introduce the principle of superposition, and use it to explain how a depolarization wavefront generates a dipole-like field, which is represented as the instantaneous heart vector. Students are shown how the spread of excitation can be represented as a sequence of heart vectors describing a vector loop. The relationship of ECG and VCG is demonstrated by an animation of projection and back-projection of the vector loop on standard limb leads I, II and III. Finally, students record their own ECG and VCG and perform exercises demonstrating the role of signal filtering, noise detection and measurement of ECG intervals.

Students are provided with a set of template slides, which are completed during the lecture by the teacher using an interactive pen display in overlay mode. Students can finish their notes on their own tablet or on printed handouts. Animations and interactive simulation tools (Java, Physlets, Flash), both developed in-house and acquired from free and commercial sources, are embedded in the course material. These interactive resources provide the simplest possible models of the physical effects relevant to understanding the VCG.

For practical experiments we developed a 2D-conductor apparatus with a rotatable dipole, whose angle is set by the teacher but remains hidden to the students. Field potential measurements are performed around the hidden dipole using polar, Cartesian and cardiac lead axes. This allows the students to identify the angle of the hidden dipole vector and to verify the law of projection.

Commercially available ECG recorders are closed systems. We therefore developed hardware and software for an open system ECG-VCG recorder, where two arbitrary lead signals can be recorded simultaneously using a standard laptop computer. Students can introduce power-interference noise, experiment with different lead systems, analyze the power spectrum of the ECG, test the impact of various digital filters on noise and on the waveform, and display the vector loop of the subject. With these diverse teaching technologies and methods, we constructed a robust framework for teaching the origin of VCG from simple physical laws.

SP125.5 - matRad: a multimodality open source treatment planning toolkit

Author(s): Eduardo A. Cisternas¹, Andrea Mariani², Peter Ziegenhein³, Oliver Jäkel⁴, Mark Bangert¹

¹Department Of Medical Physics In Radiation Oncology, German Cancer Research Center, Heidelberg/GERMANY, ²Centro Nazionale di Adroterapia Oncologica, Pavia/ITALY, ³Joint Department Of Physics At The Institute Of Cancer Research And The Royal Marsden Nhs Foundation Trust, London, Uk, The Institute of Cancer Research, London/UNITED KINGDOM, ⁴Heidelberg Ion-Beam Therapy Center (HIT), Heidelberg/GERMANY

We present matRad, an open source software for three-dimensional radiation treatment planning supporting intensity-modulated photon, proton, and carbon ion therapy. matRad is entirely written in MATLAB; it is developed for educational and research purposes. The code features high modularity and consequently flexibility. At the same time, matRad allows for an efficient workflow considering realistic patient cases. It comprises descriptive visualizations of the underlying physical aspects. Besides the source code itself, matRad also includes example patient data and appropriate base data for photon, proton, and carbon ion irradiation.

Starting from a segmented patient CT, the toolkit features a set of individual functions modeling the entire treatment planning workflow based on well-established algorithms. The main modules are:

Dose calculation: For photons, matRad uses a singular value decomposed pencil beam algorithm. For particles, matRad uses a pencil beam algorithm facilitating a single Gaussian to approximate the lateral dose profile. Base data for the dose calculation algorithms is obtained during measurements at the German Cancer Research Center (photons), analytical computation (protons), and Monte Carlo simulations (carbon ions).

Ray tracing: All modalities facilitate an exact three-dimensional ray tracing algorithm for the computation of radiological distances.

Fluence optimization: Fluence optimization is performed with pre-computed dose influence data through the minimization of a piece-wise quadratic objective function.

Sequencing: For photon IMRT, matRad includes a multileaf collimator sequencing algorithm to translate the continuously optimized fluence weights into deliverable segments.

Visualization: The result of matRad's treatment planning workflow can be visualized via dose volume histograms and two-dimensional dose distributions.

Using a voxel resolution of 3 X 3 X 2.5 mm³ and a bixel resolution (spot distance) of 5 X 5 mm², we achieve computation times of 60-100s (60-400s) for realistic patient cases including photon (particle) dose calculation and fluence optimization. Memory consumption ranges between 0.2GB and 2.2GB. Figure 1 shows an example photon dose distribution from our benchmarking experiments using AAPM's TG119 phantom.

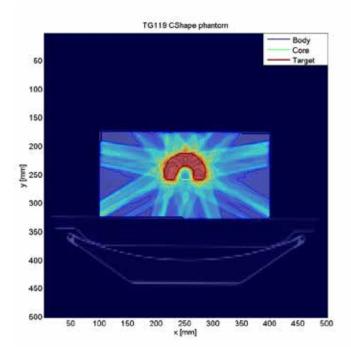

Figure 1: Transversal dose distribution of a photon treatment plan applying nine equi-distant coplanar fields on AAPM's TG119 phantom.

matRad is the first open source toolkit supporting treatment planning for intensity-modulated photon, proton, and carbon ion therapy. Both the computational and dosimetric results encourage a future use of matRad in an educational and scientific setting. A first beta release of matRad is available at http://e0404.github.io/matRad/

This work has been supported by the DFG coordinated research program SFB/Transregio 125 Cognition-Guided Surgery.

SP125.6 - Creation of a model for online education of clinical engineering and management of medical technologies to reach professionals worldwide.

Author(s): <u>Maria E. Moreno Carbajal</u>¹, Marco A. De Roman Mello² ¹Education, CLINICAL AND BIOMEDICAL ENGINEERING INSTI-TUTE, PUEBLA/MEXICO, ²Biomedical Engineering Department, MEXICAN GENERAL HOSPITAL, MEXICO CITY/MEXICO

The Institute of Clinical and Biomedical Engineering, SC (ICYB), was created at the end of 2012, to meet the needs of training and updating professionals involved with the performance of : assessment, installation, maintenance, and replacement of medical devices; processes better known as clinical engineering and management of health technologies.

Due to the need of Mexico and Latin American countries to train professionals in order to perform management in benefit of better decision making regarding health technologies, a survey was developed and launched to identify the real need as well as an effective online education model. The survey conducted to the development of an e-learning model that permits the interaction of both experts and professional students from different regions of the world. After almost 3 years of the beginning of the institute, most of our expert teachers are heads of departments in hospitals at Mexico, Canada and Colombia.

Up to date, we have trained 126 chief engineers of biomedical engineering departments. The method of education we use has reported good results and can be taken as a model for developing similar projects in other developing countries.

SP125.7 - Develop of a Mixed, Haptic and Virtual System to Simulate Radiographic Images

Author(s): <u>Guillermo E. Avendaño</u>¹, P Pizarro² ¹Escuela De Ingeniería Biomédica, Universidad de Valparaíso, Valparaiso/CHILE, ²BIORAD LIMITED, Valparaiso/CHILE

It has been conceived, designed and built a system, simulator of conventional equipment x-ray made to work on technique called *two-points* is selecting values of kVp and mAs, with the aim of teaching professionals who must make radiographic pictures of patient, such as Medical Technologist, Biomedical Engineers and others to obtain correct images without the need for an actual equipment emitting X-ray, the system consists of similar technical devices to real in terms Hardware and software, suitable for generating images of different quality depending on the parameters selected and the student learns without generating radiation or spend consumables, advantages that allow manufacture and market a highly innovative system, safe and friendly with environmental.

SP126 - Computational Biology & Hemodynamics

TRACK 19: BIOPHYSICS AND MODELLING

SP126.1 - Evaluation of Decomposition Analysis on Multi-Models for Digital Volume Pulse Signal

Author(s): <u>Sheng-Cheng Huang</u>¹, Hao-Yu Jan¹, Wen-Chen Lin¹, Cheng-Lun Tsai², Kang-Ping Lin¹

¹Department Of Electrical Engineering, Chung-Yuan University, Taoyuan/TAIWAN, ²Department Of Biomedical Engineering, Chung-Yuan University, Taoyuan/TAIWAN

Photoplethysmography (PPG) is an important technique to evaluate and monitor vascular health. Pulse Decomposition Analysis is (PDA) a method widely used to analyze DVP waveform in physiology and hemodynamics. There are several different models used to decompose DVP wave, but there is no common model. This research intends to investigate and evaluate some efficient models for decomposition analysis of digital volume pulse wave signal. The multi-Gaussian models and Gamma-Gaussian complex models are used in this study. Each model is evaluated by residual analysis. In this paper, four multi-Gaussians models and four Gamma-Gaussian Complex models have comparatively good results.

SP126.2 - Discordant alternans in a one-dimensional cable of ischemic heart tissue.

Author(s): <u>Yunuen A. Cervantes Espinosa</u>, Jorge H. Arce Rincón Science Faculty, Physics Department, National Autonomous University of Mexico, Mexico city/MEXICO

T-wave alternans are related to discordant alternans in the cellular action potential. T-wave alternans have been associated with block in the propagation, induction of reentry and to ventricular arrhythmias.

The hypothesis of this study is that discordant alternans could be initiated during ischemia in a simulated one-dimensional cable of ischemic heart tissue stimulated at fixed frequency.

The ventricular tissue of the cable was simulated with the Luo Rudy 1 [Circ.Res. 68, 1501-1526 (1191)] ionic model, the effect of ischemia was model by raising the external potassium ion concentration [K⁺] o in the whole strand. [K⁺] o increases from 5 up to 12 mM. To search for the discordant alternans, the stimulation frequency in the cable varied. Meaning that for every [K⁺]o, there is a fixed stimulation frequency. Several cable lengths were studied from 10 to 4 cm.

We found that discordant alternans appear at high pacing frequencies during ischemia. In fact, there is a range of $[K^+]o$ in which discordant alternans are initiated, depending on the cable length. The larger the cable length, the window to initiate the discordant alternans is wider. These cases are presented in a bifurcation diagram.

The discordant alternans formed in the cable of ischemic heart tissue present one or multiply nodes, and in some cases block in the conduction was observed. SP126.3 - A Novel Biomechanical Model of the Left Ventricle for Cardiac Contraction Force Reconstruction Applications Author(s): <u>Seyyed Mohammad Hassan Haddad</u>¹, Maria Drangova², James A. White³, Abbas Samani⁴

¹Graduate Program In Biomedical Engineering, Western University, London/ON/CANADA, ²Imaging Research Laboratories, Robarts Research Institute (RRI), London/ON/CANADA, ³Libin Cardiovascular Institute Of Alberta, University of Calgary, Calgary/AB/CANA-DA, ⁴Medical Biophysics, Western University, London/ON/CANADA

Accurate regional viability assessment of the myocardium is critical for assessing reversibility of ischemic injuries. While viability assessment of cardiac tissue can be achieved through a number of imaging techniques, none of them provide information pertaining directly to the tissue mechanical efficiency. A major constraint with some imaging modalities is that their data cannot be interpreted easily, leading to diagnosis uncertainty. As such, we are developing a technique for imaging myocardial contraction forces. This technique involves a reconstruction method which inputs the myocardial displacement data acquired using imaging techniques and outputs the myofibers contraction forces through an optimization procedure. This forward model must be run iteratively within the optimization algorithm to determine the contraction forces. Hence, a computationally cost-effective cardiac mechanics model is required which was developed in our laboratory.

In typical myocardial mechanical models, hyperelasticity, anisotropy, and active response of the cardiac tissue leads to intricate nonlinear Finite Element (FE) formulations which are not fully incorporated in commercial FE solvers. As such, custom-developed FE solvers are required which are cumbersome to develop, and may have sub-optimal performance and convergence issues. Moreover, these models cannot be easily adapted for simulating diverse cardiac pathological conditions as appropriately altered passive and active tissue responses are necessary for modeling the pathological tissue portion. To tackle these issues, we propose a new left ventricle (LV) mechanical model which considers all cardiac mechanics aspects, including cardiac anisotropy, hyperelasticity, and active fiber's contraction forces. The novelty of the model lies in modelling of the myofibers and their contraction forces. This model treats the myocardial tissue as a composite material including a background tissue through which microscopic reinforcement bars are distributed. These bars simulate the fibers within the myocardial tissue whereas their orientations are in accordance with the fibrous cardiac anatomy, leading to a self-contained anisotropic model. As a result of applying contraction forces to the bars while blood pressure is applied to the LV endocardial surface, LV contraction occurs. This model can be developed using many off-the-shelf commercial FE solvers and it does not require custom-developed solver. Hence, the proposed model is optimized to be less time-consuming and less prone to divergence. Our model was applied to normal and infarcted LV and demonstrated. Figure 1 shows stress distribution through the infarcted LV which indicates higher stresses at the infracted region similar to what is reported in the literature frequently.

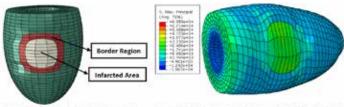

Figure 1a. Infarcted in silico LV model constructed using finite elements

Figure 1b. Maximum principle stress field of the infarcted LV model at the instance when the bars' active stresses reach their maximum value

SP126.4 - A simulative model approach of cardiopulmonary interaction

Author(s): <u>Chuong Ngo</u>¹, Berno Misgeld², Steffen Leonhardt², Robert Schlözer², Thomas Vollmer³, Stefan Winter³

¹Rwth Aachen University, Chair of Medical Information Technology, Aachen/GERMANY, ²Chair Of Medical Information Technology, RWTH Aachen University, Aachen/GERMANY, ³Philips Research, Aachen/GERMANY

We introduce a new sophisticated model of the cardiopulmonary system. The model consists of the heart, circulation and respiration systems with emphasis on the cardiopulmonary interaction. Heart and lungs are anatomically and physically coupled through the intra-thoracic pressure since they are both located in the same chest cavity. A novel extended lung model with emphasis on the pleural dynamics was developed. Interactions with the cardiovascular system were modeled using the pleural pressure. This model was implemented in MATLAB Simscape using electrical equivalent circuits. Simulation results for spontaneous breathing show a high agreement with physiological knowledge. Hence, the model could be used to explain many observed phenomena in the physiology.

SP126.5 - The Development of SIM to Characterize Blood Volumetric Flow Rate and Hemodynamics in Human Coronary Arteries

Author(s): Ivad Fayssal, Fadl Moukalled American University of Beirut, Beirut/LEBANON

The genesis and progression of heart diseases are primarily originated from hemodynamic disorders. Among the important hemodynamic parameters to estimate is the blood volume flow rate in coronary arteries. Knowing how the volumetric flow rate is related to geometric and physiologic parameters is challenging. The end product of this paper is a Seven Input Model (SIM) developed to characterize blood volume flow rate in human coronary arteries which can be translated into clinical applications. Several mathematical relations were established relating all primary hemodynamic (pressure and velocity), geometric, and boundary parameters to the volume flow rate. An equation for predicting blood volumetric flow rate was first developed for arterial segments of uniform cross section by solving the set of continuity and momentum equations in cylindrical coordinates. The governing equations were coupled with a total pressure formulation at the inlet and a dynamic pressure-flow lumped model at the outlet to capture in-vivo coronary hemodynamics. The model was then generalized for an artery of variable cross section area and for arteries with low to medium stenosis severities. Two different algorithms were also developed to solve the set of developed equations; (1) a numerical algorithm following Gauss-Seidel method with successive iterative forward and backward substitution; and (2) an alternative analytical approach where an equation of blood volume flow rate was obtained and related to all model parameters, including geometry, inlet and outlet boundary parameters, blood density and viscosity, and normal shear stress at inlet. In the analytical approach, the blood flow rate is directly computed from a single developed model (SIM); local pressure and velocity distributions are then directly obtained. The performance of the developed models and algorithms were tested on (i) an artery with uniform cross section; (ii) an artery of variable cross section; and (iii) an artery with low severity symmetrical stenosis. Predictions were then compared with a full CFD 3D model for validation purposes. An excellent agreement was achieved.

SP126.6 - Determination of Bermang's Minimal Model parameters for diabetic mice treated with Ibervillea sonorae Author(s): Agustin I. Cabrera Llanos, María G. Ramírez-Sotelo, Emmanuel Sánchez-Velarde, Nayely R. Budar-Alemán, Alejandro A. Sotelo-De Ávila, Itzamná O. Rico-Asención, <u>Rodrigo Sánchez-González</u>

Bioprocesos, Unidad Profesional Interdisciplinaria de Biotecnología - IPN, Distrito Federal/MEXICO

This article shows the estimation of Bergman's Minimal Model parameters for glucose-insulin interaction in three stages: evolution of the concentration of insulin, evolution of glucose and glucose/insulin interaction itself. First, the dynamics of glucose measured in healthy mice treated with extracts of Ibervillea sonorae root in a range of 100-400 mg/kg; likewise, for mice previously induced with diabetes mellitus type 2 values are determined The different parameter values obtained are compared showing how they influence the dynamics of Bergman's Model. The values of the glucose/insulin interaction where obtained in vivo by blood samples of the mice every hour. The evolution and variability of the estimate are shown in graphical form; also he estimation error is quantified by performance curves, which were associated to the energy that is implied in the difference between the values of the parameters obtained and the data obtained in the kinematics of the mice. The results indicate the estimated level reached, where the upper value of the performance curve was 3.0128, while the lower was 0.1978, with standard error values between 1.55% and 10.47%

SP126.7 - Investigation of flow and turbulence in carotid artery models of varying compliance using particle image velocimetry Author(s): <u>Amanda Dicarlo</u>

Physics And Astronomy, University of Western Ontario, London/ CANADA

Atherosclerosis in the carotid artery is one of the main risk factors for stroke. Arterial compliance, a measure of the elasticity of blood vessels, is a common indicator of vascular disease and is known to decrease in association with other stroke risk factors, including age, diabetes, and hypertension. Decreased local compliance leads to changes in the flow and pressure waveforms and corresponding changes in the velocity field. Resulting hemodynamic parameters, such as shear stress and turbulence, play a primary role in the process of plaque and clot formation. While it is difficult to accurately extract complex in vivo blood flow structures using clinical techniques, in vitro experimental models can be used to mimic physiological flow systems. Particle image velocimetry (PIV) is an established optical technique for measuring velocity fields with high temporal and spatial resolution that can be applied to study specific aspects of the flow system when used in controlled test models. The aim of this work was to analyze the effect of compliance on carotid artery flow patterns and turbulence intensity experimentally within carotid artery phantoms using PIV. This was accomplished using a custom in vitro flow facility. Two types of polydimethylsiloxane (PDMS) phantoms were used to study compliance, a thin-walled vessel or rigid block phantom model, with identical vessel geometry, 50% eccentric stenosis of the internal carotid artery. Phantoms were perfused using a computer controlled pump to generate a physiologically realistic pulsatile flow rate waveform. A custom bloodmimicking fluid with matching refractive index serves to minimize distortion and model the dynamic viscosity and density of human blood. Downstream flow resistors create a physiological 60:30 flow division at the bifurcation. PIV data were collected using a commercial stereoscopic PIV system (LaVision Inc). Turbulence intensity (TI) was calculated from central plane velocity maps as a metric for quantifying flow disturbances. Slightly higher overall velocity magnitude was observed in a more rigid phantom model compared to the geometrically-matched compliant version, with maximum jet internal carotid artery velocities reaching 1.98 m/s compared with 1.90 m/s.

A stiffer vessel wall resulted in increased maximum average turbulence intensities, 0.41±0.02 m/s in compliant models and 0.48±0.03 m/s in rigid phantom models. The rigid vessel region of maximum turbulence also occurred more proximal to the bifurcation apex (i.e. more upstream). Mean TI over a downstream region of interest at the location of maximum TI was seen to drop off slower with cardiac cycle phase in rigid models suggesting a higher cumulative exposure to disturbed flow over time due to reduced compliance.

SP127 - Informatics In Health Care And Public Health / Biosensor, Nanotechnology, Biomems And Biophotonics

PRESIDENTS CALL

SP127.1 - Astudy on the leading cause of immunisation schedule fall up defaulting and early child hood malnutrition sicknesses in developing countries(uganda in particular) rural areas/villages

Author(s): <u>Waigonda Saad</u> Physiology, MAKERERE UNIVERSITY, kampala/UGANDA

Uganda is one of the countries that make up east Africa. It's one of the developing countries in the world, one of the countries on this globe that has been affected by immunizable diseases and child hood malnutrition every year. A study to assess the causes of the rampant immunization schedule fall up defaulting by mothers and early child hood malnutrition in developing countries rural areas was conducted in ten districts of Uganda,(Kampala, jinja, wakiso, kaliro, i ganga,mayuge,bugiri,namutumba,namayingo,and kamuli districts) for a period of 12months. The target population were all babies aged one year who had completed polio,DPT1,DPT2,DPT3 AND Measles vaccinations by one year. A total of 1000babies were collectively seen. While immunization services were easily available at every health centre from health centre's one to hospital settings and free of charge, a total of 902 (90.2%) babies had not completed their immunization as scheduled and a total of 780(78%) babies had been affected by malnutrition. A total of 805(80.5%) mothers had lost their babies immunization cards by one year and so couldn't recall when their babies were to be taken back for fall up vaccinations.15% of the mothers couldn't find any reason for immunizing their babies since they looked health from day one. I proposed to design a phone application which will keep tracking all registered babies mile stones and keep reminding mothers on the next immunization dates of their babies through sending short messages on to their phones two days before as well keep sending mothers nutrition information of their babies per milestone reached.

SP127.2 - From Smart Phones to Smart Health

Author(s): Melannie Pin¹, J Huang¹, Diego Zelaya¹, Julio Cruz¹, Ronald Alvarado¹, <u>Ricardo Silva²</u> ¹Ciencias Médicas, Universidad de Guayaquil, Guayaquil/ECUA-DOR, ²Senescyt, Guayaquil/ECUADOR

All progress in Telemedicine we has opened new destinations so far only dreamed, allowing use Smartphones as valuable tools for continuous monitoring, recordkeeping, medical alerts, prevention and prediction of various diseases related to our master pump, the human heart. And these devices can do all this without our assistance and in parallel with our recreational, household and daily work. Therefore smart phones are paving the road for smart health. We present the possibilities of smart phone based smart health for cardiovascular patients and our particular approach to this field.

SP127.3 - Diagnostic Data: a Manifesto

Author(s): <u>Peter Pennefather</u>¹, West Suhanic² ¹Leslie Dan Faculty Of Pharmacy, University of Toronto, Toronto/ CANADA, ²gDial Inc, Toronto/ON/CANADA

Diagnostic data is the fuel that drives medical information systems by enabling independent input variables to be related to dependent

outcome variables within models of care in ways that can guide medical decision making. By definition, diagnostic data-sets are assembled with specific purposes in mind. The ISO definition of quality is: "the degree to which a set of inherent characteristics fulfills requirements". Therefore the quality of that data, and of that data's ability to fulfill requirements, is dependent of the quality of the documentation concerning data generation. We propose as self-evident therefore that for diagnostic value-sets entered into medical information systems to become diagnostic data-sets, then those value-sets must include not only the measured values but also other values that are needed to verify data-quality. The process generating all of those values must be the product of a well documented, replicable and qualified process and must be accompanied by documentation and values that can assist independent evaluators to understand precisely how those value-sets were produced. Our manifesto is that it is the co-location of all values needed to evaluate data quality in addition to those needed to specify value relationships that transforms value-sets into data-sets. This implies that the documentation informing evaluators of why the value-set is a data-set is also in the same data-envelope as the name/value pairs proscribed by that documentation. A complete diagnostic record therefore is one where all steps that led to the generation of the data-set are described and registered in sufficient detail so that those trained in the art can: i) judge the likelihood that each step in the process is within known boundaries of reasonableness, relevance, and reliability, ii) plan how to replicate the process and attempt to acquire similar values and iii) assess the validity of the values. For diagnostic values-sets to be considered diagnostic data-sets, a capacity to support those three steps is both necessary and sufficient. This leads to simplificarions of the data-quality management process and flexibility in interpreting the data. For example data-sets entered into medical information systems can support data-analysis, an inferential process aimed at estimating newly derived values from previously recorded data. As with the original data, such data transformations need to be sufficiently documented so as to allow those transformations to be replicated. By meeting that condition the derived value-set can be considered a part of the original diagnostic data-set. Indeed there is no need to distinguish between primary or secondary data or even data and metadata as their meaning should be clear. There is only data. For information systems used to garantee the quality of medical decision making, there should only be classes of data and not-data. We will describe a diagnostic data-recording method that allow this diagnostic-data manifesto to be respected (see http://www.google. com/patents/US20140122491).

SP127.4 - Comparative analysis of co-expression networks reveals molecular changes during the cancer progression Author(s): Pegah Khosravi¹, Vahid H. Gazestani², Brian Law³, Gary

D. Bader⁴, Mehdi Sadeghi⁵ ¹School Of Biological Sciences, Institute for research in fundamental sciences, Tehran/IRAN, ²Institute of Parasitology, McGill University, Montreal/QC/CANADA, ³Department Of Computer Science, The Donnelly Centre, University of Toronto, toronto/CANADA, ⁴The Donnelly Centre, University of Toronto, toronto/CANADA, ⁵National Institute of Genetic Engineering and Biotechnology, Tehran/IRAN

Prostate cancer is a serious genetic disease known to be one of the most widespread cancers in men, yet the molecular changes that drive its progression are not fully understood. The availability of high-throughput gene expression data has led to the development of various computational methods for the identification of key processes involved.

In this paper, we show that constructing stage-specific co-expression networks provides a powerful alternative strategy for understanding molecular changes that occur during prostate cancer. In our approach, we constructed independent networks from each cancerous stage using a derivative of current state-of-art reverse engineering approaches. We next highlighted crucial pathways and Gene Ontology (GO) involved in the prostate cancer. We showed that such perturbations in these networks, and the regulatory factors through which they operate, can be efficiently detected by analyzing each network individually and also in comparison with each other.

Using this novel approach, our results led to the detection of 49 critical pathways and GOs related to prostate cancer, many of which were previously shown to be involved in this cancer.

Correct inference of the processes and master regulators that mediate molecular changes during cancer progression is one of the major challenges in cancer genomics. In this paper, we used a network-based approach to this problem. Application of our approach to prostate cancer data has led to the re-establishment of previous knowledge about this cancer, as well as prediction of many other relevant processes and regulators.

SP127.5 - Copper Meshed Carbon Black PDMS Electrode for Underwater ECG Monitoring

Author(s): Justin Bales

Biomedical Engineering, University of Connecticut, Storrs,/CT/ UNITED STATES OF AMERICA

The traditional method to obtain an electrocardiogram (ECG) in an underwater environment requires the industry standard silver/ silver chloride (Ag/AgCl) electrodes to be completely insulated and adhered to the skin with a form of chemical water proof adhesive. However, this can lead, to severe skin irritation with prolonged use and damage to the surrounding area of skin when the covering is removed. To alleviate these discomforts, we developed hydrophobic copper-meshed carbon black/poly-dimethyl siloxane (CB/ PDMS) dry bio-potential electrodes that are non-irritating, re-usable, in addition these electrodes do not require wetting, or hydrogel, making them compatible for long term application in more extreme environments. To evaluate the performance of the novel electrodes, we tested them alongside the other various commercially available electrodes (Polar® textile, silver coated textile, and carbon rubber electrodes) as well as our previous CB/PDMS design without the embedded copper meshed wire under a submerged use-case scenario.

We found that only the meshed CB/PDMS electrodes provided highfidelity ECG signal morphologies without any amplitude degradation when collecting ECG data in a freshwater scenario. In fact, based on preliminary data from 5 subjects, the meshed CB/PDMS electrodes provided ECG signal amplification during. The textile electrodes did not fare well as there was significant ECG signal amplitude reduction. Both carbon rubber and non-meshed CB/PDMS electrodes 'performance in immersed conditions fared better than textile-based electrodes, however, they too had significant ECG signal amplitude reduction.

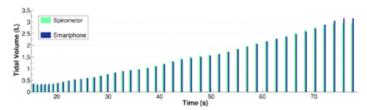

ECG signal amplitude reduction in water immersion holds a particular significance due to the fact that with body movements, the ECG waveform's morphologies may not be easily discernible due to motion artifacts. By being able to record an corrupted signal the newly developed meshed CB/PDMS electrodes have the potential to be used for a wide variety of application in a various environments where collecting the fine features of a bio-impedance measurement such as an ECG is critical.

SP127.6 - Smartphone-based Monitoring of Tidal Volume and Respiratory Rate

Author(s): <u>Bersain Reyes</u>¹, Natasa Reljin¹, Youngsun Kong², Yunyoung Nam², Ki Chon¹

¹Biomedical Engineering, University of Connecticut, Storrs/CT/ UNITED STATES OF AMERICA, ²Department Of Computer Science And Engineering, Soonchunhyang University, Asan/KOREA

A breathing monitor should provide information about the frequency of breathing (respiratory rate, RR) and about the depth of breathing (tidal volume, VT). Clinical devices exist for such tasks, e.g. spirometry or inductance plethysmography, but the need for a portable, accessible to the general population, and low-cost monitoring device still remains. This study employs an optical approach coupled with an algorithm implemented directly on a smartphone for non-contact estimation of both RR and VT. The algorithm tracks chest wall displacements via the smartphone's frontal camera and provides a chest movement signal from which the two aforementioned breathing status parameters are estimated. Spirometerbased volume signal was regarded as reference and was simultaneously recorded while the volunteers (N=8) were breathing at VT ranging from 0.3 to 3 L. The Empirical Mode Decomposition was used to detrend the spirometer and smartphone signals. Regarding the RR estimation, a time-frequency analysis based on the smoothed pseudo Wigner-Ville distribution was employed. The smartphone-based RR estimates showed a strong linear relationship with the corresponding reference values from spirometry $(r2=0.999 \pm 3.85 \times 10^{-5}, \text{ mean} \pm \text{SD})$ with a root-mean-square error (RMSE) of 0.338 ± 0.043 bpm. Bland-Altman analysis showed a statistically significant bias of -0.014 bpm, and 95% limits of agreement of -0.675 to 0.647 bpm. Regarding the VT estimation, the relationship between the peak-to-peak amplitude of the smartphone-acquired chest movement signal and the VT from spirometry was analyzed and a strong linear relationship between both quantities was found ($r2=0.974 \pm 0.016$). Therefore, a calibration was performed on a subject-by-subject basis with half of the data randomly selected to obtain the model parameters via least squares linear regression, while the remaining half of the data was used to test the computed model. No statistically significant bias was found (bias=0.006,p=0.46), the RMSE was 0.219 ± 0.137 L, and the 95% limits of agreement were -0.253 to 0.265 L on the test data set. An example of the VT estimates is shown in Figure 1. Given these results, we foresee the possibility of developing a portable and inexpensive monitor which provides information about both frequency and depth of breathing, when calibrated on an individual basis, and that could be available outside the research and clinical settings due to the increasing ubiquity of smartphones.

SP128 - Multimodality Imaging

TRACK 01: IMAGING

SP128.1 - Localizing cortical motor representation: A comparative study between navigated transcranial magnetic stimulation, BOLD contrast and arterial spin labeling fMRI Author(s): Elisa Kallioniemi¹, Minna Pitkänen², Mervi Könönen³, Ritva Vanninen³, Petro Julkunen¹

¹Department Of Applied Physics, University of Eastern Finland, Kuopio/FINLAND, ²Department Of Neuroscience And Biomedical Engineering, Aalto University, Espoo/FINLAND, ³Department Of Clinical Radiology, Kuopio University Hospital, Kuopio/FINLAND

Introduction and aim of the study

Localizing the cortical motor representations accurately is important in clinical applications as brain tumours and traumas, such as stroke may relocate, expand or reduce the representation to abnormal locations [1, 2]. In this study, we used navigated transcranial magnetic stimulation (nTMS) for mapping motor representation areas through excitatory motor evoked potential (MEP) and inhibitory silent period (SP) responses, as well as BOLD contrast fMRI and pseudo-continuous arterial spin labelling (ASL) fMRI. Considering that both fMRI and nTMS are widely used in clinical practise to locate the motor cortex, the aim of the study was to evaluate the consistency of those methods.

Methods

Ten healthy right-handed volunteers participated in the study (5 females, age range 21-32 years). Block design fMRIs were scanned with a 3T Philips Achieva MR scanner by using finger wiggling as the motor task. nTMS was performed by first roughly mapping the cortical representation of the first dorsal interosseous and determining the resting motor threshold (rMT) and silent period threshold (SPT) [3]. This was followed by the actual mapping with a stimulation intensity of 110% of rMT in MEP mapping and 120% of SPT in SP mapping. In all the measurements, both hemispheres were studied in random order. The statistical analyses of fMRI local maxima and nTMS center of gravities (CoGs) were done in MNI space using a linear mixed model with Sidak post-hoc test (significance-level at p = 0.05).

Results

In lateral-medial direction, there were no differences between the methods (*F*=1.32, p=0.277) but representations were more lateral on the left hemisphere (*F*=4.13, p=0.046). Furthermore, there was a significant interaction between method and hemisphere (*F*=3.11, p=0.033).

In anterior-posterior direction, there was a significant difference between the methods (*F*=6.78, *p*<0.001). There was no difference between nTMS MEP and nTMS SP representations, but they together differed from ASL (*p*<0.025). No difference was found with nTMS and BOLD contrast (*p*>0.751), but ASL and BOLD differed (*p*<0.001). Hemisphere had no influence on the representations (*F*=1.22, *p*=0.274). On average, the Euclidian distance between nTMS and BOLD representations was 7.4±0.8mm and nTMS and ASL 7.2±1.5mm.

Discussion and conclusion

Statistically, BOLD contrast fMRI was slightly more consistent with nTMS than ASL, as ASL local maxima seemed to be more posterior than BOLD and therefore possibly having stronger sensory compo-

nent. However, the Euclidian distances of BOLD and ASL to nTMS were in the same range. In conclusion, all the methods agreed well generally, but demonstrated somewhat systematic differences. The relevance of those differences should be evaluated in the future in the applied clinical setting.

SP128.2 - Evaluation of probable dementia with Lewy bodies using 123I-IMP brain perfusion SPECT, 123I-MIBG myocardial SPECT and voxel-based MRI morphometry

Author(s): <u>Naoki Kodama</u>¹, Yasuhiro Kawase², Hiroshi Takeuchi¹ ¹Department Of Healthcare Informatics, Takasaki University of Health and Welfare, Takasaki/JAPAN, ²Kawase Neurology Clinic, Sanjo/JAPAN

Dementia with Lawy bodies (DLB) is the second most common cause of degenerative dementia after Alzheimer's disease. Approximately, 20% of elderly Japanese manifest DLB. The main symptoms of DLB are visual hallucinations, fluctuating cognitive impairment and parkinsonism. Current imaging modalities for DLB are magnetic resonance imaging (MRI), computed tomography (CT), single photon mission computed tomography (SPECT), and positron emission tomography (PET). We evaluated the diagnostic usefulness of studies with statistical methods in ¹²³I-IMP brain perfusion SPECT, cardiac sympathetic nerve function by ¹²³I-MIBG, and voxeI-based MRI morphometry for patients with probable DLB.

Twenty-six patients with probable DLB (16 male, 10 female; mean age +/- SD, 80.7 +/-5.7 y; range, 74-90 y) was enrolled this study. Three-dimensional stereotactic surface projections (3D-SSP) were used to analyze the results of ¹²³I-IMP SPECT. For ¹²³I-MIBG imaging, we calculated early and delayed heart-to-mediastinum (H/M) uptake ratios. Whole brain T1 weighted three dimensional magnetization prepared rapid acquired echo MPRAGE turbo flash sagittal sequence (slice thickness 1mm) was acquired using a 1.5T Siemens Magnetom Avanto MR imaging system. Using a free software program, the voxel-based specific regional analysis system for Alzheimer's disease (VSRAD) based statistical parametric mapping 8 plus DARTEL.

Qualitative analysis using 3D-SSP demonstrated occipital hypoperfusion in 22 patients (84.6%). Twenty-five patients (96.2%) had decreased cardiac MIBG uptake in the delayed images. Fourteen patients (53.8%) showed z-score of VSRAD exceeded 2.0. We found reduced gray matter in midportion of the middle and inferior temporal gyrus, amygdala, rectal gyrus, and sylvian vallecula in DLB.

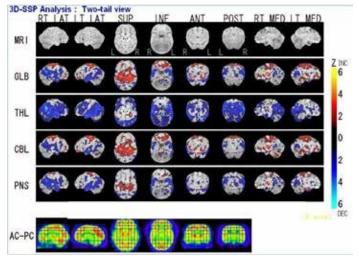

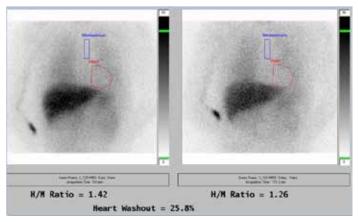

Figure 1 ¹²³I-IMP SPECT

These results suggest that cardiac sympathetic nerve function with ¹²³I-MIBG would be useful supporting diagnostic inpatients with DLB. Furthermore, degree of midportion of the middle and inferior temporal gyrus, amygdala, rectal gyrus, and sylvian vallecula atrophy may be a useful imaging biomarker.

SP128.3 - Targeted all-organic nanovesicles for multimodal PET/CT and optical fluorescence assessment of lymphatic disseminations in gynaecologic cancers: A radio-pharmaceutical kit to prepare parenteral injections for a "first-in-woman" clinical study.

Author(s): <u>Michael S. Valic</u>¹, Wenlei Jiang², Marcus Q. Bernardini³, Gang Zheng⁴

¹Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/ON/CANADA, ²Techna Institute For The Advancement Of Technology For Health, University Health Network, Toronto/ ON/CANADA,³Division Of Gynecologic Oncology, Princess Margaret Hospital/University Health Network, Toronto/CANADA, ⁴Department Of Medical Biophysics, University of Toronto, Toronto/CANADA

Motivation: Metastatic tumour spread through the lymphatic vessels and regional lymph nodes (LNs) occurs with a predictable pattern and prevalence in women with gyneacologic cancers (GCs). It has been an outstanding goal in the treatment of GCs to develop a robust diagnostic tool that can guide patient selection for whom lymphadenectomy—that is, the surgical assessment of regional pelvic and para-aortic LN-basins for disease—is indicated. Recent approaches using either optical dyes or radiographic tracers for

lymphatic and sentinel lymph node (SLN) mapping have yielded mixed clinical results (e.g., low sensitivity and specificity) in GC patients. Lacking in these approaches are mechanisms for resolving microscopic extra-uterine and lymphatic disseminations either preor, preferably, intra-operatively in order to accurately identify LNs positive for metastatic disease.

Problem Statement: To address this and other issues, we have developed an intravenously administered lymphotropic multimodal contrast agent as a sensitive imaging tool of LN metastasis in GCs. We have previously described an all-organic unilamellar nanovesicle (Porphysome) with intrinsically activatable biophotonic properties. In addition to being biodegradable and biocompatible, Porphysomes can directly and stably chelate radioactive copper-64 (64Cu) to serve as a highly accurate and non-invasive PET/CT imaging tool. 64Cu-Porphysomes functionalized with targeting ligand peptide-folate have been experimentally validated for measurable tumour-specific accumulation lasting 48 hours in primary ovarian cancer xenografts overexpressing folate receptor. We hypothesize that optimising for nanovesicle physiochemical properties including size, surface charge, and targeting ligand, we can anticipate the performance of 64Cu-radiolabelled Porphysome nanovesicles as selective lymphotropic agents for LNs burdened with metastatic disease in preclinical tumour models with reproducible lymphatic dissemination.

Methodology: Porphysome nanovesicles are prepared with pyropheophorbide-lipid, cholesterol, and 1,2-distearoyl-*sn*-glycero-3-phosphoethanolamine-N-[methoxy(polyethylene glycol)-2000] (DSPE-mPEG-2000) in molar ratios 55/40/5, respectively. For folate receptor targeting, 1 mol/mol % peptide-folate conjugated DSPE-PEG-2000-Folate was subrogated into the above formulation. Variously sized unilamellar Porphysomes were formed following conventional liposomal preparation. To investigate the lymphotropic performance of optimally sized Porphysomes, four preclinical models of reproducible lymphatic tumour dissemination were developed: a VX2 endometrial carcinoma model with pelvic and retro-peritoneal LN metastasis in rabbits, an intra-prostatic MAT-Ly-Lu tumour and a subcutaneous intra-footpad hyperplasia models in rats, and an intra-uterine VEFG-C overexpressing tumour model with augmented lymphangiogenesis in mice.

Results: Radio-pharmaceutical Porphysome kits are manufactured in accordance with good manufacturing practices (GMP); specifically, suitable pharmacopeial grade materials were used throughout manufacture and each production batch is subjected to quality control assays typical of pharmacopeial standards for non-sterile pharmaceutical compounding (e.g., pH, sterility, bacterial endotoxins, etc.) before release. One-step radiolabelling of Porphysome kits with copper-64 prepared parenteral quality injections with high radiochemical purity (> 98%) and specific activity of approximately 2,800 Ci/µmol per nanovesicle. The sensitivity, specificity, and accuracy of optimally sized ⁶⁴Cu-Porphysome kits for malignant LNs was quantified for both imaging modalities and correlated with histopathology in our preclinical models.

Implication: Our ⁶⁴Cu-Porphysomes will permit the synchronous, non-invasive evaluation of GCs for (1) the extent of metastatic tumour spread and LN dissemination by PET/CT (i.e., pre-operative staging), followed by (2) intra-operative fluorescent imaging to detect cancerous LNs in real-time for image-guided lymphadenectomy.

SP128.4 - Generation of 4-Class Attenuation Map for MRI Based Attenuation Correction of PET Data in the Head Area Using a Novel Combination of STE/DIXON-MRI and FCM Clustering

Author(s): Parisa Khateri¹, <u>Hamid Saligheh Rad</u>¹, Amir Homayoun Jafari², Anahita Fathi¹, Afshin Akbarzadeh¹, Mohsen Shojae Moghadam³, Arvin Aryan⁴, Pardis Ghafarian⁵, Mohammad Reza Ay¹ ¹Research Center For Molecular And Cellular Imaging, Institute for Advanced Medical Technologies, Tehran/IRAN, ²Research Center For Biomedical And Robotics Technology, Institute for Advanced Medical Technologies, Tehran/IRAN, ³Mri Imaging Center, Payambaran Hospital, Tehran/IRAN, ⁴Imaging Center, Imam Khomeini Hospital Complex, Tehran/IRAN, ⁶Chronic Respiratory Diseases Research Center, National Research Institute Of Tuberculosis And Lung Diseases (nritld), Shahid Beheshti University of Medical Sciences, tehran/IRAN

Purpose: Despite remarkable advances in positron emission tomography (PET), the effect of photon attenuation still remains unsolved. The act of attenuation correction based on magnetic resonance imaging (MRI) is a challenging issue, since distinguishing between air and bone in adjacent areas is not possible in conventional MRI. In this study, a novel combination of short echo-time (STE) MRI and a dedicated image segmentation method is proposed to derive bone tissue. A four-class attenuation map (μ-map) is proposed based on STE/Dixon-MRI for attenuation correction of positron emission tomography (PET) data of head.

Methods: 5 normal volunteers underwent MRI and CT scans. Two consecutive MRI pulse sequences; STE technique, (echo-time, 1.1 msec; repetition time, 12 msec; voxel size, 1.2×1.2×2 mm3; acquisition time, 462 sec), and Dixon technique for fat and water decomposition (echo-time 1, 2.38 ms; echo-time 2, 4.76 msec; repetition time, 12 msec; voxel size, 1.2×1.2×2 mm3; acquisition time, 462 sec) were applied. Therefore, 3 MRI data sets for each volunteer were available: STE images (from STE technique), in-phase and out-of-phase images (from Dixon technique).

A four-class µ-map including cortical bone, soft tissue, fat tissue, and air regions was derived from MR images. The image analysis protocol was mainly performed by an in-house-developed software written in MATLAB (The MathWorks, Inc.). Steps for this generation of u-map are illustrated in Figure 1. Tissue attenuation coefficients were calculated using ICRU 44 report.

To assess MRI-based μ -maps, ultra-low dose CT (ULDCT) data were acquired. After registration CT with MRI, CT-based μ -maps were generated. Quantitative assessment was applied to evaluate the MRI-based μ -maps in comparison to CT-based μ -maps. The values of sensitivity, specificity and accuracy were calculated performing a voxel-by-voxel comparison between segmentation results. To assess correlation between MR-based and CT-based μ -maps, joint histogram was plotted and correlation coefficient was calculated.

Results: The voxel-by-voxel comparison of the MRI-based and CT-based segmentation results showed that values of accuracy and specificity were more than 95% for classes of cortical bone, soft tissue and air region. The average value of sensitivity was calculated 75% for cortical bone and more than 90% for other classes. Evaluation of correlation between MRI and CT results yielded an overall correlation coefficient of 0.98 and 0.97 for integrated μ -maps over 15 slices.

Conclusions: Results indicate that STE/Dixon-MRI data in combination with FCM-based segmentation yields precise MR-based μ -maps for PET attenuation correction in hybrid PET/MRI systems.

SP128.5 - A new low field MRI/gamma detector hybrid system. Author(s): <u>Andrea Abril</u>¹, Luis Agulles-Pedros²

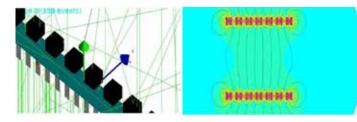

¹Physics, Universidad Nacional de Colombia, Bogotá/COLOM-BIA, ²Physics, Universidad Nacional de Colombia, bogotá/COLOM-BIA

The hybrid systems like MRI/PET and MRI/gamma camera, offer advantages, combining the resolution and contrast capability of MRI with the better contrast of nuclear techniques. This work presents, the design of a low field NMR system made up of permanent magnets compatible with a γ radiation detector. The γ detector is based on gel dosimetry. This gel undergoes a T2 relaxation time dependence with the dose. The design is performed using the software ffme for estimation of the magnetic field, and geant4 for the physical process involved in radiation detection and effect of magnetic field.

Low field MRI (IfMRI) is, in one hand, a cheaper and versatile alternative to high field MRI. On the other hand, high field MRI is not easily compatible with other techniques that involve radio frequencies and ferromagnetic materials.

The homogeneity in magnetic field is achieved with an array of NbFeB magnets in a linear configuration with a separation between the magnets, minimizing the effect of Compton back scattering compared with a no-spacing linear configuration. The final magnetic field in the homogeneous zone is ca. mT.

The radiation detector used in this work is a Gel, which is the innovative part. The radiation detectors are expensive and need an electronic set-up, which can interfere with the NMR process or viceversa.

Geant4 and ffme simulation of the hybrid system.

In our hybrid proposal, although the gel detector do not have spatial resolution, it is possible to obtain a dose profile as a function of the x-axis position by using a collimator array. We present two different

methods of collimation. The first one uses sheets of lead, and the other one uses the magnets of the IfMRI array as collimator, taking advantage of the high density and atomic mass of its components.

As a result, the system described allows a complete integrated radiation detector within the IfNMR system. Finally we present the better configuration for a hybrid system capable of obtain a 1D image, MRI and gamma dose, simultaneously.

SP129 - Image Quality Assessment (Mammography and Other)

TRACK 01: IMAGING

SP129.1 - Kilovoltage-CBCT of a Linear Accelerator as a relative imaging device of a spiral CT scanner - dosimetric results Author(s): James K. Annkah¹, Ivan Rosenberg², Naina Hindocha², Syed A. Moinuddin³, Kate Ricketts¹, Abiodun Adeyemi⁴, Gary Royle¹ ¹Department Of Medical Physics & Biomedical Engineering, University College London, London/UNITED KINGDOM, ²Radiotherapy Physics Department, University College Hospital, London/UNITED KINGDOM, ³Radiography Department, UCLH, London/UNITED KINGDOM, ⁴Radiotherapy Physics Department, Royal Berkshire Hospital, Reading/UNITED KINGDOM

Title: kV-CBCT of a Linear Accelerator as a relative imaging device of a spiral CT scanner - dosimetric **results**

Purpose: Many African countries are in the process of replacing Co-60 equipment with linacs as part of upgrading radiotherapy centers. The purpose of this work is to investigate kV-CBCT of stateof-the-art linacs as a relative imaging device of a spiral CT scanner, which may be useful in radiotherapy centers in developing countries, and evaluate the dosimetric accuracy of a simple method of HU-ED calibration on the Truebeam.

Problem Statement: Radiation oncology in developing countries is hindered by numerous factors including availability and choice of equipment. Currently, sub-Saharan Africa depends on Co-60 in most cancer centers, with standard equipment in a typical state-funded radiotherapy center being Co-60, CT scanner, TPS and other dosimetric equipment. However, with the combination of the modern equipment and techniques, cancer care in Africa can see an exponential rise with higher survival rates.

Due to maintenance and service costs, CT scanners frequently breakdown so RT centers rely on external CT scanners operated by individuals for commercial purposes. Clinical images are acquired and eventually sent to the radiotherapy centers for treatment planning. Since each CT scanner has its own calibration curve, it is nearly impossible for the TPS to have all the individual HU-RED calibrations of the commercially available CT scanners. Treatment plans from such CT scanners may therefore be prone to dosimetric errors. CBCT has been reported to provide accurate dosimetric results where they have been used directly to perform treatment plans. Therefore, a simple method to obtain accurate dosimetric results can be useful in radiotherapy centers in developing countries in the event of replanning or the breakdown of a CT. This may be considered as an alternative to relying on commercial CT scanners if dosimetric accuracy is established.

Method: HU-ED calibrations were performed without a bowtie filter. Images for treatment planning were acquired on GE Light Speed CT scanner at 120 kV, 220 mA and 2.5 mm slice thickness. Another set was acquired using the Truebeam using at half fan beam mode using clinical parameters. IMRT plans were produced on the Eclipse TPS using both set of images while all dosimetric calculations were based on the HU-RED calibration curve of the CT scanner. The results were evaluated, considering HU accuracy, geometric and dosimetric accuracies of the Truebeam.

Results & Conclusion:

Previous results using sophisticated correction methods produced results of \pm 3% of the prescribed doses. This simple approach pro-

duced \pm 5% of the prescribed doses, but can also produce results with better accuracies. Further modifications to the setup and calibration can improve dose accuracy, and this can be advantageous in situations where the TPS software has limited features.

SP129.2 - Overall performance, image quality and dose in CR mammography systems operating in the Mexico public health sector

Author(s): <u>María-Ester Brandan</u>¹, Cesar Ruiz-Trejo¹, Juna Carlos Cruz-Hernandez¹, Naxi Cansino¹, Lizbeth Ayala-Dominguez¹, Adriana Moreno-Ramirez², Jaime Aeberto Rodriguez-Lopez², Mario Gomez-Zepeda², Margarita Chevalier³

¹Instituto De Física, Universidad Nacional Autónoma de México UNAM, Mexico City/MEXICO, ²Centro Nacional De Equidad De Genero Y Salud Reproductiva (cnegsr), Secretaría de Salud, Mexico City/MEXICO, ³Fisica Medica, Facultad De Medicina, Universidad Complutense de Madrid, Madrid/SPAIN

Breast cancer is the first cause of cancer death in Mexican women. Approximately, 20 million women are 40 years old or older; annually, 20,444 new cases (35.4 per 100,000 women) and 5,584 deaths (17.2 per 100,000 women older than 25) are due to this disease. Breast cancer prevention, diagnostics, treatment, control and monitoring is regulated by National-Official-Regulation NOM-041 that recommends a mammogram every 2 years for women 40-69 y.o. NOM-229 stablishes technical requirements for mammography equipment. Compliance with these regulations is controlled and monitored by COFEPRIS, a Ministry of Health (SS) commission.

About 2 million mammographic screening studies are performed annually in public services. Public services own 754 mammography units, 351 of these belong to SS. Three technologies are employed: screen/film (33% of SS units), digital flat-panel-detectors-DR (26%) and computed-radiography-CR (41%). An independent 2014 study for 65 CR systems in central Mexico reported that only 6% of services met NOM-041 standards, 79% produced images with artifacts and non-uniformities, and 42% met the minimum score of ACR phantom.

This study, collaboration with CNEGSR-SS, has focused on CR systems operated by SS institutions. The goal was to evaluate overall performance, image quality and dose in 15 CR systems which perform approximately 64,000 studies yearly. 40 evaluation tests, including use of CDMAM phantom and MTF evaluation, were applied in services located in 8 States.

Quality control procedures were those suggested by IAEA QA Programme for Digital-Mammography, Spanish Protocol for Quality Control in Diagnostic Radiology and Spanish Protocol for Quality Control in Digital-Mammography, and those in NOM-229 and -041.

The evaluation was grouped into 7 areas: Electromechanical performance, automatic exposure control, radiation yield, beam quality, dose, image quality and monitor visualization conditions. Systems were combinations of various mammography units with Carestream, Konica or Fujifilm CR plates. Within a month after the evaluation, services received a report with results, description of deficiencies, and strong recommendations to solve problems immediately.

Severe failures in the equipment performance, and general noncompliance with Mexican regulations and international recommendations were found. Percentage of systems complying with recommendations for representative tests were: Mammography unit mechanical evaluation (50%), compression force (64%); AEC thickness compensation (0%); mean-glandular–dose (57%); quantum noise dominance in images (9%); plate homogeneity (0%); spatial resolution (38%); visualization of CDMAM 0.1 mm object (8%); absence of artifacts (0%). 50% of centers had 5 MP interpretation monitors and 30% of rooms presented appropriate visualization conditions. On the positive side, 100% of systems showed appropriate half-value-layers, linearity of yield with mAs, and linear (in terms of ln(ESAK)) detector response function. Some positive changes happened after sending the reports: 3 mammography units were replaced, one high-resolution monitor was purchased and conditions in two interpretation rooms were improved. On Dec-2014, after these results, SS informed that CR systems will no longer be purchased for the CNEGSR-Breast Cancer Program, promoting migration to DR systems. It is hoped that this collaboration might result into needed actions, particularly, NOM-229 update.

We thank J Márquez, MJ Villagómez-Casimiro, A Álvarez-Luquin, and grants IAEA RC17683 and PAPIIT-UNAM-IN105813.

SP129.3 - A Catphan attachment for three dimensional measurements of the modulation transfer function

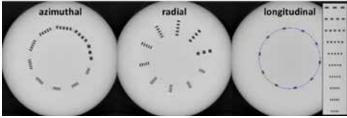

Author(s): Balazs J. Nyiri, Elsayed S.M. Ali

Medical Physics Department, The Ottawa Hospital Cancer Centre, Ottawa/CANADA

Commercial image quality phantoms (e.g., Catphan) suffer from two limitations related to the modulation transfer function (MTF). First, the phantoms are suitable for determining the cutoff frequency only, not the full MTF shape. Second, the potential directional dependence of the MTF is ignored, making the quantification of directional blur difficult. In this study, these two limitations are addressed by proposing a Catphan attachment for 3D measurements of the full MTF shape (figure 1). Example results are shown for the Elekta XVI CBCT system. Cylindrical coordinates are chosen because MTF directional dependence is likely along these coordinates - e.g., lag/ ghosting blurs the image along the rotating scan direction, thus affecting the azimuthal MTF. The cyclic pattern in each dimension consists of ten groups of line pairs with frequencies from 1.00 to 4.55 lp/cm in increments of 0.4 lp/cm. This frequency range is chosen to capture the sloping portion of the MTF for the XVI system. All lines are 5 mm long and 3 mm deep, and the centers of the line groups in the three coordinates are 36° apart and 5 cm off-center. The MTF is extracted using Fourier analysis of the line profiles along the cyclic patterns to determine the amplitude at the principal frequency. Figure 2 shows example results for the XVI system. For a given set of scan parameters, the longitudinal MTF is superior to the other two directions, and the radial MTF is better than the azimuthal MTF at higher frequencies (ghosting/lag could be a factor). For a given mAs per scan, reducing the scan time from 2 to 1 minute leads to deterioration of the longitudinal MTF and to improvement in the azimuthal MTF. In conclusion, the proposed 3D MTF attachment can be a useful tool to evaluate the overall performance of imaging systems.

Figure 1: Top: 3D MTF phantom (clear Acrylic) attached to the Catphan (dark blue). Bottom: Images of the MTF attachment in the three cylindrical coordinates.

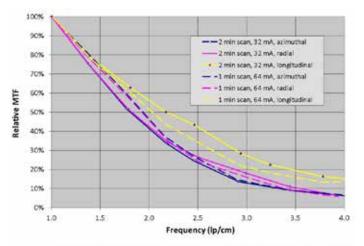

Figure 2: Relative MTF for scans with the following parameters: 120 kVp, bowtie filter, medium FOV, 40 ms per pulse, clockwise, high resolution reconstruction

SP129.4 - Sensitometric analyses of screen-film systems for mammography exams in Brazil Author(s): Luis Magalhaes

Universidade do Estado do Rio de Janeiro - UERJ, Rio de Janeiro/ BRAZIL

A determination of the sensitometric parameters of screen-film systems to evaluate their qualities was performed. The quality control of the automatic film processor was carried out to ensure a high level of efficiency. Based on ISO 9236-3, the following potentials were applied on the X-ray tubes: 25 kV, 28 kV, 30 kV and 35 kV. Four different mammography films from different manufacturers with and without screens were tested for curve shape, speed and average gradient. The results indicated that film 1 exhibited better contrast, film 3 demonstrated the highest energy dependence, and film 4 presented the largest base+fog density. None of the four mammographic films tested achieved satisfactory results in all parameters analyzed. Improvements in the manufacturing process for these films must be completed to avoid losses in the image quality.

SP129.5 - New Line Contrast Figure of Merit for image quality assessment

Author(s): <u>Aris Dermitzakis</u>, Anastasia Daskalaki, Kristina Bliznakova, Nicolas Pallikarakis

Biomedical Technology Unit, Dept. Of Medical Physics, University of Patras, Patras/GREECE

A novel Figure of Merit (FoM) is presented which is based on analysis of data extracted from line profiles within the image. This FoM is referred as Line Contrast (LC). In order to evaluate its performance, the proposed FoM along with Contrast to Noise Ratio (CNR), are applied in a simulated phase contrast image and the resulting figures are compared. Phase contrast image is created using the XRAYImagingSimulator an in-house developed software platform for x-ray imaging simulation. A semi-cylindrical phantom especially designed for phase contrast applications that contains materials mimicing the refractive properties (indexes) of breast tissues was used. Images were produced at 20 keV with source to isocenter distance (SID) 23m and object to detector distance (ODD) 400mm and pixel size of 5µm. Results from the application of both FoMs shows that LC comes into full accordance with visual assessment and that it overpass the traditionally used CNR, especially in the ability of detecting the edge enhancement due to phase contrast, of the different structures within the image. The edge detection features make it optimal for phase contrast investigation where the effect on the edge enhancement is of outmost importance.

 SP129.6 - Assessment of Photostimulable Storage Phosphor Imaging Plates Quality in Computed Radiography
 Author(s): <u>Bárbara Q. Friedrich</u>¹, Ana Maria Marques Da Silva¹, Renata M. Luz², Jéssica V. Real², Alexandre S. Capaverde²
 ¹Núcleo De Pesquisa Em Imagens Médicas, PUCRS, Porto Alegre/ BRAZIL, ²Hospital São Lucas, PUCRS, Porto Alegre/BRAZIL

Image quality of Computed Radiography (CR) systems has been studied, but there have been little effort to evaluate the physical performance of the photostimulable phosphor imaging plates (IPs). Due to their reusability, they are subjected to normal wear and tear from scratches, scuffs, cracks, and contamination with dust and dirt, which may interfere with the production of an appropriate diagnostic image. Some manufacturers discard the IPs only based on the number of exposures. However, this parameter is insufficient to evaluate their quality and lifetime indications. The aim of this study is to investigate quantitative and qualitative quality control (QC) procedures which can assure the IPs quality in CR systems, providing evidences of the lost of diagnostic quality. Two groups of Fujifilm HR-BD IPs were investigated: four plates were in use and four plates had been discarded. The IPs were stimulated using phantoms (PMMA, aluminium sheets and a mammographic phantom) in Mammomat 3000 Siemens mammography equipment, and scanned by Fuji FCR system, model Profect CS Plus. The QC procedures evaluated were: signal-to-noise ratio (SNR); contrast noise ratio (CNR); contrast; ghost effect; uniformity; visual analysis of the image; and integrity. The results indicated that the ghost effect, integrity and uniformity QC tests give evidences to evaluate CR imaging plates' degradation.

SP130 - Treatment Planning

TRACK 04: RADIATION ONCOLOGY

SP130.1 - Comprehensive Dosimetric Planning Comparison for Early Stage Non-Small Cell Lung Cancer with SABR: Fixed-Beam IMRT versus VMAT versus Tomotherapy Author(s): Ilma Xhaferllari, Stewart Gaede Department Of Medical Biophysics, Western University, London/ ON/CANADA

Introduction: Volumetric modulated arc therapy (VMAT) is emerging as leading technology in treating early-stage non-small cell lung cancer (NSCLC) with Stereotactic Ablative Radiotherapy (SABR) due to its efficiency. However there are other various techniques available to deliver IMRT: fixed-beam, and helical Tomotherapy (HT). TrueBeam[™] linear accelerators (Varian Medical Systems, Palo Alto, USA) allows for fixed-beam and VMAT techniques to be executed using flattening filter free beams, achieving dose rates up to 2400 MU/min, significantly reducing treatment times. The purpose of this study is to provide an extensive dosimetric comparison among the IMRT techniques previously mentioned for treating early-stage NSCLC with SABR.

Methods: Ten early-stage NSCLC patients were retrospectively optimized using three fixed-beam techniques with 9-11 beams (high and low modulation step-and-shoot (SS-IMRT), and sliding-window (SW-IMRT)), two VMAT techniques using two partial arcs (SmartArc (SA-VMAT) and RapidArc (RA-VMAT)), and three HT fan beam widths (1 cm, 2.5 cm, and 5 cm); accounting for 80 plans total. SS-IMRT and SA-VMAT, HT plans, and, SW-IMRT and RA-VMAT were optimized using Pinnacle v9.1, Tomoplan v.3.1.1, and Eclipse (Acuros XB 11.3 dose calculation algorithm), respectively. All plans met target coverage and critical organ constraints according to the SABR-COMET protocol.

Dose-volume histogram statistics, dose conformality, and treatment delivery efficiency variables were analyzed. To determine statistical significance, the Shapiro-Wilk test checked for normality. For normal distributions, ANOVA and Tukey post-hoc tests were performed; otherwise, Krukal-Wallis followed by a Mann-Whitney test were performed (significance defined as p-value <0.05).

Results: Conformality index, ratio of the volume of 80% and 50% isodose to the planning target volume (Cl80%, Cl50%), significantly increased with HT-5cm compared to all other modalities, with RA&SA-VMAT being the most conformal. The percent volume of contralateral lung receiving 5 Gy or more (V5GyC) significantly increased in all HT plans (p=0.002) and mean lung dose significantly increased in the HT-5cm plan (p=0.002). In both scenarios, RA&SA-VMAT achieved the lowest values.

When RA&SA-VMAT were grouped and compared to SS-IMRT; the maximum dose to the bronchus (p=.011) and heart (p=.005) significantly increased, whereas, all lung parameters expect lung covered by 10 Gy or more (V10Gy), and the maximum dose to cord significantly reduced with RA&SA-VMAT. When comparing RA&SA-VMAT, Cl80%, Cl50% and D2cm were significantly reduced with the RA plan, whereas V10Gy and total monitor units significantly increased.

Estimated treatment time significantly increased amongst HT (p<0.001), 13.2 \pm 1.8, 8.3 \pm 5.2, and 6.4 \pm 4.1 minutes for HT-1cm, HT-2.5cm and HT-5cm respectively, and fixed-beam IMRT plans (p<0.001), 2.5 \pm 0.3, 3.0 \pm 0.5, and 4.4 \pm 1.4 minutes for SS-IMRT low and high modulation, and SW-IMRT respectively, compared to both, RA&SA-VMAT, 2.0 \pm 0.3, and 1.9 \pm 0.2 minutes respectively. However,

there was not a significant difference between RA vs. SA-VMAT (p=.393).

Conclusion: RA&SA-VMAT outperformed HT in all parameters measures and statistical difference was observed in ten parameters, none of which showed VMAT to be inferior. Despite an increase in dose to the heart and bronchus, this study shows that VMAT is dosimetrically advantageous in treating early-stage NSCLC with SBRT compared to fixed-beam IMRT, while providing significantly shorter treatment times than any other modality studied.

SP130.2 - Development and Validation of an Open Source Tool for Determining Planning Target Volume Margins in Intracranial Stereotactic Radiotherapy

Author(s): <u>Winnie Li</u>, Tim Craig, An Wang, Young-Bin Cho, Tara Rosewall, Kristy Brock, David Jaffray Badiation Medicine Program, Princess Margaret Cancer Centre

Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/CANADA

Purpose/Objective(s): Awareness of inter- and intra-fraction uncertainties is increasingly important in the era of stereotactic radiotherapy (SRT); their incorporation into the planning target volume (PTV) margin (MPTV) is essential to ensure prescribed dose to the target. The purpose of this work is to develop a method to formulate MPTV for Gamma Knife (GK) intracranial SRT to manage geometric uncertainties.

Materials/Methods: The Margin Calculator was developed in open-source software to determine patient-specific MPTV. The tool was initially validated against van Herk's (MvH) formula using a synthetic sphere and stochastic simulations for a range of systematic and random uncertainties over several fractionation schedules. Under ethics approval, 10 GK intracranial stereotactic radiosurgery targets and dose distributions underwent stochastic simulations for systematic and random uncertainties ranging from 0 - 1.5 mm and 4 fractionation schedules (1, 3, 5, 10). Simulation of MPTV expansion in the calculator was performed through dose distribution image scaling. Incremental MPTV expansions were performed until cumulative dose population histograms reached a goal of 90% population receiving a near-minimum dose of 95%. The performance of image scaling as a method of MPTVexpansion was validated through comparison of the automatic scaled plans on the required MPTV versus manually generated replans for 22 cases in the treatment planning system. The new dose distribution was imported back into the Margin Calculator, and simulations repeated using the original target volume (i.e. no MPTV added), the new dose distribution (i.e. including the MPTV), specified fractionation schedule, and original set of systematic and random uncertainties. If the MPTV-Initial satisfies the coverage criteria with the prescribed dose, additional MPTV (MPTV-Additional) required should be minimal.

Results: Phantom sphere validation results showed strong agreement between the MvH-predicted and calculator generated MPTV (R²=0.965). 640 MPTV were generated for 10 intracranial targets over 4 fractionation schedules. A 73% agreement within ±1 mm between calculated to MvH-predicted MPTV was observed, showing larger (80%) margins were required with the MvH approach. Lower fractionation and irregularly shaped targets required larger MPTV. Compared to manual replans, the automatically scaled plans required an additional 0.2 mm MPTV-Additional in 81% (18/22) of the cases; all targets required <1 mm additional MPTV-Additional to ensure dosimetric coverage.

Conclusion: A process for a *Margin Calculator* has been developed and validated. This open-source tool accounts for patient-specific target size, target contour, dose specifications, geometric uncertainties, fractionation schedules and treatment goals, and is useful for deriving evidence-based MPTV for intracranial GK-SRT.

SP130.3 - Dosimetric impact of accurately delineating of the left anterior descending artery in photon and proton radiotherapy

Author(s): Janid Blanco Kiely¹, Benjamin M. White¹, Sabina Vennarini², Andrea Dimofte¹, Lilie Lin¹, Gary Freedman¹, Stefan Both¹ ¹Radiation Oncology, University of Pennsylvania, Philadelphia/ UNITED STATES OF AMERICA, ²L'unita` Operativa Di Protonterapia, Azienda Provinciale per i Servizi Sanitari, Trento/ITALY

Purpose: The purpose of this study was to quantify the dosimetric impact of motion on the dose delivered to the left anterior descending artery (LAD) in deep inspiration breath hold (DIBH) CT using proton uniform scattering (US), pencil beam scanning (PBS) and 3D conformal photon radiotherapy (3DCRT). Because dose volume histogram (DVH) indicators based on whole heart dose do not consistently predict radiation-induced risk for myocardial infarction, dose to the LAD itself has been suggested as a better indicator of radiation-induced cardiac toxicity. Routine radiotherapy treatment planning clinical imaging protocols do not compensate for heart motion, introducing a source of uncertainty in contouring and in reported dose to the LAD. Ultimately, a method that quantifies the dosimetric impact of motion could improve the LAD's dose estimate.

Materials and **Methods:** Ten consecutive patients with left breast cancer received a routine clinical DIBH CT where cardiac motion was not accounted for during patient simulation. An expert radiologist contoured the LAD in the routine DIBH CT. Using an unsharp filter, the LAD's uncompensated motion blurring in the DIBH CT images was extracted from the contoured LAD to create a corrected LAD volume. Treatment plans were created using proton (US and PBS) and photon (3DCRT) planning techniques. In order to be consistent with literature, the maximum and mean dose to the LAD were used as DVH endpoints. The relative dosimetric impact of using a corrected LAD volume on the LAD DVH indicators was determined by quantifying the relationship between the DVH indicators, which were calculated from the corrected versus the uncorrected LAD volume.

Results: Using a corrected LAD volume for calculation of the maximum dose LAD DVH indicator reduced its reported value by 2% (3DCRT), 4% (US), and 25% (PBS). The maximum absolute dose reduction was greatest for the 3DCRT plans, where the corrected LAD volume reduced the maximum dose by 87.5±117.4cGy. Proton plans had a smaller difference: US and PBS plans had a LAD maximum dose reduction of 35.8±55.4cGy and 16.3±17.0cGy respectively. The corrected LAD volume had the dosimetric impact of increasing the mean LAD dose for each treatment modality by 25% (3DCRT), 61% (US), and 35% (PBS). The greatest overall mean dose increase was found in the 3DCRT plans, where the average mean LAD dose increase was 167.9±163.9cGy. Both the US and PBS plans had less average mean dose difference (1.9±3.8cGy and 0.4±1.3cGy, respectively).

Conclusion: Uncompensated coronary motion in DIBH CT might reduce the accuracy of the LAD DVH indicators for all photon and proton modalities. Therefore, overestimating LAD volume could potentially be the source of inconsistencies within dose and radiation-induced cardiac toxicity correlations reported in the literature. These findings may be more clinically relevant for photon therapy, since photon therapy tends to deliver higher LAD doses relative to proton modalities (proton modalities are already associated with low LAD doses with or without motion correction).

SP130.4 - Objective function surrogates for iterative beam angle selection

Author(s): Mark Bangert¹, Jan Unkelbach²

¹Division Of Medical Physics In Radiation Oncology, German Cancer Research Center DKFZ, Heidelberg/GERMANY, ²Radiation Oncology, Massachusetts General Hospital, Boston/UNITED STATES OF AMERICA

Optimized non-coplanar beam ensembles may yield substantial improvements of radiation therapy treatment plan quality. However, beam angle selection (BAS) is a non-trivial process and automated beam ensemble optimization is not supported by most commercial treatment planning systems, in part due to the lack of efficient algorithms.

We focus on iterative BAS, where a beam ensemble is sequentially constructed: the basis for BAS during iteration n is a treatment plan containing n-1 fixed beams. To select the nth beam, each remaining beam from a discrete set of candidate beams is added one-by-one to the current beam ensemble and the fluence map optimization (FMO) problem is solved. The beam that yields the lowest objective function value is selected.

In this work we investigate two alternative methods relying on objective function surrogates to score candidate beams in order to make iterative BAS computationally more efficient: Conventional iterative BAS is compared to (1) an approach where the FMO problem is not solved to optimality but stopped after five iterations of a gradient based algorithm and (2) an approach where candidate beams are scored based on a projected gradient of the FMO problem in the first iteration.

In a treatment planning study including one pancreas, one prostate, and one intracranial case, it is observed that both iterative BAS methods using objective function surrogates yield similar plan quality compared to naïve iterative BAS with regard to the resulting the objective function values (see figure 1) and DVHs (see paper). At the same time, the surrogates enable reductions in computation time by a factor of 50-100 making them highly attractive for clinical application.

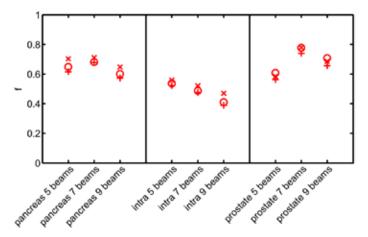

Figure 1: Normalized objective function value vs. number of beams for the three investigated cases for iterative BAS using the objective function value after a full FMO (plus signs), the objective function value after five FMO iterations (circles), and the initial projected gradient (crosses). 1 corresponds to the objective function value of a coplanar equi-spaced beam ensemble with the same number of beams; 0 corresponds to the objective function value of an unattainable benchmark IMRT plan that uses all candidate beams.

SP130.5 - A preliminary study on the effect of modulated photon radiotherapy (XMRT) optimization for prostate cancer treatment planning

Author(s): <u>Philip Mcgeachy</u>¹, Jose E. Villarreal-Barajas¹, Yuriy Zinchenko², Pooyan Shirvani², Rao Khan¹

¹Medical Physics, Tom Baker Cancer Centre, Calgary/CANADA, ²Mathematics And Statistics, University of Calgary, Calgary/CANADA

This preliminary work compared a new optimization technique, modulated photon radiotherapy (XMRT), with intensity modulated radiotherapy (IMRT) in a treatment planning study on a cohort of eight prostate cancer patients. XMRT differs from IMRT in that it allows the typically fixed beam energy to act as a variable such that the optimizer finds a dose distribution by simultaneously optimizing photon beamlet fluence and energy. Plans were comprised of a seven-coplanar beam arrangement, with IMRT restricted to 6 MV while XMRT used 6 and 18 MV beams. Both IMRT and XMRT optimization was based on a linear programming model with partial-volume constraints implemented through the conditional variable at risk (cVaR) approach. A dose-volume histogram for one of the patients is given in figure 1. XMRT and IMRT provided similar coverage to 95% of the target (PTV) with the prescribed dose (78 Gy), however XMRT improved the homogeneity index (HI) (Table 1). XMRT was able to reduce the dose to a greater extent (p <0.05) for the rectum, bladder, and femoral heads, particularly in the low-dose region (\leq 40 Gy). Further, XMRT provided an improvement in the high dose-region of the bladder with a lower near maximum dose, D2%, Bladder, and reduced volume receiving at least 80 Gy, V80, Bladder (p < 0.05). Although there was a statistically significant decrease in certain dosimetric parameters for healthy organs using XMRT, whether or not this has a clinical impact has yet to be determined and is a point of interest for future investigations. Further, neutron dose needs to be considered for XMRT and the possible ramifications on the risk of secondary cancers.

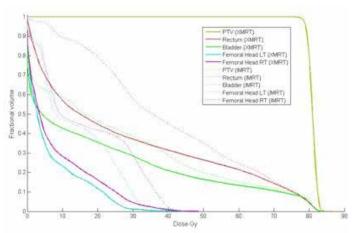

Fig 1. Dose-volume histogram for XMRT (solid) and IMRT (dashed) solutions for a prostate patient.

Table 1. XMRT and IMRT results for cohort of eight patients, presented as the mean \pm standard deviation.

	XMRT	IMRT	p-value

SP130.6 - Measuring radiation treatment plan similarity in the cloud

Author(s): <u>Jennifer Andrea</u>, Csaba Pinter, Gabor Fichtinger School Of Computing, Queen's University, Kingston/ON/CANADA

Measuring radiation treatment plan similarity in the cloud

J. Andrea, C. Pinter and G. Fichtinger

Laboratory for Percutaneous Surgery, School of Computing, Queen's University, Kingston, ON, Canada

Radiation therapy is a form of cancer treatment in which carefully designed plans are used to direct treatment over multiple occasions (fractions). Creating radiation plans is quite laborious, so it is not feasible to manually create a plan for each fraction to maintain treatment quality. We propose to use a database of plans to find the most similar anatomy, based on which a suitable daily plan might be automatically created, thus reducing staff time. However, the computation for finding the most similar plan is long and computationally intensive, which presents an obstacle to performing the procedure clinically. We present a method for finding the most similar plan using cloud resources to reduce computation time. Using the cloud to perform the comparison computation enables each comparison between the daily study and an assigned study from the database to be computed in parallel.

The similarity analysis computation was performed on Amazon Web Services (AWS) Elastic Cloud Compute instances, using 3D Slicer and SlicerRT. 3D Slicer (www.slicer.org) is an open source platform for medical image analysis and visualization and SlicerRT (www. SlicerRT.org) is a radiation therapy research extension for 3D Slicer. The AWS Simple Storage Service and Simple Queue Service were also used, for storage of the studies and messaging between the local computer and the instances, respectively. The similarity of the studies were evaluated by computing the Dice coefficient for pairs of matching contoured structures from each study. As contouring is a time-consuming process, contour comparison was used as a proof-of-concept for using the cloud and SlicerRT together to find the most similar plan. In the future, the similarity measure of raw anatomical data will be used for comparison instead.

The system was tested on simulation data created by applying random deformation fields to an existing phantom radiation plan. The system was evaluated both in terms of accuracy and in terms of time. Five different studies were presented to the system as the daily study, and the system returned the correct result in each case. The preliminary, unoptimized implementation finds the most similar plan in less than 7 minutes when choosing from 5 plans, and it is anticipated that increasing the number of plans will result in only a small relative increase in computation time. The estimated computation time for 10 comparison studies is less than 10 minutes, which is acceptable for this use case. This system, while currently set up for five studies, can easily be extended to hundreds or thousands of studies with little effort if other patients' plans are also included. The decrease in time required to perform this computation when using the cloud decreases the time to the point where it would be reasonable to perform this computation clinically. This will lead to a reduction in the time required to create a new optimized radiation plan for the same patient.

SP131 - Quality Assurance: Part 3

TRACK 04: RADIATION ONCOLOGY

SP131.1 - Sensitivity of Helical Tomotherapy and Elekta Agility VMAT dose distributions to multileaf collimator motion uncertainties for breast radiation treatment with extensive nodal irradiation

Author(s): Jason Belec, Eric Vandervoort

Medical Physics, Ottawa Hospital Cancer Center, Ottawa/CANADA

Purpose: Breast radiation therapy treatments including extensive nodal irradiation require additional photon intensity modulation to properly spare normal tissues such as the heart and the lungs. In this work, we use Monte Carlo dose calculation methods to quantify the sensitivity of those treatments to uncertainties in the motion of multileaf collimator (MLC) for treatment delivered using Helical Tomotherapy (HT) and Elekta Agility VMAT (EA-VMAT).

Materials and Methods: Treatment plans for 10 patients were generated using TomoTherapy Planning 5.0 and Elekta Monaco 3.1 treatment planning systems. Monte Carlo simulations were performed with a modified version of the BEAMnrc/DOSXYZnrc codes. Errors in the MLC motion were introduced in the treatment plans and the impact on the dose distribution was assessed by comparing the dose with and without the errors.

Results: Figure 1 shows an example of dose volume histograms for HT and EA-VMAT. The EA-VMAT plans were optimized using a 5 mm minimum leaf gap soft constraint to achieve similar treatment plan quality as with HT. The sensitivity of the EA-VMAT mean target dose was 3.0% per mm of error in the leaf gap size (0.5 mm error in the position of each leaf). The sensitivity of the HT mean target dose was 0.5% per ms of error in the opening time of each leaf. The sensitivity of the target dose to single leaf error was also investigated for HT. The maximum dose change to a point in the target due to a 5 ms opening time error in one leaf is between 0.4% and 0.7% depending on the leaf. An ongoing investigation is currently extracting similar information for EA-VMAT.

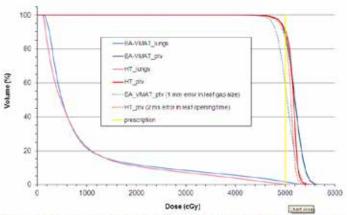

Figure 1 Example of curvaletive does value histograms of planning target values (ptv) and lungs for a breast treatment with extensive nodal invadiation. Dotted lines also also use immach of introducing errors of 2 ms in the leaf goesing time (HT) and errors of 1 mm in the leaf goesize (EAVMAT).

Conclusion: Breast radiation therapy treatments including extensive nodal irradiation require additional photon intensity modulation to properly spare normal tissues such as the heart and the lungs. Results show that it is possible to achieve similar treatment plan quality with EA-VMAT as with HT. The sensitivity of the EA-VMAT mean target dose to MLC position uncertainties is 3.0% per mm of

error in the leaf gap size (0.5 mm error in the position of each leaf). The sensitivity of the HT mean target dose to MLC position uncertainties is 0.5% per ms of error in the opening time of each leaf.

SP131.2 - Use of Varian Trajectory Log Files for Patient Specific Quality Control of TrueBeam VMAT FFF Treatment Deliveries with Portal Dosimetry and Eclipse

Author(s): <u>Michael Fan</u>, Francois Deblois, Jonathan Thebaut Radiation Oncology, Jewish General Hospital, Montreal/QC/CANA-DA

Purpose:

Varian Portal Dosimetry System (PDS) (Varian Medical System) is an integrated tool for dosimetric quality control (QC) of flattened beams. However, flattening filter free (FFF) beams are not yet supported in PDS. In this work, we propose a workaround to (1) analyze FFF beam deliveries in PDS and (2) visualize treatment delivery discrepancies within Varian Eclipse treatment planning system (ETPS) by using the Varian TrueBeam trajectory log files.

Method and Material:

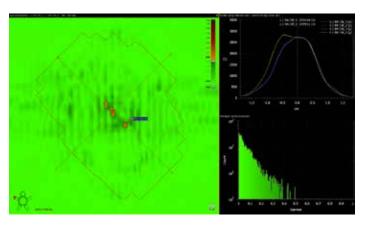

Five brain stereotactic radiosurgery plans were optimized with ETPS using a volumetric modulated arc delivery (VMAT) technique for 6 MV FFF beam on TrueBeam. Treatment verification plans were validated in a phantom by taking a point dose measurement with a Farmer-type ionization chamber (IC) and with a Gafchromic EBT3 film (Ashland Inc.). The trajectory log-files (version 1.5) were generated for every treatment and QC plan delivered. The log-files contain cumulative monitor units (MU) delivered, leaf positions, gantry positions, and other machine parameters sampled every 20 ms. We developed a user-friendly web application to parse log-files and automatically generate corresponding DICOM-RT reconstructed plans (DRP). The DRPs were imported into the ETPS and the dose distribution was recalculated on both the original QC and patient CTs using the delivered MUs. The planned mean dose to the IC was compared to the measured dose and the DRP dose. Gamma map analysis was performed between (1) the planned photon fluence (PFF) and the film measurement and (2) the PFF and DRP dose. The latter was analyzed in PDS by converting the DICOM dose files (PFF and DRP) to a format readable by PDS. Treatment delivery discrepancies on planning objectives were analyzed by comparing dosevolume histogram metrics between the original plan and the DRP.

Results:

The point dose differences between ETPS and IC and between ETPS and DRP were 1.6 \pm 1.5% and 0.17 \pm 0.08% respectively. The percentage of pixels passing fluence map gamma analysis between ETPS and film was 99.0 \pm 0.7% (3%/3 mm) and between ETPS and DRP (FIG1) was 99.8 \pm 0.2% (0.5%/0.5 mm). Across all analyzed plans, ETPS and DRP showed an average difference of 0.56 \pm 0.33% for V[10 Gy] to brain excluding PTV and an average difference of 0.22 \pm 0.15% for V[100% of prescription] to PTV.

Conclusion:

This work demonstrates the successful use of TrueBeam trajectory log-files with a user-friendly web application to reconstruct the delivered dose in ETPS for patient specific QC.

SP131.3 - Machine Learning Facilitates Failure Mode Analysis and Virtual QA for IMRT

Author(s): <u>Gilmer Valdes</u>, Ryan Scheurmann, Chun-Yu Hung, Marc Bellerive, Arthur Olszanski, Timothy D. Solberg

Radiation Oncology, University of Pennsylvania, Philadelphia/UNIT-ED STATES OF AMERICA

Purpose: To develop metrics that describe the deliverability of IMRT plans and use them for a priori prediction of IMRT QA results.

Methods: 498 IMRT plans from multiple treatment sites were planned in Eclipse version XI and delivered using a dynamic sliding window technique on two linac platforms (Clinac iX and TrueBeam, Varian Medical Systems, Palo Alto, CA). Using 2% dose / 2mm distance tolerances with local normalization, 38 plans failed the 90 % gamma criterion. Four failure modes were identified: MLC leafs' transmission, leaf end leakage, jaws' transmission and the tongue and groove effect. 23 different metrics were defined to characterize these failure modes. Geometrical features as well as those features weighted by the monitor units were included. Machine Learning Algorithms (MLA) were developed to analyze the data. A two-leaf decision tree with information gain maximization was used for each feature to determine thresholds that result in maximizing the probability of identifying failing plans. Features were ranked according to T- test, Kolmogorov-Smirnov Test and the information gain in 2 leaf decision trees. Additionally, a RUSBoost algorithm with oversampling was developed to predict the virtual passing results of each plan. All the statistical analysis was performed using Matlab R 2014a.

Results: All features analyzed were significantly different in the plans that failed compared to the plans that passed QA at a 5% confident interval for all the tests performed, and the weighted geometrical features were determined to be highly significant. Thresholds resulting in a substantial increase of the probability of plans failing QA were determined. The most important feature for each failure mode, and accompanying threshold, are shown in Table 1. The weighted average ratio of MLC to jaw aperture (WAveRatio) was the most important feature overall. Plans with a WAveRatio smaller than 0.1090 were approximately 37 times more likely to fail. The modulation factor, which relates to different failure modes, was also an important feature in that plans exceeding a value of 6.86 were approximately 19 times more likely to fail. Finally, a cross-validated decision tree ensemble resulted in correctly classifying 87% percent of failing plans and 88% of passing plans.

Conclusion: Passing rates of IMRT plans can be described by weighted geometrical features. Different thresholds for these features can be used to improve the plan deliverability. MLA can play a key role in planning and QA, particularly for adaptive strategies, which may require QA to follow clinical delivery.

Failure Mode:	MLC leafs' transmission	Leaf end leakage	Jaws' transmission	Tongue and Groove effect
Features:	Weighted av- erage ratio of MLC to jaw aperture	Fraction of Moni- tor Units delivered through leaf gaps smaller than 2mm	Weighted fraction of area receiving out-of-field radiation	Weight- ed average perim- eter
Threshold:	<0.11	>0.21	> 0 .01	> 45.05 mm
Increased probabil- ity of plans failing:	probabil- ity of plans 37.02		5.86	5.29

Table 1. Failure Modes, features and their respective thresholds.

SP131.4 - Dosimetric analysis of respiratory-gated RapidArc with varying gating window times

Author(s): Ju Young Song

Radiation Oncology, Chonnam National University Hwasun Hospital, Hwasun-Eup/KOREA

The volumetric modulated arc therapy(VMAT) which modulates beam intensity with the variation of a dose rate, a gantry speed and a multi-leaf collimator(MLC) positioning in each rotation angle can also use the respiratory gated method for the treatment of moving lesions. The gated VMAT method is inherently can make a dosimetric inaccuracy due to the uncertainty of gantry position during the stop and go motion of the heavy gantry. In this study, the dosimetric inaccuracy in a gated VMAT was reviewed with the analysis of measured dose distribution according to the variation of beam-on time period. The linear accelerator used in this study was Novalis Tx (Varian, USA) and total 10 VMAT plans for the treatment liver cancer were prepared. The used gate system was RPM-gating system (Varian, USA) and the Dynamic Platform Model 008PL (CIRS Inc., USA), which can simulate respiratory motion, was used to set up the beam-on time. Two different delivery quality assurance(DQA) plans for VMAT plans were created. One is the portal dosimetry method which use EPID(electronic portal imaging device) measurements and the other is the measurement of dose distribution using 2-dimensional diode detector array, MapCHECK2(Sun nuclear, USA). The respiratory period was set to 4 sec and the DQA for gated VMAT was performed with the two different beam-on time sets, 1 sec and 2 sec. The matching rate in absolute dose mode was calculated by the gamma evaluation method for the gamma index, a 3% dose difference, 3 mm distance to agreement with 10% dose threshold. The calculated matching rates in each DQA measurement are shown in Table1. The average matching rates of portal dosimetry analysis were 98.72% in the no gating treatment, 94.91% in the gating with 1 sec beam-on time and 98.23% in the gating with 2 sec beam-on time. The average matching rates of MapCHECK2 analysis were 97.80% in the no gating treatment, 95.38% in the gating with 1 sec beam-on time and 97.50% in the gating with 2 sec beam-on time. The dosimetric error was increased as beam-on time became shorter, which made more stop and go motion during a gated VMAT process. The results showed that a gated VMAT is proper to the patients who can sustain longer exhalation phase time, which enables longer beam-on time and less stop and go motion.

		Portal Dosimetr	у	MapCHECK2 with MapPHAN

SP131.5 - Current status of dose-tracking using an integrated commercial system

Author(s): <u>Stina Svensson</u>¹, Mehrsima Abdoli², Jan-Jakob Sonke², Björn Hårdemark¹

¹RaySearch Laboratories, Stockholm/SWEDEN, ²Department Of Radiation Oncology, The Netherlands Cancer Institute, Amsterdam/ NETHERLANDS

We have investigated the current status of dose tracking using an integrated commercial system (RayStation v4.7, Raysearch Laboratories). Ten patients treated for head and neck squamous cell caricoma with dual arc VMAT plans were retrospectively dose-tracked based on daily acquired cone-beam CTs (CBCTs).

For each fraction, the following (automatic) steps were performed:

1. establishment of a frame-of-reference (rigid) registration between planning CT (pCT) and CBCT based on the treatment position alignment,

2. establishment of CBCT values to density table using a bulk density approach,

3. segmentation of external contour,

4. propagation of support ROIs from planning CT (pCT) to CBCT based on the treatment position alignment,

5. dose computation on CBCT by moving the beam setup according to the treatment position alignment and using the density table,

6. deformable image registration (DIR) between pCT and CBCT,

7. contour propagation of relevant organs-at-risk from pCT to CBCT for evaluation using the DIR, and

8. deformation of the dose computed on CBCT in step 5 to pCT geometry using the DIR for subsequent dose accumulation.

For the first fraction, all steps were done manually in RayStation. Thereafter, the remaining fractions were processed using a script.

The external contour was visually inspected by browsing through the CBCT in the transversal plane. In all cases but one, where the input threshold was adjusted manually, the automatic algorithm was judged to perform well. For 6% of the fractions, the DIR algorithm did not succeed in creating an invertible deformation vector field using the default settings. In those cases, a volume of interest (VOI) excluding the shoulder region was defined and used as input to the DIR algorithm.

For DIR, the ANACONDA algorithm was used. It has shown to perform well in comparison with state-of-the-art methods for thoracic 4DCT data as well as being an improvement with respect to rigid registration for CT / CBCT DIR (Weistrand, Svensson, Med Phys, 2015). ANACONDA was run without using contour guidance as no contours were initially defined on the CBCTs. All DIRs, together with propagated contours, were qualitatively validated by visual comparison to rigid registration in a side-by-side view. Contours on pCT and CBCT were shown overlaid. In all cases, the DIR and propagated contours were satisfactory.

Average processing time for one fraction using scripting was 53 seconds on a machine running Windows 8.1 (64-bit) operating system with 32GB RAM, one Intel Xeon E5-2697 (12 cores) CPU and two AMD FirePro D700 GPUs. Both DIR and dose computation use GPU acceleration. Estimated time spent on visual inspection of external contour, propagated contours and DIR was around one minute. VOI creation and DIR recomputation took around two minutes for the fractions mentioned above.

To summarize, we have shown that retrospective dose-tracking can be done in an integrated commercial system. The process can be efficiently implemented using scripting. Some manual interaction is still required (6-10%) for initialization and occasional adjustment in segmentation and DIR.

SP131.6 - Enabling Continuous Quality Improvement in a Rapidly Changing Clinical Environment through a Multi-Year Multi-Centre IMRT QC Program: 3 Year Experience Author(s): <u>Andrea Mcniven</u>, David A. Jaffray, Daniel Létourneau

Radiation Medicine Program, Princess Margaret Cancer Centre, Toronto/ON/CANADA

Introduction: Several different audit or credentialing programs have been created in multiple jurisdictions to assess radiotherapy planning and/or delivery performance using a variety of methodologies. The Collaborative Quality Assurance (CQA) Program is unique in that it was created as a multi-year program to assess site-specific planning and delivery quality through on-site visits that also incorporate diagnostic tests. Quantitative results for phantom positioning accuracy and MLC calibration from Year 3 is reported as well as the cumulative experience.

Methods and Materials: Fourteen independent radiotherapy centres have participated in the CQA Program. The yearly test includes a clinically realistic site-specific planning exercise (Year 1: head and neck, Year 2: prostate, Year 3: spine SBRT), and an on-site visit. The site visits include phantom imaging (diode array), dose calculation and dose delivery. The measurement portion of the visit includes delivery of the centre's own plans (IMRT or VMAT), re-delivery of plans from previous visits and diagnostic tests. Diagnostic components include a vendor/MLC-specific IMRT plan created by the CQA program and quantitative analysis of phantom positioning accuracy and MLC calibration (introduced year 2 and 3 respectively). Measured to planned dose agreement is analyzed using both 3%/3mm criteria with gamma analysis and 3%/2mm criteria with composite analysis.

Results: 41 site visits completed to date, 14 in Year 3, incuding measurement of 17 spine SBRT plans (15 VMAT and 2 IMRT), redelivery of 11 H&N and 6 prostate plans, and 3 new H&N plans and 6 new prostate plans. There has been a rapid adoption of VMAT delivery during the 3-year course of the program as only 3 of the 15 H&N plans in Year 1 were VMAT. Year 3 visits included 9 difference combinations of treatment planning system (4) and linac/MLC (5), and over 3 years the site visits have included 14 difference combinations. For the Year 3 spine SBRT plans, the percentage pass rate ranged from 97.3 - 100% for 3%/3mm gamma analysis and 89.4-100% for 3%/2mm composite analysis. Phantom positioning was good (all translational errors <2 mm) and was found to have no correlation with dosimetric results. Tighter tolerances are being investigated for correlation with MLC calibration. MLC calibration was quantified on 15 different linacs using portal imaging with all leaves (assessed at 5 different positions) within 2 mm of nominal position, and average impact on field size was < 1mm for 14/15 linacs. Overall, no significant change in performance was observed over three years for a single treatment site, however, on a single-centre basis, improvements up to 10% (3%/2mm criteria) were observed and can be linked to changes in planning technique and infrastructure.

Conclusion: The CQA Program has been established as a unique multi-year IMRT QA program incorporating diagnostic tools that can enable continuous quality improvement through feedback to the participants. Achievable performance levels have been identified as targets and the repeat visit model can highlight changes in IMRT planning and delivery performance and assess the impact of clinical practice changes, technology implementation or infrastructure change.

SP131.7 - A new approach to spatial gradient signal encoding for external beam radiotherapy delivery verification

Author(s): <u>Robert K. Heaton</u>¹, Xun Lin², Bern Norrlinger³, David Jaffray¹, Mohammad K. Islam¹

¹Radiation Oncology, University of Toronto, Toronto/ON/CANA-

DA, ²Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/ON/CANADA, ³Radiation Physics, Princess Margaret Cancer Centre, Toronto/CANADA

Introduction: A spatially encoding dose-area product transmission chamber provides an effective method to monitor the delivery of external beam radiotherapy. Previous designs achieved spatial signal encoding by introducing a sloped separation between electrodes. The wedge shaped collection volume generates a linearly varying signal which depends on the position of the field on the chamber. In this study, we report on a chamber design to achieve a spatial gradient from a uniform electrode separation while providing measurements from complementary spatial gradients.

Methods: A spatial gradient is achieved by replacing the uniform area collecting electrode with an interleaved conducting comb pattern etched into an insulating substrate. The gradient is achieved by changing the width of the tines in the comb linearly with position, while the complementary interleaved pattern varies in the reversed pattern. In this configuration, a constant electrode plate spacing of 0.5 cm was used between polarizing and collection electrodes, with each measurement comprised of signals from each of the two combs.

Investigations of this chamber configuration used collection patterns etched into a PCB circuit board and a fluorine doped TiO2 coating on a glass substrate, with a pair of complimentary tines occupying a width spanning 0.5 cm with a maximum widths varying from 0.05 to 0.45 cm over a length of 23 cm and 26 cm on PCB and glass, respectively. Field sizes on the order of 1 to 6 cm² were investigated, with the chamber moved through the beam to sample chamber positional response.

Results: Measurements for small fields performed at different positions along the gradient of the chamber show the expected positional dependence behavior, with complementary combs exhibiting a mirrored positional response. An example of the gradient response is shown in Figure 1. Simple calculations of the expected gradient yield a value of 0.067 cm⁻¹, which compares favourably to the measured gradient of 0.056 cm⁻¹ in the linear gradient range.

Conclusions: This study demonstrates the feasibility of using an interleaved comb collection electrode in a parallel plate chamber geometry to achieve spatial encoding for radiotherapy treatment monitoring. Comparable signal behavior was achieved for both the PCB and glass based substrates. Future work will focus on optimizing the design of chamber for clinical use.

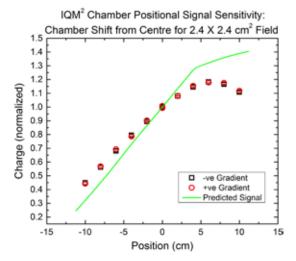

Figure 1: Detector signal as a function of position along the gradient direction. Note that the negative gradient has been reflected in position for ease of comparison.

SP132 - Guidelines and Radiation Protection Reference Levels for Patients and Personnel

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP132.1 - Implementation of the new BSS including radiation safety culture in medicine

Author(s): M.M. Rehani¹, O. Holmberg², P. Jimenez³ ¹Radiology, Harvard Medical School, Massachusetts General Hospital, Boston/MA/UNITED STATES OF AMERICA, ²Radiation Protection of Patient sUnit, IAEA, VIENNA/AUSTRIA, ³World Health Organization/Pan American Health Organization (PAHO), WASHING-TON/DC/UNITED STATES OF AMERICA

The International Basic Safety Standards for Protection against Ionizing Radiation and for the Safety of Radiation Sources, commonly known as BSS, provide a robust framework of safety requirements for medical exposures that can serve as a powerful tool for countries to strengthen radiation safety regulations and for medical physicists to strengthen their position and professional involvement. The new BSS have been jointly sponsored by 8 intergovernmental organizations, including the WHO, and published by the IAEA in 2014. The medical physicist (MP) as defined in the BSS is: "A health professional with specialist education and training in the concepts and techniques of applying physics in medicine and competent to practice independently in one or more of the subfields (specialties) of medical physics". This definition is very important as it categorizes the MP as a health professional. Previously the requirements for MPs were stringent primarily for radiotherapy; now, they have expanded as well for other areas like high dose procedures in radiology, image guided interventional radiology and nuclear medicine. The words medical physics/physicist occur more than 20 times in new BSS as many requirements and responsibilities have been assigned to the MP. Further there is clear assignment of responsibility to the Radiation Protection Officer (RPO) as pertains to oversight of the application of regulatory requirements, particularly insofar as radiation protection of workers and members of the public rather than patient protection. In some facilities, the MP can have additional responsibility as RPO whereas the inverse is not applicable. Promotion and maintenance of safety culture are requirements in the new BSS and MPs have an inherent role in its implementation, in fostering commitment and creating a common understanding, in providing means for implementation at the level of individuals and teams, and in practicing and encouraging dually inguisitive and learning attitudes. The presentation, while reviewing actions on implementation taken by IOMP, IAEA and WHO, will invite feedback and suggestions on implementation in different countries.

SP133 - Validation and Verification of Therapy Dose Delivery: Part 2

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP133.1 - Dosimetric Comparison of 3DCRT, IMRT and VMAT for Spine Radiotherapy based on Secondary Cancer Risk Author(s): J Rehman¹, J Ashraf¹, M Isa¹, M Afzal¹, G Ibbott², James Chow³

¹Islamia University of Bahawalpur, Bahawalpur/PAKISTAN, ²UT MD Anderson Cancer Center, Houston/UNITED STATES OF AMERI-CA, ³Princess Margaret Cancer Center, Toronto/CANADA

This study evaluated the secondary cancer risk after 3D-conformal radiotherapy (3DCRT), intensity modulated radiotherapy (IMRT) and volumetric modulated arc therapy (VMAT) for spine. Computed tomography image set of a RPC spine anthropomorphic phantom was exported to the Pinnacle³ treatment planning system. Radiation treatment plans for spine were created using the four-field 3DCRT. seven-field IMRT and dual-arc VMAT techniques. The mean and maximum doses (Table 1), dose-volume histograms and volumes receiving more than 2 Gy and 4 Gy of organs-at-risk (OARs) (Table 2) were calculated and compared. The lifetime risk for secondary cancers was estimated according to NCRP Report 116. Quality Assurances of IMRT and VMAT were performed using the Arc-CHECK method with gamma index criteria set to 3%/3mm. For our dosimetric comparisons, planning target volume coverages were found to be 90.5 %, 91.4 % and 95.9 %, for 3DCRT, IMRT and VMAT, respectively. VMAT was found to deliver the lowest maximum dose to esophagus (3.22 Gy), bone (6.48 Gy), heart (1.69 Gy), spinal cord (5.15 Gy) and the whole lung (4.52 Gy). Volumes of esophagus receiving more than 4 Gy were 0% for VMAT, 37.56% for IMRT and up to 43.76% for 3DCRT. The estimated risk for secondary cancer in the respective OAR is considerably lower in VMAT compared to other techniques. Results of maximum doses and volumes of OARs suggest that the risk of secondary cancer induction for spine in VMAT is lower than in IMRT and 3DCRT, whereas VMAT has the best target coverage.

Table 1: Maximum and mean doses of OARs.

Organs-at-Risk	3D0	CRT	IM	RT	VMAT		
Dose	Mean dose (Gy)	Max Dose (Cy)	Mean dose (Gy)	Max Dese (Cy)	Mean dose (Cy)	Max Dose (Gy) 3.22 6.48 1.69 5.15

SP133.2 - Validation of VMAT FSRT calculated doses using a multi-configurational phantom

Author(s): <u>Michel Lalonde</u>¹, Kevin M. Alexander², Tim Olding³, Tim Owen¹, Andrew Kerr¹

¹Cancer Centre Of Southeastern Ontario (ccseo), Kingston General Hospital, Kingston/ON/CANADA, ²Department Of Physics, Engineering Physics And Astronomy, Queen's University, Kingston/ON/ CANADA, ³Department Of Oncology, Queen's University, Kingston/ ON/CANADA

Introduction

Volumetric modulated arc therapy (VMAT) allows for a simultaneous integrated boost (SIB) technique to be employed for the delivery of brain fractionated stereotactic radiation therapy (FSRT). The goal of this study is to validate VMAT FSRT plans by comparing calculated doses against measured doses using a variety of dosimeters in a multi-configurational phantom.

Methods

VMAT FSRT plans were prepared using Eclipse treatment planning (Varian) and delivered with a Truebeam linac (Varian) onto an acrylic multi-configurational phantom (Fig. 1) that allows gel (Fricke-xylenol orange), film (EBT3 Gafchromic), or ion chamber (Capintec PR-05P 0.07 cm3) dose measurements. In each plan, an 18 cm diameter spherical structure was contoured to mimic the whole brain within the phantom. Additionally, four spherical boost PTV structures ranging in diameter from 3-20 mm were contoured and positioned in a diamond pattern in the coronal mid-plane of the phantom (100 cm SAD). An SIB VMAT plan comprising two 6 MV coplanar full arcs was then optimized (AAA v10.0.25) to deliver 200 cGy/fraction to the whole brain structure and 400 cGy/fraction to each boost PTV. The plan was normalized to ensure that 95% of each boost PTV volume was covered by 400 cGy. Dose profiles were generated to compare calculated and measured dose. Gamma analysis was also performed for both film (2D) and gel (3D) dosimeters.

Results/Conclusion

Dose profile comparisons for certain boost PTV sizes are shown in Fig. 2. Ion chamber point dose measurement (at isocentre) agreed within 1% of the calculated dose. Measured peak boost PTV doses agreed with calculated doses to within 3.1% and 4.9% for gel and film respectively. Both 2D and 3D gamma analyses (3%/3 mm) showed greater than 95% agreement with calculated dose distributions. Film and gel dose profiles successfully characterized the full shape and gradients of the calculated profiles.

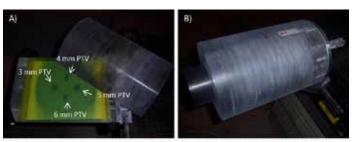

Fig. 1: Multi-configurational cylindrical phantom in two configurations: a) for film: overhead view with post-irradiation film at coronal mid-plane with top half removed, and b) for gel: lateral view of phantom with gel jar insert. The phantom is made of acrylic, measures 20.4 cm diameter by 30 cm length and is supported over the end of the linac couch. The third configuration for a point ion chamber is not shown.

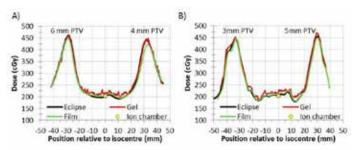

Fig. 2: Dose profiles through the isocentre in the coronal mid-plane of the phantom in the a) crossplane and b) inplane direction at 100 cm SAD. The PTV sizes for the corresponding dose peaks are labeled.

SP133.3 - Dosimetric verification for tangential breast irradiation in commercial treatment planning system using indigenous female wax torso.

Mohan Dai Oswal Hospital Department of radiation Oncology, Ludhiana (Punjab), INDIA.

Introduction:

Accuracy of Clarkson algorithm employed in a commercial 3D TPS was evaluated for conditions simulating tangential breast treatment. A breast phantom was fabricated from machineable wax to examine the accuracy of tangential breast irradiation. This Paper specifically describes the use of unique self-designed wax breast phantom to validate the accuracy of three-dimensional dose calculations performed by Xio- CMS planning system for breast tangential irradiation. Steven et all⁽¹⁾ has done a related study using anthropomorphic breast phantom .In our study the accuracy of dose calculations has been verified using 0.6cc ionization chamber. The treatment plans has been generated using the combined 6 and 15 MV photon beams and field in field technique. Measured doses have been compared to those calculated from the treatment planning system and found to be in good agreement with previously published results. Our results indicates that the inexpensive wax phantom can be used for verification in absence of expensive anthropomorphic breast phantom which may be of great help for verification of 3D breast plans in developing countries.

Material and Method:

A Wax phantom of size {33(I)*34(w)*29(h)} cm³ was fabricated in the departmental mould room. An important consideration in the design of the phantom was the reproduction of a geometry that could realistically duplicate the female torso in treatment position was taken care. The ion chamber was positioned 4.5 cm below from the surface of the breast phantom. The medial, lateral, superior, and inferior field borders previously marked on the phantom, were delineated with fiducial marker. CT images of the phantom with 0.6cc chamber were taken with 3-mm slice thickness. The images were imported to Cms Xio TPS for planning via Focal system after contouring. A phantom plan was created taking the calculation point at centre of chamber cavity volume by superimposing each patient plan in the indigenous breast phantom. 20 patients were taken for this study & Measurements were performed using a 0.6cc ionization chamber.

Result and Discussion:

Comparison was made between measured and calculated dose. We got good results for maximum number of patients within 1.5% and few patients above 3%. The dose-calculation verification measurements performed in this study utilizing a indigenous phantom clearly demonstrate absolute homogenous dose calculation accuracy even in case of tangential irradiation of the breast.

Conclusion:

A measurement of dose in the phantom shows good agreement in variety of treatment field configurations. This confirmed the utility of an indigenous breast phantom as a tool to assess accuracy of 3D tangential breast dose measurements for photon dose calculation.

SP133.4 - Dosimetric comparison of IMRT versus RapidArc (VMAT) optimization in whole breast irradiation of early stage breast cancer

Author(s): Nader Moshiri Sedeh

Physics, Florida Atlantic University, BOCA RATON/UNITED STATES OF AMERICA

Dosimetric comparison of IMRT versus RapidArc (VMAT) optimization in whole breast irradiation of early stage breast cancer

1. Florida Atlantic University, Department of Physics, Boca Raton, FL, 33431

2. South Florida Radiation Oncology, Boca Raton, FL, 33431

3. South Florida Radiation Oncology, Jupiter, FL, 33458

Purpose: The purpose of this study is to compare the dose-volumetric results of intensity modulated radiation therapy (IMRT) with RapidArc (RA Varian Medical Systems, Palo Alto, CA) for whole breast irradiation.

Methods: 25 patients previously treated for whole left breast (either RapidArc plan or IMRT) were the subjects of this planning study. Eclipse v 11.0.47 was used to make all retrospective plans using the same contours, energy, machine and normalization. Prescription dose to the planning target volume was 5000 Gy in 25 fractions. All

plans were normalized such that 100% covered 95% of planning target volume (PTV).

Results: V10, V20 and Dmean Gy of left lung significantly differed between the two plans (p-value <0.0001, =0.0473 and <0.0001 respectively), but V30 Gy did not (p-value 0.463). V25, D33 and Dmean Gy of heart significantly differed between the two plans (p-value =0.034, <0.0001 and 0.01 respectively), but V10 Gy did not (p-value 0.058). V5 of both right breast and right lung significantly differed between the two plans (p-value <0.0007 and =0.0112, respectively). Also Dmean of both right breast and right lung significantly differed between the two plans (p-value <0.0001 for both). The mean conformity index did not significantly differe, p-value 0.142. There was a significant difference between the mean MUs of the two plans as well, p-value <0.0001.

Conclusion: The dose-volumetric results of IMRT vs RA were different for most of the constraints although all plans were made within the threshold values recommended by RTOGs. Mean doses to left lung, heart, right lung and right breast were significantly different in RA than IMRT plans. It's been said that RA is more efficient/faster in the treatment delivery than IMRT in terms of total monitor units used, but in this study the results did not prove that. In fact, since both plans have the same mean of conformity index, based on what was observed in this study IMRT is not only faster but also safer regarding not irradiating the organs at risk.

SP134 - Biosignal Sensing and Body Sensor Networks

TRACK 08: BIOSENSOR, NANOTECHNOLOGY, BIOMEMS AND BIOPHOTONICS

SP134.1 - Impedance and comfort of dry multipin electrodes for electroencephalography

Author(s): <u>Patrique Fiedler</u>¹, Richard Mühle¹, Stefan Griebel², Carlos Fonseca³, Filipe Vaz⁴, Lena Zentner², Frank Zanow⁵, Jens Haueisen¹ ¹Institute Of Biomedical Engineering And Informatics, Ilmenau University of Technology, Ilmenau/GERMANY, ²Mechanism Technology Group, Ilmenau University of Technology, Ilmenau/GER-MANY, ³Departamento De Engenharia Metalurgica E De Materiais, Faculdade de Engenharia, Universidade do Porto, Porto/PORTU-GAL, ⁴Departamento De Física, Universidade do Minho, Guimarães/ PORTUGAL, ⁵Eemagine Medical Imaging Solutions GmbH, Berlin/ GERMANY

Dry-contact electrodes allow for rapid, preparation-free EEG acquisition and new applications of brain signal analysis. However, dry electrodes require reproducible and stable electrode-skin contact to provide signal qualities comparable to conventional wet electrodes. Our recently introduced dry multipin electrodes comprise 30 pins on a flat baseplate. A non-conductive Polyurethane substrate is subsequently coated with a conductive Ag/AgCl film. Our earlier studies proved this design to enable hair layer penetration and a stable contact as long as sufficient contact force is applied.

In this study we focused on the influence of contact force and substrate flexibility (shore hardness) on the electrode-skin impedance on a hairless frontal position (Fpz) and a hairy temporal position (T4). The study was performed with 10 volunteers of similar age and different gender and hair length. An analogue force sensor and a custom-made electrode adduction and fixation mechanism allowed for reproducible variation of the adduction force between approx. 0.25 to 4 N. Furthermore, we tested shore A98, 90, 80, and 70 substrates. Positioning of the electrodes was performed manually. The evaluation of wearing comfort was performed using a scale 1-10 wherein 1 is absolute comfort while 10 is maximum pain. Impedance and force were recorded simultaneously. Comfort evaluation was performed prior and after each measurement.

The mean interfacial impedance for shore A98 electrodes decreased on average from 67 kOhm at 1 N to 36 kOhm at 2N, 30 kOhm at 3N, and 26 kOhm at 4 N at the frontal position. Furthermore, the standard deviation decreased from 34 kOhm to 20 kOhm, 16 kOhm, and 14 kOhm, respectively. Mean impedances on the hairy temporal positions decreased similar from 79 kOhm at 1N down to 21 kOhm at 4 N with standard deviations of 200 kOhm and 11 kOhm, respectively. A similar trend was visible for the other shore values. However, Shore A80 and A70 electrodes showed increased standard deviation and required higher contact pressure. The wearing comfort was best up to 1 N while it in started to decrease to 1.2, 1.7 and 2.1 at 2, 3 and 4 N, respectively.

In summary, a shore hardness of A98 or 90 in combination with contact forces between approx. 2 and 3 N reliably provide sufficiently low and reproducible impedances while avoiding extensive pressure and thus maintaining wearing comfort. This information provides the base for designing future cap or helmet systems enabling comfortable, reliable rapid dry EEG acquisition.

SP134.2 - Wearable Gait Analysis using Vision-aided Inertial Sensor Fusion

Author(s): Eric Ma, Milos Popovic, Kei Masani

Toronto Rehabilitation Institute, University Health Network, Toronto/ CANADA

Gait analysis is useful in characterizing impaired gait in patients with various neuromusculoskeletal disorders. Contemporary gait analysis is conducted in a laboratory setting, typically consisting of numerous optical cameras and force plates. However, this setup is restricted to a constrained and artificial testing environment, which may lead to unnatural movements that poorly represent real-world human gait. In recent years, it has been demonstrated that the wearable inertial measurement units (IMU)-composed of accelerometers, gyroscopes, and magnetometers—can be an alternative for gait analysis in natural and ambulatory environments. IMU is capable of estimating the position and orientation of the human body during walking by integrating from acceleration and angular velocity. However, they are prone to unbounded drift due to the integration operation. Additionally, the relative positions of multiple IMUs cannot be accurately estimated using IMUs alone. These limitations prohibit the estimation of the global COP, which is an important gait parameter for the evaluation of postural stability and requires the knowledge of the relative positions of the feet. In this study, we introduced a solution to constrain the integration drift and to obtain the relative position of IMUs using vision-aided inertial sensor fusion.

We proposed a shoe-mounted system composed of two 9-axis IMUs, an IR camera, and a pair of instrumented shoes. Foot orientations and 3D foot travel trajectories were estimated using the IMUs, enhanced using zero-velocity updates and maximum spatial separation constraints. Using the camera on one foot and a four-point LED frame on the other foot, the relative position between the two feet was obtained using a pose estimation algorithm from computer vision. The inertial and vision measurements were sensor fused using an Extended Kalman Filter to minimize the errors in the 3D foot position outputs. The in-shoe COP of each foot was estimated using the instrumented shoes. Knowledge of the 3D foot positions was fused with the in-shoe COP to calculate the global COP. The proposed system estimated the 3D foot trajectories and the global COP. Based on these, the system was capable of estimating for key gait parameters such as step length, stride length, gait phases, and COP excursion. The validation of this system was performed against gait laboratory results for standing and walking tasks.

The proposed system is the first wearable system that provides

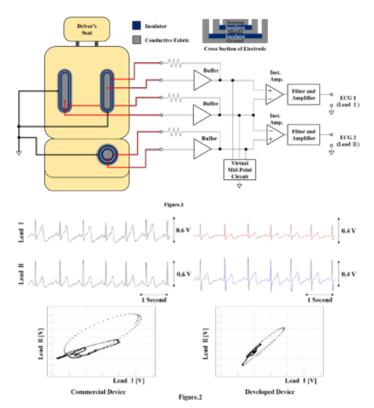

the estimation of global COP during gait. It provides a portable and unobtrusive method of performing lower-limb gait analysis in unconstrained and ambulatory environments, and it may enable new and practical applications in areas of clinical gait evaluation, long-term monitoring, rehabilitation, and sports performance.

SP134.3 - Two-Vector Capacitive Electrocardiogram Measurement Using Three Fabric Electrodes for Automobile Application Author(s): <u>Shunsuke Takayama</u>, Akinori Ueno

Electrical And Electric Engineering, Tokyo Denki University, Tokyo/ JAPAN

With a view to applying to driver's sensing, we propose a method for measuring two-vector capacitive electrocardiogram (cECG) from three electrodes placed on a driver's seat. The proposed method consists of three techniques of electrode arrangement, circuit grounding and an electrode configuration. The proposed electrode arrangement (see Fig.1) enables detection of biopotentials corresponding to limb lead I, II and III. Also, it has a feature that can keep steady electrode coupling. As shown in Fig.1, two of electrodes were horizontally placed on the right and left side of backrest, and another is placed beneath driver's left breech. Consequently, three electrodes form a triangle similar to Einthoven's triangle. The introduced circuit grounding technique is so called virtual middle point. All of three electrodes were used as exploring electrode and connected indirectly to the middle point. Two-vector cECG corresponding to lead I and II can be measured without any ground electrode. This technique has a tolerance to individual vectorcardiographic difference. Fig.2 shows measured two-vector cECG while subject is sitting on the driver's seat. The employed electrode configuration is composed of fivefold layers of sensing layer, shielding layer, ground layer and insulating layers (see Fig.1). It is reported to have a tolerant with movement artifact. [1]

SP134.5 - Detection of REM Behaviour Disorder Based on Low-Power Compressive Sensing of EMG

Author(s): Jeevan K. Pant¹, Mehrnaz Shokrollahi², <u>Sridhar Krishnan¹</u> ¹Department Of Electrical And Computer Engineering, Ryerson University, Toronto/CANADA, ²Department Of Computer Science, University of Toronto, Toronto/CANADA

Background:

Rapid eye movement (REM)-behaviour disorder (RBD) can be detected by using electromyogram (EMG) signals measured from the chin of the subject. Portable sensors attached to the chin and equipped with wireless transmission capability can be effective for the acquisition of such EMG signals. For durable operation, such sensors are desired to be power efficient. We study a low-power sensing framework based on compressive sensing (CS) for detection of RBD. This framework involves application of the CS technique based on sparse random projection matrix, and application of the CS reconstruction algorithms based on promoting temporal correlation. Classification algorithm used is based on nonnegative matrix factorization followed by kernel-based sparse representation.

Method:

The database contained several EMG signals recorded during the period of REM from the persons suffering from the RBD disorder and from those not suffering from it. Each record contained two signals obtained using two sensors placed on the left and right sides of the chin. CS was applied on the difference of the left-chin and right-chin signals with four values of the compression ratio (CR), namely, . Reconstruction of the difference signal was carried out by using the -RLS, -RLS, and BSBL-BO algorithms. The classification algorithm was used to classify whether the reconstructed difference signal corresponded to the RBD disorder or not.

Results & Conclusion:

Fig.1(a) shows classification accuracy (CA) averaged over total 10 realizations of the CS measurement matrix, and Fig.1(b) shows variance of CA over the same 10 realizations. As can be seen, approximately 72% average CA of RBD can be attained by applying CS with a compression ratio of 90%. By realizing a CS-based wireless sensor with a CR of 90%, its power consumption can be significantly reduced. Yet, 72% classification performance can be acceptable in various applications, including the one requiring rough estimation of the risk of happening RBD.

Variance of CA for -RLS algorithm is the smallest relative to that for the other algorithms. Thus, the -RLS algorithm offers the most stable classification performance.

Hence, the CS-based RBD classification system can be useful for the development of low-power CS-based sensor for a stable detection of RBD.

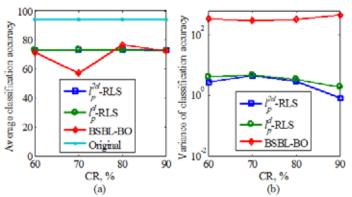

Fig. 1: (a) Average classification accuracy, (b) Variance of classification accuracy.

SP134.6 - Externally applied pressure on the skin electrode impedance

Author(s): <u>Bahareh Taji</u>¹, Adrian D.C. Chan², Shervin Shirmohammadi³

¹University of Ottawa, Ottawa/CANADA, ²Carleton University, Ottawa/ CANADA, ³Engineering, University of Ottawa, Ottawa/ON/CANADA

The objective of this abstract is to introduce the effects of externally applied pressure on the skin-electrode impedance for electrodes such as standard Ag/AgCl and orbit electrodes. This issue is of interest because it is one of the factors that affect the quality of signal collected from that electrode. Skin-electrode impedance is modeled as an electrical circuit including a resistor (*Rs*) in series with a paralleled resistor (*Rd*) and capacitor (*Cd*). Skin-electrode impedance is measured by an impedance interface device and a frequency response analyzer.

Pressure is applied with a regular Omron blood pressure cuff. Experiments are done in several trials to verify electrodes behaviour under pressure and their tendency to keep the changes due to applied pressure. Measurement procedure steps are as follows:

a. Two electrodes were placed on the subject's right bicep at a 7 cm distance from each other and connected to the measurement devices.

b. The Omron cuff was wrapped around subject's bicep on top of the electrodes.

c. The pressure was set to 0 mmHg or 30 mmHg appropriate for the trial (Table 1).

d. Wait for 1 minute.

e. The impedance was measured.

f. Repeat, starting from step c, until all trials are completed.

Table 1 Cuff pressure per trials

Trial	T1	T2	Т3	T4	T5	T6	T7	T8	Т9	T10	T11
Cuff pres- sure (mmHg)	0	30	0	30	0	30	0	30	0	0	0

Results show that skin-electrode impedance of orbital electrodes decreases as pressure increases and after some trials they tend to keep the changes and vary less and less when pressure is applied and removed, whereas Ag/AgCl electrodes variation due to pressure are small and negligible.

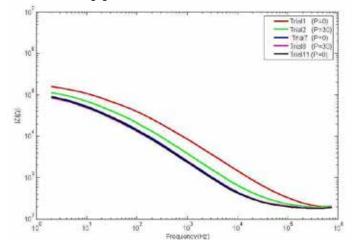

Figure 1 Skin-electrode impedance of Orbital electrodes

SP135 - Neural Signal Processing: Part 2

TRACK 11: NEUROENGINEERING, NEURAL SYSTEMS

SP135.1 - Epileptogenic zone estimation by localizing the generators of delta and high-frequency rhythms extracted from human scalp EEG

Author(s): <u>Daniel Jacobs</u>¹, Chunsheng Li¹, Trevor Hilton¹, Yotin Chinvarun², Jose Martin Del Campo³, Peter Carlen³, Berj L. Bardakjian¹ ¹Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA, ²Phramongkutklao Hospital, Bangkok/ THAILAND, ³Toronto Western Hospital, Toronto/CANADA

Up to 20 million people globally might develop drug-resistant epilepsy and may become candidates for surgical intervention. However, 40% of patients who undergo surgery to remove seizure onset zones (SOZs) do not achieve long-term seizure freedom. This may be because the SOZs identified by electroencephalography (EEG) do not completely represent the epileptogenic zone (EZ). Correct identification of the EZ remains a challenge. Our lab has identified that EEG rhythms with delta and high frequency oscillations (HFO), recorded intracranially from subdural electrode grids (SEGs) placed in patients suffering from epilepsy, contain novel markers for the seizure onset zone. This work hypothesizes that these rhythms may be isolated from scalp EEG, whereupon their generators can be approximately localized to an intracranial location. This would facilitate the placement of intracranial electrodes to more completely identify the EZ.

The patient data used to compare rhythm localization between scalp and intracranial EEG was recorded from 4 patients with epilepsy at the Toronto Western Hospital, Toronto, Canada. The patient data used to validate the rhythm localization method consists of intracranial EEG recorded from 7 patients with epilepsy at the Phramongkutklao Hospital, Bangkok, Thailand.

Methods: Electrical noise and all harmonics are removed via notch filtering. Rhythmic decomposition of individual scalp EEG traces is performed by ensemble empirical mode decomposition (EEMD). This permits isolation of the rhythms of interest. Artifact within the selected rhythms is distinguished by analysing components produced by independent component analysis (ICA): blink components can be manually distinguished, and other artifactual components are identified by the Multiple Artifact Rejection Algorithm (MARA) plugin within the EEGLAB toolbox. These artifact components are removed, and the remaining rhythmic components are reconstructed to their original scalp distribution. Localization of the generators of this distributed rhythmic activity is performed using standardized low-resolution brain electromagnetic tomography (sLORETA).

Results: Preliminary investigations indicate that the generators of particular rhythms can be localized to intracranial regions with the following properties: (a) They coincided with placement of intracranial SEGs in patients as determined by the neurologists, and (b) the patients were seizure free (Engel class I) after surgery. As such, this technique may serve as a useful tool in the placement of SEGs.

The authors would like to acknowledge financial support from NSERC and CIHR.

SP135.2 - Automated Alzheimer's Disease Diagnosis Using a Portable 7-Channel Electroencephalography Device Author(s): <u>Raymundo Cassani</u>, Tiago H. Falk INRS-EMT, Montreal/QC/CANADA

The world elderly population is growing at its fastest rate ever; by 2050, 2 billion people will be aged over 60. For many individuals, age-related diseases cause cognitive decline and eventually limited functional capacity. Across North America, Alzheimer's disease (AD) has become the fifth leading cause of death in persons aged over 65 years. In order to tackle these problems, the WHO, together with Alzheimer's Disease International, have called on governments to implement national dementia plans to improve early diagnosis. In response to this call, several new biomarkers have been found based on expensive equipment, such as SPECT and fMRI. Such equipment, however, is scarce in low- and middle-income countries, as is the availability of trained medical personnel to operate them. Recent projections, on the other hand, suggest that by 2050, 71% of all people with dementia will live in low- or middle-income countries, thus it is crucial that lower-cost solutions be found.

Recently, the authors have proposed a new feature extracted from electroencephalography (EEG) that showed to discriminate healthy elderly patients from patients with AD with over 90% accuracy [1-3]. The proposed features characterize the cross-frequency coupling of EEG amplitude modulations, as detailed in [3]. These previously obtained results, however, relied on 20+ channel EEG systems, which can cost in the order of several tens of thousands of dollars. In this paper, we explore the use of a lower-cost solution, namely the use of the 7-channel portable COGNISIONTM system (Neuronetrix, USA). Data was collected across seven centers in the USA during a clinical trial led by Neuronetrix [4]. Eighty-three healthy participants (age: 73 ± 7 years; education: 15 ± 3 years; 49 female) and 93 patients with mild-AD (age: 76 ± 7 years; education: 14 ± 3 years; 49 female) were recruited and performed a 30-minute ERP test followed by a 3-minute resting (eyes-open) period.

Here, fourteen cross-frequency amplitude modulation features were extracted, for each of the seven electrodes, from the 3-minute resting period. Features were extracted after automated EEG artifact removal [1]. A Kruskall-Wallis test with Dunn-Sidak posthoc correction was performed to test the discriminative power of the features. Of the 14 extracted features, six were found to provide significant difference between the two groups across the seven tested electrode sites. Features that resulted in superior separation between the two classes related to beta-theta, alpha-delta, and alpha-theta amplitude modulation couplings. These features coincide with those found with higher-density EEG systems, thus show their importance for AD diagnosis. Such findings suggest that AD risk assessment may be done in-situ not only in some of the poorest countries in the world, but also in remote or rural regions of developed countries that have with limited access to qualified medical personnel. In such cases, remote patient monitoring could play a key role.

SP135.3 - Transient Propagation of Information Among Cultured Hippocampal Cell Assemblies in a Two-Chamber MEMs Device

Author(s): <u>Bruce C. Wheeler</u>¹, Gregory J. Brewer², Thomas Demarse¹

¹Biomedical Engineering, University of Florida, Gainesville/UNITED STATES OF AMERICA, ²Biomedical Engineering, University of California at Irvine, Irvine/CA/UNITED STATES OF AMERICA

Transiently active neuronal cell assemblies are thought to underlie many operations within the brain and provide the basis for a number of complex cognitive processes. Perhaps one of the most well known structures is that of the hippocampus. Using advanced MEMs technologies combined with multi-electrode electrophysiological recording (shown in Figure 1), we created a two-chamber system in which cell populations from distinct regions of the hippocampus are co-cultured and communicate via axon growth through micro-scale tunnels connecting each chamber including DG(dentate gyrus)-CA3, DG-DG, and CA3-CA3. In a prior report we verified the cell composition and specificity unique to each region using genetic (PCR) analysis and provide evidence for directional connectivity between DG and CA3 that recapitulates the feed-forward nature of the hippocampus.

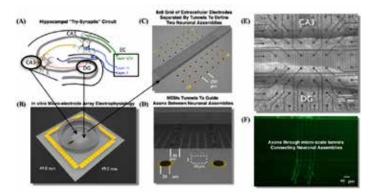

Figure 1. A MEMs device for the study of cell-assembly activation and transmission of information in an in vitro pair-wise model of the Hippocampal Tri-Synaptic loop (Panel A). Neurons from each region are cultured on a multi electrode array (B) containing a two-chamber PDMS device (C-E) that connect each population via axons through the tunnels (F).

Each region became spontaneously active with the emergence of population-wide neuronal oscillations in the form of rapid bursts of neural activity that appeared to propagate from region to region. This ensemble of activity in each region was then analyzed to detect the presence and activation of cell-assemblies within these oscillations and measure any communication that might occur between assemblies within and between each region. An average of 4.4±0.1 cell assemblies per region were detected during each 5 min recording. Each assembly was composed of an average of 9.6±0.3 member neurons with 2.2±0.1 of those neurons belonging to more than one assembly. We also found that the anatomically correct pairing of DG with CA3 resulted in DG and CA3 regions with more cell-assemblies and differences in the number of neurons within each assembly compared to DG-DG and CA3-CA3 alone. The average duration of each activation of an assembly was for 60±2 ms during bursts. Cell Assemblies were also persistent recurring 177±7 times during each recording. Finally we show that neurons that are members of cell-assemblies activated during each burst event in DG-CA3 communicate across regions with greater fidelity compared to the other groups.

SP135.4 - Investigating the Cortical Dominance in the Pre-Motor Potential during Unilateral Voluntary Task Author(s): Raquel S. Branco, Paulo José G. Da Silva, Maurício Cagy, Antonio F.C. Infantosi

Lapis - Signal Proc Lab, Biomedical Engineering Program - COPPE - UFRJ, Rio de Janeiro/BRAZIL

The Bereitschaftspotential (BP), a negative-slope electroencephalographic (EEG) activity that precedes voluntary movement, is related to the neuronal motor planning and postural control strategies. Generally, this pre-motor potential is generated 2s prior to onsetmovement, with predominance over the contralateral motor cortex area. In this study, the influence of cortical dominance was investigated using the BP from 26 healthy subjects (17 right-handed). Motor task consisted of self-paced unilateral shoulder flexion carried out in orthostatic posture with eyes open (in order to minimize alpha activity). During this task, EEG (C3: right shoulder cortical response; C4: the left one), EMG of the anterior deltoid muscle and accelerometer signal (positioned on the styloid process of the radius) were acquired simultaneously. A set of 100 unilateral movements (50 for each shoulder) and 50 bilateral movements (used as distracter stimuli) were carried out in random order and distributed into five blocks. An inter-block interval of 3min (subjects resting seated) was used to avoid EEG habituation and muscle fatigue. The BP was estimated by coherent averaging artifact-free EEG epochs, synchronized by the onset-movement detected by the accelerometer. Figure 1a depicts, for a right-handed volunteer, the BP and its PMM (movement-monitoring potential), in which it is noticeable higher slopes and PMM amplitude in the dominant cortex (C3: right shoulder) compared to those of the non-dominant (C4: left shoulder). Besides, the PMM occurred previously for dominant cortex. Similar results was observed for left-handed volunteer (Figure 1b). These findings could suggest that the motor planning is related to cortical dominance and therefore the ability to perform the task with the dominant limb. Nevertheless, for all subjects, independently on the laterality, the Wilcoxon sign-rank test suggested no difference (p=0.38) between the slopes (and also the PMM amplitudes) for dominant and non-dominant cortices. Moreover, no difference was observed (Wilcoxon p=0.58) in the PMM time occurrences. Besides, regardless the dominant cortex, no difference was observed between right and left-handed volunteers (Wilcoxon-Mann-Whitney, p=0.16). These findings are maybe explained by the inter-subjects variability to plan and perform the motor task. Alternatively, independent on the laterality of the subjects, they indicate no influence of the dominant cortex in the pre-motor potential during unilateral self-paced shoulder tasks.

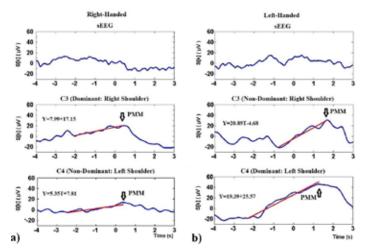

Figure 1. Coherent average of the spontaneous EEG and task (C3: right shoulder; C4: left shoulder): a) right-handed volunteer (#14); b) left-handed volunteer (#3). The regression line (red) estimated from the minimum of BP (between -2500 and -700ms) and PMM.

SP135.5 - A New Dynamic Virtual Stimulation Protocol to Evoke M-VEP and Linear Vection during Orthostatic Posture Control Author(s): Paulo José G. Da Silva, Maurício Cagy, <u>Antonio F.C.</u> Infantosi

Lapis - Signal Proc Lab, Biomedical Engineering Program - COPPE - UFRJ, Rio de Janeiro/BRAZIL

Cortical processing of visual motion and self-motion sensation has been related to the perception-action cycle during postural control protocol. The dynamic virtual reality stimulation (DS) was employed to investigate postural control response using the motion-related visual evoked potential (M-VEP) and linear vection. The multi-channel electroencephalogram (EEG) and the center-of-pressure (COP) displacement signals were acquired simultaneously during stabilometric test with DS scenes interspersed by 10s of static scene (SS). The trials from 29 healthy volunteers were performed in orthostatic position on a force platform observing a virtual scene (1.72 × 1.16m) projected 1m ahead and centered at the vision line (visual angle: θ / = 81.4° and $\theta v = 60.2^{\circ}$). The scenario was moved randomly in forward (DSF) or backward direction (DSB), during 250 ms (velocity: 2m/s), so that the furniture was expanded or reduced, while the chessboard floor, walls and ceiling were moved in parallel direction. For each DS, the luminance varied 2 cd/m². Such dynamic effect was employed to generate an optical flow as a tunnel pattern. Thus, DSF increases optical flow up to the periphery of the visual field. Otherwise, DSB, optical flow decreases. For each subject, the M-VEP was estimated by coherent averaging up to 50 artifact-free EEG epochs, synchronized by the onset of DS. Similar procedure was applied for the COP signal. Figure 1 depicts the grand-averaged M-VEPs (N2 peak dominance) and the COP displacement response due to vection. The running t-test (alpha = 0.05) suggested that there is difference between DSF and DSB M-VEPs 600 ms after DS onset, with an increasing time delay from occipital to central derivations (gray area, Figure 1a). Moreover, considering no significant change in COP displacement just preceding DS (ANOVA, p > 0.8), the DS induced COP displacements in the same direction of the exhibiting scene (Figure 1b, p < 0.001). Therefore, vection is dependent on the DS direction, mainly during DSF, for which the linear vection varies from 72% to 90% (Figure 1c). These findings suggest that the cognitive, planning and motor processing to control balance depends on the DS direction and hence indicate the potential applications of this dynamic virtual protocol in postural control studies.

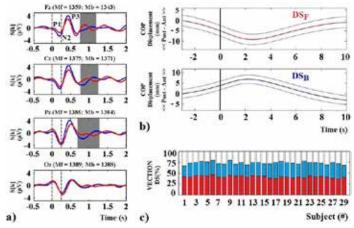

Fig. 1 Grand-averaged: a) M-VEP from DSF (red) and DSB (blue). Vertical dashed lines indicate DS (250ms). In gray, time interval where the waveforms differs (running t-test, p < 0.05); b) COP displacement; c) amount of vection.

SP135.6 - Assessment of Bilateral SSEP Signals Enhancement following Transectional Spinal Cord Injury Using Linear Modeling Author(s): Hasan Mir¹, Hasan Al-Nashash¹, Thow Thow Xin Yuan², Jukka Kortelainen², Soo Min Chua², Janani Manivannan², Astrid Astrid², <u>Angelo H. All</u>³

¹Bme, American University of Sharjah, singapore/SINGA-PORE, ²Sinapse, National University of Singapore, Singapore/ SINGAPORE, ³Orthopedic Surgery And Biomedical Engineering, National University of Singapore, Singapore/SINGAPORE

Introduction: Partial or complete loss of sensory and motor function between the brain and peripheral nerves is a likely consequence of spinal cord injury. However, it has been reported that a certain degree of plasticity in the central nervous system may result in functional recovery. Somatosensory evoked potentials (SSEP) have been used extensively in assessing the functional integrity of spinal cord pathways by examining the reduction or increase in signal amplitude and time latency. In this study, we use linear modeling coefficient values to quantify the degree of relationship between contralateral forelimb SSEPs recordings. Preliminary results demonstrate the effectiveness of this method in quantifying the level of similarity between SSEP signals obtained from different limbs.

Protocol: The SSEPs were recorded from 4 epidural screw electrodes implanted to the cranium of 22 rats. The electrodes were located at the specific somatosensory cortex areas of hindlimbs and forelimbs. Dental cement was applied to fix the electrodes to the cranium. Four different types of spinal cord transection injuries were produced, located at either the T8 or T10 of the rat spinal cord: (i) left-hemisection at T8, (ii) right-hemisection at T10 (iii) left T8 and right T10 hemisection and (iv) full transection at T8. SSEPs were recorded from a cohort of 20 animals with 5 animals in each injury type. The SSEP recordings were recorded day 4, 7, 14, and 21 postinjury. The evoked potentials were generated by stimulating the left and right Tibial nerves of the hindlimbs and Median nerves of the forelimbs, one limb at a time, with a pair of stainless steel sub-dermal needle electrodes. The stimulation of each limb was carried out using 150 consecutive current pulses with amplitude of 3.5 mA and a duration of 200 µsec delivered at a frequency of 0.5 Hz. During the stimulation, the SSEPs were recorded with a sampling frequency of 4882 Hz.

Method: The post-injury SSEP signals were modeled as a transformation of the baseline signal. The transformation was assumed to generate from a finite-impulse response (FIR) filter with a sparse set of delays. The solution of the filter coefficients were combined into a single metric, termed the H-index, in order to reflect the level of injury,

Results: Figure shows the H-Index obtained after modeling the SSEP signals recorded from the left cortex (corresponding to RF) after stimulating the RF. The SSEP signals recorded on Days 4 and 7 from the right cortex (corresponding to LF). The x-axis shows the rat number increasing with the level of injury. It is observed that the H index increases with injury level depicting an increased degree of correspondence between signals recorded from left and right sides of the cortex.

SP136 - Brain, Head/Neck, Spine: Part 1

TRACK 12: MEDICAL DEVICES

SP136.1 - Photopolymerization device for minimally invasive implants: application to nucleus pulposus replacement Author(s): Andreas Schmocker¹, Azadeh Khoushabi², Pierre-Etienne Bourban³, Dominique Pioletti², Christophe Moser¹ ¹Microengineering Institute, Ecole Polytechnique Fédérale de Lausanne, Lausanne/SWITZERLAND, ²Institute Of Bioengineering, Ecole Polytechnique Fédérale de Lausanne, Lausanne/SWITZER-LAND, ³Laboratory Of Polymer And Composite Technology, Institute Of Materials, Swiss Federal Institute of Technology, Lausanne/ SWITZERLAND

Photopolymerization is a common tool to harden materials initially in a liquid state. A surgeon can directly trigger the solidification of a dental implant or a bone or tissue filler. Traditionally, photopolymerization has been used mainly in dentistry. Over the last decade advances in material development including a wide range of biocompatible gel- and cement-systems open up a new avenue for in-situ photopolymerization for musculoskeletal, cardiovascular or neurosurgical applications.

However, at the device level, surgical and endoscopic probes need to be developed to deliver the liquid photopolymer, harden it by light and to monitor that the hardened material has the appropriate property. Here we present a miniaturized light probe where a photoactive material can be 1) mixed, pressurized and injected 2) photopolymerized or photoactivated and 3) monitored during the chemical reaction. The device enables surgeries to be conducted through a hole smaller than 1 mm in diameter. Beside basic injection mechanics, the tool consists of an optical fiber guiding the light required for photopolymerization and also for chemical analysis. Using fluorescence spectroscopy, the current state of the photopolymerization is inferred and monitored in real time.

Biocompatible and highly tunable Poly-Ethylene-Glycol (PEG) based hydrogels were used as injected material. The device was tested on a model for intervertebral disc replacement and hydrogels were successfully implanted into a bovine caudal model. These insitu photopolymerized implants were evaluated at the tissue level (tissue integration and mechanical properties), at the cellular level (biocompatibility and cytotoxicity) and ergonomic level (sterilization procedure and feasibility study) and thus seem to be a promising alternative to traditionally used tissue and bone fillers.

Currently further promising applications are under investigation. The results will be presented at WC2015.

SP136.2 - Design and Technical Evaluation of an Implantable Passive Sensor for Minimally Invasive Wireless Intracranial Pressure Monitoring

Author(s): Mohammadhossein Behfar, Elham Moradi, Lauri Sydänheimo, Toni Björninen, Leena Ukkonen

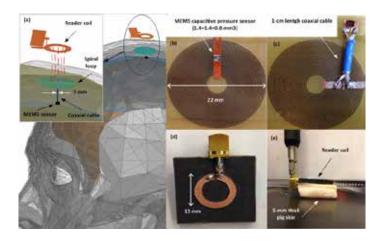

Electronics And Communications Engineering, Tampere University of Technology, Tampere/FINLAND

Elevated Intracranial pressure (ICP) is characterized as neurological problem mainly caused as a consequence of traumatic brain injuries (TBI) and cerebrospinal fluid (CSF) circulation disorders. Early detection of increasing ICP is of great importance in management of TBI. The main complications with the existing methods are the risk of infection and hemorrhage due to catheter insertion into the intracranial cavity. To address this issue, battery powered implant-

able wireless ICP measurement devices were proposed. The main drawback of this kind of devices is the increased size of the implants and limited lifetime. Therefore, passive (battery less) implantable sensors are attractive for minimally invasive ICP monitoring.

In this research, we designed and evaluated an implantable passive sensor for continuous wireless subdural ICP monitoring. The sensor consists of a 30-turn spiral loop in parallel with a mm-size $(1.4\times1.4\times0.8 \text{ mm}^3)$ microelectromechanical systems (MEMS) capacitive pressure sensor forming an LC tank (Fig. 1b). The sensor is made on an ultra-thin (50 µm) flexible polyimide substrate making it minimally invasive for implantation. The pressure sensor is wirelessly interrogated through the near field inductive link between the implantable sensor and an on-body reader coil. The on-body reader coil is connected to a capacitor to form an LC circuit. The two LC tanks form a simple and efficient telemetric system communicating through strong magnetic coupling. Consequently, ICP variation can be detected through: 1) change in the resonance frequency of the implantable sensor, 2) variations of the magnitude and phase angle of the reader coil's input impedance.

The effect of human skin on the wireless operation was simulated by placing a 5-mm thick pig skin between the sensor and the reader coil (Fig. 1e). The sensor was designed so that the spiral loop is implanted under the skin and the pressure sensor is placed into the subdural space (Fig. 1a). The spiral loop and the pressure sensor are connected through a coaxial cable with the length of 1 cm (Fig. 1c). In order to evaluate effects of the cable on the sensitivity of the pressure readout, we conducted two sets of experiment with and without the cable. The results show that the cable only reduces the sensor's sensitivity toward the resonance frequency variation and does not affect the sensitivity toward the magnitude and phase angle variations. Evaluation of the sensor proved the capability of highly linear pressure measurement ranging from 0 to 70 mmHg at 5-mmHg intervals.

SP136.3 - Investigating the Feasibility of EVestG Assessment for Screening Concussion

Author(s): Abdelbaset Suleiman¹, Brian Lithgow², Behzad Mansouri³, <u>Zahra Moussavi²</u>

¹Biomedical Engineering, University Of Manitoba, Winnipeg/CANA-DA, ²Electrical And Computer Engineering, University Of Manitoba, Winnipeg/MB/CANADA, ³Internal Medicine (neurology), University Of Manitoba, Winnipeg/MB/CANADA

In this project we evaluated a new technology, Electrovestibulography (EVestG[™]) that holds the potential to objectively, quickly and cost-effectively measure both the severity of concussion and quantitatively measure recovery from concussion. EVestG signals are recorded painlessly and non-invasively from the external ear in response to a vestibular stimulus; they are the brainstem sensory oto-acoustic signals modulated by the vestibular response. When concussed, people commonly experience balance (vestibular) problems, dizziness, confusion and memory loss. Considering the well-known bidirectional anatomical links of the vestibular system, it is expected that the EVestG signals will change after a concussion.

In this study, we investigated the relationship between characteristic features of the extracted field potentials (FPs) of EVestG signal in people with side-impact concussion in comparison to those of control subjects. Our study included 10 side-impact concussed individuals (4 Right side-impact and 6 left side-impact) and 10 age and gender matched healthy individuals as control subjects. We analyzed the EVestG signals recorded during side tilt motion. The results show that the difference between the left and right FP width, is significantly (P<0.05) different between two groups. Figure 1 shows the left-right difference in the area (bounded by the baseline and the action potential (AP) point) of the normalized FPs extracted from acceleration and deceleration phases of the EVestG signals during the side tilt. The features show a clear asymmetry between the left and right side vestibular responses for the concussed but not control group. In 3 out of the 4 right side-impact patients, the FP in the right side was narrower than the left side. In 5 out of the 6 left side impact patients, the FP in the left side was narrower than the right side.

The results of this study is encouraging on the use of EVestG analysis for monitoring the effects of concussion.

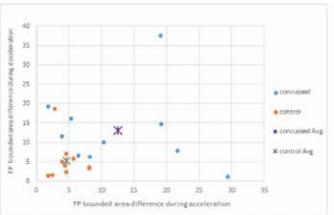

Figure 1: Control vs. Side concussed patients (n=1010) officer subtracting the area (bounded between the baseline and the AP point) in right side from the left side during acceleration and deceleration phases of side tilt.

SP136.4 - Transcranial Direct Current Stimulation of the Rat Medial Prefrontal Cortex: Antidepressant Effects and Regional Brain Changes

Author(s): <u>Francis R. Bambico</u>, Jose N. Nobrega Centre For Research Imaging, Centre for Addiction and Mental Health, Toronto/CANADA

Transcranial direct current stimulation (tDCS) is a neuromodulation procedure that employs weak DC to stimulate brain regions non-invasively. Its basic design has been investigated for psychiatric disorders, such as melancholic depression, as far back as the early 19th century (Parent, *Can J Neuro Sci* 2004). It has recently regained attention and has been demonstrated to produce some benefits in cognitive performance and psychiatric symptoms (Mondino et al., *Biol Psychiatry* 2014). However its precise therapeutic mechanisms remain unknown. We therefore developed a rat model of tDCS and tested effects in the forced swim test (FST), novelty-suppressed feeding test (NSFT) and elevated plus maze test (EPMT), all of which

predict antidepressant/anxiolytic activity. We targeted the medial prefrontal cortex (mPFC) because clinical and animal studies have shown antidepressant effects of mPFC deep brain stimulation (DBS) (Hamani and Nobrega, Eur J Neurosci 2010). We devised a current generator that delivered low power current (0.1 mA) onto a conducting cathodal metal plate (1.5±0.25 x 2.5±0.25mm) fixed on the skull surface over the mPFC (AP+4.7 to +2.2mm; Paxinos and Watson. The Rat Brain in Stereotaxic Coordinates 2005). The anodic end was connected to a stainless steel screw lodged behind the cerebellum (AP+18). Animals received sham (n=6) or tDCS (n=6) twice on day 1 and once on day 2 (30 min before behavioural testing). In the FST, stimulated animals exhibited significantly lower (56.16%) immobility episodes (p<0.05), which was not a result of non-specific motor activation, and therefore suggests an antidepressant-like activity. Indeed, motor activity was increased only during stimulation, and not immediately after cessation of stimulation or 5-6 hours after the last stimulation. A non-significant increase in anxiety-like behaviour was observed in tDCS animals in the NSFT and EPMT. Post-mortem brain analyses using in situ hybridization imaging of the immediate early gene zif268, a marker of cell activation, revealed lasting significant increases in neural activity almost exclusively within the target regions. In particular, there was an increase (p<0.01) in the cingulate (Cg), prelimbic (PrL) and orbital (Or), as well as in the insular cortex (Ins) and claustrum (CI), as indicated in the figure. Together, these data suggest that tDCS can be effectively modeled in the rat, yielding highly selective patterns of brain activation. Furthermore, mPFC tDCS shows antidepressant-like properties, which can further be investigated as a potential non-invasive alternative for mPFC DBS.

SP137 - SPECIAL SESSION: Building Medical Physics Capacity in Developing Countries

TRACK 17: EDUCATIONAL AND PROFESSIONAL ACTIVITIES

SP137.2 - Implementing Training Modules of the Emerald Program in Brazil

Author(s): <u>Ricardo A. Terini</u>¹, Paulo R. Costa², Slavik Tabakov³, Elisabeth M. Yoshimura², Denise Y. Nerssissian² ¹Depto. De Física, Pontifícia Universidade Católica de São Paulo, São Paulo/BRAZIL, ²Departamento De Física Nuclear, Instituto de Física da Universidade de São Paulo, São Paulo/BRAZIL, ³Medical Engineering And Physics, King's College London, London/UNITED KINGDOM

Introduction: The Leonardo EU project for European Medical Radiation Learning Development (EMERALD) (www.emerald2.eu/cd/ Emerald2/), a Consortium of Universities and Hospitals from many countries, developed three training modules in medical radiation physics: X-ray Diagnostic Radiology, Nuclear Medicine and Radiotherapy. The modules are for the training of graduated university students in Medical Physics (MP) or related disciplines, their tutors, as well as other Hospital employees. The Institute of Physics of the University of São Paulo, Brazil, and the King's College of London established a research cooperation program to conduct the translation to Portuguese language, adaptation and update of the X-Ray Diagnostic Radiology training module of the Emerald Program. The Emerald teaching material in X-Ray Diagnostic Radiology is divided in ten topics covering the basics of Diagnostic Radiology, Quality Control and Radiation Protection.

Methodology: The referred work, besides the translation of the texts into Portuguese, comprised the review of the previously produced material. During the review process, it was decided to update some of the training tasks and add more information related to current topics, such as digital X-ray imaging modalities, multi-slice computed tomography and tomosynthesis. These new additions will also be available in English. The translated or composed texts have been submitted to a cross-reviewing process by the co-authors in order to standardize the language. Moreover, national radiological protection recommendations were included to assist the users of the teaching material with the Brazilian rules of radiation safety and guality control in X-ray medical applications. A Workshop was held in São Paulo in March 2014, to diffuse and discuss a preliminary version of the Brazilian modules, named Emerald-BR. During this meeting, part of the material was submitted to a validation and also to a practical assessment process by means of a critical analysis by experts in Medical Physics education (Fig. 1).

Results and Discussion: Finally, a pilot implementation has been organized and scheduled in order to do the last adjustments before making the material available to other users in Portuguese language. Further assessment and feedback procedures were planned in both London and São Paulo, aiming to evaluate and disseminate the final product (Med. Phys. Int. J., v. 2(1), p. 18-21, 2014). Emerald-BR will certainly contribute to the offer of organized training programs in the country (and in Latin America) to the growing number of young physicists starting in Medical Physics area each year in the region.

Fig. 1 Participants of the Workshop for diffusion of the Emerald-BR project in São Paulo.

SP137.3 - Pilot Implementation In The Philippines Of Structured Medical Physics Residency Programs Using The Iaea Training Guides For The Clinical Training Of Medical Physicists Author(s): <u>Agnette D.P. Peralta</u>¹, Lilian V. Rodriguez², Joyce N. Melchor¹

¹Department Of Health, Center for Device Regulation, Radiation Health, and Research, Food and Drug Administration, Manila/ PHILIPPINES, ²Radiotherapy Department, Jose R. Reyes Memorial Medical Center, Manila/PHILIPPINES

The Philippines piloted the implementation of the structured medical physics residency training programs in radiation oncology medical physics (ROMP) from 2009 to 2012 and in diagnostic radiology medical physics (DRMP) from 2010 to 2013. The pilot programs were undertaken under the Regional Cooperation Agreement project RAS 6/0/38 "Strengthening Medical Physics through Education and Training" of the International Atomic Energy Agency (IAEA). Used as the training guides were the IAEA publications "Clinical Training of Medical Physicst Specializing in Radiation Oncology" and "Clinical Training of Medical Physicsts Specializing in Diagnostic Radiology".

The full support of the Department of Health (DOH) was essential to the project. The national project coordinator (APPeralta), the national program coordinator for ROMP (LVRodriguez), and the national program coordinator for DRMP (JNMelchor) all came from the DOH. A National Steering Committee (NSC) was created for each program. Represented in the NSC for ROMP were the Center for Device Regulation, Radiation Health, and Research (CDRRHR) of the Food and Drug Administration of the DOH, the Philippine Nuclear Research Institute, the Philippine Organization of Medical Physicists, the Philippine Association for Radiation Protection, the Philippine Radiation Oncology Society, and one of the training hospitals. For the DRMP NSC, the Philippine College of Radiology was the medical specialty society represented. These assignments were all covered by Department Orders issued by the Secretary of Health.

For the ROMP pilot, the original number of five participating hospitals was reduced to four. All the hospitals were private hospitals. For DRMP, the original number of participating hospitals (one private and three government) was maintained.

Not all the residents were actually employed by the hospitals. For ROMP, one of the four residents was teaching undergraduate physics to support himself during his residency. For DRMP, none of the residents was employed by the hospitals where they did their residency. Two residents worked for a company providing radiology equipment testing services, three worked for the national regulatory agency for radiation facilities, one worked for another hospital, one taught undergraduate physics, and one was supported by her parents.

Assistance from the IAEA in the form of experts sent to give lectures and to undertake assessment of the residents during and at the end of the residency training were invaluable, especially because none of the supervisors had had previous experience in a structured onthe-job training program.

Three ROMP residents successfully completed the program. Seven out of eight DRMP residents successfully completed the program.

Important lessons have been learned from the pilot. Solutions for the problems encountered have been proposed.

SP138 - Biosensor, Nanotechnology, Biomems And Biophotonics / New Technologies In Cancer Research And Treatment

SP138.1 - Measurement of the Received Power in a Realistic Intrabody Communication Scenario

Author(s): <u>Zeljka Lucev Vasic</u>, Igor Krois, Mario Cifrek Faculty Of Electrical Engineering And Computing, University of Zagreb, Zagreb/CROATIA

In intrabody communication (IBC) the human body is an integral part of the signal transmission channel. Previously, we have measured transmission characteristics of the IBC channel in the frequency range from 100 kHz to 100 MHz using the same network analyzer as the transmitter and the receiver, galvanically decoupled from the IBC channel by two balun transformers. In this paper, a proprietary battery-powered transmitter and battery-powered spectrum analyzer mimicking the receiver are connected directly to the test subject. The received signal power is measured for four electrode configurations (transmitter A - receiver A (AA), transmitter A - receiver B (AB), transmitter B - receiver A (BA), and transmitter B - receiver B (BB)) and eight transmitter-receiver distances along both arms. The results agree qualitatively with the transmission characteristics of the IBC channel. It was also noticed that, especially for some electrode configurations, a standing wave occurs between a transmitter and a receiver along the human body.

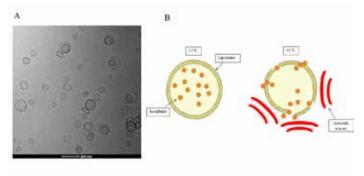

SP138.2 - Focused ultrasound-triggered release of Sorafenib from temperature sensitive liposomes for treating renal cell carcinoma

Author(s): <u>Hakm Murad</u>¹, Caleb Abshire², Jaspreet Arora³, James Liu², Vijay John³, Benajamin Lee², Damir Khismatullin¹ ¹Biomedical Engineering, Tulane University, New Orleans/LA/ UNITED STATES OF AMERICA, ²Surgery, Tulane School of Medicine, New Orleans/LA/UNITED STATES OF AMERICA, ³Chemical Engineering, Tulane University, New Orleans/LA/UNITED STATES OF AMERICA

Specific Aims: High-intensity focused ultrasound (HIFU) emerges as a powerful technology for noninvasive or minimally invasive non-ionizing treatment of cancer. HIFU deposits a large amount of acoustic energy at the focal region within the target tissue (i.e., tumor), causing tissue heating and necrosis. Limited research has been performed applying focused ultrasound, alone or in combination with other therapeutic modalities, to renal cell carcinoma. The aim of this study was to explore focused ultrasound as an adjuvant to chemotherapy; particularly as a method to thermally trigger the release of drug from Sorafenib-encapsulated liposomes into cancer cells.

Research Methodology: Liposomes were fabricated using Dipalmitoylphosphatidylcholine, L-a-Phosphatidylcholinehydrogenated Soy and Cholesterol at a molar ratio of 70:20:10 using the thin film hydration protocol. Liposomes were formulated with addition of Rhodamine B or D-282 for uptake visualization and encapsulated Sorafenib for the treatment arm. The liposomes were characterized for their particle size, surface morphology and the percentage of drug entrapment. Fluorescent liposomes were used to study their uptake in an *in-vitro* model. A suspension of RCC 7860 human renal cancer cells (100 µl, 2.7 million cells/ml) was placed in a 0.2 ml thin-wall PCR tube to mimic dense tumor aggregation. Cell pellets were then inoculated with Sorafenib alone or Sorafenib loaded liposomes and treated with focused ultrasound for 90 seconds. The focused ultrasound signal was generated by a 1.1MHz transducer at an acoustic output power of 2.73W to ensure the temperature rise to 43°C. This temperature is above the transition temperature of the heat sensitive liposomes and triggers the rapid release of Sorafenib. The viability of the cells was measured by the MTT assay at 2, 24, and 72 hours post-treatment.

Results: Liposomes were similar in their surface morphology. The mean particle size was 150 ± 12.33 nm, and their zeta potential was -2.55 ± 3.21 mV. Sorafenib encapsulated liposomes demonstrated $101.2 \pm 1.3\%$ entrapment efficiency based on UV spectrometry. Fluorescent and confocal microscopy consistently confirmed particle uptake by the cells. According to the MTT assay, cellular death rates were 2.8%, 3.0%, and 7.4 % for Sorafenib alone, Sorafenib loaded liposomes, and Sorafenib loaded liposomes with HIFU 24hr post-treatment. Cellular death rates increased to 4.5% for Sorafenib alone, 7.2% for Sorafenib loaded liposomes alone, and 52% for Sorafenib loaded liposomes with HIFU 72hr post-treatment. Thus, focused ultrasound triggered liposomes show significant promise as a feasible strategy for chemotherapy.

- A) TEM imaging of the Sorafenib loaded heat sensitive liposomes. Average size of liposomes are 150nm. The cancer cells uptake liposomes through endocytosis.
- B) Schematic showing the drug Sorafetib encapsulated by the heat sensitive liposomes. The intense acoustic waves caused by the HIFU exceeds the glass transition temperature of liposomes causing the release of drug into cell.

SP138.3 - Synthesis and Characterization of SPION Functionalized third Generation dendrimers Conjugated by Gold Nanoparticles and Folic acid for Targeted Breast Cancer Laser Hyperthermia: An Invitro-assay

Author(s): <u>Mohammad Khosroshahi</u>¹, Maryam Tajabadi², Shahin Bonakdar³, Vahid Asgari³

¹Biomedical Engineering, Amirkabir University of Technology, Tehran/IRAN, ²Amirkabir University of Technology, Tehran/IRAN, ³Pasture Institute, Tehran/IRAN

Abstract- In this study, 9 nm superparamagnetic iron oxide nanoparticles (SPION) were functionalized by polyamidoamine (PAMAM) dendrimer. Magnetodendrimer samples were conjugated by gold nanoparticles (Au-NPs) using two reducing agents of sodium borohydride and hydrazine sulfate. Presynthesized 10-nm Au-NP were used to evaluate the efficiency of conjugation method. Laser Induced Fluorescence Spectroscopy (LIF) of these materials showed that the nanocomposite and magnetodendrimer have the fluorescence properties covering the whole range of visible spectrum. For targeting and the biocompatibility, the synthesized materials were conjugated by folic acid molecules. Laser-induced hyperthermia using Au-NPs was performed. The samples were characterized using X-ray diffractometry (XRD), transmission electron microscopy (TEM), Fourier transform infrared (FTIR) spectroscopy, UV-Visible spectroscopy, and fluorescent spectroscopy. Two cell lines of breast cancer, i.e. MCF 7 and MDA MB 231, were chosen for cytotoxicity evaluation of the synthesized nanostructures. The Results indicated a high biocompatibility of nanoparticles (up to 50 µgr/mL.

SP138.4 - FIB/SEM Characterization of Microcavity Surface Plasmon Resonance Biosensors Author(s): <u>Nazanin Mosavian</u>

Physics, Indiana University, Bloomington/IN/UNITED STATES OF AMERICA

A miniature, integrable surface plasmon biosensor using a dielectric sub-micron diameter core utilizes a noble metal spherical shell structured with a subwavelength nanoaperture believed to excite stationary surface-plasmon-resonances at the biosensor's surface. The sub-micron cavity enhances the measurement sensitivity of bonding molecules to the sensor surface. Visible range spectroscopy is used to study the wavelength shift as bio-molecules absorb/ desorb at its surface. The microcavity surface plasmon resonance sensors (MSPRS) were used to analyse conformational changes of bound biomolecules as the oxidation state changes. Present work uses Scanning Electron Microscopy (SEM) and Focused Ion Beam (FIB) to study the characteristics of MSPRS using a novel fabrication technique.

SP138.5 - The current status of Microbeam Radiation Therapy at the ESRF and future perspectives

Author(s): Elke T. Brauer-Krisch

Experiments Division, ESRF, Grenoble Cedex /FRANCE

Background: Microbeam Radiation Therapy (MRT) uses a spatially fractionated filtered white X-ray beam from a high energy wiggler Synchrotron Source (energies 50-350keV) with extremely high dose rates (up to about 20kGy/s). The typical planar beam width in an array is 25-100µm with 100-400µm wide spaces between beams . Such beams are very well tolerated by the tissue, even the high "peak" doses delivered in the path of the microbeams, when respecting a dose prescription in the "valley' that corresponds to a dose used of conventional Radiation Therapy (RT) converted to a single exposure . The superior tumor control when compared to that realized by conventional RT is achieved by differential effects of MRT on the normal tissue vasculature versus the tumor vasculature.

Materials and Methods: The MRT technique has been technically set up, tested and successfully applied during the last 20 years on various tumor models. Presently, the project is mature enough to be used for the treatment of spontaneous tumors in pets. Unified efforts from several teams with very different expertise now permit Microbeam Radiation Therapy in animal patients with a high degree of safety, in pursuit of the ultimate goal of clinical applications in humans.

Results: The MRT trials for animal pets as tumor patients required substantial work for developing, upgrading and progressively implementing instrumentation, dosimetry protocol, as well as the crucial patient safety systems. Progress on the homogenous dose measurements using ionisation chambers and Alanine dosimetry as well as the comparison of high resolution dosimeters with the dose calculations based on a novel tumor planning system will be summarized. A general overview on the different achievements will be presented as well as a vision for possible human trials.

SP139 - Optical Imaging: Methods

TRACK 01: IMAGING

SP139.1 - Toward super-resolution imaging of proton radiation-induced DNA double-strand breaks for characterization of γ -H2AX foci clusters

Author(s): <u>Arash Darafsheh</u>, Consuelo Guardiola, Jarod C. Finlay, Alejandro Carabe, Timothy D. Solberg Radiation Oncology, University of Pennsylvania, Philadelphia/PA/ UNITED STATES OF AMERICA

Repair kinetics assays can be used to characterize the sensitivity to radiation for patients that require radiotherapy as a treatment option. v-H2AX foci assays have been recognized as one of the most powerful techniques to characterize the repair kinetics properties of radiation induced damage to DNA. The interests in these assays are the rate at which radiation-induced foci disappear, which is presumably related to the rate of DNA damage repair; and the foci size, which is related to the clustering complexity of the DNA damage. Both aspects are interconnected by the fact that larger foci take longer time to disappear, meaning that the larger the clustering the slower the repair rate. Therefore, it is important to understand both aspects in order to understand repair kinetics effects, especially after radiotherapy with particles high linear energy transfer (LET), such as protons. Due to much higher damage density in the DNA in the case of irradiation by protons compared with the case of irradiation by particles with low LET, using high-resolution microscopy to enhance the imaging resolution for y-H2AX foci characterization is desirable.

Foci counting and size measurement is usually performed by optical microscopy, however, the far-field spatial resolution of any standard lens-based optical microscope is limited by the wavelength of imaging light (λ) and by the numerical aperture (NA) of the lens system due to diffraction of light waves. A variety of imaging techniques have been developed in the past to overcome the diffraction-limit in optical microscopy; most of these techniques, however, have complex design and high economic cost, and require scanning across the specimen that increases the acquisition time.

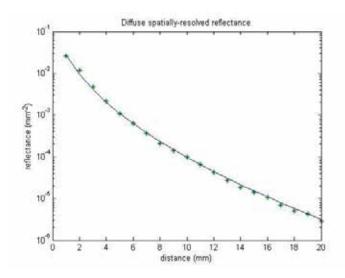

In this work, we investigated a novel simple super-resolution imaging technique for application in γ -H2AX foci characterization. We fabricated super-resolution microscope coverslips composed of barium titanate glass microspheres (Diameters ~30-150 µm and refractive index ~1.9-2.1), fixed in a polydimethylsiloxane (PDMS) elastomer layer, to collect high spatial frequency harmonics present in the optical near-field of the object and transmit them to the far-field with magnification providing high imaging resolution. When the super-resolution coverslip is placed over the specimen, each microsphere forms a magnified virtual image underneath the specimen's surface that is simply captured by the objective lens.

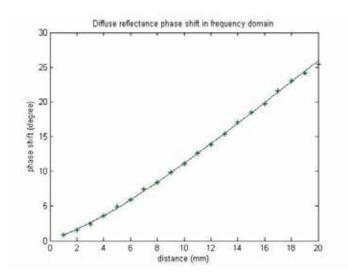

We used microsphere-assisted imaging technique for the observation of double-strand DNA breaks, manifested as foci using an immunofluorescence treatment, in U87 glioblastoma cells irradiated by proton beams. Our results indicate magnification and resolution advantages of microsphere-assisted super-resolution imaging over conventional fluorescent microscopy. Our imaging method is a promising candidate in developing various applications in biomedical imaging and nanophotonics.

SP139.2 - Solution of radiative transport equation in turbid layered media in spatial and frequency domains Author(s): <u>Heping Xu</u>

Cape Breton Cancer Centre, Sydney/CANADA

Study of light transport in turbid media has many applications in biomedical imaging and therapeutic research. Although approximate diffusion solution is widely used to circumvent difficulties in exactly solving for the radiative transfer equation, seeking exact solution is still interesting biomedical optics community as it not only serves as a bench mark for Monte Carlo (MC) simulation, but also well describes light transport in the region when diffusion theory fails (in high absorption region). This abstract obtains exact solutions for two layered media in spatial and frequency domains. Monte Carlo method has been employed to verify the obtained solution. The turbid medium consists of a top layer with the absorption and scattering coefficients 0.02/mm and 1.3/mm, and a bottom layer with the absorption and scattering coefficients 0.01/mm and 1.2/mm. The thickness of the first layer was 2.0 mm. The second layer is much thicker than that of the first one and can be considered as semi-infinite. The refractive index of the medium was 1.4. Anisotropic factor in Hengyey-Greestein phase function is 0.9. The source beam was incident perpendicularly on the top layer with no lateral dimension. Exact solution of RTE was obtained through the method of rotated reference frame (MRRF) as demonstrated in previous literatures. In this method, all quantities were expanded in terms of the spherical harmonics which was defined in a coordinate system, whose z axis coincided with the direction of the wave vector k. The solutions can be expressed with eigenvalues and eigenvectors of a series of infinitely-dimensional matrices in an analytical form. In practice, sufficiently accurate solutions were obtained through truncating those matrices to finite dimensions. Spatially-resolved reflectance, photon density waves at 100MHz modulating frequency (amplitude and phase shift) were calculated using the exact solution and were successfully verified by Monte Carlo methods.

SP139.3 - Development of a hybrid optical-gamma camera: A new innovation in bedside molecular imaging

Author(s): <u>Aik Hao Ng</u>¹, Sarah L. Bugby², Layal K. Jambi², Mohammed S. Alqahtani², Patricia E. Blackshaw¹, Paul S. Morgan³, John E. Lees², Alan C. Perkins³

¹Radiological And Imaging Sciences, School Of Medicine, University of Nottingham, Nottingham/UNITED KINGDOM, ²Space Research Centre, University of Leicester, Leicester/UNITED KINGDOM, ³Medical Physics And Clinical Engineering, Nottingham University Hospitals NHS Trust, Nottingham/UNITED KINGDOM

Introduction:

A novel prototype compact hybrid optical-gamma camera has been developed through collaboration between the Space Research Centre at the University of Leicester and Medical Physics at the University of Nottingham. This system offers high resolution gamma imaging together with real-time optical imaging for use at the patient bedside or in the operating theatre. This presentation describes the innovative design characteristics and the first results of use in the clinical setting.

Material and Methods:

The camera comprises of a CsI(TI) columnar scintillator coupled to a charge-coupled device (CCD), a tungsten pinhole collimator and an optical camera. Both optical and gamma cameras are co-aligned to allow accurate fusion of images. The camera can be mounted on a trolley with flexible articulated arm for hand free use. A qualitative user survey was carried out to obtain feedback for optimising ergonomic factors for use of the camera and trolley system in the clinical environment. A sentinel node phantom was fabricated using polymethyl methacrylate (PMMA) to validate the performance of the camera for sentinel node localisation in the presence of high activity at the injection site.

12-20 MBq sources of Tc-99m were used to simulate radioactivity at the injection site and lymph nodes with the node-to-injection site activity ratios of between 1:100 and 10:100. These were placed at different separations and depths to simulate the uptake at different anatomical sites in the body.

The first patient studies using the hybrid camera were carried out in the Nuclear Medicine Clinic at Queen's Medical Centre, Nottingham.

Results:

The system spatial resolution, system sensitivity and energy resolu-

tion of the camera system with 0.5 mm diameter pinhole collimator was 1.28 mm (@ 13 mm), 214 cps/MBq (@ 3 mm) and 58 % (full width half maximum at 141 keV) respectively. Phantom simulations revealed that the camera system could detect low-activity in nodes up to the depth of 45 mm from the phantom surface by visual examination of images. Overall the user feedback indicated satisfactory design of the bedside trolley system and influenced the final design of the camera head casing, mounting and arm assembly. The initial patient studies included bone, lymphatic, and lacrimal drainage investigations. These showed that the hybrid images provided good evidence of localisation of radiotracer distribution with reference to the visible anatomical features, thus aiding the diagnostic utility.

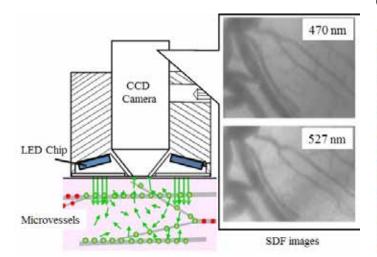

Conclusion:

A novel hybrid optical-gamma camera system has been developed, characterised and the first studies performed in the clinical environment. This system would be ideally suited to use in operating theatre for procedures such as sentinel node detection and tumour localisation. This system offers potential for use with the new generation of hybrid fluorescent-radionuclide tracers currently under development.

SP139.4 - Sidestream Dark-Field Oximetry with Multicolor LEDs Author(s): Tomohiro Kurata¹, Zhenguang Li¹, Shigeto Oda², Hiroshi Kawahira³, Takashi Ohnishi³, Hideaki Haneishi³ ¹Graduate School Of Engineering, Chiba University, Chiba/JA-PAN, ²Graduate School Of Medicine, Chiba University, Chiba/ JAPAN, ³Center For Frontier Medical Engineering, Chiba University, Chiba/JAPAN

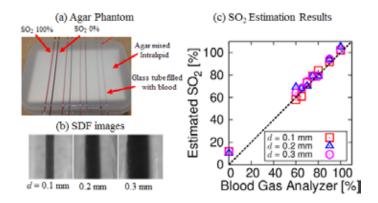

We investigate the possibility of oxygen saturation (SO2) estimation from images obtained by the sidestream dark-field (SDF) technique. The SDF technique is a noninvasive optical technique allowing direct visualization of microvessels near tissue surfaces.

To advance the capability of the SDF technique, we develop an image-based oximetry method with the SDF technique (SDF oximetry) with LED illumination sources. This method is based on the Lambert-Beer's law with dual-wavelength illumination. For establishing the method, we developed a trial SDF device used multicolor light-emitting diodes (LEDs) (peak wavelengths: 470 and 527 nm) to obtain two-band images. Figure 1 shows the configuration of our trial device and microvessel images.

In this study, we propose a SDF oximetry method with the trial device and report evaluation results of the validity of the method. As an approach to verify the method, we performed both a Monte Carlo photon propagation simulation and experiments with a phantom and *in vivo* small intestine of a pig. In the phantom experiment, we

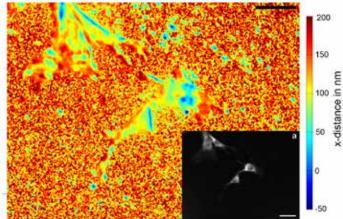

tested the proposed method with a phantom made of agar and 10% Intralipid. In order to simulate vessels, glass tubes filled with bovine blood were embedded just below the surface of the phantom. Figure 2 shows the phantom, the SDF images, and SO2 estimation results with different internal-diameter tubes. From the results, we found that there was strong correspondence between estimated SO2 values and measured values by a blood gas analyzer. This result suggested the validity of the proposed SDF oximetry method. Moreover, we estimated SO2 of microvessels near the surface of the small intestine of a pig. Although the validation of the experiment is still under study, the results of the validation and computer simulation will be presented at the conference.

SP139.5 - Development of Polymer Substrates for Waveguide Evanescent Field Fluorescence Microscopy

Author(s): <u>Rony Sharon</u>¹, Frederik Fleissner², Silvia Mittler² ¹Biomedical Engineering, the university of western ontario, London, ON/CANADA, ²Physics And Astronomy, The university of western ontario, London, ON/CANADA

False color representation of a dye distance map with four osteoblasts. The inset represents an overexposed Waveguide Evanescent Field Flurescent (WEFF) Microscopy image of the same field of view. Osteoblasts appear at dye/plasma membrane distances between ~ 75 to 110 nm. Dye locations very close to the surface, adhesion areas, are labeled blue. Both scale bars represent 50 µm. The color bar shows a range from - 50 nm to 200 nm. One pixel is equal to $(0.266 \ \mu m)^2$.

WEFF Microscopy was developed recently to image ultra thin films (quality control) and to investigate adhesions of cells to substrates and to produce quantitative distance maps of the plasma membrane to the substrate.

A key component in WEFF microscopy is the glass substrate optical

device containing a planar waveguide and an optical coupling grating.

Previous work has shown a better growth of cells on polymer substrates. Therefore, the objective of this study is the development and fabrication of polymer based substrates with similar characteristics to existing glass substrates.

Polymethymethacrylate (PMMA) substrates were fabricated by hot embossing a coupling grating from a master silicon mold, and subsequent spin coating of OrmoCore, a photoresist, or alternatively polystyrene serving as waveguides. The master mold was fabricated by spin coating Shipley 1805 photoresist on a silicon wafer followed by laser interference lithography implementing the grating pattern. Photoresist gratings were developed and oxygen plasma cleaned before preforming reactive ion etching to embed the structure within the silicon.

The correlation between the embossed substrate and the silicon mold grating constant was examined with scanning electron microscopy: taking the variations of temperature, the time and process pressure into consideration. The results determined a set of parameters for PMMA substrate fabrication, and demonstrated that the same quality of coupling gratings can be achieved as seen in existing glass substrates. The next step is the fabrication of optical quality polymer waveguides on top of the PMMA substrate to start imaging fixed and living cells.

WEFF microscopy could have many applications, especially in the field of tissue engineering, cellular biology and implant development. Paving the rode for mass production of WEFF substrates and to foster WEFF microscopy, spreading it among optical microscopy users which will be able to upgrade their existing microscopes to a surface sensitive tool and extend research capabilities without major modifications, is the driving force and importance of this work.

SP139.6 - Higher-Order Structural Investigation of Mammalian Septins by Super-Resolution Fluorescence Microscopy Author(s): Adriano Vissa¹, Maximiliano A. Giuliani², Theodore Pham³, William S. Trimble³, Peter K. Kim³, Christopher M. Yip² ¹Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA, ²Institute of Biomaterials & Biomedical Engineering (IBBME), Toronto/ON/CANADA, ³Cell Biology, Hospital for sick children, Toronto/CANADA

Septins belong to a family of GTP-binding structural proteins that are thought to have various functions in mammalian cells including acting as scaffolds for protein recruitment, forming diffusion barriers, and participating in cytokinesis. Defects in Septin organization have been linked to hereditary neuralgic amyotrophy and several types of cancers. During interphase, these heterooligomeric complexes colocalize with F-actin stress fibers and have been shown to stabilize their formation through direct interaction with non-muscle myosin II. However during cytokinesis septin complexes maintain NM II association and form characteristic higher order ring structures at the midbody scaffold to facilitate cell division. The structural versatility of septins is likely directly related to their many roles yet the organizational motifs by which oligomeric building blocks form filaments and higher order structures has not been elucidated in mammalian cells. In addition, their intricate spatial relationship with F-actin and myosin is of great interest in understanding the formation of stable cytoskeletal stress fibers. To address these questions, we used the sub-diffraction imaging technique dSTORM (Direct Stochastic Optical Reconstruction Microscopy), one of several recently developed methods of super-resolution microscopy. Also known as nanoscopy, it has revolutionized the optical study of proteins and cellular processes by achieving resolution below 20 nm, and its implementation is at the crossroads of cell biology, biomedical engineering and computer science. We report two-colour dSTORM imaging of Septin2/Septin9 in filament and ring structures and

characterization of their periodic structural contribution in human fibroblast cells using AlexaFluor 647 and ATTO 532 on a custombuilt combinatorial microscopy platform. To gain insight into septins' role in nanoscale cytoskeletal protein organization, an array of two colour superresolution imaging was carried out on combinations of septin proteins, F-actin and non-muscle myosin II isoforms A and B and discrete nanoscale spatial arrangements were characterized.

SP140 - Special Treatment Techniques: Part 1

TRACK 04: RADIATION ONCOLOGY

SP140.1 - Credentialing of radiotherapy centres in Australasia for a phase III clinical trial on SABR

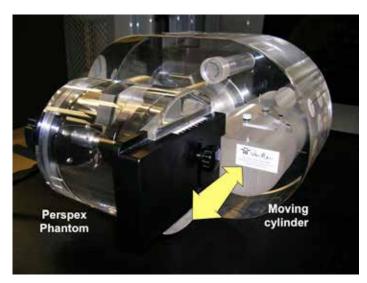

Author(s): <u>Tomas Kron</u>¹, Brent Chesson², Nick Hardcastle¹, Natalie Clements¹, Mark Burns², Melissa Crain³, David Ball⁴ ¹Physical Sciences, Peter MacCallum Cancer Center, Melbourne/ AUSTRALIA, ²Radiation Therapy, Peter MacCallum Cancer Centre, East Melbourne/AUSTRALIA, ³Quality Assurance, Trans Tasman Radiation Oncology Group, Newcastle/AUSTRALIA, ⁴Department Of Radiation Oncology, Peter MacCallum Cancer Center, Melbourne/ VIC/AUSTRALIA

Aim

Stereotactic Ablative Body Radiotherapy (SABR) is a relatively new treatment modality that utilises image guidance, motion management and many small often non-coplanar radiation beams to deliver high biological doses of ionising radiation in very few fractions. A randomised phase III clinical trial comparing SABR with conventional radiotherapy for early stage lung cancer in peripheral location is running in Australia and New Zealand under the auspices of the Trans Tasman Radiation Oncology Group (TROG). As SABR technology at the commencement of the trial was new to most participating centres a credentialing program was developed for centres wishing to join the trial.

Methods

The credentialing program was developed using a prospective risk management approach. Key elements include the ability to create a plan that meets all dosimetric constraints, the dose calculation in the presence of inhomogeneities and the management of motion. Participating centres were asked to develop treatment plans for two test cases made available in DICOM format, and inhomogeneity corrections and dose delivery was assessed during a site visit using a phantom with moving inserts as shown in figure 1.

Results

Site visits were conducted in 20 radiotherapy facilities. All centres were able to produce acceptable plans for both test cases using 54Gy in 3 fractions, or for lesions close to the chest wall, 48Gy in 4 fractions. The tests with lung and air inhomogenieties confirmed

known shortcomings of the AAA algorithm for dose calculation behind the inhomogeneity. The dose was assessed in the phantom using an ionisation chamber and radiochromic film both in a stationary and moving cylinder as shown in figure 1 (sinusoidal motion, 1cm amplitude, 4s period). These measurements including at least one non-coplanar beam, confirmed in an end-to-end test that all participating centres were able to treat a lesion with the required accuracy. The site visit took 3 hours of linac time and was well received by participating staffproving to be a useful step in the process of developing a SABR program.

Conclusion

The credentialing process based around a site visit documented that participating centres were able to deliver dose to a phantom as required in the trial protocol. It also gave an opportunity to provide education about the trial and discuss technical issues such as 4D CT, small field dosimetry and patient immobilisation with staff in participating centres.

SP140.2 - LED-optimized SBRT for Peripheral Early Stage Lung Cancer: A technique to reduce lung dose and potentially allow for re-irradiation

Author(s): Brandon Disher, George Hajdok, Stuart Gaede, Alexander Louie, Jerry J. Battista

London Regional Cancer Program, London Health Science Center, London/CANADA

Introduction

Stereotactic Body Radiation Therapy (SBRT) is a treatment option for early stage lung cancer. Initial reports suggest local control rates comparable to surgery (87.2%, 3 years). 1 Survivors are at risk of developing a second primary lung cancer (SPLC) at a rate of approximately 3% per year.² Patients with recurrent disease or SPLC may benefit from a second course of SBRT, but normal lung dose may limit retreatment. Recently, we developed LED-optimized SBRT (LED-SBRT),³ which exploits lateral electron disequilibrium (LED) to produce steep dose gradients at the tumor/lung interface. Here, we demonstrate that LED-SBRT can potentially reduce normal lung dose to avoid possible toxicity from re-irradiation.

Methods

Ten early stage lung cancer patients, with peripherally located disease, were retrospectively selected at random. Time-averaged 4-Dimensional CT image sets were acquired with a Philips 16-slice helical CT scanner. For each patient, two treatment plans (Pinnacle³ TPS) were created for comparison: 1) a 6MV 225° VMAT plan (control), and 2) a 6MV 180° arc LED-SBRT plan (field size $\approx 2x2$ cm²). An internal target volume (ITV) was created to account for tumor motion due to breathing. Two planning target volumes (PTV) were created: PTVVMAT = ITV + 5mm, and PTVLED = ITV + 2mm. A reduced margin was used for PTVLED to accommodate a smaller field size. Plans were generated using the collapsed-cone convolution algorithm, and dose was normalized such that 95% of the PTV received at least the prescription dose (i.e. 54Gy/3fractions or 60Gy/8fractions).

Results

The LED-SBRT plan created a steeper dose gradient at the tumor/ lung interface (see Figure 1), which reduced normal lung dose. For example, the average percent reduction [(LEDSBRT – VMAT)/VMAT x 100%] in the mean lung dose, V5, and V20 were 27.4+/-11.9%, 25.0+/-8.5%, and 35.1+/-11.9%, respectively, averaged over all patients. On the contrary, the PTV hot spot and mean dose increased on average by 86.4 + -32.5% and 45.1 + -11.9%, respectively.

Conclusions

LED-SBRT can be used to reduce normal lung dose, and may allow for retreatment of small peripheral early stage lung lesions. As this technique relies on small field sizes (< 3x3 cm²) and reduced target margins, advanced forms of image-guidance, gating, and/ or tracking must be implemented for tumor targeting. Furthermore, only those algorithms that model electron transport must be used to ensure dose accuracy in regions of severe LED. With these precautions, LED-optimized lung re-irradiation could prove to be clinically viable for re-treatment situations.

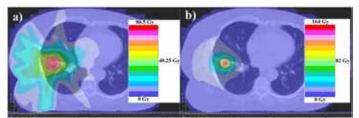

Figure 1 a) and b) display the VMAT and LED-SBRT dose distributions overlaid on patient 10's CT anatomy (prescription dose = 60Gy in 8 fractions). Comparing Fig. 1 a) and b), LED-SBRT creates steeper dose gradients at the tumour/lung boundary compared to the conventional VMAT plan. This effect can be exploited to greatly increase the tumour hot spot, while reducing normal lung dose.

SP140.3 - Delivery of VMAT treatments with nonstandard SAD using dynamic trajectories

Author(s): Joel Mullins¹, Krum Asiev², Francois Deblois², Jan Seuntjens¹, Alasdair Syme³

¹Department Of Physics, McGill University, Montreal/CANA-DA, ²Medical Physics Unit, Department Of Oncology, McGill University, Montreal/CANADA, ³Radiation Oncology Department, Jewish General Hospital, Montreal/CANADA

Introduction: The Varian TrueBeam[™] offers an optional research mode that permits dynamic control over many of its radiation and mechanical systems. Translational couch motion can be programmed in synchrony with gantry rotation to emulate treatment at either shortened or extended SADs. Shortened SADs offer the benefit of an increased dose rate and better dose conformality to the target volume due to the decreased leaf projection size, while extended SADs allow for increased field sizes and can obviate the need for field junctions (for example in cranio-spinal irradiation).

Materials and Methods: Water tank measurements were used to commission an 85 cm SAD and a 120 cm SAD beam model in the Varian Eclipse™ treatment planning system. For each beam model, reference dosimetry (AAPM TG-51) and beam validation tests (IAEA TRS 430) were performed. A total of 9 VMAT treatment plans were generated (four at 85 cm SAD, five at 120 cm SAD) and exported from Eclipse™ to DICOM-RT plan files. A software routine was developed in Python using the pydicom library (v0.9.8) to convert the plans into an .xml-formatted file for delivery with the TrueBeam[™] research mode. To emulate nonstandard SAD delivery on a conventional SAD linear accelerator, translational couch motion was added to move the treatment couch in a circular trajectory as a function of the gantry and couch rotation angles, and the MLC leaf and jaw positions were scaled by the ratio of conventional to nonstandard SAD. Ionization chamber and Gafchromic EBT3 film measurements were used to record point dose and planar dose distributions for comparison with corresponding dose calculations in Eclipse[™]. MATLAB software was written to generate gamma index comparisons with

the Eclipse-exported dose planes.

Results: The beam models for both 85 cm SAD and 120 cm SAD agreed with measurement to within 1% for in-field profiles and PDDs beyond dmax for all field sizes. For profiles in penumbra and out-of-field regions, agreement was mostly within 5%, with some exceptions reaching up to 10%. Validation measurements indicated good agreement between measurement and Eclipse[™] calculation. Ionization chamber measurements for the treatment plans at 85 cm SAD yielded an average agreement of -3.9±2.0%; Eclipse[™] underestimated the measured dose in all cases. With 120 cm SAD, the average agreement for four of the five plans was -0.33±0.55%, with an outlier measurement of -7.4% for ionization chamber positioned in a steep dose gradient area. Ignoring out-of-field regions, the film gamma index pass rates for all treatment plans at both SADs were above 90%.

Conclusion: Dynamic couch trajectories were used to emulate nonstandard SAD delivery on the Varian TrueBeam[™] STx with VMAT treatment plans, yielding good agreement between Eclipse[™] treatment planning system dose calculations and both ionization chamber and film measurements. Discrepancies included a systematic underestimation of the delivered dose compared to measurement at 85 cm SAD, and poor agreement for one measurement located in a high dose gradient region at 120 cm SAD, but relative dose distributions showed good agreement as evidenced by the gamma index analysis of film measurements.

SP140.4 - Cone-Beam CT assessment of inter-fraction and intra-fraction motions during lung stereotactic body radiotherapy with and without abdominal compression Author(s): Mengying Zhang¹, <u>Runqing Jiang</u>², Lixin Zhan² ¹Medical Science, University of Western Ontario, London/ON/ CANADA, ²Medical Physics, Grand River Regional Cancer Centre, Kitchener/ON/CANADA

Purpose/Objective(s): The purpose of this study is to assess the effect of abdominal compression on the inter-fraction and intra-fraction variations for lung stereotactic body radiotherapy (SBRT) using cone-beam computed tomography (CBCT).

Materials/Methods: Sixty-nine lung stereotactic body radiation therapy patients were investigated in this study. The patients were separated into two groups, one with abdominal compression, and the other without abdominal compression. Seven to nine conformal beams were used for SBRT treatment plans. The prescriptions doses were 50 Gy in 5 fractions or 48 Gy in 4 fractions. At each treatment, two CBCTs were performed before and during the treatment. Set-up errors were measured on the first CBCT, which were recorded as inter-fraction variation. Tumor movements during treatment were measured by the second CBCT during treatment, which were recorded as intra-fraction variation.

Results: For intra-fraction variation, the shifts \geq 3 mm for "abdominal compression" group were 12.0% in AP direction, 4.6% in SI direction, 5.0% in LR direction, corresponding to 17.3% in AP direction, 21.2% in SI direction and 11.5% in LR direction respectively, for the group "without abdominal compression" For inter-fraction variation, The shifts \geq 5 mm for "abdominal compression" group were 22.8% in AP direction, 22.8% in SI direction, 24.9% in LR direction, corresponding to 15.4% in AP direction, 48.1% in SI direction and 15.4% in LR direction, respectively for the group "without abdominal compression". Abdominal compression reduced breathing organ motion during SBRT lung treatment in all three directions. However, setup error was just reduced significantly in SI direction for abdominal compression group. There is a slightly increase for setup error in AP and LR direction for abdominal group. Both inter-fraction and intra-fraction variations had been greatly reduced in SI direction after abdominal compression was applied.

Conclusion: Abdominal compression reduced the amplitude of intra-fraction lung breathing motion in all directions during lung SBRT treatment. However, the use of abdominal compression seemed to increase the inter-fraction variation in AP and LR directions although the inter-fraction variation in SI direction was reduced significantly. Therefore, target matching is required to localize the inter-fraction variation.

SP140.5 - Initial experience in establishing frameless intra-cranial stereotactic radiosurgery program with Varian TrueBeam STx, 6DoF couch and VisionRT motion control system

Author(s): <u>Sergei Zavgorodni</u>¹, Isabelle Gagne¹, Will Ansbacher¹, Derek M. Wells¹, Tony Mestrovic¹, Quinn Matthews¹, Tracy Mitchell², Isabelle Vallieres²

¹Medical Physics, BC Cancer Agency, Victoria/CANADA, ²Radiation Oncology, BC Cancer Agency, Victoria/CANADA

Implementation of a stereotactic radiosurgery (SRS) program requires linac and TPS commissioning, selecting planning and delivery techniques, "end-to-end" treatment delivery verifications for clinically appropriate treatment scenarios, establishing planning and imaging protocols (including planning CT and MRI, pre-treatment position verification and image-based intra-fraction monitoring). The program must also include SRS-specific daily and monthly QA procedures (on top of regular machine QA) as well as pre-treatment patient dose verification.

Commissioning of the TrueBeam STx linac and Eclipse TPS was performed keeping in mind its intended use for both intra- and extra-cranial treatments; therefore the beam model was tuned to cover small as well as medium VMAT/IMRT fields. Micro-diamond detector was used in beam data collection in the range of field sizes from 1x1cm² to 22x40 cm².

Conformal, conformal arc, IMRT and VMAT techniques were evaluated, and VMAT was the method of choice for the majority of cases due to its versatility and capability of combining steep dose fall-off with fast delivery. We anticipate mostly using co-planar treatments with 6MV and 10MV-FFF beams and simultaneous dose delivery to multiple targets.

End-to-end target localization and dosimetry tests were performed using a customized anthropomorphic head phantom with imbedded tungsten bead and an insert for the detector. Treatment plans for localization tests were created with the isocentre of circular conformal fields positioned on the bead. CBCT imaging was used for moving the phantom to treatment position. Portal images were then taken for each field, and offset of the beam axis from the bead was measured. For dose verification the center of calculated dose distributions was positioned at the measurement point of micro-diamond detector, and measured dose was compared to TPS calculation. QFix S-Frame Aqualast (3.2mm thick) head immobilization mask is also being evaluated for intra-fraction motion control by acquiring CBCT images pre and post treatment from CNS patients enrolled in this study.

For patient-specific dosimetry QA we intend to use in-house EPIDbased 3D dose calculations as well as Monte Carlo calculated dose, reconstructed from trajectory files. Isocal calibration that confirms the congruence of imaging and treatment isocentres will be performed pre-treatment.

Anticipated work-flow of the SRS treatments involves patient CT and MR imaging, treatment planning, patient-specific QA, pre-treatment daily SRS-specific machine QA. During treatment CBCT images will be used to move the patient to the treatment position and to verify the move. Optical image will be captured by VisionRT system (not installed yet) immediately after verification CBCT and will be used to insure no motion during treatment. Once the treatment completed,

trajectory log files will be saved for dose reconstruction.

So far results for the mask immobilization intra-fraction were acquired for 3 patients and showed a mean intra-fraction motion of 0.7mm and a maximum of 1.1mm. Localization tests confirmed the beam axis to be within 0.5 mm from the bead target. Dosimetry verification tests showed good agreement (within 2%) of planned and measured dose for targets of 10 mm diameter and larger. For smaller targets the measured dose exceeded the plan by as much as 11%.

SP141 - Development of New Methods in Therapy Dosimetry: Part 3

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP141.1 - Theoretical description of the saturation correction of ionization chambers in pulsed fields with arbitrary repetition rate

Author(s): Leonhard Karsch

TU Dresden - OncoRay, Dresden/GERMANY

Purpose: Gas-filled ionization chambers are the most important radiation detectors in radiotherapy. The recombination of radiation induced charge carriers causes an incomplete charge collection resulting in a reduced dose measurement value. A quantitative description and correction of the recombination effects exists for two cases, for continuous radiation exposure and for pulsed radiation fields with short single pulses, i.e. pulses of vanishing pulse duration and low repetition rate, so that the pulses do not affect each other. These two cases result in different dependencies of the collection efficiency on the chamber voltage which allows their experimental and theoretical differentiation. This work gives a new description for pulsed beams with arbitrary pulse rate, for which the prerequisites of the two existing descriptions are not fulfilled. Furthermore, an extension of the validity of the two existing cases is investigated. Method: The process of charge collection and recombination between two pulses was described for a plane-parallel ionization chamber with a differential equation system. This differential equation system was solved by assuming simplified charge distributions and calculating the first terms of series expansion at recombination. The resulting complex formular for the correction term was simplified for easier handling and discussion.

Result: A formula describing the collection efficiency of plane parallel ionization chambers in pulsed fields with arbitrary pulse rate was developed which allows calculating the exact amount of recombination. This new formular contains the two existing descriptions for exposure by single pulses and continuous irradiation as limiting cases. By comparing the dependency of the new formula with the different dependencies on chamber voltage for the two existing cases, it was possible to determine the pulse rate range for which each of the three descriptions is applicable.

Discussion: As long as the time between two pulses is lower than one third of the collection time of the chamber, the collection efficiency can be very well described by the description for a continuous exposure. The description for single pulse irradiation is only valid if the repetition rate is less than 1.2 times the inverse collection time. Even if the calculation is done for plane parallel chambers, the derived formula and results should also be applicable for cylindrical ionization chambers by introducing an effective electrode gap. The work is supported by the german government BMBF (no. 03Z1N511).

SP141.2 - Performance characteristics of Gafchromic EBT3 film in therapeutic electron beams and its practical application as an in-vivo dosimeter in the clinic.

Author(s): <u>Amanda Barry</u>, Lynda Fennell, Alan Pembroke, Eimear O'Neill

Radiotherapy, UPMC Whitfield Cancer Centre, Waterford/IRELAND

Purpose:

To assess the dosimetric properties of self-developing Gafchromic[®] EBT3 film in therapeutic electron beams with a view to assessing its suitability as an in-vivo dosimeter for electron beam radiotherapy.

Background:

Self-developing EBT2 film has been used by our organisation for in-vivo dosimetry in electron beam radiotherapy. [1] In 2012, a new generation of selfdeveloping Gafchromic[®] film namely EBT3, became available providing the same practical solution as EBT2 for in-vivo dosimetry in electron beams. The suitability of EBT3 film for in-vivo dosimetry is due largely to the simplicity and flexibility with which films can be prepared and analysed. As it is practically water equivalent with a thickness of 0.28 mm, it does not give rise to the large perturbation effects that are typically associated with the use of electron diodes. Compared to EBT2 film, EBT3 has the added advantage of having a symmetrical composition which eliminates both sideorientation dependence and Newton's rings.[2]

Methods:

EBT3 film calibrations were performed under reference conditions using two electron beam energies. MapCheck[®] was used with an EPSON V750 Pro scanner to generate calibration curves and read films under different test conditions.

Post-exposure developing time, dose-rate dependence, MU linearity, inter- and intra-film reproducibility, film orientation and position on the scanner and effects of repeated scanning were measured for films irradiated in a 9 MeV beam. The film's energy dependence was assessed in electron beams ranging from 6 to 18 MeV.

Minitab[®] was used to perform a statistical analysis to determine: (1) the variability in the EBT3 films dose response under the different test conditions; (2) the statistical significance of differences in the dose response of films irradiated with electron energies in the range 6-18 MeV using two calibration energies; and (3) the absolute dose measured using an ion chamber.

Results:

Initial results show that for a particular batch of film, there is no significant difference in recorded dose between individual sheets. Within one sheet of film, there is a maximum variation of 5%. Placing films on the scanner's central axis eliminates scanner inhomogeneities. Films scanned in the up orientation showed no difference to those scanned in the down orientation. However, rotating films by 90° reduced the recorded dose by up to 17%. The calibration energy did not affect the film dose response for any given electron beam energy. However, the films appeared to show a weak energy dependence.

Conclusions:

From our results, we conclude that EBT3 film may be suitable for invivo dosimetry in therapeutic electron beams providing the correct tolerance levels are applied.

SP141.3 - Photon and electron spectra inside small field detectors for narrow and broad 6 MV photon beams Author(s): <u>Hamza Benmakhlouf</u>¹, Pedro Andreo² ¹Department Of Medical Physics, Karolinska University Hospital, Stockholm/SWEDEN, ²Department Of Physics, Medical Radiation Physics, Stockholm University, Stockholm/SWEDEN

To investigate differences in detector response with respect to field size and detector type, photon and electron fluence spectra were calculated inside eleven small field detectors and in a small volume of water in narrow (0.5cm x 0.5cm) and broad (10cm x 10cm) Varian Clinac 6 MV photon beams. The usercode PenEasy, based on the PENELOPE MC system, was used to simulate three ionization chambers (IBA-CC01, PTW-T31016, PTW-T31018), two diamond detectors (PTW-T60003 and PTW-T60019), and six silicon diodes (IBA-EFD, IBA-PFD, IBA-SFD, PTW-T60016, PTW-T60017, PTW-T60018). This work follow the calculations in Benmakhlouf *et al.* 2014 *Med Phys.* This compilation of detectors include air and liquid ion chambers, natural and synthetic diamond detectors, shielded and unshielded silicon diodes of different sizes, all of interest for small field dosimetry.

Peaks in the photon spectra were found in all silicon diodes at energies between 22 keV and 26 keV due to characteristic x-rays emitted from some detector components surrounding the active detector volume. An additional very large peak was found (for both fields) in the shielded IBA PFD diode due to the emission of characteristic x-rays from the dense shielding material surrounding the diode. The photon fluence spectra inside the detectors for both field sizes were in general similar to the photon fluence spectra in water except for the shielded silicon diodes (in the case of the broad beam as expected) where the shielding causes a significant reduction of the fluence at low energies. The electron fluence spectra inside the ion chambers and diamond detectors were close to that in water whereas large differences between the detector spectra and water spectra (up to 50% difference) were found; the difference increased with decreasing field size due to lack the of charged particle equilibrium.

The MC-calculated doses for both field sizes were compared to analytically determined collision kerma and restricted cema using the scored fluence spectra. The collision kerma was always larger than the MC-dose for the narrow beam due to lack of lateral charged particle equilibrium whereas the restricted cema (based on a common cutoff value of 15 keV for all detectors) was smaller and larger than the MC-dose (within ±2%) depending on the detector type and field size. The differences increased with decreasing field size.

SP141.4 - Real Time Dose Reconstruction in MV Photon Therapy using a 2D solid state detector array.

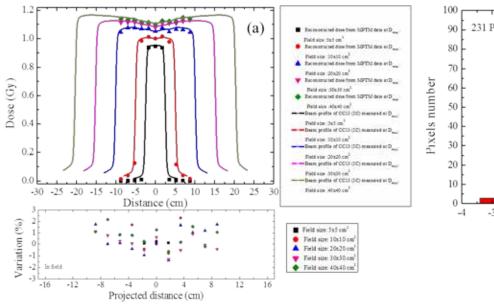

Author(s): Ziyad A. Alrowaili¹, <u>Michael L.F. Lerch</u>¹, Martin Carolan², Marco Petasecca¹, Peter Metcalfe¹, Anatoly B. Rosenfeld¹ ¹Centre For Medical Radiation Physics, School Of Physics, Faculty Of Engineering, university of Wollongong, Wollongong/NSW/ AUSTRALIA, ²Radiation Oncology, Illawarra Cancer Care Centre, Wollongong/AUSTRALIA

Introduction: Real time verification of the dose delivered during the patient treatment is important step for quality assurance in IMRT and VMAT. We have developed such a system based on a solid state transmission 2D detector array called "Magic Plate".

Purpose: We study the performance characteristics of the MP system operated in Transmission Mode(MPTM). Of particular interest is to quantitatively demonstrate direct dose reconstruction for different field sizes in a phantom based on the response of the MPTM.

Methods and Materials: The MPTM was positioned in the block tray of a linac so that the central detector of the array lies on the central axis of the radiation beam. The response of the central MPTM diode was compared with depth dose distribution along the central beam axis in a phantom for field sizes ranging from 5x5 cm² - 40x40 cm² to determine a conversion factor from measured diode response to dose in the phantom, which is independent of the field size. The same conversion factor is used for all diodes in the 2D array to reconstruct the dose along rays projected from the source through each detector and into the phantom, at any depth of interest.

Results: The optimum(i.e. independent of field size) response-todose conversion factor for the central diode of MPTM was found at a depth of 1mm in the phantom. Figure 1(a) shows a comparison of the measured and reconstructed dose profiles in the phantom for several field sizes. Figure 1(b) demonstrates that for all detector infield elements in the 2D array and all field sizes that the 2D reconstructed and measured doses in a phantom at depth of Dmax agree to within $\pm 2.48\%(2$ SD). Both in and out of field PDD change is less than 1% with the MP in place.

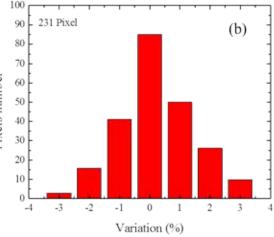

Figure 1. (a) 6MV beam dose profiles measured with CC13 IC in comparison with those reconstructed from MPTM response dose at depth of Dmax for diodes along the central row(row 6 of 11 rows) .(b) Frequency histogram of the variation between measured and reconstructed dose at depth of Dmax for all in-field points and field sizes tested.

Conclusions: A 2D MP detector array in a transmission mode provides negligible beam perturbation and is an exciting potential candidate for real-time, 2D and 3D dose reconstruction. The success of this work is an exciting development toward real time QA during radiotherapy treatment.

SP141.5 - Energy Correction factor for Plane Parallel ion-chamber and its Use in Clinical photon Beam Dosimetry

Author(s): Konthoujam Manimala Devi¹, Arun S. Oinam², <u>Kamlesh R.</u> Passi¹, Suresh C. Sharma²

¹Department Of Radiation Oncology, Mohan dai oswal hospital, Ludhiana/INDIA, ²Department Of Radiotherapy, post graduate institute of medical education and research, chandigarh/INDIA

Purpose:

Plane Parallel ion-chambers are recommended as reference dosimetry for photon beam measurements. In dosimetry protocols, experimental values of energy correction factor available for a particular chamber can compare with theoretical calculation considering perturbation factors. However, for Plane parallel chamber, energy correction factor are not available as they are not recommended for photon beam due to the relatively large uncertainty in the wall perturbation factor. Brag-gray theory and Spencer–Attix water/air stopping-power ratios, *sw*,air, of beam qualities *Q* and *Qo*, are employed in this study to investigate the energy correction factors for plane parallel chambers considering the perturbation factor of the specific chamber in high energy photon beams.

Material and Method:

Water phantom RFA-300, Exradin A19 farmer chamber, PPC-40 Roos, and Standard imaging Max 4000 electrometer were used. Using TRS-398 and Spencer Attix data available in TRS-277 protocol, values of perturbation factor are calculated with high statistical precision for Plane parallel chamber for both 6 and 15 MV photon beams. The dependence of perturbation factor on the beam quality are also studied.

Result and Discussion:

The variations of beam quality index for "PPC-40Roos" from "Exradin A19" were very much lesser as 0.0026 (or 0.39%) and 0.00 22 (or 0.29%) for 6 and 15 MV respectively. This result indicates that the responses of both the chambers are within acceptable limit of 1%. Energy correction factors "KQQo"for PPC-40Roos which was determined theoretically and experimentally shows that the variation between theoretical and experimental for PPC-40 Roos was very much less as 0.5% and 0.08% for 6 and 15 MV respectively. Variation of 0.5%*and* 0.09% of absorbed dose was observed for 6 &15 MV respectively between theoretical and experiment and experiment values of

PPC-40. However, there was no variation in absorbed dose between the experimental value of PPC-40Roos and Exradin A19.

Conclusion:

The appropriate selection of the reference point of plane parallel chamber is an important issue. If it is accounted correctly then Pdis would be almost independent of depth. With precise calculation of perturbation factor, energy correction factors of PPC-40 for higher beam energy can be determined theoretically and compared with experimental value, obtained a good result which is within 0.5%. So, PPC-40 Roos can be recommended for dosimetry of high energy photon beams after considering specific chamber perturbation factor.

SP142 - Light Ion Radiotherapy

TRACK 06: NEW TECHNOLOGIES IN CANCER RESEARCH AND TREATMENT

SP142.1 - Proton Minibeam Radiation Therapy (pMBRT): implementation at a clinical center

Author(s): Cécile Peucelle¹, Catherine Nauraye², Annalisa Patriarca², Eric Hierso², Nathalie Fournier-Bidoz², Immaculada Martínez-Rovira¹, <u>Yolanda Prezado¹</u>

¹Laboratoire D'imagerie Et Modélisation En Neurobiologie Et Cancérologie, Centre National de la Recherche Scientifique (CNRS), ORSAY/FRANCE, ²Centre De Protonthérapie D'orsay, Institut Curie, ORSAY/FRANCE

Purpose

The more selective energy deposition of protons in depth is advantageous compared to photons to preserve normal tissues. Nevertheless, an even better tissue sparing might be possible in proton therapy if combined with the well-established tissue preservation of spatially fractionated submillimetric beams. This sparing effect has been observed in studies performed with synchrotron minibeam radiotherapy (MBRT) [1,2].

The innovative approach proposed here, called pMBRT, was shown to provide favourable dose distributions in Monte Carlo studies [3]. The dose profiles in normal tissue consist in peaks and valleys, while the tumour receives a (quasi)-homogenous dose distribution [3]. The goal of this study was to verify the technological feasibility of creating minibeams in a clinical environment and to evaluate their dosimetric aspects.

Material and methods

The implementation of pMBRT was carried out at the ICPO. To generate minibeams patterns, collimators with micromillimetric line apertures were manufactured. Gafchromic EBT3 films were irradiated in water phantoms by an array of 100 MeV protons (700 µm-wide) minibeams. Depth dose distributions and lateral dose profiles were studied. Relevant dosimetric parameters in spatially fractionated techniques, namely peak and valley doses and their ratio (PVDR) [4], were assessed. Beam penumbras and output factors were also evaluated.

Results

The technical implementation met pMBRT dosimetric specifications. A spatial fractionation of the dose was obtained in normal tissues (PVDR up to 7) while a quasi-homogeneous dose distribution was reached at the Bragg peak location (see figure 1), in agreement with theoretical predictions [3]. The reduced penumbras (600-1100 μ m) in healthy tissue make pMBRT a good candidate for radiosurgery applications.

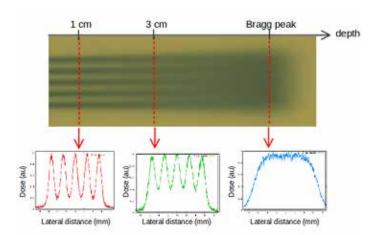

Figure 1: Gafchromic film, irradiated longitudinally, showing a spatial fractionation in normal tissues and a (quasi)-homogeneous dose distribution at the Bragg peak position.

Conclusion

This study experimentally proves the technical feasibility of pMBRT at a clinical center. The first experimental dosimetry measurements were successfully performed despite the extreme irradiation conditions. The PVDR values obtained showed the potential of this approach, which might conduct to a reduction of the normal tissue complication probability. Animal irradiation experiments are planned to confirm the normal tissue sparing capability of pMBRT.

SP142.2 - Hadron minibeam radiation therapy: feasibility study at Heidelberg Ion Therapy Center

Author(s): Immaculada Martínez-Rovira¹, Iurii Sorokin², Stephan Brons³, O Kovalchuk², V Iakovenko², M Campbell⁴, X Llopard⁴, S Pospisil⁵, V Pugatch², <u>Yolanda Prezado</u>¹

¹Laboratoire D'imagerie Et Modélisation En Neurobiologie Et Cancérologie, Centre National de la Recherche Scientifique (CNRS), ORSAY/FRANCE, ²Kiev Institute for Nuclear Research, Kiev/ UKRAINE, ³Heidelberg Ion Beam Therapy Center (HIT), Heidelberg/ GERMANY, ⁴CERN, Geneva/SWITZERLAND, ⁵Institute of Experimental Applied Physics (IEAP), Prague/CZECH REPUBLIC

Introduction and Purpose

Despite recent advancements in radiotherapy and radiosurgery, significant limitations remain. Although hadrontherapy, being in clinical use for more than 15 years, has shown remarkable effectiveness, it still could benefit from a lower impact on non-targeted tissues to allow its administration at higher doses. This is the reason why we propose a new approached called hadron minibeam radiation therapy (hadron MBRT). The technique is based on the well established tissue-sparing effect of arrays of parallel, thin or small beams, observed in studies performed with synchrotron radiation [1-2]. In parallel, significant tumor growth delay was observed in highly aggressive tumors by using interlaced irradiations [1-3]. Hadron MBRT combines the advantages of MBRT with the high dose conformability and the remarkable biological effectiveness of hadrontherapy. This novel strategy might guarantee tissue recovery and reduce the side effects of radiation in healthy tissues. The main goal of this study was to explore this new approach from dosimetric point of view and to verify its technical feasibility at a clinical center (Heidelberg Ion Therapy Center, Germany). In particular, carbon and oxygen minibeams were studied.

Materials and Methods

Carbon and oxygen minibeams were generated through a tungsten multislit collimator with line apertures of 700 μ m-wide separated by 3600 μ m. Several beam spots were used to cover a given irradiation field size (1x1 cm²) and a spread out Bragg peak (SOBP) region of 5 cm at 8 cm-depth in water. Radiochromic films (EBT3) were placed at several depths in a solid-water slab phantom to evaluate dose distributions. Quenching effects of these films were also assessed and results were accordingly corrected. Metal Microstrip and Micropixel (TimePix) detectors were explored for beam distribution measurements [4].

As a figure of merit, the ratio between the central dose of one minibeam (peak dose) and the dose in the middle of two consecutive beams (valley dose) was evaluated. This magnitude, named peakto-valley dose ratio (PVDR), is a very relevant magnitude in such spatially fractionated techniques [5].

Results

The measured lateral dose profiles in carbon and oxygen MBRT consisted in a pattern of peaks and valleys, which prove the technical feasibility of this approach. This first dosimetric study showed PVDR values around 10-20 in the first centimeters of the phantom. PVDR values progressively decrease up to around 5 at 8-cm-depth. These PVDR values are in the order of the ones obtained in x-rays MBRT, for which biological effectiveness has already been proven. Finally, Metal Microstrip and Micropixel (TimePix) detectors have demonstrated excellent performance measuring PVDR values, in agreement with radiochromic films.

Conclusions

This is the first exploratory study that experimentally proves the technical feasibility of hadron MBRT at a clinical center. The PVDR values obtained showed the potential of this radiotherapy approach, which might allow to reduce side effects in the healthy tissues. Animal experiments are warranted.

SP142.3 - Acoustic Range Verification of Proton Beams: Simulation Assessment of the Challenges of Clinical Application Author(s): Kevin C. Jones¹, Chandra M. Sehgal², Stephen Avery¹ ¹Department Of Radiation Oncology, University of Pennsylvania, Philadelphia/UNITED STATES OF AMERICA, ²Department Of Radiology, University of Pennsylvania, Philadelphia/UNITED STATES OF AMERICA

For radiation treatment of cancer, proton therapy efficacy is limited by range uncertainty. The ability of protons to deliver substantial dose at the Bragg peak is a benefit that improves localization, but it also magnifies the risk of range uncertainty; over- or undershooting the target drastically changes the delivered dose. *In-vivo* proton range monitoring has the potential to eliminate range uncertainty and the associated risks. The measurement of sound waves generated by proton beams (protoacoustics), is an undeveloped technique with potential for *in-vivo* range verification. Similar to thermoacoustics, protoacoustic emissions are generated because the energy deposited by pulsed proton beams is converted into heat, which causes expansion and emission of pressure waves.

Previous work has established the viability of protoacoustic range verification under ideal conditions. Simulations with 5 mm diameter, 1 μ s proton beams have shown that protoacoustic measurements can determine the Bragg peak position to 1 mm accuracy. Previous experiments with fast, <1 μ s rise-time proton pulses have measured the acoustic signals. Simulations and experiments under non-ideal, common clinical conditions are still lacking. Here, through Green's function based numerical simulations of 5 mm diameter pencil beams, we assess the challenges to translating protoacoustics into the clinic, where proton currents are often limited to nanoamperes and proton pulse rise-times are in the 10's of microseconds.

Based on the simulation results, the protoacoustic signal amplitude is linearly proportional to the current and weakly dependent on the rise-time. A current of 300 nA is expected to generate ~0.1 Pa, which is at a level that is measurable with commercially available detectors. As the rise-time increases from 1 to 40 µs, the pressure amplitude drops by 20%. The most significant observed effect of increasing rise-time is a broadening of the protoacoustic signal, which decreases the time-of-flight range-verification accuracy from 1 mm (1 µs rise-time) to greater than 1 cm (40 µs rise-time). For a homogeneous medium irradiated with 5 mm diameter beams, the simulated signals have frequency spectra centered at 80 kHz (1 µs rise-time) and 5 kHz (40 µs rise-time). Although clinical proton beam characteristics limit the protoacoustic amplitude, simulations predict that protoacoustic signals are detectable under clinical conditions. Long proton pulse rise-times degrade the accuracy of range calculations based on simple time-of-flight calculations, suggesting that multiple measurements or comparisons to modeling are necessary to improve accuracy.

SP142.4 - Radiochromic Film Based Dose Calibration and Monitoring for Radiobiological Experiments using Low Energy Proton Beams

Author(s): <u>Belal Moftah</u>¹, Saad Aldelaijan¹, Mamoun Shehadeh¹, Faisal Alzorkany¹, Ghazi Alsbeih¹, Jan Seuntjens², Slobodan Devic³ ¹Biomedical Physics, King Faisal Specialist Hospital and Research Center, Riyadh/SAUDI ARABIA, ²Medical Physics Unit, McGill University, Montreal/CANADA, ³McGill University, Montreal/CANADA

Purpose

Low energy proton beams could be of potential interest for radiation treatments of shallow lesions (intra-operative radiotherapy, melanomas, non-cancerous skin diseases) due to expected higher relative biological effectiveness (RBE) and sharp fall off behind clinical target. Output measurements for MTT assay were performed using the EBT3 model GafChromic[™] film based reference dosimetry system.

Methods

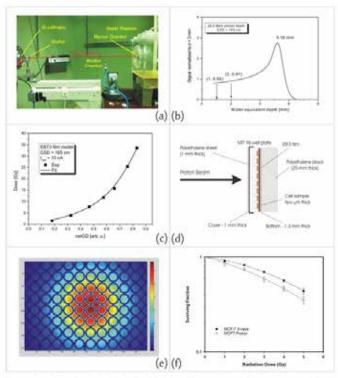

Figure 1.a represents experimental setup used to measure depth dose curve (Fig.1.b) and beam output with a calibrated PTW Markus ion chamber. To improve stability of irradiations (26.5 MeV protons originating from CS30 cyclotron) an aluminum cylinder was added in front of the beam exit serving as a timed shutter. Measured signal was corrected by monitor chamber reading and subsequently scaled by ratio of stopping powers for water and air at given depth, while the effective depth of measurements was scaled by ratio of CSDA ranges water to air. Output was measured at 3 mm depth in the middle of the plateau ahead of the Bragg peak where PDD was normalized. Following the TRS398 reference dosimetry protocol for proton beams, output was measured in water in terms of Gy/ nC where nC is reading of the monitor chamber. Once the output of the beam was known, we calibrated EBT3 film model for doses of up to 35 Gy (Fig.1.c). For MTT assay, attached breast cell cultures (MCF-7, MCF-12, MDA-MB-231) in 96-well plates were irradiated by horizontal beam (Fig.1.d). Behind the plate, piece of film was placed to monitor dose distribution during each experiment.

Results

For each irradiated 96-well plate, a dose image was reconstructed (Fig.1.e) and then scaled by the measured PDD data. Natural Gaussian shape of the beam was used to obtain multiple dose points within the same plate from a single exposure. Dose values per wells were used to construct the survival curve (Fig.1.f). The average RBE of proton beam compared to x-ray at the ID50 (50% inhibitory dose) was 1.22 (SD = 0.05) which was statistically higher (P = 0.02) than the 1.1 commonly used in standard clinical proton therapy.

Conclusions

Radiochromic film-based dose monitoring system that can be used for MTT radiobiology assays with a low energy proton beam was described. Having a sharp dose fall-off behind the Bragg peak, a high dose rate proton beam originating from a production cyclotron could further allow for dose escalation protocols in the case of superficial lesions. This work was supported by NSTIP 11-BIO1428-20.

SP142.5 - Development of 3D measurement device dedicated for range-compensator QA

Author(s): <u>Shigekazu Fukuda</u>¹, Eriko Urakabe¹, Kiyohiro Yamada² ¹Research Center For Charged Particle Therapy, National Institute of Radiological Sciences, Chiba/JAPAN, ²Accelerator Engineering Corporation, Chiba/JAPAN

Purpose

In light ion therapy including carbon beam therapy, the broad-beam method is used to irradiate beams to the tumor conformally. The broaden beams are cut to the shape of the target tumor projected in the beam's eye view by a patient collimator or multileaf collimator (MLC). To adjust the range of the beams to the target in the depth a range-compensator is used. The range-compensator is a block that has an engraved depression in the shape of the target tumor. [1] Though it is desirable to check the 3D shape of the range-compensator compared to the planned shape at all points, over 2000 points, in terms of QA/QC, only the limited points, 30-40 points, are usually checked by the contact length measurement sensor device (CLMSD). To verify all points automatically in a short time, the 3D measurement device (3DMD) dedicated for range-compensators QA has been developed.

Desk-Size (Smaller than existing mechanical measurement device)

Methods

The 3DMD has a XY-stage with high precision and a range-compensator is attached to the XY-stage. Two CCD laser displacement sensors were employed to measure the height of each point of the range-compensator by detecting reflected laser. We verified some range-compensators.

Results

Due to the shape there were some points which cannot be measured, but the ratio of the number of the unmeasured points to that of all points was less than 1%. The precision of the measurements by the 3DMD was within less than 0.1 mm, and the concave positions were verified as acceptable. It took less than 20 minutes to measure and verify the all points of the large patient compensator such as 20 cm x 20 cm x 15 cm.

Conclusion

After further commissioning of the 3DMD, we plan to use this device to check the range-compensators routinely.

SP143.1 - Sliced Mary: a deformable phantom for the validation of set-up based on surface imaging in radiotherapy treatments Author(s): <u>Stefania Pallotta</u>¹, Serenella Russo², Marco Esposito², Livia Marrazzo³, Cinzia Talamonti¹, Pierluigi Bonomo³, Fabiola Paiar³, Lorenzo Livi⁴, Cristina Svensson⁵

¹Department Of Experimental And Clinical Biomedical Sciences, University of Florence, Florence/ITALY, ²Azienda Sanitaria di Firenze, Florence/ITALY, ³AOU Careggi, Florence/ITALY, ⁴Department Of Experimental And Clinical Biomedical Sciences, University of Florence, Florence/ITALY, ⁵C-RAD Positioning AB, Uppsala/SWEDEN

Ionizing radiation is generally used to check patient setup in radiotherapy treatments but data concerning patient position can also be derived using surface imaging (SI) systems. The absence of additional radiation exposure and the execution rapidity make this approach particularly interesting. The main drawback of these techniques consists in the worse accuracy caused by the deformation of external body surfaces. As deformable image registration algorithms could potentially solve this problem, some SI developers have included elastic deformation tools in their software. In this work a deformable phantom, suitable for SI acquisition, and with internal tissue contrast for both kilovoltage (kV) and megavoltage (MV) imaging modalities has been developed to evaluate deformable image registration algorithms. The phantom consists in 33 slices of expanded polystyrene slabs shaped thus to simulate part of a female body. Anatomical details, simulating ribs and spinal cord, together with internal targets are included in thorax and abdominal parts. Two mammalian prosthesis and two objects, simulating arms, were fixed to the phantom which was finally covered with a white Lycra tissue. Independent and realistic head rotation, arms flexion as well as body torsion around a longitudinal axis and bending around lateral and vertical axes can be achieved. A preliminary test to assess the deformable phantom usability was performed. The elastic registration algorithm implemented in C-RAD Catalyst software was tested by applying to the phantom different head and arm rotations and comparing SI and portal imaging (PI) registration results.

SP143.2 - Evaluation of ion chamber response in high dose per pulse electron beams of IORT accelerator using EGSnrc Monte Carlo code

Author(s): Mostafa Robatjazi¹, Seied Rabi Mahdavi², Abbas Takavar¹ ¹Medical Physics, Tehran University of Medical Sciences, Tehran/ IRAN, ²Medical Physics, Iran University of Medical Sciences, Tehran/IRAN

Introduction: The use of high dose per pulse electron beams produced by mobile dedicated linacs for intraoperative radiotherapy (IORT) has been increasing in recent years. The dosimetry of such beams requires particular care when performed by ionization chambers. A delicate aspect in this respect is the determination of the factor, ks , that corrects for ion recombination in the irradiated chamber. There are some methods and studies in evaluation of Ksfor the purpose of application in IORT fields. One of the standard methods in dosimetry is the Monte Carlo (MC) simulation. In this study, we evaluated the response of parallel plate chamber response in high dose per pulse electron beams of dedicated IORT linac using MC simulation.

Material and Methods: The following MC calculations are performed with the EGSnrc user codes. The BEAMnrc code was used for linac head modeling and DOSRZnrc was used for tuning of the relative and absolute dosimetry. In evaluation of relative dosimetry gamma-index was used. The criteria for this purpose was selected 2% (Dose Difference) and 2mm (Distance To Agreement). In the tuning of the virtual linac for absolute dosimetry, we used the fact that linac was tuned to deliver the 1 cGy/MU in the depth of maximum dose (Damx). The dose of the monitor chamber of the linac was used as a normalization point and application of MU in dose calculations. The geometry of ion chamber in water phantom and dose in sensitive volume of the chamber was simulated using CAVITY. CPP code. The correction factors of chamber such as Pcav, Pwall, and absolute dose in Dmax was calculated in this code. Finally, the absolute dose value using this code was compared by experimental data.

Results: There was good agreement between experimental and simulated relative dosimetries. More than of 95% of gamma values were passed in evaluation of relative dose comparisons. The experimental measurements using ion chamber were performed in Dmax. The correction factors of chambers (Kqq0, Ktp, Kpol) was done using IAEA-TRS398. The Ksat in experimental measurements were performed by Laitano method. The chamber response in experimental measurements was 0.994 cGy/MU whereas the simulated value for chamber without and with applying the Kwall and Kcav was 0.9374297(\pm 0.21%) and 0.993072951(\pm 0.3%) cGy/MU, respectively. The discrepancy between the measured and experimental response of chamber was about 0.09%.

Conclusion: One of the uncertainty sources in high dose per pulse electron beams in dedicated IORT linac is determination of Ksat. In this study, we showed that the response of parallel plate chamber using mentioned correction factors has a good response in high dose per pulse electron beams of dedicated IORT linacs.

SP143.3 - Compared QA of APEX Radiosurgery System using ARCHECK Phantom in Dynamic Conformal Arc System and VMAT System

Author(s): Jae Hyuk Seo¹, Hun Joo Shin², Shin-Wook Kim², Choong-II Lee¹, Mina Yu¹, Se-Cheol Yoon¹, Tae-Suk Suh³, Young Nam Kang⁴ ¹Radiaton Oncology, The Catholic University of Korea Bucheon St.Mary's Hospital, Bucheon-si, Gyeonggi-do/KOREA, ²Department Of Radiation Oncology, Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Incheon/KOREA, ³Department Of Biomedical Engineering, College Of Medicine, The Catholic University of Korea, Seoul/KOREA, ⁴Department Of Radiation Oncology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul/KOREA

PURPOSE

In this study, we estimated the accuracy and usefulness of APEX system for the radiosurgery with the use of the ArcCHECK phantom in dynamic conformal arc therapy (DCAT) and volumetric modulated arc therapy (VMAT) system.

MATERIAL AND METHOD

We used the ArcCHECK phantom and APEX system. When APEX system which is mounted to the gantry is rotating, we compared DCAT and VMAT System. MONACO (ver. 3.3) was utilized as a radiation treatment planning system (RTPs). APEX system has the micro multi leaf collimator (mMLC) with leaf thickness of 2.5 mm. INFIN-ITY Tx Machine was used. We performed two different techniques for the comparison. One is DCAT plan and the other is VMAT plan. In order to evaluate the APEX system, 3D gamma analyses were conducted using 3% / 3 mm and 2% / 2 mm criteria.

RESULTS

The difference between the DCAT and VMAT plans was found to be less than 3%. Also, the 3D assessment showed a significant difference between the DCAT and VMAT (both gamma pass rate of above 98% with 3% / 3 mm criteria, both gamma pass rate of above 95% with 2% / 2 mm criteria).

CONCLUSIONS

DCAT plan can not modulate the intensity of radiation while the gantry is rotating. And mMLC shape and gantry rotating speed is fixed at the each control point. However, VMAT plan can modulate the intensity of radiation through the optimized mMLC shape and gantry rotating speed. Therefore, our results show that the VMAT plan is superior to the DCAT plan. we conclude that APEX system should adapt the VMAT system for the accurate radiosurgery.

SP143.4 - Head and Neck CT/CBCT Deformable Registration for Image-guided Accurate Radiotherapy System ARTS-IGRT

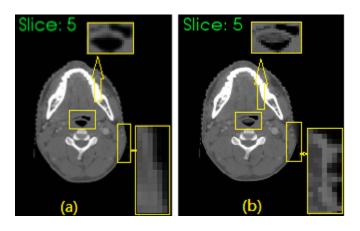

Author(s): Qian Wu¹, Ruifen Cao¹, Jing Jia¹, Liqin Hu¹, <u>Xi Pei²</u> ¹Key Laboratory of Neutronics and Radiation Safety, Institute of Nuclear Energy Safety Technology, Chinese Academy of Sciences, heifei/CHINA, ²Key Laboratory of Neutronics and Radiation Safety, Institute of Nuclear Energy Safety Technology, Chinese Academy of Sciences, Heifei/CHINA

Objective: Deformable image registration (DIR)between the planning CT and the daily cone-beam CT (CBCT) played a key component in image-guided radiation therapy (IGRT). The traditional DIR algorithms, such as Demons, failed in CT/CBCT image registration due to CBCT worse image quality and intensity inaccuracy. The purpose of this work was to develop aCT/CBCT DIR methodfor ARTS-IGRTprototype systemand implementation GPU in CUDA programming environment. Methods: Our algorithm tried to correct CBCT intensity value in the processing of symmetric Demons registration. CBCT intensity value was corrected based on that of the corresponding CT, because of the relative better image quality and more accurate intensity value of CT. The algorithm was carried on as follows: (1) CT and CBCT images were split into several disjoint tissues by intensity histogram matching, image label was assigned to voxel according to the intensity value and spatial neighboring voxels. (2) The deformation field was calculated by the displacement field formula of symmetric force Demons. (3) CBCT intensity value was corrected voxel by voxel. There didn't exist a global intensity correspondence in light of all voxels of CT and CBCT. We firstly modeled the intensity correspondence by linear polynomial model; and further interpolated the intensity values where the voxel pairs were at the same tissue to estimate those of voxel pairsconsisting of different tissue type, becauseover-correction will appear for different tissue type voxel pairs. (4) CBCT was rescaled and a new deformation field was calculated with the corrected CBCT and the deformed CT, then returned to (3) for the next iteration.

Results: Registration tools were tested for head-neck images. From the result of symmetric Demons algorithm, we can found that anatomical structures in the deformed CT were significantly distorted due to CBCT intensity inconsistency, especially in those regions with severe scatter artifacts. Our algorithm yielded undistorted deformed CT that matched well with corrected CBCT. The performance was also quantitatively evaluated by normalized mutual information (NMI), the average NMI increased to 0.68±0.02 and the computational time decreased to 50seconds for the image size of 256X256X49.

Conclusions: We implemented an effective intensity correction based CT/ CBCT DIR method. CT/ CBCT was considered as monomodality image after CBCT intensity correcting and the corrected CBCT with better image quality could be used for radiotherapy such as inter-fractional setup error correction and replanning.

SP144 - EMG/MMG

TRACK 09: BIOSIGNAL PROCESSING

SP144.1 - Estimation of dorsiflexion torque from a mechanomyogram using a Kalman filter

Author(s): <u>Takanori Uchiyama</u>, Shunichi Otsuka Applied Physics And Physico-informatics, Keio University, Yokohama/JAPAN

A mechanomyogram (MMG) is a vibration detected on a skin surface with a displacement sensor or an acceleration sensor. Measuring an MMG is easier than measuring dorsiflexion torque because sensors are simply fixed on the skin's surface. The measurement technique does not require the restriction of human motion. An MMG is a signal that reflects mechanical properties of muscle and subcutaneous tissue. We assume that an MMG contains a signal from muscle contraction as a low-frequency component and noise from subcutaneous tissue as a high frequency component. We propose a method for estimating dorsiflexion torque from the mechanomyogram smoothed by using a Kalman filter. Six healthy male subjects participated in the experiments. A subject sat on a chair, and his thigh and leg were immobilized with nylon belts. His foot was fixed on the equipment to measure the dorsiflexion torque during isometric contraction. First, the dorsiflexion torque was measured by applying a transcutaneous electrical stimulation to the common peroneal nerve with Aq-AqCl surface electrodes. The system from the electrical stimulation to the dorsiflexion torque was identified by the singular value decomposition method, and the system, control, output, and feed-forward matrices of the state-space equations were calculated. Then, a Kalman filter was constructed using the matrices. Second. the subject was instructed to perform a task while tracking a target dorsiflexion torque displayed on a screen in front of the subject. The torque was approximately 50% of the maximum voluntary contraction. The onset and duration of the contraction were random. The MMG of the tibialis anterior muscle was measured with a laser displacement meter. The neural action potential was measured for 60 s with the Ag-AgCl electrodes, which were used as stimulation electrodes in the first experiment. The EMG of the tibialis anterior muscle was also measured to compare the proposed method to the conventional method of using the root mean square of the full-wave rectified EMG (EMGrms). The signals were sampled at 2,000 Hz and stored on a PC. The MMG was smoothed with a Kalman filter constructed by the matrices of the state-space equations of the dorsiflexion torgue. Here, the neural action potential was used as an input signal to the system. We regarded the smoothed MMG as the extracted dorsiflexion torque from the MMG. The time course and frequency response of the extracted torque and the EMGrms were compared to those of the observed dorsiflexion torque. The observed torque was approximated well by the extracted torque as compared to the EMGrms in both the time and frequency domains for all six subjects. In conclusion, a noble method of extracting the dorsiflexion torgue from the MMGs was proposed in this study. The method provided a better approximation of the dorsiflexion torque as compared to the conventional method that uses EMGrms.

SP144.2 - Upper-Limb Force Modeling using Rotated Ensembles with Fast Orthogonal Search on High-Density Electromyography

Author(s): <u>Gregg Johns</u>¹, Evelyn Morin², Keyvan Hashtrudi-Zaad³ ¹Electrical & Computer Engineering, Queen's University, Kingston/ CANADA, ²Electrical & Computer Engineering, Queen's University, Kingston/ON/CANADA, ³Electrical And Computer Engineering, Queen's University, Kingston/CANADA Robust estimation of net limb forces has a plethora of important applications. However, the most reliable methods are invasive and are not feasible in most cases. The use of surface electromyography (EMG) for estimating muscle forces is non-invasive, and generally unobtrusive. However, many physiological and non-physiological factors limit the precision of these methods. The rich spatiotemporal information collected from high-density surface EMG (HD-EMG) grids has been used to mitigate the problem; however, the instability of electrode-skin contact for these systems creates outlying channels, which may lead to substantial error. We build non-linear predictors on rotated ensembles, which when aggregated provide robust and highly accurate (RMSE<2.6%) estimation of the force induced at the wrist under isometric contractions.

SP144.3 - MMG detection of intentional movement in the presence of dyskinetic movements

Author(s): <u>Marcela Correa Villada</u>¹, Tom Chau² ¹University of Toronto, Toronto/ON/CANADA, ²Bloorview Research Institute, Toronto/CANADA

Cerebral palsy (CP) is a permanent disorder that affects an individual's development of movement and posture and is characterized by the presence of variable involuntary movement that may affect the individual's desire to communicate and interact with their surroundings. Assistive technologies may enable these individuals to perform functional activities such as communication (Tai, Blain, and Chau 2008, 204-219).

One of the access pathways commonly used for assistive technologies is muscle activity. Muscle activity can reflect the condition of muscles as well as reveal the underlying user intention. While EMG is widely used in many fields for the study of muscle activity, the mechanomyogram (MMG) is gaining popularity in biomedical engineering applications. MMG is a technique used to study the mechanical activity of muscles which arises from the lateral oscillation of muscle fibers during active voluntary contraction(Posatskiy and Chau 2012, 320-324; Uchiyama and Miyazaki 2013, 461-464; Islam et al. 2013; Kim et al. 2008, 33-42; Orizio 1993, 201-243; Jaskólska et al. 2007, 336-347).

This research intends to answer the following question:

In what ways can information about muscle contractions be combined to enhance the detection of intention amid dyskinetic movements beyond that achievable by conventional agonist-based detection?

This study has two main objectives: first, to detect the contribution of task muscles in a reaching movement in children with DCP, and second, to combine information from a group of task muscles to enhance the detection of movement intention

We are recruiting a control group of typically developing children and a group of children and youth with dyskinetic cerebral palsy between the ages of 8 and 18. MMG signals are simultaneously recorded using a tri-axial accelerometer placed on the surface of the skin of 6 muscles (flexor, extensor, biceps, triceps, anterior deltoid and pectoralis major) involved in the reaching and drawing task. Participants are asked to perform horizontal and vertical lines on a tablet for a period of 25 minutes. The signal has been processed by wavelet analysis decomposition and denoising in order to filter out gross motor movement. The mother wavelet used for this analysis is Daubechies 10. Preliminary data collected from participants has shown that Singular spectrum analysis (SSA) is a promising noise reduction technique to determine muscle contraction, onset time of contraction, and offset time of contraction.

In order to achieve objective 2, we will develop a model to predict movements with varying number of MMG inputs. Possible models will include an artificial neural network with time series inputs (Specht 1990, 344-353). We will compare the predictability of a movement while changing the number of MMG signals used for input data.

Children and youth with physical disabilities could benefit from the use of MMG as an access technology system. However, there is not enough research on the adequate use of MMG on children with dyskinetic cerebral palsy. This project aims to evaluate the information from task muscle contractions during a reaching task in order to enhance the detection of intentional muscle activity in the presence of dyskinetic movements.

SP144.4 - Dynamic Noise Reduction in Accelerometer-based Mechanomyography during Pediatric Gait

Author(s): Katherine Plewa¹, Tom Chau²

¹Institute of Biomaterials and Biomedical Engineering, University of Toronto, Toronto/CANADA, ²Bloorview Research Institute, Toronto/CANADA

Neurological lesions result in a loss of motor and sensory function needed to effectively produce complex movements. The patient's adaptability to these dysfunctions depends on their substitution for missing afferent information; therefore, measuring impaired muscles during gait may provide a pathway for redefining that functional movement. Mechanomyography (MMG) is a method for measuring muscle activity, contraction timing, and providing biofeedback [1]. However, research in MMG has been limited to simple contractions because the muscle signal is lost within motion artifacts from gross limb movements during dynamic activities [1].

Improving the signal-to-noise ratio of MMG is important because of the overlapping frequency content of both motion artifact and useful muscle information[1]. Although microphone and coupled transducers have been suggested for measuring MMG in dynamic environments [2, 3], this study will focus on improving accelerometerbased MMG by developing noise reduction and feature extraction techniques that have been previously utilized [4, 5]. Wavelet based methods have been successful in de-noising and detecting muscle contractions; however, they have not been implemented in dynamic environments. Therefore, the main objective of this study is to optimize accelerometer-based MMG during gait.

MMG data will be collected from 100 healthy pediatric participants (ages 8-18) during self-paced gait using tri-axial accelerometers. MMG will be measured at four muscle locations (i.e., tibialis anterior, medial gastrocnemius, vastus lateralis, and biceps femoris). Electromyography (EMG) data will be simultaneously collected from the same muscles and used to validate MMG muscle activity. Once the sensors have been attached, participants will be asked to walk at their typical pace around a track for 15-minutes. MMG and EMG data will be bandpass filtered, then wavelet-based denoising will be applied to the MMG signals to isolate muscle activity. Feature extraction algorithms will then be applied to identify muscle contractions. We will further use this MMG data to characterize the sequence of coordinated muscle activations and derive stride intervals for fractal analysis. Initial results indicate that waveletbased denoising is a promising method for isolating muscle signals from noising MMG signals, and singular spectrum analysis has been successful at identifying bursts of muscle activity. We hope that by improving MMG noise reduction methods in dynamic activities, we can utilize MMG for fractal analysis of gait and as a biofeedback tool in gait rehabilitation settings.

SP144.5 - EMG-EMG Coherence in Multisite Writer's Cramp Waveforms - A Study with Advanced Multi-Channel EMG System

Author(s): <u>Venkateshwarla R. Raju</u>¹, Roopam R. Borgohain² ¹Biomedical Eng & Neurology & Neurosurgery And, Nizam's Inst of Medical Sciences (NIMS) University & Hospital, HYDERABAD/IN-DIA, ²Neurology, Nizam's Inst of Medical Sciences, Hyderabad/INDIA

We setup an multichannel EMG amplifier for capturing signals with special reference to Writer's cramp (WC) from the subject having input impedance greater than 100MegOhm(MΩ). Using the setup we gathered EMG-EMG data signals from WC subjects (diseased conditions) hand muscles: ECR and ECU. FCR and FCU. followed by fifth muscle using a set-of-five innocuous micro-wire-electrodes (50µ) in each-subject. We then assessed coherence and conducted chi-square (χ 2) tests on these data in eight subjects of concordant(C) group and 4 subjects of discordant (D) group of right-hand-writingsignal (RHWS) and in left-hand-writing-signal (LHWS)) studied. We compared the difference between flexor-aspect-of-forearm and extensor-aspect-of-intrinsic hand-muscles. This showed significantcoherence in both concordant and discordant groups of WC mirrormovements (MMs) in mirror-Dystonia. These observations suggest that the nature of EMG-EMG coherence in dystonic WC may be constrained by the descending-motor-systems, both in terms of their anatomical-distribution and their frequency-characteristics. In our computation, coherence showed symmetry along the diagonals in graphs. We thus state that, this study showed significant quantifiable EMG differences in the signals/waveforms seen while writing with the right and left hands between those WC subjects with concordant MMs (C group) versus those with discordant MMs (D group).

SP144.6 - An Exploration of the Erector Spinae Muscle for Knee Exoskeleton Control

Author(s): Denis D. Rodriguez, Ana Cecilia Villa Parra, <u>Teodiano</u> Freire Bastos

Post-graduate Program In Electrical Engineering, UFES, VITORIA/ BRAZIL

Lumbar erector spinae muscle has been little explored for knee exoskeleton control through sEMG signals, which could improves the onset and offset of motion. In this study, a simultaneous sEMG record was obtained in three movements routine (knee extensionflexion, stand-up from seated position and seat-down from up position) from five trunk levels, and five muscles of the leg. sEMG signals were smoothed to obtain the envelope through the captured sample entropy method, which can be used to detect the onset/offset through an adaptive threshold value.

The onset/offset related to knee motion was obtained on trunk muscles, during knee extension-flexion, stand-up and sit-down activities, which is suitable for knee exoskeleton control.

SP145 - Developing Tools for Successful Aging: Independent Mobility & Visual Impairment

TRACK 10: REHABILITATION MEDICINE, SPORTS MEDICINE, REHABILITATION ENGINEERING AND PROSTHETICS

SP145.1 - Aging Successfully at Home: Research and Development to Address the Biggest Challenges Older Adults Face Author(s): <u>Tilak Dutta</u> Idapt, Toronto Rehab Institute, Toronto/ON/CANADA

Learning Objectives:

1. To support older adults living in their homes we need to find better ways to prevent falls while encouraging safe mobility and preventing injury in caregivers. We can do this through the development of new products and policy changes.

2. Researchers need to stay involved with the product ideas they develop to ensure they get on the market. The passion and vision behind a disruptive product can be lost if intellectual property is transferred to a centralized technology transfer office.

3. The use of simulators allows for efficient and safe iterative testing of new products/policy changes.

Abstract:

Older adults often do not have the tools they need to age successfully in their own homes. Our team develops products and policies to overcome the biggest barriers to growing older in place.

Our team includes clinicians (OTs, PTs, nurses), technical experts (industrial designers, machinists, engineers) as well as trainees. We work closely with commercial partners and policy makers throughout the development process to ensure products/policies get taken up quickly.

We use a series of simulators to safely evaluate products with target users in challenging conditions ranging from a cold, snowy winter day to cramped home to a patient's room in a hospital. Three projects will be described that demonstrate our development process:

1. It is difficult for consumers to assess the performance of footwear - most marketing information available to consumers is misleading. We have a developed a method for accurately measuring footwear slip resistance by having participants walk on ice and snow covered surfaces to determine the maximum angle that each type of footwear can achieve (Figure 1).

2. Development of the MoveEasy Pole System (Figure 2): An affordable, modular system of pressure-fit vertical grab poles and clip-on horizontal rails. The MoveEasy system can be easily installed using pressure-fit poles in areas where the user needs support without permanently modifying the home (no screws or nails are needed).

3. Caregiver back injury prevention with a novel patient lifting tool called SlingSerter (Figure 3) that removes the need to turn/log-roll patients when inserting a sling under them. This device makes using a patient lift effortless even with very large bariatric patients.

Figure 1. WinterLab being used to test footwear slip resistance on ice.

Figure 2. HomeLab being used to test the MoveEasy Kit.

Figure 3. SlingSerter being tested in CareLab.

SP145.2 - The effect of age and previous exposure to slippery surface on gait adaptation

Author(s): Sharon Ravindran¹, <u>Yue Li</u>², Adam Katchky², Tilak Dutta², Geoff Fernie³

¹Engineering Science, University of Toronto, Toronto/CANA-DA, ²Technology Lab, Toronto Rehab, Toronto/ON/CANADA, ³Surgery, University of Toronto, Toronto/CANADA

Introduction

Falls are a leading cause of injury in Canada [1]. Many falls result from slipping on ice [2]. Humans adapt their gait when exposed repeatedly to a postural challenge or in anticipation of a slippery surface to prevent injury [3]. It is unclear whether individuals will continue to employ gait adaptations when moving from a slippery to a non-slippery surface. This study examines the gait adaptations of both young and older adults after walking on ice to understand the preventative strategies adopted.

Methods

Twelve younger adults (7 females-5 males;19-34 years) and twelve older adults (8 females-4 males;65-78 years) participated in this experiment. Harnessed participants walked along surfaces made of concrete (baseline surface) and wet ice, both 4m by 0.5m. Reflective markers on the footwear and pelvis were used to quantify kinematics using motion capture system before and after walking on a weticy surface. All participants wore the same winter boots and walked at a preferred self-selected pace. All variables were analyzed with a mixed model repeated measures ANOVA, with significance defined as p<0.05.

Results

Younger participants demonstrated significant decrease in adaptive gait changes in floor foot angle (FFA) and anterior-posterior distance from the pelvis to the heel (PHAP) at heel contact, and step time between both baseline surfaces (Table 1). Age was not found to have a significant effect on the change of any of the gait parameters. A decreased FFA is often associated with hazardous slips, indicating a flatter foot was preserved after walking on a slippery surface[4]. Younger participants shifted their centre of mass anteriorly (indicated by reduced PHAP) thereby adopting a more conservative gait strategy [5] and possibly a mechanism to prevent backward falls.

		Younger Pop	sulation (n=12)		Older Population (n=12)				
	Before Wet	ice Surface	After Wet Io	e Surface	Before Wet	ice Surface	After Wet ic	e Surface	
Variable	Mean	510	Mean	\$1.0	Mean	5eD	Mean	\$eD	
D_Piv_Heel (m)	0.38	0.02	0.35*	0.04	0.38	0.05	0.37	0.05	
FFA (")	27.9	4.8	25.2*	6.2	25.4	4.9	23.9	6.1	
T_step (s)	0.38	6.03	0.37*	0.03	0.38	0.04	0.37	0.04	

Table 1: Data was collected in Winter Lab in the Challenging Environment Assessment Laboratory at Toronto Rehab. Twelve younger (Y) participants (7 females, 5 males, age: 24.6.5.4.8, weight: 67.6.213.2 kg) and twelve older (D) participated in this experiment. D, Mc, Meel represents the anterior: postciol dataset from the pelvis to the heel in meters (m) at heel contrast (HC). FFA represents the floor foot angle at HC, measured in degree (Y). T_step is the amount of time taken to complete one step, measured in seconds (s). (*) indicates a 9 - 0.05 between the baseline confittion before and after the weil ice surface.

Discussion & Conclusion

Younger participants showed adapted gait strategies after walking on a slippery surface, demonstrating the preservation of adaptations when walking on a non-slippery surface. Age was not found to be a significant factor; only young adults altered their gait to prepare for future surfaces. The alteration was small but statistically significant. Further research is required to investigate whether this conserved gait strategy represents a large enough modification to be beneficial in preventing future falls and moreover, understanding the implications for the lack of gait adaptation by older adults.

SP145.3 - An intelligent rollator for people with mobility impairment

Author(s): <u>Olof Lindahl</u>¹, Tomas Bäcklund¹, Marcus Karlsson¹, Thomas Hellström², Peter Hohnloser², Anna Bråndal³, Xiaolei Hu⁴, Per Wester³

¹Radiation Sciences/biomedical Engineering, Umeå University, Umeå/SWEDEN, ²Computing Sciences, Umeå University, Umeå/ SWEDEN, ³Public Health And Clinical Sciences, Umeå University, Umeå/SWEDEN,⁴Community Medicine And Rehabilitation, Umeå University, Umeå/SWEDEN

Assistive technology for the mobility impaired includes canes, wheelchairs and walkers. The walker is a very common mobility device and is used by approximately 0.7 percent of the population according to statistics for US in the mid 1990's. Corresponding statistics for Sweden show almost 4 percent in 2003. More than 47,000 accidents related to falls associated with walkers and canes occurred in the US 2009. Apart from direct costs related to the accidents, increased and safer usage of walkers may delay transition of the elderly people to nursing homes considerably. Hence, technical improvements of walkers can lead to large cost savings for society, in addition to greater convenience and safety for the users. Possible improvements include support for collision avoidance, automatic braking, navigational support, and additional functionality like automatic parking. Navigating walkers in small passages and doorways are regarded as particularly problematic.

We describe the development of an automated walking aid, an intelligent rollator (IRO). While walkers strictly do not have wheels, and rollators do, the two words are often used interchangeably. We refer to IRO as a rollator, while other walking aids most often are referred to as walkers. IRO functionality for indoor and outdoor use includes detection and avoidance of corners, doorposts, furniture and other obstacles. The IRO rollator is a retrofit on a commercial fourwheeled rollator. The added equipment comprises rollators (Rebel and Carl-Oscar, Human Care), an embedded computer (Arduino Mega 2560), two electrically controlled solenoid brakes (Multicomp MCSMT-3257L 12STD), rotation hall sensors on the wheels (Allegro Microsystems A3423) and a series of IR-distance sensors (Sharp GP2Y0A02). The sensors are used to detect obstacles and direction of motion, and brakes are used to influence the direction of motion. The distance reported by each distance sensor is compared in the computer to the nominal distance determined from reflection against a surface (wall or floor). A shorter distance indicates presence of an obstacle such as a wall or piece of furniture. Negative obstacles such as curbs and holes in the ground cause the distance to be longer than normal and can be detected in a similar fashion. The information from the sensors is used to control the brakes and thereby affect the direction of motion. A detected obstacle to the left causes activation of the right brake, causing the rollator to turn away from the obstacle if and when the user continues to push the rollator forward. This passive control mechanism leads to safer usage. Detection of an obstacle straight in front of the rollator will activate both brakes such that the rollator rather stops than turns. The design also includes a novel approach to detect and prevent sideway drift that may occur both indoors and outdoors. Our approach to use a

commercially available rollator as base, and low cost components with low power consumption is believed to enable an affordable and useful product for the health care market.

Preliminary testing on healthy subjects and patients with stroke in a controlled indoor and outdoor environment shows promising results.

SP145.4 - Rehabilitation Engineering: A review of current teaching tools ad project based learning

Author(s): Anastosis Kessaris¹, Prdrag Pesikan², <u>Charanjit Bambra³</u> ¹Biomedical Engineering Technology, Centennial College, Toronto/ CANADA, ²Biomedical Engineering Technology, Centennia College, Toronto/CANADA, ³Biomedical Engineering Technology, Cetennial College, Toronto/ON/CANADA

Many of Ontario colleges are developing an applied research capacity to participate in industrially relevant R&D activities. The key drivers for Canadian biomedical industry are the aging population, managed care/cost containment, and miniaturization of devices and equipment. Taking into account that only a few formal academic rehabilitation training programs exist in Ontario, rehabilitation engineering was identified as a key area for potential expansion. While "learning by doing" is a popular mantra at many engineering schools, many experts agree that it needs to be formally reinforced through project based learning (PBL). Tools exist for teaching biomechanics and robotics and these have resulted in "Lego Mindstorms" and means for teaching hepatics. A project based educational paradigm is currently being used to design assistive rehabilitation devices (Roach et al., IEEE Pulse 51). A review of currently available teaching tools, and our experience with the project based education in rehabilitationengineering, will be presented.

SP145.5 - Effects of sloped icy surface on older adults' gait in a simulated winter environment

Author(s): <u>Yue Li</u>¹, Sharon Ravindran¹, Adam Katchky¹, Tilak Dutta², Geoff Fernie²

¹Technology Lab, Toronto Rehab Institute - UHN, Toronto/ON/CAN-ADA, ²University of Toronto, Toronto/ON/CANADA

Introduction

Falls and fall-related injuries among older adults are a significant and growing public health concern. Fall-related injuries among older adults are associated with adverse weather events[1].Slips and falls occur more frequently while walking up and down slopes[2]. However, older adults' balance and gait on icy slopes have not been examined. This study investigates how older adults alter their gait on icy slopes.

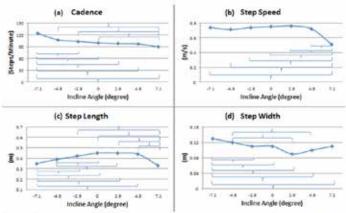

Methods

This study was conducted in WinterLab (Challenging Environment Assessment Laboratories). The ice walkway was 4m long by 0.5m wide and 7 incline angles were tested (-7.1°,-4.8°, -2.9°, 0°, +2.9°, +4.8°, and +7.1°). A positive angle denotes walking uphill, negative angle denotes walking downhill. All 12 able-bodied older adult participants (65-78 years; 4 male, 8 female) wore the same type of winter boots and walked at their preferred self-selected pace. Step length, step width, step speed and cadence were calculated using an motion capture system (Motion Analysis) tracking reflective makers placed on participants' footwear. All data were analyzed across 7 slope angles with a mixed model repeated measures ANOVA (p < 0.05).

Results & Discussion

During uphill walking on the icy surface, as the angle of incline was increased, older participants increased their step width and

decreased their cadence, step length and walking speed (Figure 1) to avoid a slip[3]. However, during downhill walking, when the incline angle increased to 7.1°, older adults increased their cadence significantly but did not change their walking speed. Moyer et al.[4] showed that hazardous slips were associated with greater step lengths and decreased cadence, and that walking with increased cadence was beneficial when anticipating a slippery floor [5]. Older participants appeared to intuitively increase their cadence and step width while decreasing step length, in order to negotiate the most slippery condition (downhill at 7.1°).

Conclusion

Spatiotemporal kinematic data were measured and analyzed for 12 able-bodied older adults walking on level, up and downhill slopes. A similar data set has not been previously reported for a cohort on this range of inclines on an icy surface. When walking on the sloped icy surface, older adults adopted different strategies for uphill and downhill walking. Additional research is needed to determine if this gait speed control strategy is effective for reducing slip events.

SP145.6 - Judging Weight of an Object by a White Cane

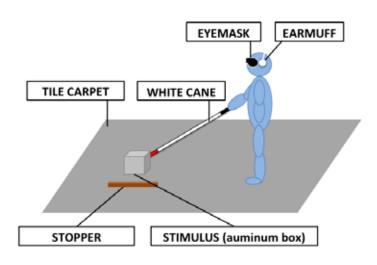

Author(s): <u>Kiyohiko Nunokawa</u>¹, Kouki Doi², Manabu Chikai³, Shuichi Ino³

¹School Of Human And Social Sciences, Tokyo International University, Kawagoe/JAPAN, ²National Institute of Special Needs Education, Yokosuka/JAPAN, ³National Institute of Advanced Industrial Science and Technology, Tsukuba/JAPAN

The purpose of this study is to collect basic knowledge to develop an operation method that improves the accuracy of a white cane target recognition. The primary purpose of using a white cane is to be able to detect street conditions and obstacles based on the reverberations and tactile information that is gathered from the tip. But some users reported being able to differentiate between specific kinds of materials and objects. Allowing the recognition of target attributes through the contact of a white cane is an important function. In training courses for the visually impaired, three methods

are taught for holding a white cane: 1) stretch the index finger across the flat face of the grip and lightly hold the grip with the thumb and other three fingers, 2) hold the grip like a pen or pencil, and 3) press the thumb on the flat face of the grip and hold the grip with the four fingers. Different methods can be selected based on the circumstances. In this study, to understand a weight perception using white canes, we compared using a hand pushing and using a white cane without accompanying auditory information. And to examine the influence of a manner to grasp a white cane on object's weight perception, we compared the three methods for holding a white cane. Participants were sighted university students. They gave magnitude estimates for six weights that changed by 100g from 500g to 1,000g. Results indicated that using a white cane produced higher sensitivity level than using a hand. Therefore, using a white cane enhances the information of object's weight. And the difference of sensitivity for weight perception was caused by manner to grasp the white cane.

SP145.7 - The Effect of Sub chronic Low Dose of DDVP and Sodium Azide on some Bone Biochemical Indices of Albino Rats Author(s): <u>Patrick U. Agbasi</u>

Prosthetics And Orthotics, FEDERAL UNIVERSITY OF TECHNOL-OGY OWERRI NIGERIA, OWERRI/NIGERIA

Background: The frequent use of organophosphorous insecticides in our everyday life especially in our houses, offices and even against pests to preserve foods and agricultural products especially in the third world and sodium azide (a herbicide) extensive use in the farms have necessitated this study. Purpose: This research is designed to investigate the effect of low dose DDVP (dichlorvos) and sodium azide co-administration on some bone biochemical parameters (calcium and phosphate) of Albino rats bearing in mind the rising cases of chronic arthritis and deformities. Method: Seven groups of five rats each were used for the study. Group A was used as control and received no chemical treatment, groups B and C were injected with 1% and 3% LD50 of sodium azide respectively, while groups D and E received 1% and 3% LD50 of DDVP respectively. Equally, group F received combined doses of 1% LD50 of DDVP and 1% LD50 of Sodium azide while group G received 3% LD50 of DDVP and 3% of LD50 Sodium azide. The chemicals were administered at alternate days for twenty one days. At the end of twenty one days study period, the animals were anesthetized with chloroform and blood were aspirated through cardiac puncture into empty clean 5ml containers and then allowed to clot. The serum were then separated and frozen before calcium and phosphate estimations were carried out. Results: The two dose levels of sodium azide did not produce any statisticant significant effect on calcium and phosphate levels where as 3% DDVP did. The calcium and phosphate values of group G (3% LD50 of DDVP and 3% LD50 of Sodium azide) produced significant increase when compared to control and also dose dependently increased compared to group F.

Conclusion: Co- administration of DDVP and sodium azide produced significant increase in calcium and phosphate values in rats in sub chronic administration.

The effect low dose DDVP and Sodium azide on the calcium and phosphate values Albino rats

Group	Calcium	Phosphate
Group A Control	2.08±0.08	3.58±0.09
Group B		
(1% sodium azide)	2.08±0.16	3.54±0.06
Group C		
(3% sodium azide)	2.2±0.15	3.6±0.12

TRACK 12: MEDICAL DEVICES

SP146.1 - Development of Personalized Tourniquet Systems Using a New Technique for Measuring Limb Occlusion Pressure

Author(s): <u>James Mcewen</u>¹, Bassam Masri², Brian Day², Alastair Younger²

¹Electrical And Computer Engineering, University of British Columbia, Vancouver/CANADA, ²Department Of Orthopaedics, University of British Columbia, Vancouver/BC/CANADA

A new technique has been developed to facilitate safer personalized tourniquet systems for surgery, using a unique dual-purpose tourniquet cuff that enables automatic measurement of tourniquet Limb Occlusion Pressure (LOP), while overcoming limitations inherent in manual and automatic techniques of LOP measurement. A study was performed to determine the accuracy of this new technique compared to LOP measured using a gold standard Doppler ultrasound technique. 252 pairs of LOP measurements were taken from upper and lower limbs of 143 surgical patients, enrolled from three different surgical clinics, using the new technique and the Doppler technique. LOP difference was defined as new technique reading minus Doppler technique reading. The mean LOP difference (new-Doppler) \pm SD mmHg was $+0.56 \pm 11.73$ for all limbs (252 limbs). $+0.99 \pm 7.79$ for upper limbs (134 upper), and $+0.08 \pm 15.03$ for lower limbs (118 lower). Additional analysis was performed to further improve the performance of the new technique by noise detection and by development of rules allowing identification and removal of outlier data prior to completion of each LOP measurement. In this study, the additional analysis removed 3/252 pairs of LOP measurements and reduced the SD: mean LOP difference (new-Doppler) ± SD mmHg was improved to +0.30 ± 10.31 for all limbs (249 limbs), $+0.99 \pm 7.79$ for upper limbs (134 upper), and -0.50 ± 12.62 for lower limbs (115 lower). We conclude that the new technique of LOP measurement has surgically acceptable accuracy comparable to LOP measurement by Doppler ultrasound. Additionally, the new technique may facilitate adoption of safer personalized tourniquet systems by incorporating inherent advancements over manual and automatic techniques of LOP measurement, including: elimination of a distal LOP sensor; reduced procedural complexity and surgical time; related improvements in the rate of success of LOP determination; and reduced direct and indirect costs.

SP146.2 - Vertebral Metrics – development of a third and improved prototype

Author(s): <u>Ana Teresa Gabriel</u>¹, Cláudia Quaresma², Mário Secca³, Pedro Vieira¹

¹Physics, Faculty of Sciences and Technology New University of Lisbon, Caparica/PORTUGAL, ²Physics, LIBPhys-UNL, Faculty of Sciences and Technology New University of Lisbon, Caparica/POR-TUGAL, ³Ressonância Magnética, Caselas/PORTUGAL

Back pain is among the most common health problems worldwide and is the leading cause of activity limitations. A forehand identification of people affected by spinal disorders is extremely important because early and specific interventions may be applied. Methods currently available to assess spinal curvatures include several types of diagnostic imaging, however, the most frequently used techniques are not radiation free and, for that reason, its application should be avoided. Vertebral Metrics is a non-invasive system that was designed to study the biomechanical changes of the spine. Through the identification of the tridimensional position of the vertex

of the spinal processes it is able to provide a 3D reconstruction of the spinal column, in the standing position. Studies with the two previous prototypes indicated that the equipment is reliable and has sufficient accuracy for the global evaluation of the spinal column. however, the required time for data collection is too long. Because of that the further development of the system has become necessary. The required steps to develop a new prototype are presented in this work. Before each scan a fluorescent dye will be used to identify the spinal processes above the skin. During a complete scan, the improved device will move upwards while is recording a video of the back. Once finished the video recording, image processing algorithms will be applied to recognize the fluorescent marks in the skin. The stereo vision method will be used to determine the spatial position of each mark. Preliminary tests were performed using a skin phantom. Fluorescent points became clearly visible in the binarized images. The determined position of each point is very close to reality. In addition, pictures of the skin were collected and binarized. The perfectly identification of the fluorescent marker in the images is a huge success for the development of equipment ...

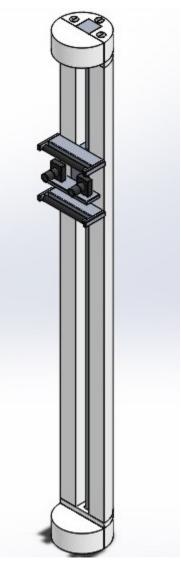

Figure 1 Scheme of Vertebral Metrics.

SP146.3 - Does low-intensity pulsed ultrasound stimulation effectively promote bone fracture repair? An overview Author(s): Orlando Rey R. Rúa

Física Industrial Y Bioingeniería, Instituto de Cibernética, Matemática y Física, La Habana/CUBA

This work is an overview of evidences to evaluate the effectiveness of low-intensity pulsed ultrasound (LIPUS) stimulation to promote bone fracture repair. A search of MEDLIN, LILACS and Google Scholar was performed using the keywords 'low-intensity ultrasound' and 'bone fracture', limited to English and Spanish languages up to December 2014. Clinical eligible studies were randomised and quasi-randomised trials (RCTs) that considered skeletally mature patients with any kind of fractures. Also, special attention was dedicated to the results reported in previous reviews and metaanalyses conducted in the issue, resulting finally 19 trials for our analyses. Furthermore, LIPUS physical mechanisms of action that can be paralleled to an improvement of bone healing and the associated biological responses were reviewed. It was found that the efficacy of LIPUS to enhance fracture healing is reported controversially in several RCTs, showing substantial heterogeneity in the related outcomes. In addition, there was not appreciated a consensus concerning how to evaluate the efficacy of LIPUS therapy regarding to important outcomes for the patient. Therefore, the impact of this physical intervention in the medical management of bone fracture is relatively limited nowadays. But, frequently insufficient attention has been devoted to the ultrasound beam profile and its characteristic parameters that finally determine the local ultrasonic cellular or tissue stimulation, in a context that besides consider the biomechanical model utilized to validate the therapy, even for a process of fracture healing consistent for all fractured bones. Despite, when the healing criterion was a radiological and/or a clinical healing of the fracture, LIPUS significantly shorten the time to the radiological union for acute fractures undergoing non-operative treatment and acute fractures of the upper limb, the clinical and radiological healing of non-operative treated distal radius fractures and the treatment time in tibial distraction osteogenesis. On the other hand, physical mechanism of action of LIPUS and its mechanotransduction pathways are not well understood, basically by the intrinsic complexity of the biological tissue and the number of cells that respond to the mechanical stimulus in a complex cellular-molecular network of signally pathways. Yet, some of the reported LIPUS induced effects are a higher cellular membrane permeability; in vitro increase of collagen synthesis in human fibroblast; augmentation of intracellular concentration of calcium; stimulation to IGF, TGF-B, VEGF and PDGF-AB growth factors; elevation of levels of PGE2; increment of the vascularity at the fracture site; enhancement to osteogenic activity in human periosteal cells; promotion to osteogenic differentiation of human bone marrow stromal cells. Conclusion: further randomized controlled trials of high methodological quality are needed to investigate LIPUS effectiveness to improve bone fracture repair using a multidisciplinary approach, considering important healing outcomes for the patient.

SP146.4 - Electrical Stimulation of the Calf Muscle to Reduce Seated Leg Fluid Accumulation and Subsequent Rostral Fluid Shift While Supine

Author(s): <u>Daniel Vena</u>, Milos R. Popovic, Azadeh Yadollahi Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/ON/CANADA

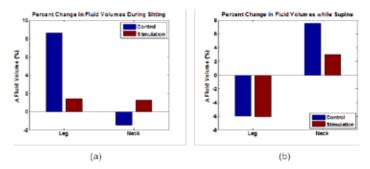

Introduction: A sedentary lifestyle or prolonged sitting could enhance the effects of gravity to increase fluid accumulation in the legs during the day. Upon lying supine, fluid shifts rostrally from the legs and accumulates in the neck. Fluid accumulation in the neck is a risk factor for increases in the upper airway narrowing and resistance during sleep. Therefore, reducing leg fluid accumulation during the day could be an effective method for reducing neck edema when

lying supine and protecting against the partial or complete collapse of the upper airway. The objective of this study is to test the efficacy of electrical stimulation (ES) of the calf muscle pump on reducing daytime leg fluid accumulation and the subsequent rostral fluid shift upon lying supine.

Method: The study is a randomized, single-blind double crossover protocol in which participants sit for two and a half hours and receive either active ES or sham ES (control). Following the seated period, participants lie supine for one hour. After one week, participants crossed-over to the other study arm. Fluid is estimated by measuring bioelectrical impedance in the dominant leg and neck simultaneously and continuously throughout the seated and supine periods.

Results: Two men (age 49 and 63) have completed the protocol to date. Results demonstrate that ES substantially reduces fluid accumulation in the legs, where mean increases in leg fluid were 8.4% (75 ml) with sham ES and only 1.6% (13 ml) with active ES (Figure 1a). Upon lying supine, the amount of fluid leaving the legs was similar, however less fluid shifted into the neck, where mean increases in neck fluid were 7.5% (19.7 ml) with sham ES, and only 3% (8 ml) with active ES (Figure 1b).

Conclusion: Our preliminary results demonstrate ES as an effective means of reducing fluid accumulation in the legs while seated and subsequent rostral fluid shift into the neck when lying supine. Future work is focused on investigating the effects of this reduced leg fluid accumulation and subsequent rostral fluid shift on respiratory pathologies such as sleep apnea.

SP146.5 - Surgical process analysis identifies lack of connectivity between sequential fluoroscopic 2D alignment as a critical impediment in femoral intramedullary nailing Author(s): Hamid Ebrahimi¹, Albert Yee¹, Cari Whyne² ¹University of Toronto, Toronto/CANADA, ²University of Toronto, toronto/CANADA

The current standard of care in lower extremity long bone fracture stabilization is closed intramedullary (IM) nailing. The surgical protocol associated with this surgery is well defined. Yet, challenges arise that impede the surgical workflow, add operative time and radiation exposure (to patients and medical staff), and lead to frustration in the operating room. Clear description and analysis of a surgical process can expose challenging steps and activities that can facilitate surgical workflow optimization, guide surgical technology development, improve surgical planning, and enhance surgical training and education. To date, a number of studies have presented methodologies to model individual surgical process models or to develop generic surgical process models. Comparisons between surgical process models have also been studied with respect to procedure parameters such as operating time, number of activities, etc., to evaluate the impact of surgeon experience or to understand differences in terms of sequentiality of activities during surgeries. However, implementation of identified surgical models to optimize the surgical process has received little attention. Hence, the aim of this study was to map the IM nailing process, identify surgical challenges that impede the surgical process and elucidate their underlying causes.

This study consisted of semi-structured interviews and surgical observations. Eight surgeons from community (three) and teaching hospitals (five) were interviewed to identify the IM nailing surgical procedure, surgical challenges, and their use of adapted surgical techniques. During the eight IM nailing surgeries, information on the surgical procedure was grouped into activities (physical tasks), steps (sequence of activities) and phases (major events) to represent different levels of granularity in the surgical process. In steps identified as challenging or when barriers were encountered, individual activities were analyzed to elucidate underlying causes.

Seventy-five percent of surgeons identified reduction as the most challenging step of IM nailing, consistent with the surgical observations. The greatest challenges were manipulation of fracture fragments for realignment and identifying their 3D orientation using 2D x-ray images (where fragments aligned in one plane were misaligned out of plane). Adapted manipulation techniques used universal chucks with T-handles, mallets, wraps or Shanz screws. In one unsuccessful case the fracture was opened to allow realignment. The entry point step was identified as most difficult by 25% of surgeons, due to challenges in access and 3D K-wire orientation. Adapted techniques aimed to alter patient positioning (torso abduction and/ or knee adduction) or eliminate the need for a straight access line through use of an awl. Lateral positing was suggested to facilitate entry point access in obese or muscular patients.

In both the reduction and entry point steps identified as challenging by IM nailing surgical process analysis, 3D alignment was the critical barrier. Utilization of repeated 2D fluoroscopy without connectivity between sequential images to guide reorientation was a consistent impediment to 3D entry point guidewire positioning and femoral fragment realignment. These findings have important implications toward guiding technological improvements and competency based surgical training.

SP147 - Information Technologies in Healthcare Delivery and Management: Part 2

TRACK 14: INFORMATION TECHNOLOGIES IN HEALTHCARE DELIVERY AND MANAGEMENT

SP147.1 - The Electronic Medical Record: Can it be integrated with Treatment Delivery and Management? Author(s):

In the United States (and other venues), there have been numerous efforts to promote an integrated Electronic Medical Record (EMR), one that will incorporate all (or at least key) aspects of the patient's history (medical and social), diagnostic examinations, treatments, results, and follow-ups. The Meaningful Use (MU) program has as one of its goals to provide improved clinical decision support (CDS) to healthcare providers. The reality is that current EMR systems function more as data repositories, providing much improved access to clinical information, but not making the leap to true clinical decision support. There are many impediments to closing this gap, including the reticence of most EMR manufacturers to enter the realm of treatment delivery, which would likely result in significant changes in their FDA risk classification. This has been shown in Radiation and Medical Oncology Information Systems, some of the earliest EMR systems to be fully integrated into the treatment process, but not connected to ambulatory EMR systems due to the differences in FDA classification.

SP147.2 - AIM Quality Assurance Program Development for CT X-Ray Systems

Author(s): Douglas J. Mctaggart

Medical Engineering, University Health Network, Princess Margaret Cancer Centre, Toronto/CANADA

The University Health Network purchased Toshiba Aquilion CT X-ray systems that offer improved diagnostic image quality. It is clinically important to maintain good image quality on these systems. The problem that was addressed was how to develop and implement a comprehensive CT image quality assurance program at the University Health Network.

Important image quality parameters were identified using X-ray system specifications. An appropriate image quality test phantom was selected and evaluated using measured results. This topic deals with the technical problem of how to develop and implement an x-ray image quality assurance program for the Toshiba Aquilion CT systems at the University Health Network. This is a significant project because the outcome will assist both the technical and clinical staff to monitor and maintain the stability of the image guality of the CT system. Optimal image guality is essential for the clinical staff to view patient anatomy and perform an accurate diagnosis of the patient's condition. The project will deal with the selection of an image quality phantom, establishing baseline data derived from the phantom and storing the data for future reference. An important objective is to provide a user friendly interface for viewing the image quality data. Since the scope of the project deals with CT scanners across five hospitals, the process must be clear and concise to all clinical users of the image quality program. It was decided that the best way to implement a program like this was to develop a website interface to allow all clinical users to access the image quality data on the available desktop computers. This presented the problem of setting up a dedicated image quality server and creating software that will satisfy the needs of the image quality assurance program.

Another challenge of the project was to develop a quality assurance program that will satisfy the corporate vision of the University Health Network. This vision is concerned with achieving global impact. The work done in this report will be relevant to Canadian standards and incorporate global standards as well. These standards were used for build a formal AIM CT Accreditation Program. This internal UHN CT Accreditation program was developed to satisfy the needs for a standardized annual testing of CT dose and image quality parameters.

A comprehensive quality assurance program was then developed and implemented. The program was used to baseline existing system parameters and record variations in image quality. The AIM server provided an ideal centralized interface to store and display CT image quality data, CT Accreditation reports and CT clinical protocols. It is recommended that a CT image quality program be used at other hospitals to maintain and improve system performance and clinical protocol standards.

SP147.3 - Evaluation of Improved Automatic Speech Recognition Prototype for Estonian Language in Radiology Domain Author(s): <u>Andrus Paats</u>¹, Tanel Alumäe², Einar Meister², Ivo Fridolin¹ ¹Department Of Biomedical Engineering, Technomedicum, Tallinn University of Technology, Tallinn/ESTONIA, ²Laboratory Of Phonetics And Speech Technology, Institute Of Cybernetics, Tallinn University of Technology, Tallinn/ESTONIA

The aim of this study was to determine the dictation error rates in finalized radiology reports generated with a new automatic speech recognition (ASR) technology prototype for the Estonian language. Apart a preliminary attempt, no Estonian language based ASR systems exist currently in radiology. Lack of a mother-language supported ASR system for under-resourced and agglutinative languages could be one reason. The scientists from Tallinn University of Technology in collaboration with radiologists from North-Estonian Medical Centre (NEMC), Tallinn, Estonia, took a step closer towards an ASR application in radiology for Estonian language by performing a study using Estonian based models.

The training of language model was performed in two steps. Firstly, for training a language model, 177 659 real radiology reports from different imaging modalities were used including 77 067 x-ray, 30 929 ultrasound, 28 825 computed tomography, 14 815 mammography, 12 082 endoscopic, 8 792 magnetic resonance tomography, 3 950 radiology consultation and 1 199 angiographic reports. Manually normalized versions of 1299 randomly selected reports were created to standardize the report corpus. The ASR prototype, incorporating the trained language and acoustic models, was tested in Radiology Department, North Estonia Medical Centre, Tallinn, Estonia, by 17 radiologists (11 female and 6 male). In total, 261 reports were dictated, including 13 x-ray, 12 ultrasound, 119 computed tomography, 37 mammography, 12 endoscopic, 66 magnetic resonance tomography, and 2 angiographic reports. Word error rates (WER) and report error rates (RER) were calculated for each speaker and modality.

In second phase, the model was improved by taking account the errors from the first test. Moreover, applying of deep neural network based acoustic model and adapting acoustic and language model based on dictated speech, an enhanced ASR prototype was achieved. Additionally, 500 000 real radiology reports from different imaging modalities were included into model training. In the first ASR prototype, total WER over all material was 18.4% and total RER 93.1%, not sufficient for clinical practice. Live experiments with the ASR prototype showed differences between the users depending on their experience and speech characteristics. An improved ASR prototype was applied onto dictated records resulting total WER 5.0%, which is acceptable for real clinical use. In summary, the ASR prototype for Estonian language in radiology domain was the first time successfully applied and assessed in routine clinical practice. User feedback based automatic correction of language model is planned to implement into next ASR prototype.

SP147.4 - Usability engineering approach towards secure open networks in the integrated operating room of the future Author(s): <u>Klaus Radermacher</u>, Armin Janss

Chair Of Medical Engineering, RWTH Aachen University, Aachen/ GERMANY

Nowadays, the number of technical systems in the operating room increases constantly. Besides improving the therapeutic guality, these changes may also lead to new human-induced risks for patients, therapists and third parties. In particular, within intraoperative activities requiring a safe and fast operation, surgeons and nurses rely on sophisticated and efficient solutions in terms of Human-Machine-Interfaces in order to perform their tasks effectively, efficiently and reliably [1]. Therefore, proprietary integrated workstations with a central user interface cockpit have been provided for the operating theatre in recent years. Risk management as well as usability validation have to be provided by the integrating manufacturer. However, these "monolithic" solutions limit the flexibility of the operators and users regarding interoperability and integration of independent innovative devices in these integrated OR solutions. Against this background, the project OR.NET - Secure Dynamic Networking in Surgery and Clinic - funded by the Federal Ministry of Education and Research (2012-2015; overall budget 18,5 M€; www.ornet.org) is a national flagship project involving more than 50 partners from the fields of research, industry, clinical operators and standardization,. The main objective of the OR.NET project is to develop the technological as well as legal and operational basis for an open platform and standards for the modular dynamic integration of medical devices and IT systems into the future operating room and its clinical environment. Regarding the aspect of usability engineering, open modular integration, a modular definition of workflows, contexts of use as well as device configuration scenarios seems to be mandatory. Whereas modular standardization on an abstract application specific level limits flexibility to a certain extend, it enables risk management and usability control of modular networks. In this context, we develop a concept of Medical Device Profiles (technical specifications) including Medical Devices User Interface Profiles (MDUIP) representing specifications of human resources required for the interaction with the specific device and related process-dependent medical device functionality for the modular design of a central user interface in the integrated operating room. The use of standardized MDUI Profiles will allow the manufacturers to integrate their medical devices, respectively the provided functions in the OR.NET network, without disclosing the risk analysis and related confidential know-how or proprietary information- and without explicit knowledge on the final configuration of the device set-up and combination in the integrated OR. The MDUI Profiles will allow both, an automated optimized selection and composition of various user interfaces, and implicitly an optimal design of a central GUI with respect to the criteria of usability and an integrated human risk analysis in terms of Human-Machine Interaction. The concept has been evaluated for neurosurgery. The overall OR.NET concept and the evaluation of the MDUIP approach for the integration of an ultrasound dissector and an OR microscope in a neurosurgical test scenario (navigated spinal decompression) will be presented.

SP147.5 - Whiteboard ESB: Next Generation Data and Workflow Management for Radiation Oncology

Author(s): John Wolfgang¹, Harold Beunk², Hanne Kooy¹ ¹Radiation Oncology, Massachusetts General Hospital, Boston/ UNITED STATES OF AMERICA, ²Healthcare, ICT Automatisering, Eindhoven/NETHERLANDS

Introduction

The practice of Radiation Oncology has evolved into a data dependent operation involving a diverse set of specialized subsystems whose interactions in the clinical environment require careful management. While much effort has been applied to the quality and efficiency of the operations themselves (e.g. dose calculation, delivery, image fusion, segmentation), the interoperability and data management of these systems has been of a secondary concern.

This work introduces a electronic service bus to improve data and workflow management infrastructure for the evolving radiotherapy clinic, we refer to as the MGH Radiation Oncology Whiteboard. Using a web-based architecture to maximize access, ideas such as data immutability, data availability and data-driven workflow management are directly addressed. This new system has been designed using DICOM 2nd Generation models, and implements IHE-RO standards in order to ensure interoperability between the multiple subsystems encountered in a radiotherapy clinic.

Methods

The intent of this system is to support 'best-of-class' technologies in a multiple vendor environment rather than reliance upon a single monolithic software implementation. In this implementation, all systems interact with a central patient context constructed from interactions with the service applications tasked with patient care operations.

Such a system allows for direct workflow management, where activities are orchestrated by a centralized workflow logic management system. Given the patient state from all proceeding states, the system is able to automate the next steps in the patient workflow sequence. Ideally this system shall integrate all clinical subsystems, including but not limited to; CT simulation, intake, PACS, treatment planning, treatment QA, image fusion and segmentation and treatment delivery.

Workflow management is implemented using the DICOM UPS pull model, where subsystems, corresponding to desired activities, are provided with worklists. These worklists defined and orchestrated by the workflow management system, define the tasks to be performed along with the corresponding data needed to accomplish this task. Extending the functionality, the system may then automate much of the information access requirements of the task, pushing the appropriate data as referenced by the patient model to the appropriate subsystem and initializing the task itself.

This design allows for the proactive design of clinically "safe" workflow models where the underlying workflow business logic may be interrogated to identify hazardous workflow operations. These clinical behaviors may then be mitigated before clinical implementation occurs.

Treatment session management is provided as a service in this architecture, where the IHE-RO IPDW (Integrated Position and Delivery Workflow) model is applied to a proton treatment facility. The system introduces management of imaging, registration, positioning and treatment activities, requiring a return from the positioning and delivery system a report regarding the performed procedures.

Conclusion

This system introduces a careful redesign of information system architecture for the radiation oncology clinic. Motivation for this change comes from risk abatement due to unmanaged clinical subsystems and ad-hoc practice behaviors from care givers. By providing clinical workflow management, we aim to focus the clinician on patient care decision operations and automate the information gathering tasks, maximizing the strengths inherent in an electronic information environment.

SP148 - Medical Devices / Surgery, Computer Aided Surgery, Minimal Invasive Interventions, Endoscopy And Image-Guided Therapy, Modeling And Simulation

PRESIDENTS CALL

SP148.1 - Oncometer

Author(s): Priyajit Ghosh

Electronics And Communication Engineering, asansol engineering college,india, durgapur/INDIA

Cell culture is a process by which cells are grown under controlled conditions.Using artificial cell cultured medium/growth medium we wish to artificially culture different types of cells in the body.Apart from common salts, amino acids, sugars, vitamins and organic nutrients that are required, we also require catalysts which promote cell division. The artificial cultural medium will be contained in a specifically designed piezoelectric container. A piezoelectric container is a normal artificial cultural container but it will be connected to a piezoelectric crystal in one of its sides.As the cells in the cultural medium grows, the inner compartment gets filled.it applies pressure on the piezoelectric crystal which is measured using a sensitive device. We wish to use this mechanism on cancerous cells.unlike normal cells,cancerous cells have different properties.cancerous cells would not exhibit the property of contact inhibition and if the growth nutrients and catalysts in the cultural medium are sufficient, the cells would grow enough to exert more pressure on the crystal and therefore a high volatage would be generated.

Using the above results,we aim to build a simple device based on simple mechanisms which can detect cancer cells.the device will basically contain 2 compartments as shown in figure below---As shown above,the first compartment has a piezoelectric crystal on its boundary,the second one consists of an artificial cultural medium.a common movable wall in between will separate the 2 compartments.one side of the wall will have a protruding flat hammer head pointing towards the piezoelectric crystal at the boundary of the device.

When the cell sample will be given into compartment 2,cells wold start dividing.however normal cells on account of their property of contact inhibition,would stop dividing after sometime without exerting sufficient pressure to move the inner wall.

If the sample contains cancer cells, they would continue to divide and in sometime would create a mass of cells large enough to start exerting pressure on the inner wall.after sometime, the inner wall would move towards compartment 1 and strike the piezoelectric crystal.the crystal would generate voltage from the sudden pressure and the voltage output would be recorded.sufficcient experiments would be conducted to see the value of voltages, as well as time range of producing the voltage.also it will be taken care if practically normal cells produce miniscule voltages, but then we would also note the differences of voltages produced.The voltage value would be recorded using a special circuit so that the output can be checked anytime who is using the device,

We wish to create a potable,home using cancer testing device.

SP148.2 - Ways to outreach medical devices in low resource countries (LRC)

Author(s): K Siddique Rabbani

Biomedical Physics & Technology, University of Dhaka, Dhaka/BAN-GLADESH

ECG and X-ray machines were invented more than one hundred years back, still almost 80% of global population living in the LRCs does not get benefits of these devices. We can easily visualise the situation with more modern equipment. This failure pains us as scientists or engineers. Some factors for this failure, particularly in medical devices, are: i) design and manufacture only in the developed countries of the world, ii) long periods of patent protection allows some people or group to monopolise, leading to technology disparity and the consequent economic disparity, which in turn caused unaffordability of medical devices in LRCs, iii) engineering education in LRCs not geared to design of devices. Because of manufacture in a remote developed country, the problems faced with the current medical devices in an LRC are, i) the procurement cost is very high, ii) the devices are not user friendly to people in different LRCs as they have different cultures and languages, iii) the devices do not suit local power line abnormalities and weather conditions resulting in premature failure, iv) the devices are not repairable in many instances. The last factor happens because of a) remoteness of manufacturer, b) unavailability and/or high price of spares, c) lack of manpower with adequate technological know-how and d) tendency of manufacturers to keep technology secret, which has increased in recent times with the advent of microcontroller based equipment where software can easily be kept hidden. Again one important point often unnoticed is that the technology innovator in an LRC has also to be the entrepreneur for commercial manufacture. In fact this happened during the industrial revolution in Europe which led to industries that can support R&D for manufacture of new products now. Unfortunately no industrial revolution happened in the LRCs and such R&D based industries do not exist.

Therefore, the single major solution to the unacceptable situation hinted above is empowering persons with engineering background in all LRCs in the design, manufacture and marketing of medical devices. With this aim we have recently initiated a 'Centre for Technology Equalisation (CTE)' in Bangladesh under a registered society. At CTE we are planning to organise a workshop where electronics engineers from the LRCs will be trained in the design, development and commercial manufacture of a computerised ECG machine that we have developed indigenously and which has performed well for more than a year of field trial. What WHO, UN and other world bodies can do is to provide support to such local initiatives for technology development and dissemination, which may have different characters in different countries depending on local situations and conditions. Based on the results of such initiatives, the better ideas and models can then be promoted in other LRCs through special educational, training and other supportive programmes.

SP148.3 - South African – Swedish effort on pre-hospital diagnostics of stroke and traumatic injuries Author(s): <u>Mikael Persson</u>

Signals And Systems, Chalmers Universitry of Technology, Gothenburg/SWEDEN

Global health faces a number of unprecedented challenges that cannot be approached effectively from the perspective of a single discipline or a single country. During the last century many countries in the western world has undergone a transition in the spectrum of diseases away from communicable diseases towards chronic diseases often depending on considerable resources from society. The one billion people living in the world's poorest countries have yet to make this transition and the burden of disease, which is already extremely high, is set to escalate. Stroke care represents one of these major global unmet challenges of the global health care system. The human cost of stroke is horrific. Out of the 15 million people that suffer a stroke each year, 5 million die and another 5 million are permanently disabled. Among stroke survivors, 20% have serious remaining dysfunctions. A much larger proportion has less conspicuous, dysfunctions, which still seriously affect quality of life for the patient and relatives. In the western world, stroke is placed third among reasons for acute death, and first among reasons for neurological dysfunction, resulting in most days of hospital nursing and therefore the most costly disease within western world health care. In the developing world statistics are more uncertain. In South Africa, stroke was found to be the fourth most common cause of death, accounting for 6% of all deaths in 2000.

The purpose of the present project is to start the path towards implementation, of cost efficient, easy to use, diagnostic tools for stroke in the sub-Saharan Africa, where there are very limited resources in terms of medical personnel, hospitals and diagnostic devices. We have developed and tested a new diagnostics system for stroke intended for the around 200,000 ambulances and the 17 million yearly stroke patients, around the world. For the society this product will help reducing the large cost of stroke and traumatic brain injuries. While of uttermost importance for the western world, less developed countries may come to benefit even more due to the potentially low cost and easy handling of the technology used.

SP148.4 - A portable multi-frequency impedance measuring device for biodynamic analysis

Author(s): <u>Takao Nakamura</u>¹, Toshimasa Kusuhara¹, Yoshitake Yamamoto²

¹Graduate School Of Health Sciences, Okayama University, Okayama/JAPAN, ²Okayama University, Okayama/JAPAN

[Introduction]

[Materials and Methods]

The four-electrodes technique is used in the proposed device for the measurement of human body impedance. This device consists of five oscillators whose frequencies are 4, 10, 20, 40, and 100 kHz; a differential amplifier; analog switches for synchronous rectification; and low-pass filters. The voltage signal obtained by adding sine waves of the five frequencies is converted to constant current (RMS value: 250 μ A). The current flows to the human body via two current electrodes and the voltage in the measured body part is detected using two potential electrodes and the detected differential voltage is amplified. The amplified signal is rectified for each frequency using analog switches and low-pass filters (cutoff frequency: 25 Hz). The output signals of this device are resistance *R* and reactance *X*, for each of the five frequencies. This device is powered by USB mobile phone battery.

[Results and Discussions]

The measurement range of the device is 0–80 Ω . The errors in resistance and reactance were less than ±1% and ±2%, respectively. The impedance parameters are calculated from the five sets of resistance and reactance with a numerical optimization. For example, in a conventional system, when 200 sets of the impedance parameters every second need to be measured, the sampling frequency and data acquisition rate must be 2 MHz and 800 kS/s. In contrast, in the proposed device, a sampling frequency of 200 Hz and a data acquisition rate of 2 kS/s is sufficient.

[Conclusion]

The proposed multi-frequency impedance measuring device is sufficiently accurate for measuring bioelectrical impedance parameters. Further, it requires no external oscillator or high-speed A/D convertor, and it is powered by a USB mobile phone battery. Therefore, the proposed device is easy to use, portable, and well suited for outdoor use. A future study will further develop the use of impedance parameters in biodynamic analysis.

SP148.5 - A Study of the Challenges of Donating Medical Equipment to Developing Countries

Author(s): <u>Bill Gentles</u>¹, Beverly D. Bradley², Shahrzad Mirzazadeh¹ ¹International Outreach Committee, CMBES, Toronto/ON/CANA-DA, ²Centre For Global Engineering, University of Toronto, Toronto/ CANADA

Previous studies conducted in the United States and Europe have shown that as much as 70% of medical equipment that is donated to low-income countries is never put into use in these countries [1]. As a result an unnecessary burden is created, and many of the recipients' equipment needs remain unresolved. In this study, funded by the International Development Research Centre in Canada, we are examining the practices of Canadian organizations that donate equipment to developing countries. In addition, we plan to trace the path of shipments of donated equipment from their point of origin, to their ultimate destination. The goal is to better understand why so many organizations are still making inappropriate donations despite the existence of well-publicized guidelines promoting donation best practices [1]. To achieve the goals of the study, we are building on partnerships with the biomedical engineering community in Ghana, including their recently established Biomedical Engineering Association.

To date we have identified about 70 Canadian organizations that donate medical equipment and supplies to developing countries. We have contacted these organizations and asked them to answer a survey questionnaire; we received 43 survey responses. Based on these responses, we approached the most active organizations and asked if we could visit their facilities and interview key staff so that we could better understand their processes. We have visited 12 of these facilities, and conducted telephone interviews with an additional 5 facilities.

We have also hired a research assistant in Ghana to collaborate with us and track down the ultimate destination of some of the shipments of donated equipment from Canada to Ghana. By doing this we hope to gain a better understanding of which shipments had the highest success rate in meeting the needs of the recipients, and what type of planning process was involved in preparing these shipments.

Through the survey, interviews, and shipment tracking, we intend to develop a number of case studies or 'stories of unsuccessful donations' in which we trace the path of a donation from the wellintentioned donor, through the hazards of international shipping and customs brokers, to the final destination – often in the hands of an unsatisfied recipient. We plan to use these case studies to promote as widely as possible a better understanding of the pitfalls of medical equipment donations, and educate Canadian donor organizations on best practices and the causes of unsuccessful donations.

In our presentation at the World Conress, we will present a summary of what we have learned to date, as well as future plans to continue this work. We also hope to make contact with recipients of donated equipment from developing countries other than Ghana, so that we can expand our study in the future.

SP148.6 - The Clinicopathologic Characters and Activity Survey of Sudden Death of Infant in a Depressed Economy: South-Eastern Nigeria Experience.

Author(s): <u>Gideon I. Ndubuka</u>¹, Kenneth Ngwogu², Kenneth I. Nkuma-Udah¹, Chuks I. Kamanu³, Tobias I.N. Ezejiofor⁴, Samuel C. Iwuji¹

¹Biomedical Technology, Federal University of Technology, Owerri, Nigeria, Owerri/NIGERIA, ²Chemical Pathogy, Abia State University, Aba/NIGERIA, ³Obstetric And Gynaecology, Abia State University Teaching Hospital, Aba/NIGERIA, ⁴Biotechnology, Federal University of Technology, Owerri, Owerri/NIGERIA

Sudden death of infant (SDI) is among the clinical conditions called sudden infant death syndrome (SIDS) referred to as death situation in which all clinical causative factors play apparent and hideous roles within an hour of unexpected death of infant within one year of age. To ascertain SDI at ABSUTH, a 6 year study of all infant death cases in record books were searched and two types of questionnaires added. Medical officers and hospital staff involved in infant healthcare were 343, and 1400 mothers contacted were of age ranges 18-40 years. Causes of SDI were respiratory failure 107, RTA 4, circulatory failure 25, alimentary distress 103, trauma and domestic accident 10, and cardiac failure 70 cases. Highest Frequency of occurrence in the vears was observed in 1999 and gave 104. Commonest clinical characters were anaemic heart failure, child neglect and abuse, drug toxicity, heamorrhage, and vagal inhibition. The rapidity with which SDI occurred in 25.2% of 107 respiratory failures was within 10 seconds to 5 minutes, and to 232 cases was within 24 minutes of hospitalization. Common clinical symptoms were mild to high fever, intermittent coughing and vomiting, malnourished body, respiratory distress, and apnea while 77.1% full term birth cases had body weight of 2100 to 2500g. Child neglect and abandonment were evident in 49.3% mothers of lean economies. SDI peak was from 5th to 8th months, at which

periods 112 female and 168 male infants were wean to death by 280 mothers. Yearly highest incidence of SDI is 1999.

SP149 - Iterative Reconstruction

TRACK 01: IMAGING

SP149.1 - Preliminary study on reduction of cartoon artifact in the iteratively reconstructed images from sparse projection views

Author(s): <u>Sunhee Wi</u>, Sajid Abbas, Seungryong Cho Korea Advanced Institute of Science and Technology, Daejeon/KO-REA

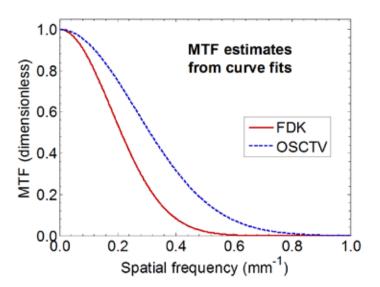

OBJECTIVES In this study, we developed an approach that can help reducing cartoon artifact in the reconstructed images from sparse projection views. Sparse-view CT has been actively investigated as a viable option for low-dose CT, and compressive-sensinginspired image reconstruction frameworks have been developed accordingly. One of the problems in such algorithms is the oversmoothing in the reconstructed images often called the cartoon artifact. Sparsity of the transformed image is maximized during the iterative image reconstruction steps from the insufficiently sampled data, which helps preserve the edge information but may cause such an over-smoothing. The cartoon artifact not only degrades accuracy of the reconstructed images but also may confuse the clinician's interpretation. In this study, we analyzed the noise statistics of the reconstructed images and performed a preliminary study to reduce cartoon artifact.

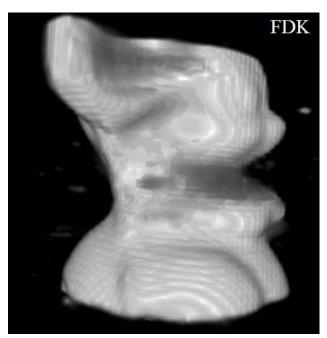

METHODS Projection-Onto-Convex-Sets (POCS)-based Total-Variation (TV) minimization algorithm was employed for image reconstruction from sparse-view projection data set. We separated the noise image using a conventionally reconstructed image from full-views and examined the noise statistics. A random number generation following the investigated noise statistics was realized from Pearson type-4 Distribution and was added to the image pixel values during iterations. The frequency and amplitude of the added noise were empirically determined. We considered a case of using 25% sparse projection views compared to the full-view case, and applied the proposed method. The XCAT numerical phantom was used for simulating a male patient with his heart containing iodine.

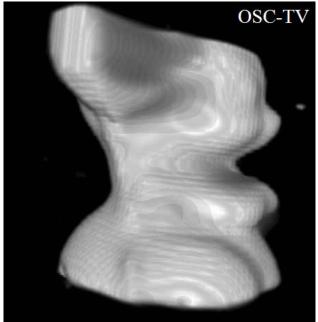

RESULTS Kurtosis of the conventionally reconstructed images from full-views was relatively lower than POCS-TV reconstructed images from sparse-views. Accordingly, the textures of the two reconstructed images were different. Based on the findings in the noise statistics, the parameters in our noise addition module were determined. The reconstructed images using our proposed method visually appeared more similar to the conventionally reconstructed images, and the SSIM value has increased up to near 0.9. In other words, the cartoon artifact was much reduced in the narrow window setting.

CONCLUSIONS Reconstructed images using POCS-TV algorithm have shown severe cartoon artifacts in the reconstructed images from sparse-view data. The cartoon artifact reduction method was proposed to convert noise texture from a cartoon-like noise to a salt-and-pepper noise. Our preliminary study showed that the proposed method maintains the image quality and reduces cartoon artifacts in the reconstructed images. Although more investigation is necessary to optimize the condition of proposed method, the cartoon artifact reduction method seems to be potentially useful for clinical applications of low-dose CT. SP149.2 - Evaluation of the OSC-TV Reconstruction Algorithm for Optical Cone-Beam Computed Tomography Author(s): <u>Dmitri Matenine</u>¹, Yves Goussard², Philippe Després³ ¹Département De Physique, De Génie Physique Et D'optique, Université Laval, Québec/QC/CANADA, ²Département De Génie électrique / Institut De Génie Biomédical, École Polytechnique de Montréal, Montréal/QC/CANADA,³Département De Radio-oncologie, CHU de Québec, Québec/QC/CANADA

This paper evaluates an iterative reconstruction technique, the OSC-TV regularized maximum-likelihood algorithm, in the field of optical cone-beam computed tomography (CT). This imaging modality is commonly used in gel-based three-dimensional (3D) dosimetry for external beam radiotherapy. It is conjectured that model-based iterative reconstruction may improve optical CT image quality and encourage a wider use of this modality in clinical dosimetry. The OSC-TV algorithm was evaluated using experimental data from a commercially available optical cone-beam CT system, and the resulting images were compared with those obtained via filtered backprojection. Physical phantoms were scanned with the goal of evaluating the modulation transfer function, reconstruction precision and accuracy. Reconstruction artifacts were studied as well. The OSC-TV algorithm yielded images of improved quality compared to the filtered backprojections, thanks to a model-based simulation of the photon attenuation process. It was shown to improve spatial resolution, reduce noise and improve accuracy and precision of linear attenuation coefficients' estimation. In addition, image artifacts due to acquisition process and total signal loss were corrected. Overall, this study demonstrates that OSC-TV represents a valuable alternative to filtered backprojection for optical cone-beam CT

SP149.3 - Subjective low contrast performance of four CT scanners with iterative reconstruction

Author(s): <u>Azeez Omotayo</u>¹, Idris Elbakri² ¹Medical Physics, CancerCare Manitoba, Winnipeg/MB/CANA-DA, ²Medical Physics, CancerCare Manitoba, Winnipeg/CANADA

Subjective low contrast performance of four CT scanners with iterative reconstruction algorithms

Introduction

We assessed the subjective detectability of low contrast structures inside a commonly used quality control phantom for CT using modern CT scanners with iterative algorithms.

Method and Materials

We used the Catphan500 phantom low contrast module which

contains cylindrical contrast targets with contrast levels of 0.3%, 0.5% and 1% and diameters ranging from 2 - 15 mm. The module contains a supra-slice set of contrast targets arranged in an outer circumference and a sub-slice set of targets arranged in an inner circumference.

The phantom was scanned at 120 kVp over a CTDIvol range of 1.3 – 19 mGy on 4 different scanners. Images were reconstructed using FBP and the iterative algorithms available on each scanner. We used the following scanners (iterative algorithms): GE DiscoveryCT750HD (ASIR[™] and VEO[™]); Siemens Somatom Definition AS+ (SAFIRE[™]); Toshiba Aquilion64 (AIDR3D[™]); and Philips Ingenuity iCT256 (iDose^{4™}). In total, 328 images were acquired.

Four experienced clinical physicists scored the visibility of the low contrast structures using the 1% nominal contrast supra-slice targets on a 6 MP Coronis Fusion Barco display. 82 images were selected for double rating to check inter and intra-observer reliability. Rater reliability was analyzed using the 'irr' package in the R statistical program using two-way intra-class correlation models. We used the Student's t-test to compare average image scores for different scanners/algorithms.

Results and Discussion

The internal reliability of the rater scores was determined, using the Cronbach's alpha with a value of 0.97. Using the two-way fixed effects model, the inter-rater coefficient was 0.87 while the intra-rater coefficient was 0.93, signifying good agreement and consistency between raters, respectively.

The mean rater scores over the entire dose range on all four CT scanners are as shown. (a) GE Discovery CT750HD: 6.6 ± 1.1 , 6.9 ± 1.1 , 7.5 ± 1.1 , 8.2 ± 1.2 , 7.6 ± 1.2 , 8.4 ± 1.2 , and 7.1 ± 1.3 for FBP, ASIR20, ASIR40, ASIR60, ASIR80, ASIR100 and VEO respectively; (b) Siemens Somatom Definition AS+: 4.9 ± 0.7 , 5.2 ± 0.7 , 5.9 ± 0.6 and 7.6 ± 0.9 for FBP, SAFIRE-L1, SAFIRE-L3 and SAFIRE-L5 respectively; (c) Toshiba Aquilion64: 3.8 ± 0.8 , 4.6 ± 1.0 , 4.4 ± 0.8 and 5.1 ± 1.1 for FBP, AIDR3D-mild, AIDR-3Dstandard and AIDR3D-strong respectively; (d) Philips Ingenuity iCT256: 4.6 ± 0.8 , 4.9 ± 0.8 , 5.4 ± 0.9 , and 5.8 ± 0.8 for FBP, iDose⁴-L1, iDose⁴-L4 and iDose⁴-L6 respectively.

The results showed that, generally, the highest levels of iterative reconstruction gave the highest mean score at all doses for the scanners investigated. The differences in the mean rating scores using iterative reconstructions are statistically significant (P < 0.05) for SAFIREL3 – SAFIREL5, ASIR40 – ASIR100 and all AIDR3D algorithms with respect to FBP, using the average inter-rater scores. In contrast however, the results obtained for ASIR20, VEO, SAFIRE-L1 and all iDose⁴ algorithms were not significantly different (P > 0.05) with respect to FBP.

Conclusion

Our results show that higher levels of the iterative reconstruction algorithms outperform FBP on GE, Toshiba and Siemens scanners. Lower levels of iterative reconstruction algorithms produce similar results to FBP on the GE and Philips scanners.

SP149.5 - Sparse-view image reconstruction with compressed sensing and its application in low dose CT myocardial perfusion imaging

Author(s): Esmaeil Enjilela¹, Ting-Yim Lee¹, Jiang Hsieh², Kelley Branch³, Robb Glenny⁴, Aaron So¹

¹Imaging Research Laboratories, Robarts Research Institute, London, ON/CANADA, ²CT Engineering, GE Healthcare, Greater Milwaukee Area/UNITED STATES OF AMERICA, ³Division of Cardiology, University of Washington Medical Center, Seattle/UNITED STATES OF AMERICA, ⁴Division of Pulmonary and Critical Care Medicine, University of Washington, Seattle/UNITED STATES OF AMERICA

Computed tomography (CT) perfusion is a process by which perfusion to an organ is measured by CT images. This technique requires repetitive scanning together with injection of contrast agent resulting in high radiation dose (~5 to 20 mSv). We have developed a low x-ray dose method for quantitative CT perfusion imaging. It relies on reconstructing dynamic contrast-enhanced (DCE) CT images from sparsely sampled x-ray projections using a compressed sensing (CS) based algorithm. The feasibility of this approach is demonstrated in the myocardial perfusion imaging of a pig. For this purpose, we performed prospectively ECG triggered dynamic CT imaging on a 70 kg farm pig at 140 kV and 80 mA (28 mAs) with a GE Healthcare (GE) CT750 HD scanner with contrast injection (0.7 mgl/kg) at 3 ml/s. DCE images were then reconstructed from all (984) and onethird (328) of available projection views with filtered backprojection (FBP) and CS respectively. Myocardial perfusion (MP) maps from five consecutive 5 mm slices of the porcine heart generated with CT Perfusion (GE) using CS image sets were compared with those from full view FBP reconstruction and also with microsphere MP measurements. Compared with full view FBP MP measurements, CS maps had biases of -0.01 mL/min/g (95% CI -0.05 - 0.03). When measurements from CS MP maps were compared against ex-vivo fluorescent microspheres technique, the mean bias was -0.12 mL/ min/g (95% CI -0.26 - 0.03). This animal study demonstrated that the proposed sparse view coupled with CS image reconstruction is able to generate MP maps with one-third of projection views (sparse-views) required in the conventional FBP technique, resulting in 66.67% reduction in radiation dose.

SP149.6 - Feasibility study for 3D cone-beam computed tomography reconstruction with few projection data using MLEM algorithm with total variation minimization

Author(s): Dong Hoon Lee¹, Ye Seul Kim², Sung Hoon Choi², Haeng Hwa Lee², Hee Joung Kim²

¹Department Of Radiation Convergence Engineering, college Of Health Science, Yonsei university, Wonju/KOREA, ²Department Of Radiological Science And Research Institute Of Health Science, Yonsei University, Wonju/KOREA

Since, the CBCT (cone-beam computed tomography) was developed in 1967, it has been widely used in medical field. The CBCT has relatively simple geometry and less time consuming characteristics to obtain three-dimensional volume data. On the other hand, the major disadvantage of CBCT system is higher radiation exposure to the patient. Thus, it is necessary to apply proper reconstruction method to reduce patient dose.

In this study, simulated sparse projection data was obtained by GATE (Geant4 application for tomography emission) v6.0 simulation tool and those two dimensional projections were reconstructed by MLEM (maximum-likelihood expectation-maximization) algorithm. The total variation minimized image processing method was applied to improve the image quality. The images were evaluated by CNR and FWHM. Furthermore, absorbed dose in simulated phantom was evaluated by GATE v6.0 dose actor.

The images reconstructed by MLEM algorithm and total variation minimized method result in high image quality despite of sparse of projection. Especially image obtained by 60 projections showed comparable image quality with that from 360 projections.

In conclusion, sparse-projection reconstruction with MLEM and total variation minimization is a useful approach to reduce radiation dose with maintaining quality of reconstructed images.

SP149.7 - A weighted stochastic gradient descent algorithm for image reconstruction in 3D computed tomography

Author(s): <u>Davood Karimi</u>¹, Rabab Ward¹, Nancy L. Ford² ¹Electrical And Computer Engineering, University of British Columbia, Vancouver/CANADA, ²Oral Biological And Medical Sciences, University of British Columbia, Vancouver/BC/CANADA

We present and evaluate an algorithm for image reconstruction from a small number of projections in 3D x-ray computed tomography (CT). The proposed algorithm is similar to the class of projected gradient methods. Because each iteration of these algorithms for large 3D CT reconstruction is very computationally demanding, our goal is to devise an algorithm with fast convergence. To achieve this goal, in the proposed algorithm the gradient descent for reducing the measurement misfit term is carried out using a stochastic gradient descent iteration and the gradient directions are weighted using weights suggested by parallel coordinate descent. To further improve the speed of the algorithm, at each iteration we minimize the cost function on the subspace spanned by the direction of the current projected gradient and several previous update directions. We apply the proposed algorithm on simulated and real cone-beam projections and compare it with a well-known accelerated projected gradient algorithm, Monotone Fast Iterative Shrinkage-Thresholding Algorithm (MFISTA). Evaluations show that the rate of convergence of the proposed algorithm is superior to that of MFISTA.

SP149.8 - Investigation of sparse-angle view in cone beam computed tomography (CBCT) reconstruction algorithm using a sinogram interpolaton method

Author(s): Dohyeon Kim¹, Su-Jin Park², Byungdu Jo², Hyemi Kim², Hee Joung Kim¹

¹Department Of Radiation Convergence Engineering, College Of Health Science, Yonsei University, Wonju/KOREA, ²Department Of Radiological Science, College Of Health Science, Yonsei University, Wonju/KOREA

Several methods for reducing patient dose have been widely studied in computed tomography (CT). The radiation exposure dose for patient can be decreased with sparse-angle view reconstruction in CT. In sparse-angle view reconstruction, limited projection images are taken around the object and these are incomplete projection data for obtaining the complete sinogram data. A sinogram interpolation method is the one of solutions to reconstruct the image in sparse-angle view. In this study, we applied a linear sinogram interpolation method in cone-beam computed tomography (CBCT) reconstruction. We simulated the CBCT system with the MATLAB R2012a program to obtain projection data and reconstruct images using three-dimensional version of the Shepp-Logan phantom. Root mean square error (RMSE) was measured in a sinogram interpolation method and normal Feldkamp-Davis-Kress (FDK) reconstruction. The lower RMSE factor means the reconstruction image was similar to the original image. In conclusion, our results demonstrated that the sinogram interpolation method can minimize the error with original image compared with normal FDK reconstruction.

SP150 - X-Ray Phase Contrast & Scatter Imaging

TRACK 01: IMAGING

SP150.1 - Reducing signal extraction artefacts for x-ray scatter imaging with multiple pencil beams

Author(s): <u>Paul C. Johns</u>, Joseph W.S. Carter Physics, Carleton University, Ottawa/CANADA

X-ray scatter imaging is a novel radiologic technology which delivers increased soft tissue contrast. Multiple pencil beams are scanned over the object. The scatter image is built by extracting the low-angle scatter cross section integrated along each primary beam from the captured dataset of overlapping scatter patterns. The resulting image is much more sensitive to tissue composition than are conventional projection images which are based on the primary linear attenuation coefficient. In our work, a Maximum Likelihood-Expectation Maximization (ML-EM) iterative algorithm is used to disentangle the scatter patterns.[1]

Artefacts can arise from the signal disentanglement. E.g., when a bright scatter signal is adjacent to a dim signal, the algorithm generates ghosts of the signal from one pencil beam location to another. We investigate the reasons for this and possible improvements to the signal extraction algorithm. We used two categories of data: (i) experimental phantom data acquired previously at the Canadian Light Source synchrotron using five 33.2 keV beams of area ~0.6 mm² located approximately in a plane, and (ii) simulated data from a Matlab model, with scatter selectable to be from beams passing through muscle, fat, bone, and/or a minimally-scattering object such as air. Attenuation of the Laue scatter ring patterns can be selected to be azimuthally symmetric, or asymmetric, about the pencil beams. The scatter pattern data were input to the ML-EM algorithm and the sensitivity to the inputs studied. Furthermore, we modified the algorithm to segment the Laue rings in radial sectors.

Our results confirm that the ML-EM algorithm performs best when adjacent beams have comparable Laue ring intensity. For example, the algorithm is better at separating signals from two beams that passed through muscle and fat, than for two beams passing through muscle and bone, because of the greater attenuation for the latter. The cause of the ghosting artefact is established to be a fundamental limitation of ML-EM. In the first few iterations, low-spatialfrequency scatter signals are subdivided equally and assigned to multiple beam locations, swamping small signals. The global optimization minimum rectifies the problem, but ML-EM's approach to the global minimum is unacceptably slow, requiring over 10,000 iterations. Azimuthal segmentation of the scatter patterns allows a closer fit to the measured scatter data but still does not reach the global minimum. We have increased the ML-EM convergence rate. In the algorithm, the ratio of measured to estimated scatter patterns is computed and used to correct the next update. By scaling the difference from unity by a factor of 2.0 every three iterations, the resulting rms difference between the estimated and measured scatter patterns can be reduced, for example, from 2.66% at the 16th iteration to 2.02%. The global minimum however is still not reached in reasonable time. We are also investigating the use of the primary pencil beam information from adjacent beams. Spatial interpolation of these data can give approximate transmission factors with which to correct the recorded scatter data for spatially-dependent attenuation.

SP150.2 - Live animal phase contrast x-ray velocimetry of the lungs: Optimising imaging speed for synchrotron and lab source imaging

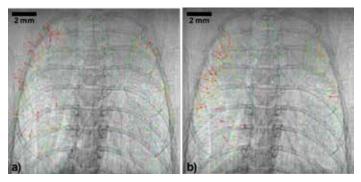

Author(s): <u>Rhiannon P. Murrie</u>¹, Kaye S. Morgan¹, Andreas Fouras², David M. Paganin¹

¹School Of Physics, Monash University, Clayton/VIC/AUSTRA-LIA, ²Division Of Biological Engineering, Monash University, Clayton/VIC/AUSTRALIA

Lung diseases such as lung cancer, asthma, emphysema and cystic fibrosis affect all ages of the world's population. One of the key difficulties in accurately diagnosing, monitoring and treating these lung diseases has been our inability to image the dynamics and detail of the lungs and airways whilst they are breathing. In particular, this limits the availability of regional information that can provide the most sensitive measure of changes in lung function.

X-ray phase contrast (XPCI) imaging allows us to image the lungs in high resolution by exploiting the difference in refractive indices between tissue and air. When imaged with x-rays of sufficient spatial coherence, refraction from the tissue/air interfaces result in high quality edge-enhanced airway images. Phase contrast imaging of the many alveoli of the lungs produces a characteristic speckle pattern (Kitchen et al., 2004). By combining XPCI with an engineering technique used to track the motion and flow of fluids, known as velocimetry, we can study the motion of the speckle pattern to reveal the local motion of the lungs and the flow of air through the lungs and airways (Dubsky et al., 2012, Fouras et al., 2012). This technique, dubbed x-ray velocimetry (XV), improves our ability to find small areas of disease under natural ventilation conditions. This allows for earlier and more accurate diagnosis of disease and allows us to expand research into treatment development and improvement through direct, real-time, high-resolution visualisation of lung dynamics.

X-ray velocimetry has, up until now, been primarily performed using a synchrotron x-ray source. As we move towards more accessible and cost-effective laboratory-based set-ups, this project investigates the optimal imaging speed to capture the lung motion in-vivo in small animals using XV. This optimisation balances the noise inherent in a short exposure with the motion blur that results from a long exposure, over a range of velocities. Results from both a synchrotron and laboratory source will be compared and considered via both simulation and experimental data.

In addition to absorption-based x-ray imaging, over the last two decades other techniques devoted to exploit the wave nature of x-rays were developed to enhance visibility of details and increase image contrast. These methods are called Phase-Contrast imaging (PCi) techniques and were developed in order to obtain high contrast and high spatial resolution images of biological samples. The first clinical study based on a PCi technique was performed at at the SYRMEP beamline (Synchrotron Radiation for Medical Physics) of ELET-TRA, the Italian synchrotron facility; the free space propagation approach was applied. The clinical study was based on 71 female patients that underwent digital mammography at hospital and, due to questionable or suspicious breast abnormalities not clarified at UltraSonography, underwent phase contrast mammography with synchrotron radiation (MSR). The study shows that Phase-Contrast allows improving the image quality and increases significantly the diagnostic performance of MSR in comparison with digital mammography: difference between methods in the area under the ROC curve is 0.2 (P<0.001). The mean glandular doses (MGD) delivered during MSR exams are, on the average, 42% lower than the ones delivered during DM exams, due to the properties of synchrotron radiation. Moreover the use of monochromatic beam, in the energy range 18-22 keV, allowed the direct measurement of the breast linear attenuation coefficients for each patient.

The new clinical project in breast imaging at the SYRMEP beamline, concerns breast tomography and it is carried out by the SYRMA-CT collaboration, an interdisciplinary team supported by INFN, ELETTRA and the Trieste University Hospital. The SYRMEP mammography facility will be deeply modified to allow the acquisition of tomographic images, and the dosimetric and safety system will be upgraded too. A complete Monte Carlo simulation code has been developed and tested for dose evaluation and exam optimization. The detector selected for this application is PIXIRAD-8: a CdTe detector working in single photon counting mode. The active area is 25x2.5 cm², the pixel size is 60 micrometers in hexagonal arrangement, the frame rate is 14 frame/s and the pixel rate capability is 5 10⁵ counts/pixel/s.

The aim is to acquire tomographic images of the breast delivering MGDs in the range 4-20 mGy. The beam energy will be in the range 38-40 keV, the upper limit is determined by the beam available at the SYRMEP beamline. To obtain high quality images at a clinical acceptable delivered dose new image reconstruction approaches will be explored, in order to reduce the number of necessary projections: simultaneous algebraic reconstruction tomography (SART) and equally sloped tomography (EST) approaches are under investigation. Moreover phase retrieval algorithms will be applied to the projection before the tomographic reconstruction in order to

increase the image contrast.

In the present communication the results of the Phase-Contrast mammography clinical study will be summarized, in terms of image quality, delivered dose and linear attenuation measurements, the SYRMA-CT project will be presented and the preliminary Phase-Contrast CT images obtained at ELETTRA in clinical compatible condition will be discussed.

SP150.4 - 4 Years of X-ray Imaging at 05B1-1 Beamline at BMIT Author(s): George Belev¹, Denise Miller¹, Nazanin Samadi², Mark A. Webb¹, <u>Tomasz W. Wysokinski¹</u>, Ning Zhu¹, L. D. Chapman², David M.L. Cooper²

¹Bmit, Canadian Light Source Inc., Saskatoon/CANADA, ²Anatomy And Cell Biology, University of Saskatchewan, Saskatoon/SK/ CANADA

The BioMedical Imaging and Therapy (BMIT) facility located at the Canadian Light Source, provides synchrotron-specific imaging and radiation therapy capabilities [1-5]. There are two separate endstations used for experiments, Bending Magnet beamline described here and Insertion Device beamline that started general user program in 2015.

The bending magnet beamline 05B1-1 was used to acquire first image in December 2008 and was officially opened for general user program in 2011. This endstation is designed for imaging and therapy research primarily in animals ranging in size from insects to mice to small dogs and cats, as well as tissue specimens including plants.

Fig. 1 3D Model of the BM Beamline components [3].

Core research programs include human and animal reproduction, cancer imaging and therapy, spinal cord injury and repair, cardiovascular and lung imaging and disease, bone and cartilage growth and deterioration, mammography, developmental biology, gene expression research as well as the introduction of new imaging methods.

The monochromatic spectral range spans 15–40 keV, and the beam is more than 200 mm wide in the experimental hutch. Several different focal plane detectors (cameras) are available with resolutions ranging from 2 μ m to 200 μ m.

SP150.5 - An energy dispersive bent Laue monochromator for K-edge subtraction imaging

Author(s): <u>Nazanin Samadi</u>¹, Ying Zhu², Mercedes Martinson³, Bassey Bassey³, George Belev⁴, L. D. Chapman⁵ ¹Bimedical Engineering, University of Saskatchewan, Saskatoon/ CANADA, ²Mccaig Inst For Bone And Joint Health, University of Calgary, Calgary/CANADA, ³Physics And Engineering Physics, University of Saskatchewan, Saskatoon/CANADA, ⁴Bmit, Canadian Light Source Inc., Saskatoon/CANADA, ⁵Anatomy And Cell Biology, University of Saskatchewan, Saskatoon/SK/CANADA

K-Edge Subtraction (KES) is a powerful synchrotron imaging method that allows the quantifiable determination of a contrast element (i.e. iodine) and matrix material (usually represented as water) in both projection imaging and computed tomography. A bent Laue monochromator is typically employed to prepare imaging beams above and below the contrast element K-edge which focus at the subject location and subsequently diverge onto a detector. Conventional KES prepares the two beams by utilizing a splitter that blocks approximately 1/3 of the vertical beam size to prevent "edge crossing" energies beyond the monochromator (Figure 1).

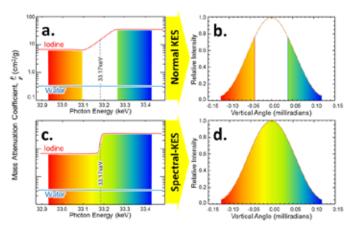

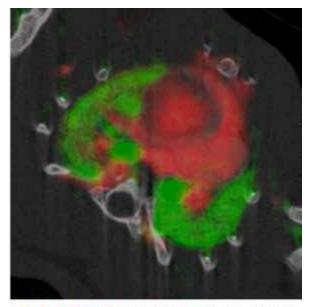

Figure 1. Iodine absorption edge (a & c) and vertical synchrotron beam profile (b & d) for a conventional bent Laue system (a & b) and Spectral-KES (c & d). Note that fully 1/3 of the beam in the conventional system is removed to avoid edge crossing energies which is not the case for Spectral-KES.

A bent Laue monochromator has been developed that has very good focal and energy dispersive properties for KES. Approximately 5% of the vertical beam profile is involved in "edge crossing" energies (Figure1c,d), thus no splitter is employed. The combination of good spatial resolution, energy dispersive properties, flux and a unique approach to data analysis make this system nearly ideal for KES.

Red – Iodine Green – Xenon Grey – Water Figure 2. composite image of rat thorax showing lodine in the heart and xenon in the lungs. Image courtesy of Prof. Nancy Ford & Dr. Pierre Deman, UBC

Details of the monochromator will be discussed, especially the focal and energy dispersive properties. Example images (i.e. Figure 2) of the beam and the object images will be presented as well.

SP150.6 - An incoherent implementation of x-ray phase contrast imaging and tomography that maintains high sensitivity at low delivered doses

Author(s): <u>Alessandro Olivo</u>, Charlotte Hagen, Paul C. Diemoz, Fabio A. Vittoria, Gibril Kallon, Anna Zamir, Dario Basta, Thomas P. Millard, Marco Endrizzi

Medical Physics And Biomedical Engineering, University College London, London/UNITED KINGDOM

X-ray phase contrast imaging (XPCI) has been one of the hottest topics in x-ray research over the last two decades, because of its potential to revolutionize diagnostic radiology and other medical applications of x-rays. Indeed, its ability to improve diagnostic potential in mammography is currently being demonstrated by the in vivo work on human patients underway at the Trieste synchrotron in Italy.

However, translation into everyday clinical use has proven very difficult, to the extent that part of the community is starting to doubt this will ever happen.

We argue that the main reason for the above lies in the fact that all implementations of XPCI proposed so far have been based on coherent approaches. While some of these are very promising, the need for source coherence prevented them from being usable in clinical practice, at least until a new generation of sources will become available that can simultaneously provide high x-ray flux and high coherence. Whenever incoherent sources have been employed, devices have been introduced to artificially increase their coherence (e.g. crystals or gratings). This resulted in a significant reduction of the x-ray flux, leading to excessive exposure time, as well as delivered dose whenever these devices are positioned after the sample.

This talk will present a solution based on a completely incoherent approach to XPCI, centred on the adaptation (through apertured masks) of the "edge-illumination" principle to polychromatic and divergent x-ray beams generated by conventional sources. This talk will show that:

1) The method is completely incoherent, but this notwithstanding provides a phase sensitivity equal to that of other coherent approaches while using unfiltered and uncollimated focal spots of up to 100 micron (compatible with e.g. current mammography sources). We will show that the coherence length is much smaller than both the size of the apertures in the used masks and the separation between them, and explain how phase sensitivity is measured. Based on recent experiments performed with energy-resolved detectors, we will also show that the method is completely achromatic.

2) In planar imaging, the delivered dose is lower or equal than in e.g. conventional mammographic examinations, and in CT it is well below the limits imposed by e.g. small-animal imaging.

3) The technique is highly flexible and can be easily adapted to tomosynthesis, microscopy and micro-CT, etc, and that "dark-field" (sometimes referred to as "ultra-small angle scattering") images are also readily achievable, still within clinically acceptable dose limits.

After the technical excursus outlined above, we will show examples from recent applications in medicine and biology, including in mammography, imaging of cartilage and joints, use of new contrast agents and monitoring of regenerative medicine processes. Finally, we will provide an outlook on future technical developments of the method, which include options for "single-shot" retrieval of attenuation, phase-contrast and dark-field images, as well as strategies to reduce the exposure time (currently ~10s for planar imaging) and the overall dimensions of the imaging system, scale up the field of view, completely automatize the alignment.

SP150.7 - Indirect measurement of average alveolar size using dynamic phase-contrast imaging

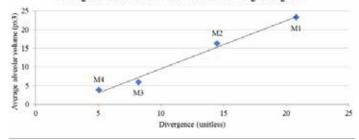

Author(s): <u>Mercedes Martinson</u>¹, Rob Lewis², Andreas Fouras³, Megan Wallace⁴, Melissa Siew⁴, Stuart Hooper⁵, Paul Babyn⁶ ¹Physics And Engineering Physics, University of Saskatchewan, Saskatoon/CANADA, ²Biomedical Engineering, University of Saskatchewan, Saskatoon/SK/CANADA, ³Division Of Biological Engineering, Monash University, Clayton/VIC/AUSTRALIA, ⁴The Ritchie Centre, MIMR-PHI Institute of Medical Research, Clayton/VIC/ AUSTRALIA, ⁵Department Of Obstetrics And Gynaecology, Monash University, Clayton/VIC/AUSTRALIA, ⁶Medical Imaging, University of Saskatchewan, Saskatoon/SK/CANADA

For some lung diseases, assessment of alveolar dimension could add critical information to inform patient care and disease progression. However, current clinical imaging techniques, such as computed tomography, lack the resolution required to measure these small structures in patients. While the gold standard imaging modality for measuring alveoli is micro-CT, this technique is not possible in clinical use due to the size of the patients and the radiation dose. An alternative imaging modality is phase-based contrast imaging, which would deliver a lower dose to patients and increase the size limit. Phase contrast X-ray imaging has previously been combined with particle image velocimetry (PIV) to measure lung motion, another indicator of lung disease. Thus it was hypothesized that average alveolar size could also be measured indirectly using PIV. In the work reported here, we show that average alveolar size shows a high correlation to the mathematical divergence of the velocity vector field that results from the speckle pattern produced by phase imaging of mouse lungs. This correlation is linear with p<0.006. If this correlation holds in human lungs, it could potentially be calibrated to indirectly measure average alveolar size in human patients using some of the grating-based phase-contrast imaging methods that are showing great promise in clinical use.

Mouse identifier	Age	Average Divergence	Average Alveolar Dimension (px3)

Introduction

Tissue engineering is an interdisciplinary field that combines the principles of engineering and life sciences with the goal of restoration, repair or replacement of tissues and their functions. Bridging the gap between isolated cells and functioning tissue, the scaffolds become an instructive extracellular microenvironment that actively guides cells both locally and in time towards tissue formation and regeneration. Additionally, the mechanical properties and the microstructure of the scaffolds play an important role to cell proliferation, differentiation and eventually regeneration of the damage tissue site. Electrospinning is a technique for the production of ultrafine polymer fibers from polymer melts or polymer solutions through electrostatic interaction¹. It is most often used as scaffold material in tissue engineering applications due to its similarity to the filamentous microenvironment in native tissues. This similarity often promotes a more positive cell response to the generated fibers than to the bulk material alone. Moreover, this method is also suitable to generate alginate 3D gel-structures for immunoisolation and cryopreservation². Here, we describe the production of aligned fibers with different 3D structures such as mats and tubes, the incorporation of bioactive substances and their biomechanical evaluation.

Materials & methods

Different kinds of biodegradable polymers of natural and synthetic origin (polycaprolactone, poly-l-lactide acid, polyethylene glycol, chitosan etc) that have been approved for biomedical applications were dissolved inside organic solvents (chloroform, acetone, ethanol etc) at adequate concentrations for electrospinning. Single jet or/ and coaxial jet electrospinning was used to create fibers gathered on the surface of collectors with different geometry (rectangular, rotating mandrel, tubular etc). Morphology of the fibrous scaffolds was examined by scanning electron microscopy (SEM) having previously been sputter-coated with gold. Uniaxial mechanical tests were performed with an electroforce tensile testing instrument by BOSE®, equipped with a 200 N load cell and a static tensile testing instrument by INSTRON®, equipped with a 500 N load cell. Young's modulus was calculated from the linear phase of the stress-strain plot. Strain and stress at failure and at maximum load were calculated and analyzed.

Results and Discussion

Scaffold design via electrospinning resulted in versatile scaffolds made out of various polymers that exhibited different macroscopic and microscopic structures, various pore sizes and porosities. From aligned fibers that could be used in nerve tissue engineering, tubular scaffolds for vascular grafts and coaxially electrospun membranes with encapsulated pharmaceuticals, artificial scaffolds were created to fit the need of various applications. The mechanical properties of the scaffolds were in line with the need for each case, comparable with natural tissues. Electrospun scaffolds showed to address both controlled release and structural cues with adequate pore sizes and resulting porosity enabling cell proliferation.

SP151.2 - The Continuous Flow Total Artificial Heart in Clinical Practice

Author(s): David Macku

Department Of Cybernetics, Czech Technical University in Prague, Prague/CZECH REPUBLIC

My minireview describes an inventive medical device for the replacement of pulsatile circulation by pulseless circulation for patients awaiting heart transplantation. The Continuous flow total artificial heart (CFTAH) is a device consisting of two continuous ventricular assist devices that produce pulseless flow into both systemic and pulmonary circulation. Its utilization is not yet widespread. The Continuous flow total artificial heart has only been implanted in humans three times as an off-label use of a ventricular assist device. All three men have been supported by chronic pulseless flow. The issue of chronic pulseless vs. chronic pulsatile blood flow and its effects on organs and tissue perfusion has been debated in medical and biomedical scientific journals for decades. There are many animal studies, views of many scientists and many hypotheses, but no clear answer to the basic question: will a person be able live a quality life with pulseless flow for months and years?

SP151.3 - Power Control Range of Operation for the Left Ventricular Assist Device in Bridge-to-Recovery Treatment Author(s): <u>Marwan A. Simaan</u>¹, George Faragallah¹, Yu Wang² ¹University of Central Florida, Orlando/FL/UNITED STATES OF AMERICA, ²University of Louisville, Louisville/KY/UNITED STATES OF AMERICA

Left Ventricular Assist Devices (LVADs) are mechanical pumps that may be used as an alternative to drug therapy for patients with congestive heart failure. These rotary pumps are implanted in patients to provide an alternative path for blood flow from the left ventricle to the aorta that supplements the natural blood flow through the aortic valve. Although the LVAD is used largely for bridge-to-transplantation or destination therapy treatments, in recent years considerable interest has been devoted to using the LVAD as a bridge-to-recovery device. This type of treatment is typically intended for patients whose heart condition may improve as a result of a limited time LVAD support. Candidates for this type of treatment may be weaned from the LVAD when their hemodynamic and physiological changes indicate recovery of the heart muscle.

The amount of blood flow supplied by the LVAD depends on the rotational speed of the pump which is controlled by the electric power supplied to the pump motor from the LVAD battery pack. Current LVAD technology allows for the option of operating the pump only at a fixed power setting. This means that the power controller cannot react to any changes in the activity level of the patient by automatically adjusting the supplied power. The next generation LVADs however, will be equipped with controllers that have this capability. The purpose of this paper is to address the important engineering challenge of determining the *range of operation* available to the power controller within which it can: (1) automatically adjust the power so that the resulting total blood flow meets the physiological demand of the patient; and (2) promote recovery by maintaining normal operation of the aortic valve. Using a mathematical model we have shown that if this power is increased beyond a certain critical value the aortic valve will close permanently due to the inability of the left ventricle to retain enough volume that can build pressure high enough to open the valve and let the blood flow through it. Permanent closure of the aortic valve may cause complications such as valve fusion or stenosis, stagnation of blood flow and/or thrombus formation, all of which may be harmful to the patient by delaying or preventing the recovery of the heart muscle. In this paper we investigate the effect of the power provided to the LVAD pump on the ability of the aortic valve to open and close regularly during the cardiac cycle hence avoiding all of the above mentioned complications. We derive a relationship between the critical value of power that causes the aortic valve to permanently close and the patient's level of activity. We show that independent of the degree of severity of the heart condition, this critical value is directly related to the patient's level of activity and that the more active the patient, the larger the range of operation available to the LVAD power controller. This means that increased activity reduces the possibility of exceeding the critical value and consequently increases the chance of faster recovery.

SP151.4 - An quantitative estimation method of peripheral perfusion by using a CCD camera during rotary blood pump support

Author(s): <u>Yasuyuki Shiraishi</u>, Kyosuke Sano, Shota Watanabe, Tomoyuki Yambe

Medical Engineering & Cardiology, IDAC, Tohoku University, Sendai/ JAPAN

The rotary blood pump support for ventricular circulatory assistance has become a standard procedure as the bridge use or the destination therapy for the surgical treatment of severe heart failure in recent years. While the outcome of the long term support by the rotary blood pumps in the patients is excellent compared with the heart transplantation, the optimal driving condition of each pump still remains to be seen. It is anticipated that the pulsatile flow can be generated by the interaction between the native heart function and the pump which is to be contributing to maintain the peripheral perfusion. One of the definitive condition of the revolution number in each pump is to investigate the aortic valve opening during the systole for providing the native heart contractile function. Recently, a pulse detection technology by using CCD cameras has been represented for the diagnostic purpose of patients' hemodynamics. We also have applied and develop the noninvasive evaluation method for the investigation of peripheral perfusion during the rotary blood pump support in order to examine the pulsatile effects of the pump characteristics on peripheral organs. In this study, the brightness of color components derived from the CCD camera (NEX-FS100JK, Sony, Japan) under the different blood density conditions was examined in vitro by using an originally designed peripheral model made of open-foamed polyurethane sponge at the density of 1.7 x 10⁻² g/cm³. After the static characteristic tests, the peripheral perfusion at a goat face was evaluated under the left ventricular assist condition using the centrifugal blood pump (Evaheart, SunMedical, Japan). The animal study was performed with the left ventricular assist using an adult healthy Saanen goat under the normal anesthesia using 2 % isoflurane with remifentanil. All the animal experimental procedure was investigated and allowed by the Animal Experiment Committee in Tohoku University.

The results were as follows: In the static model study, the relationship between the brightness and the blood density in the sponge model was calculated. It was indicated that the brightness value calculated under the green color LED lighting condition was elevated by around 30 % by the increase of sponge density by 3 %. In the animal experiment, the peripheral perfusion could be obtained as the synchronous pulsation with the cardiac beats under the rotary blood pump support. The pulsatility calculated from the goat's face perfusion indicated that the elimination of pulse might be caused by the increase of the revolution number of the pump. Consequently, the pulsation by the noninvasive CCD detection could be evaluated as the changes in peripheral blood flow based on these data.

SP151.5 - Mathematical Modeling of Left Ventricle Stroke Work Following Transcatheter Aortic Valve Replacement Associated With Paravalvular Leaks

Author(s): <u>Azadeh Saeedi</u>¹, Abdelghani Djebbari², Zahra Keshavarz-Motamed³, N Dahdah⁴, Lyes Kadem¹

¹Mechanical And Industrial Engineering, Concordia University, Montreal/QC/CANADA, ²Department Of Electronics, University of Tlemcen, Tlemcen/ALGERIA, ³Laval University, Quebec/QC/CANA-DA, ⁴Sainte-Justine Hospital, Montreal/CANADA

Objectives The objective of this study was to develop a lumped parameter model to evaluate the effect of paravalvular leaks (PVL) following transcatheter aortic valve replacement (TAVR) on the total load supported by the left ventricle (LV).

Background A significant number of elderly patients with severe symptomatic aortic stenosis are denied surgical aortic valve replacement due to its high operative risk. TAVR has recently emerged as an alternative solution for high-risk inoperable patients with aortic stenosis. However, TAVR is often associated with paravalvular leaks (PVL). PVL leads to left ventricular volume overload and increased stroke work of the left ventricle. Under such conditions it is difficult to evaluate the net benefit from TAVR since the benefit from the increase in valve area is damped by the presence of PVLs.

Methods A mathematical model was developed based solely on non-invasive data allowed for the description of the interaction between effective orifice area (EOA), PVL and the left ventricle work (LVW) pre and post- TAVR. The model was used to simulate different configurations in terms of valve areas and valve regurgitation/PVLs before and after TAVR. The following conditions were investigated: 1) Before TAVR: severe aortic stenosis with EOAs of 0.56 cm², 0.66 cm² and 0.76 cm² with no, mild, moderate and severe aortic regurgitation; 2) After TAVR: EOAs of 1.37 cm², 1.61 cm² and 1.90 cm² with no, mild, moderate and severe aortic regurgitation paravalvular leaks. For each case, LV stroke work has been computed as well as the net reduction/increase in LV stroke work as a result of TAVR.

Results and Conclusion The model was able to reproduce physiological waveforms found in patients with aortic stenosis and regurgitation. The results show that in several configurations, TAVR did not lead to a significant reduction in LV stroke work because of the presence of PVLs.

Defining a new parameter for evaluating TAVR success, as the ratio of the actual reduction in LV stroke work to the ideal reduction expected in the absence of PVLs, showed that in only 53% of cases TAVR was successful (>75% efficiency) in reducing LV stroke work. In 19% of cases the efficiency of TAVR was between 50-75%, in 18% of cases the efficiency of TAVR was between 0-50% and in 10% of cases TAVR led even to an increase in LV stroke work because the benefit of increasing EOA was damped by the negative impact of PVLs. In conclusion, TAVR is an effective option to reduce the left ventricle overload in high risk patients with severe AS. However, this is only true in the absence or mild paravalvular leaks. Severe or moderate paravalvular leaks significantly limit the benefit of TAVR and might even lead to an increase in the left ventricle overload.

SP151.6 - Criteria to study Heart Failure derived from ESPVR Author(s): <u>Rachad M. Shoucri</u>

Mathematics And Computer Science, royal military college of canada. Kingston/ON/CANADA

The problem of heart failure with normal or preserved ejection fraction (HFpEF) has been the object of extensive studies. In a series of studies by the author, basic relations were derived between the ejection fraction (EF) of the left ventricle and the parameters describing the end-systolic pressure-volume relation (ESPVR), represented by the line d3Vdm in Fig. 1 (left).

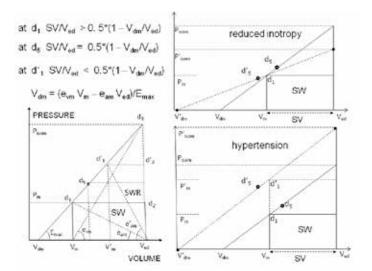

Figure 1: (left) The ESPVR is represented by the line d3Vdm with midpoint d5 and slope Emax. The pressure-volume relation is represented by the loop Vedd2d1Vm in a normal ejecting contraction. Pisom is the peak active pressure of the myocardium. (right) Normal physiological case with d1 below mid-point d5 (solid line); abnormal case with reduced contractility with d1 above midpoint d'5 (dotted line, top); abnormal case of hypertension with d'1 above midpoint d'5 (dotted line, bottom); notice that the three cases have the same EF = SV/Ved.

The ventricular pressure Pm is assumed constant during the ejection phase, d1 is the corresponding point on the ESPVR. One can distinguish three states for the operation of the left ventricle:

a) Normal physiological state, with d1 below d5 on the line d3Vdm. In this case we have stroke volume SV > (Ved - Vdm)/2, with slopes ratio Emax/eam » 2 and Pisom/Pm » 3. This case corresponds also to maximum efficiency for oxygen consumption by the myocardium.

b) Mildly depressed state, with d1 and d5 nearly coinciding. In this case we have SV » (Ved – Vdm)/2, with Emax/eam » 1 and Pisom/ Pm » 2. Notice from Fig. 1 that when d1 moves on the line d3Vdm, the stroke work SW reaches its maximum value SWx when d1 co-incides with the mid-point d5. SWR = SWx – SW is the stroke work reserve.

c) Severely depressed state, with d1 above d5 on the line d3Vdm. In this case we have SV < (Ved – Vdm)/2, with Emax/eam < 1 and Pisom/Pm < 2 (see Fig. 1, right side).

In cases (b) and (c) an increase in Pm causes a decrease in SW, resulting in cardiac insufficiency. These results are confirmed by a wide variety of clinical data taken from the medical literature and give new insight and better understanding of the mechanics of left ventricular contraction.

SP151.7 - Fluid Dynamics of Transcatheter Aortic Valve Associated with Paravalvular Leak

Author(s): <u>Azadeh Saeedi</u>¹, Zahra Keshavarz-Motamed², Philippe Pibarot², Lyes Kadem¹

¹Mechanical And Industrial Engineering, Concordia University, Montreal/QC/CANADA, ²Laval University, Quebec/QC/CANADA

Objectives The objective of this study is to investigate, using three dimensional numerical simulations, the effect of paravalvular leak on the diastolic flow-field characteristics following transcatheter aortic valve replacement.

Background Transcatheter Aortic Valve Replacement (TAVR) has emerged as the preferred therapeutic intervention for inoperable patients with severe symptomatic aortic stenosis and as an alternative option in high surgical risk individuals. However, one of the major TAVR related complications is Paravalvular Leak (PVL). PVL leads to left ventricular volume overload and increased stroke work of the left ventricle. Despite its clinical significance, only few studies addressed specifically the hemodynamic effects of paravalvular leaks after TAVR.

Methods Three dimensional simulations using finite volume method were performed on an Edwards SAPIEN 26 mm transcatheter aortic valve. PVL was modeled by creating three different orifices (with the area of 1 mm², 4 mm² and 20 mm² respectively) at the level of the aortic root. The diastolic velocity waveform applied at the inlet of the model was obtained from in vivo phase contrast magnetic resonance imaging measurements performed in a patient with PVL. The model was used to investigate flow characteristics (velocity and secondary flow) and wall shear stress (WSS) on both aortic and ventricle sides in the presence of PVLs.

Results and Conclusion Three high speed jets were generated through the regurgitant orifices. The velocity of the jets rapidly increased during early diastole to reach a maximum velocity. At the peak of diastolic regurgitant flow, peak velocities were 4.13 m/s for the 20 mm² orifice. 3.18 m/s for the 4 mm² orifice and 2.33 m/s for the 1 mm² orifice. In the aortic side, the asymmetrical flow caused by PVL leads to elevated WSS, up to 3.05 Pa, around the coaptation area of the leaflets. In addition, high localized WSS exist even on the left ventricular side close to the location of the regurgitant orifices. The highest value of WSS (11.05 Pa) is located close to the regurgitant orifice of 4 mm². We conclude that paravalvular leak following transcatheter aortic valve replacement leads to significant disruption in blood flow both upstream and downstream of the implanted valve. The abnormal flow is characterized by high speed jets, small and large scale coherent structures and markedly elevated shear stresses on both sides of the implanted aortic leaflets especially on the left ventricular side. Such unfavorable flow configuration may promote a more rapid degeneration of the transcatheter valve leaflets.

SP152 - Special Treatment Techniques: Part 2

TRACK 04: RADIATION ONCOLOGY

SP152.1 - Optimal timing in concomitant chemoradiation therapy of colorectal tumors in nude mouse treated with Cisplatin and LipoplatinTM

Author(s): <u>Thititip Tippayamontri</u>¹, Rami Kotb², Benoit Paquette¹, Leon Sanche¹

¹Nuclear Medicine And Radiobiology, University of sherbrooke, Sherbrooke/QC/CANADA, ²Systemic Therapy, BC Cancer Agency's Vancouver Island Centre, Victoria/BC/CANADA

Background: Cisplatin is a chemotherapeutic agent, which under certain conditions can become a radiosensitizer. Cisplatin given concurrently with radiation enhance cell death by several mechanisms, including the inhibition of radiation-induced DNA damage repair and the induction of additional DNA damage or modification of radiation induced DNA damage. In recent fundamental investigations on cisplatin-DNA complexes, it was found that DNA damage induced by the low-energy secondary electrons, produced by ionizing radiation, was considerably increased when cisplatin was bound to DNA. This finding implies that the highest concomitant effect should be achieved, when the amount of cisplatin binding to DNA is highest.

Materials and **Methods:** Using an animal model of colorectal cancer, we determined the platinum window of maximum radiosensitisation and synergism, defined by studying the pharmacokinetics and time-dependent intracellular distribution of cisplatin and Lipoplatin[™], the encapsulated form of cisplatin recently proposed to overcome its toxicity. In nude mice, bearing HCT116 human colorectal carcinoma treated with cisplatin or Lipoplatin[™], the platinum accumulation in blood, serum, different normal tissues, tumor and different tumor cell compartments was measured by inductively coupled plasma mass spectrometry. Radiation treatment (15 Gy) was given 4, 24, and 48 h after drug administration and was correlated to the amount of platinum–DNA adducts in the cancer cells. The resulting tumor growth delay was reported and correlated to apoptosis analysis.

Results: The optimal treatment and highest apoptosis were observed when radiation was given at 4 h or 48 h after drug injection. These times correspond to the times of maximal platinum binding to tumor DNA. An enhancement factor (ratio of group treated by combined treatment compared to chemotherapy alone) of 13.00 was obtained with Lipoplatin[™], and 4.09 for cisplatin when tumor irradiation was performed 48 h after drug administration.

Conclusion: The most efficient combination treatment with radiation and cisplatin or Lipoplatin[™] was observed when the amount of cisplatin binding to DNA is highest. These results improve our understanding of the mechanisms of platinum-induced radiosensitization and should have significant impact on the design of more efficient treatment protocols.

SP152.2 - Grid therapy: impact of radiobiological models on calculation of therapeutic ratio

Author(s): Somayeh Gholami¹, <u>Hassan Ali Nedaie²</u>, Ali S. Meigooni³, Francesco Longo⁴

¹Department Of Medical Physics And Biomedical Engineering, Tehran University of Medical Sciences, Tehran/IRAN, ²Radiotherapy Oncology Department, Cancer Research Centre, Cancer Institute, Tehran University of Medical Sciences, Tehran/IRAN, ³Comprehensive Cancer Centers of Nevada, Las Vegas/NV/UNITED STATES OF AMERICA, ⁴Department Of Physics, University of Trieste and INFN, Trieste/ITALY

Grid therapy, also known as Spatially fractionated radiation therapy, is a novel technique that has been introduced for treatment of patients with advanced bulky tumors. Several investigators have used linear quadratic radiobiological model to demonstrate the therapeutic advantages of the Grid therapy. Despite the success of the linear quadratic (LQ) model, for evaluation of the limitation of the Grid therapy with such large doses per fraction still there are challenges that need to be met. In this study we have applied both LQ and MLQ radiobiological models to calculate therapeutic ratio (TR) of spatially fractionated radiation therapy. This evaluation is performed using Monte Carlo simulation.

In this study the Geant4 (version 9.6.p02) is used to simulate the photon spectrum of a 6 MV x-ray beam emitted by a Varian2100C linear accelerator, based on vendor detailed information. Percentage depth dose (PDD) and dose profile of 6MV photon beam were obtained at 5cm depth for 10×10 cm² open radiation field size in a water phantom. To verify Monte Carlo simulation calculations, these results were compared with the experimental measured data by a calibrated PTW 31010, 0.125 cc Semifelex chamber. The Grid block with hole-diameter of 1cm and a center-to-center distance of 1.8 cm at the isocenter was also simulated.

Therapeutic ratios of tumors with different histology (Melanoma, Squamous cell carcinoma (SCC), Adenocarcinoma and Sarcoma) have been calculated using both radiobiological models. Survival fraction of tumors at 2 Gy dose (SF2) and tumors cell lines radiobilogical parameters were extracted from published data. In addition, various maximum doses are used to evaluate relationship between maximum dose and therapeutic ratio.Table 1 shows results for predicting TR at the different prescribed doses using LQ and MLQ models. The difference between the two models is less than 5% for the TR calculations.

Table 1 - Results for therapeutic ratio (TR) calculations for LQ and MLQ radiobiological models at different maximum doses								
Tumor	SF2	TR (LQ Modell)			TR (MLQ Model)			
		10 Gy	20 Gy	30 Gy	10 Gy	20 Gy	30 Gy	
Melanoma	0.485	1.22	1.37	1.55	1.27	1.42	1.56	
SCC	0.483	1.21	1.37	1.54	1.28	1.44	1.60	
Adeno.Ca	0.43	1.12	1.23	1.36	1.18	1.30	1.40	
Sarcoma	0.42	1.10	1.21	1.33	1.15	1.25	1.32	

Equivalent uniform dose (EUD) for all prescribed doses for both models has a value between 2.19 Gy and 3.87 Gy.

In this study, we have provided a dosimetric simulation and assessed the therapeutic ratio of four different types of tumor cells based on two LQ and MLQ radiobilogical models for different doses. The results indicate that using radiobiological models that are more appropriate for high dose per fraction would not change the theoretical prediction of spatially fractionated radiotherapy. This is because the value of equivalent uniform dose (EUD) in Grid therapy is in the range that LQ model is valid.

SP152.3 - Will CyberKnife M6[™] Multileaf collimator offer advantages over IRIS[™] collimator in prostate SBRT? Author(s): Vindu Kathriarachchi¹, <u>Charles Shang</u>², Theodora Leven-

touri¹, Georgios Kalantzis¹ ¹Physics, Florida Atlantic University, BOCA RATON/UNITED STATES

Physics, Florida Atlantic University, BOCA RATON/UNITED STATES OF AMERICA, ²Radiation Oncology, Lynn Cancer Institute, Boca Raton Regional Hospital, BOCA RATON/UNITED STATES OF AMERICA

Purpose: CyberKnife M6[™] InCise[™] Multileaf collimator (MLC) has become a new modality in practice. Its ability of forming irregularly shaped beamlets offers a potential for more efficient dose optimization and treatment delivery in comparison with that by IRIS[™] dodecagon beams. This study is focused on quantification of such timesaving ability in prostate SBRT with comparable dosimetry plans.

Methods: Eight prostate cancer patients were planned in Multi-Plan[™]5.1.2 respectively utilizing IRIS and MLC for 36.25 Gy in 5 fractions. PTV was outlined for treating prostate only. All plans were evaluated by dose conformity index (CI), homogeneity index (HI), new conformity index (nCI) and PTV coverage. In addition, maximum doses at the bladder and rectum, calculated treatment time per fraction and planned MUs were also compared and tested for significance with the Wilcoxon test.

Results: In both IRIS and MLC plan groups, PTV Dmax was scaled to 115% while the HI was maintained at 1.15. The mean V100 was 95.42% for IRIS, and 95.36% for MLC (p=0.48); mean Cl: 1.08 vs. 1.05 (p=0.09); and mean nCl: 1.13 vs. 1.11 (p=0.11). Between the groups, the differences of Dmax for the bladder and rectum were found insignificant (p=0.4). Changing from IRIS to MLC, the average treatment time per fraction was reduced by 35% (43.5 ± 2.6 min vs. 28.3 ± 1.6 min, p<0.01) and the planned MU's were decreased by 40% (50318 ± 8976 vs. 30286 ± 2211, p<0.01).

Conclusions: This investigation demonstrated the ability of CyberKnife M6[™] to produce prostate SBRT plans equivalent to those using IRIS in terms of target coverage, and dose sparing of critical structures. However, a significant 35% reduction in treatment time and 40% reduction in number of MUs were achieved by replacing IRIS with MLC without dosimetric compromise in planning quality.

SP152.4 - Retrospective analysis of treatment margins for stereotactic ablative lung cancer treatments based on 4D CBCT Author(s): <u>Sheeba Thengumpallil</u>¹, Jean-François Germond¹, Nicolas Péguret², Jean Bourhis², François Bochud¹, Raphaël Moeckli¹ ¹Institute Of Radiation Physics, CHUV, Lausanne/SWITZER-LAND, ²Radio-oncology Department, CHUV, Lausanne/SWITZER-LAND

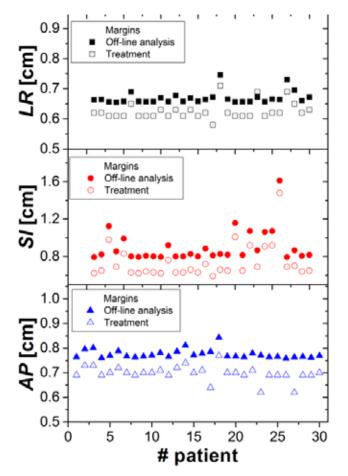

Purpose/Objective: The objective of this study was to evaluate treatment margins defined after the 4D CBCT off-line analysis and compare them with literature.

Materials/Methods: Thirty stereo-ablative T1-T2 N0 M0 lung cancer patients were analyzed (with a total of 229 fractions). All patients were treated in frameless and free breathing conditions. The treatment margins were defined according to van Herk recipe on Mid-Ventilation phase. The treatment margins before 4D CBCT off-line analysis were defined using the systematic and random components taken from literature (Sonke et al. IJROBP 2009). For each patient, we assessed the tumor motion amplitude and the intra-fraction variability from 4D CBCT images realized for tumor positioning (baseline shift), for couch correction verification and for intra-fraction motion (three 4D CBCT were performed for each fraction). From these data, we derived the resulting systematic and random errors for our patient cohort, leading to related margins for each patient.

Results: A summary of systematic and random errors are shown in the Table. When comparing the treatment margins applied to the patients (data from literature) and the margins retrospectively calculated from our patient cohort we observed that the margins applied to the patients should have been slightly larger (~1 mm 3D vector) (see Figure).

Conclusions: Tumor localization accuracy and intra-fraction motion uncertainties were assessed in our patient cohort by analyzing 4D CBCT images performed during each treatment fraction. We found that slightly larger margins should have been applied to our patients. According to the probabilistic approach of the van Herk recipe, a difference in the PTV margins as small as 1mm (3D vector) should not lead to a difference in tumor local control. However, the consequences of these differences should be evaluated in a dosimetric point of view in order to confirm that assumption. This is the object of an ongoing study.

SP152.5 - Using surgical clips in the tracking of liver tumors applied to CyberKnife SBRT treatments

Author(s): Leonie Petitclerc, Karim Boudam, Jean-Francois Carrier Radiation Oncology, CHUM, Montreal/QC/CANADA

Radiotherapy is still considered as a last resort treatment in liver cancer cases, when the patient's condition doesn't allow for more conventional treatment options. However, the same health factors that prevent the use of these methods also affect the risks associated with radiotherapy and further reduce the spectrum of treatment options that are available.

At the CHUM, liver tumors are treated using the CyberKnife system aided by the implantation of gold seeds as markers for tracking. However, some patients' liver condition doesn't permit the insertion of those markers. In these cases, we are left with the need for some other way to visualize the movements of the tumor during treatment. Surgical clips, which are already present in the liver of the patient, will then be used as surrogates to monitor the movement of the tumor. These clips have very different physical and radiological properties from gold seed markers and therefore their use needs to be investigated further to assess their relevance as markers and to optimize their use in the clinical context.

We have evaluated the in-treatment images taken at the CyberKnife for previous patient cases and using an anthropomorphic phantom for a more general outlook. It was then measured that, to maximize the contrast between the clips and the surrounding tissue, it is best to use both high kV and mA settings on the imager, as can be seen on figure 1. The capability of the CyberKnife's algorithm to detect and track the clips was evaluated by comparing the calculated and real positions of the clips in the treatment images. The ensuing error on the position could then be analyzed and compared with the corresponding error in the case of gold seed markers and the recommended margins of error for radiotherapy treatments. This displacement was also assessed experimentally by using a moving phantom with inserted clips. The margin of error and any blurring effects on the expected dosimetric treatment map were measured using dosimetric film.

This research allows us to draw conclusions as to the utility of surgical clips in tracking liver tumors. Using our conclusions as well as those found in literature, we were able to make recommendations for good clinical guidelines for treating liver tumors using surgical clips as radiological markers for tracking.

SP152.6 - A Novel Couch-Gantry Trajectory Based Stereotactic Treatment Method

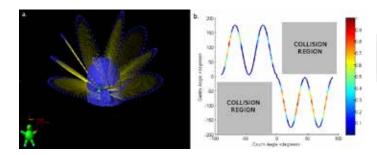

Author(s): <u>Byron Wilson</u>¹, Karl Otto², Ermias Gete¹ ¹Medical Physics, BC Cancer Agency, Vancouver/CANADA, ²Physics And Astronomy, University of British Columbia, Vancouver/BC/ CANADA

Introduction

We propose an inverse planning solution for trajectory-based stereotactic (SRS) treatments of small lesions in the brain with a c-arm linac. The beam trajectory is formed by simultaneously rotating the linac gantry and the treatment couch, thus enabling a wide selection of beam angles in a time efficient manner. Dose is optimized by dynamically varying the dose rate and the MLC leaf positions along the beam trajectory.

Methods

The trajectory-based inverse planning algorithm we propose is based on the VMAT technique developed by Karl Otto. The predefined beam trajectory (Figure1) is formed by rotating the patient couch through 180° while the gantry produces a series of 6 to 8 partial arcs of +/-170° each. This trajectory allows delivery from a wide array of directions while the couch is constrained to move at a slow and constant angular velocity, thus ensuring patient comfort. Dose rate and MLC leaf positions are modulated.

An optimized beam intensity pattern is formed along this trajectory (figure1b), while the MLC aperture changes continuously. The optimization adds controls points using the progressive sampling algorithm and varies each control points' MLC positions and dose rates with stochastic perturbations, keeping only the perturbations that lower the cost function. Since the default trajectory samples the entire phase-space, unwanted portions of the trajectory are removed by dose rate modulation. MLC aperture optimization is used mainly for target conformity. Therefore, our method emphasises beam weight perturbation and we are able to speed up the optimization by adding momentum to beam weight perturbations.

We have tested our method on two cranial cases (acoustic neuroma (plan1) and brain mets (plan2)) that were previously treated with SRS using non-coplanar dynamic conformal arcs. Treatment plans were generated and compared to the original conformal plans. These plans were successfully delivered on the TrueBeam Linac using the Developer Mode.

Results

For plan1, there was a reduction of the mean dose to the organs at risk (OAR): brainstem (17%) and optic tract (51%). For plan2, dose to OARs were comparable to the original plan and were maintained at less than 2% of the prescription dose. Conformity to the PTV improved for both plans. Delivery time for a 15Gy fraction at the isocenter was approximately 6 minutes.

Conclusion

The method proposed will be achievable on current conventional linacs once concurrent couch and gantry motion are enabled. This technique produces high quality, reproducible and efficient treatment plans for SRS patients.

SP153 - Quality Assurance: Part 4

TRACK 04: RADIATION ONCOLOGY

SP153.1 - Comparison of AAA and CCC Algorithms for H&N RapidArc pre-patient treatment QA

Author(s): Thuso M. Ramaloko¹, John K. Bhengu² ¹Medical Physics, Addington Hospital, Durban/SOUTH AFRI-CA, ²Medical Physics, Inkosi Albert Luthuli Central Hospital, Durban/ SOUTH AFRICA

Objectives: Because adherence to quality assurance (QA) is important to patient

safety, moving from gamma passing criteria to patient DVH-based QA won't be a

bad idea. The aim of the study was to evaluate OAR dose difference for $\ensuremath{\mathsf{H\&N}}$

between COMPASS and Eclipse.

Materials and Method: The

Eclipse TPS, COMPASS software, 30 H&N RapidArc patient's plans, 5 Prostate RapidArc patients' plans, Delta-4, MatrixX and Varian trilogy Linac were used. All 35 plans were computed with eclipse TPS using 2.5 Arcs, 2.5mm grid size, 1.8-2Gy per fraction for 28-33 fractions and field size ranged from 5cm² to 12cm². The computed dose fluence(s) were measured with MatrixX and Compass software dose reconstruction was carried out using 2.5mm grid size. The maximum dose (D2%) as per ICRU-83 recommendations was used for comparison between Eclipse and Compass. The prostate plans were primarily used for checking field size dosimetric effect between the two systems.

Results and discussion: Table 1 summarizes the head and neck plans comparison between the Eclipse TPS and the COMPASS verification software for different organs.

		Maximum dose diference (D _{2%})										
						N	lean±1δ (%)				
Volume	PTV	GTV	L Lens	R Lens	O Chiasm	S Chord	Pituatory	B Stem	R O Nerve	L O Nerve	R Parotid	L Parotid
Mean	-1.9	-2.0	16.8	11.4	2.3	-3.1	15.2	1.9	4.7	-6.1	-9.1	-6.7
STDEV	0.7	0.3	6.5	6.3	1.3	2.7	8.1	0.9	1.2	5.0	5.6	5.1
Table 1: Summ	arv of H&	N plans	maximu	m dose o	difference	between	the COMPA	SS and Fo	lipse			

ie 1: Summary of H&N plans maximum dose difference between the COMPASS and Eclipse

Table 2 summarizes the Prostate plans comparison between the Eclipse TPS and the COMPASS.

		Max	imum do	se difere	nce (D _{2%})	
-	Mean±1δ (%)					
Volume	PTV	GTV	Rectum	Bladder	L F head	R F Head
Mean	-1.6	-1.9	-1.3	-1.1	4.1	3.1
STDEV	0.8	0.5	0.9	0.4	2.4	2.6

The Delta-4 gamma index are 97.9±1.4% and 97.9±2.2% for H&N and prostate plans respectively, and Compass gamma index are 97.0±1.1% and 97.2±2.1% for H&N and prostate plans respectively.

Conclusion: The results were in agreement with Oncologist's guantec protocol and Physicists total dose gamma index criteria. The small volumes displayed high dose difference and were documented. The baseline values were established.

SP153.2 - Tuning treatment planning system model parameters for accurate VMAT dose calculation using conformal arc plans Author(s): Orest Ostapiak

Medical Physics, Juravinski Cancer Centre, Hamilton/CANADA

Machine models parameters within a treatment planning system (TPS) must be carefully tuned in order to accurately calculate dose due to VMAT plans. This is best achieved by comparing the results of calculations with those of measurements for VMAT plans that: deliver reproducibly; yield relatively homogeneous dose distributions; and, are sensitive to model parameters such as those characterizing the MLC. In Pinnacle version 9.2, creating deliverable VMAT plans requires first commissioning a candidate model, then running an optimization to generate a set of VMAT control points. These control points may have irregular shapes which complicate the analysis of discrepancies between calculated and measured dose.

The purpose of this work is to present a method for creating simple VMAT-like plans in a TPS that can be used to test and fine-tune MLC model parameters.

Plans were designed to irradiate a cylindrical phantom containing an ion chamber aligned along its central axis. A single voxel at the central axis in each slice comprised the target region of interest. Four conformal arcs beams spanning successive 45 degree sectors irradiated the target with a margin. Margins were tailored to create MLC slit fields of 1, 5 or 10 mm width. Each arc is created with the isocentre shifted 2 cm toward the mid-arc incident direction in order to force the MLC slit to sweep across the field. Control points were defined every 2 degrees of gantry arc. The isocentre for each arc was then centered on the ion chamber using the same control points. Each arc delivers a narrow slit field that sweeps across the ion chamber as the gantry rotates. Since

each arc is opposed, the dose varies by less than ±1.5% within 1 cm of the ion chamber cavity centre.

Doses measured using each of two chambers (A16 and PR06) agreed to within about 1% for all slit widths delivered by a single machine. Dose variation between two machines was 1, 2 and 5% corresponding to slit widths of 10, 5 and 1 mm respectively. Our clinical Eclipse model computes doses that are between 4 and 24% low compared to measurement. Adjusting the dynamic leaf gap from 0.08 mm to 1.6 mm brings computed doses within 3% of those measured. In Pinnacle, setting the MLC leaf tip radius to 12 cm and using the machine's leaf offset table yields computed doses that are between 2.5 and 13.8% low compared to measurement. Increasing the leaf tip radius to 1000cm and setting all leaf offsets to -0.08 mm (to match the Eclipse dynamic leaf gap) yields calculated results that are within 1.2% of the measured values.

Plans that mimic VMAT delivery may be created within a TPS using standard forward planning techniques. While not clinically relevant. these plans are useful for model tuning since the calculated dose is sensitive to small adjustments in MLC model parameters but robust with respect to delivery and measurement.

SP153.3 - Prostate brachytherapy with Oncentra Seeds: Intra-operative planning and delivery software validation assisted by an FMEA

Author(s): <u>Renee X. Larouche</u>, Yannick Hervieux, Dominic Béliveau-Nadeau, Jean-Francois Carrier, Daniel Taussky, Guila Delouya Radio-oncologie, CHUM - Hôpital Notre-Dame, Montreal/CANADA

Introduction: For the past 9 years, our center has been treating patients with prostate cancer with permanent seed implant prostate brachytherapy. This has been done using a Nucletron intra-operative planning and delivery system (FIRST[™]). We have now changed to a new Elekta Brachytherapy software (Oncentra[®] Seeds 4.2 (OCSe)). The goal of this study was to validate the new software for clinical use. Published guidelines from the AAPM and CPQR as well as a Failure Mode and Effect Analysis (FMEA) were used to review software and process.

Methods: We reviewed and implemented applicable guidelines from TG-43, TG-53, TG-56, TG-59, TG-64, TG-128 and TG-137. We also followed CPQR standard for Low Dose Rate Permanent Seed Brachytherapy. In total, over 60 tests were done to validate the new software. A FMEA was also performed.

Results: Using the tests, we identified weaknesses in the software:

 Discrepancy between software indication of ultrasound (US) imaging plane and the actual US imaging plane due to latency of the US image stream;

- · Contour displacement when switching between modes;
- · Line source dosimetry at 0 and 5° does not meet accuracy criteria;
- Poor robustness to system crashes. Over 10 min required to reboot system;
- · The system does not force acknowledgement of error messages;

Some of these weaknesses were due to connectivity issues with third party equipment (US scanner). Following communication with the vendor, some issues were addressed through workarounds. The FMEA (see Table 1) lead to discussions with the vendor regarding workflow. In order to make our institution's process more robust and less vulnerable to failures, planning system settings were customized to our needs.

Table 1 · Top	5 Failure modes	identified c	during the FMEA
10010 1.100			

Step	Failure modes	S	F	D	CI
4	Accidental needle update	5	5	2	50
4	Error in needle position due to frozen US image	4	5	2	40
4	Mismatch between re- constructed needle and software needle "cartoon" used for positioning	4	2	4	32
2	Wrong US scanning parameters	5	2	2	20
3	Plan transfer not possible due to empty needles	4	5	1	20

Over twenty-five patients have now been treated using OCSe. Issues not identified during the pre-clinical testing were encountered, most notably surrounding corrections for prostate motion. Our process was reviewed and adapted taking into account these issues. Our learning curve has been very quick. Time required to complete an implant is now comparable to that achieved through years of optimizing our process with the previous Nucletron system.

Conclusion: Based on data gathered so far, our results show that the extensive testing done before clinical implementation was valuable. These tests served to identify problems in the software and improve our process. Proper software validation in the context of the whole clinical process is very important and strongly recommended in assuring quality treatments.

SP153.4 - Investigation of predictive parameters for pre-treatment measurement pass rates in hypo-fractionated volumetric arc therapy (HF-VMAT) plans of single brain metastasis Author(s): Young K. Lee¹, Matt Wronski², Anthony Kim², Mark Rus-

Author(s): <u>Young K. Lee'</u>, Matt Wronski², Anthony Kim², Mark Ruschin²

¹Department Of Radiation Oncology, University of Toronto, Toronto/ ON/CANADA, ²Department Of Medical Physics, Sunnybrook Health Sciences Centre, Odette Cancer Centre, Toronto/CANADA

Purpose: HF-VMAT planning for brain metastases can be complicated, as these cases often involve small treatment volumes (planning target volumes (PTV)<25cm³) in close proximity to critical organs-at-risk (OAR). Pre-treatment dosimetric verification for such cases often yields sub-optimal pass rates. The purpose of the present study was to investigate the combined effects of OAR-to-PTV distance, as well as the differential between OAR tolerance dose and PTV prescription dose, in predicting what measurement pass rate is achievable.

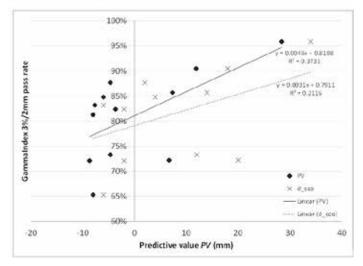

Methods: Twelve single lesion brain HF-VMAT cases were planned using Pinnacle v9.2 with 6MV Elekta Agility (Crawley, UK). The prescription doses ranged from 25 to 35 Gy in 5 fractions. All plans were recalculated and measured using an ArcCHECK diode phantom (SunNuclear Corporation, Melbourne, USA) employing Gamma analysis with criterion set at dose agreement of 3% and distance agreement at 2 mm. The predictive value, *PV*,investigated in the present study was as follows:

PV = dcco - (delta_D/G)

delta_D is the difference in dose between the prescription dose and dose-limiting OAR dose in Gy, *G* is the nominal dose gradient (150 and 400 cGy/mm for in-plane and out-of-plane of PTV, respectively), and *dcco* is the distance calculated using overlap-volume-histogram to the closest critical OAR in mm, where negative *dcco* indicates overlap between the expanded PTV and OAR. Smaller or increasingly negative values of *PV* were expected to predict increasingly modulated plans and hence lower measurement pass rates.

Results: Median (range) of PTV was 11.5 (4.1 - 24.7) cm³. The closest critical OAR observed in 8/12 cases was brainstem and for 10/12 cases the OAR was in the same plane as the PTV. Figure 1 shows the *dcco* and *PV*plotted against the ArcCHECK measurement pass rates. *PV*<10 mm show pass rates of <90% for Gamma analysis with the criterion set at 3%/2mm. A stronger correlation was observed between *PV* and pass rates than *dcco* and pass rates.

Figure 1. $d_{\rm act}$ and predictive value (PV) calculated and plotted against measurement Gamma Index pass rate of 3%/2mm.

Discussion: We show a relationship between *PV* and pre-treatment verification pass rate. Though the *PV* was calculated using a small dataset, it can be used to predict if a complicated VMAT plan may be required at the planning stage. This may allow the planner to decide if another planning methodology can be used to avoid pre-treatment verification failures that can cause problems in the planning process.

SP153.5 - Inter-centre comparison of dose delivery accuracy for six different linac-planning system combinations for SBRT lung cancer treatment using FFF beams.

Author(s): <u>David Thwaites</u>¹, Sam Blake¹, Prabhjot Juneja¹, Jonathan Sykes¹, Michael Bailey², Jeff Barber³, Regina Bromley⁴, Gwi Cho⁵, Shrikant Deshpande⁶, Sandra Fisher⁷, Joerg Lehmann¹, Carsten Brink⁸, Christian Hansen⁹

¹Institute Of Medical Physics, School Of Physics, University of Sydney, Sydney/AUSTRALIA, ²Radiation Oncology, Illawarra Cancer Care Centre, Wollongong/AUSTRALIA, ³Radiation Oncology, Nepean Cancer Care Centre, Penrith/AUSTRALIA, ⁴Radiation Oncology, Northern Sydney Cancer Centre, Sydney/AUSTRALIA, ⁵Radiation Oncology, Chris O'Brien Lifehouse at RPAH, Sydney/AUSTRA-LIA, ⁶Radiation Oncology, Liverpool Hospital, Liverpool/AUSTRA-LIA, ⁷Radiatoion Oncology, Prince of Wales Hospital, Sydney/ AUSTRALIA, ⁸Institute Of Clinical Research, University of Southern Denmark, Odense/DENMARK, ⁹Laboratory Of Radiation Physics, Odense University Hospital, Odense/DENMARK

Purpose: Flattening filter free (FFF) beams are being rapidly adopted for stereotactic body radiotherapy (SBRT). Compared to conventional flattened beams (FF), they have higher dose rates, lower lateral beam hardening changes, lower leakage and lower out-of-field doses. Together these provide the potential to improve treatment plans. Elekta and Varian have implemented FFF beams using different energy definitions and have different MLC designs; both of which might influence the achievable plan quality. In addition the MLC segmentation, IMRT optimisation and dose calculation engines employed in the various treatment planning systems (TPSs) may influence performance. This multi-centre, multi-system study compared plans and delivery accuracy of FFF lung SBRT treatments across six different linac/TPS combinations.

Materials and **Methods:**Ten lung patient cases were provided to seven different radiotherapy centres for SBRT planning with FF and FFF beams. Linac/TPS combinations included are: Varian-Eclipse, Varian-Pinnacle, Novalis/Varian-Eclipse, Elekta-Pinnacle, Elekta-Monaco and Tomotherapy-Tomoplan. The planning protocol was common for all. Prescribed minimum doses were 48Gy/4fr for tumours located <1.5cm from the thorax wall, 50Gy/5fr for those within 2cm of the main bronchial tree and 54Gy/3fr elsewhere in the lung. 180°-200° VMAT arcs were used for all standard linac plans, avoiding the contra lateral lung. Relevant DVH metrics were tested for significant differences, using a paired two-sided Wilcoxonsigned rank test and 5% significance. Plans were delivered to a Sun Nuclear ArcCheck phantom, where planned and measured doses were compared using a 3%/3 mm gamma analysis with a 10% threshold, and global normalisation. Beam on times were recorded.

Results: In the preliminary analysis, high quality dose plans and good delivery accuracy were observed for all the linac-TPS combinations across these ten plans. Mean gamma pass rates of 98.1% (FF) and 97.4% (FFF) were observed (Table 1). For Elekta-Pinnacle, FFF plans have lower pass rates than FF plans, but the relative calibration of the ArcCheck phantom (performed in low dose rates) may be a factor in this and is being investigated. FFF plan MU are higher in Varian/Novalis-Eclipse, but not for Elekta –Pinnacle. Eclipse generally used more MU than Pinnacle. Beam-on times are significantly reduced, with largest gains observed for Elekta-Pinnacle.

Conclusions: FFF beams produce acceptable plan quality and high dose delivery accuracy for SBRT lung treatments, across a range of linac-TPS combinations and representative tumour positions. Each combination has specific issues, which indicate further investigation possibilities. The TomoTherapy-Hi Art combination data is still to be fully evaluated.

SP153.6 - A pilot study investigating the impact of treatment delivery uncertainties for lung SABR using step and shoot IMRT and VMAT

Author(s): Samuel J. Blake¹, Sankar Arumugam², Lois Holloway², Shalini Vinod³, Cesar Ochoa³, Penny Phan³, <u>David Thwaites</u>¹ ¹Institute Of Medical Physics, School Of Physics, The University of Sydney, Sydney/NSW/AUSTRALIA, ²Department Of Radiation Oncology, Liverpool & Macarthur Cancer Therapy Centres and the Ingham Institute, Liverpool/NSW/AUSTRALIA, ³Department Of Radiation Oncology, Liverpool & Macarthur Cancer Therapy Centres, Liverpool/NSW/AUSTRALIA

Purpose

Advanced RT techniques require conservative approaches to planning, e.g. safety margins added to target volumes and the level of QA performed. This is partly due to a lack of detailed knowledge about the uncertainties involved in treatment delivery. The optimization and application of advanced techniques would benefit from a better understanding of such uncertainties and their impact on treatment effectiveness. This study investigates how delivery uncertainties affect target coverage for step-and-shoot IMRT (ssIMRT) and VMAT in SABR patient treatment plans.

Methods

6 MV ssIMRT and VMAT reference plans for three lung SABR patient datasets were created using the Pinnacle³ TPS (version 9.8) for an Elekta Synergy linac. Copies of these plans were modified using in-house code to generate a series of systematic 'error-introduced' plans, where the values of three beam delivery parameters were altered across all control points for each plan (gantry angle, collimator angle and MLC leaf positions). Gantry and collimator angles were changed from their reference values by +/- 1 or 2 degrees; MLC leaf positions by shifting each leaf from its reference position by +/- 1 or 2 mm. Error-introduced plans were read back into Pinnacle and dose calculations were performed on the reference patient anatomy. Target DVH metrics, including the volumes of PTV receiving 95% and 100% of the prescribed dose (VPTV95 and VPTV100, respectively) and the 50%, 100% and 105% isodose volumes (V50, V100 and V105, respectively) were extracted from each plan. The conformity index, high dose (105%) and low dose (50%) spillage were also quantified. Percentage differences between values for the errorintroduced plans and their respective reference plan were calculated to guantify the impact of varying each delivery parameter. Results were compared between the ssIMRT and VMAT plans to consider dependencies on delivery technique.

Results

For all DVH metrics considered, increasing the magnitude of the introduced error generally resulted in larger percent deviations from reference plan results. The VPTV95 and VPTV100 consistently decreased with increasing magnitude of MLC leaf shift. A maximum decrease in VPTV100 of approximately 5% was observed for MLC shifts of 2 mm in both the ssIMRT and VMAT plans. Collimator and gantry angle variations typically resulted in VPTV95 and VPTV100 deviations of <1%. Of the DVH metrics investigated, high dose spillage was the most sensitive to introduced errors for both treatment techniques. When collectively considering all beam delivery parameters investigated in this study, high dose spillage increased on average by between 12 and 27% for the ssIMRT and VMAT plans, respectively.

Conclusion

The impact of treatment delivery uncertainties on ssIMRT and VMAT patient dose distributions was investigated with an initial pilot cohort of lung SABR plans. Target coverage was typically compromised more by changes in MLC leaf positions than gantry or collimator angle. Of the DVH metrics and delivery parameters considered, high dose spillage was the most sensitive to treatment delivery uncertainties. The study is being extended to a wider set of plans with the aim of quantifying site- and technique-specific treatment delivery uncertainties in advanced RT techniques.

SP153.7 - Adaptive patient dose assessment using daily 3D cone beam CTs and Monte Carlo simulations

Author(s): <u>Nevin Mcvicar</u>¹, Parmveer Atwal¹, Julio Lobo², I Antoniu Popescu³

¹Medical Physics, BC Cancer Agency - Vancouver Cancer Centre, Vancouver/CANADA, ²Electrical And Computer Engineering, The University of British Columbia, Vancouver/CANADA, ³Physics And Astronomy, The University of British Columbia, Vancouver/CANADA

Introduction: Modern radiation therapy (RT) techniques, including IMRT and VMAT, provide very conformal dose distributions enabling high doses to be delivered to tumors. These complex delivery schemes require sophisticated quality assurance (QA) procedures to confirm accurate plan delivery. This study presents a novel workflow to assess daily dose distributions using patient position information from pre-treatment on-board imaging (OBI) cone beam computed tomography (CBCT) and Monte Carlo (MC) based dose predictions.

Methods: A clinical dataset from a patient with prostate cancer who received RT at our clinic was used. This patient was prescribed 7800 cGy/39 fx to be delivered using VMAT. A planning CT (PlanCT) was acquired 15 days prior to treatment. Critical structures and target volumes were contoured onto PlanCT and a VMAT plan was developed. A kV CBCT was acquired before each fraction. All image and contour registrations were performed automatically with the MIM software suite (MIM Software Inc, OH). The PlanCT was registered to daily CBCTs, using a deformable image registration (DIR), generating new data sets (planCTDEFORMED). Upper and lower regions of planCT were added to planCTDEFORMED to create planCTFINAL (**Figure 1**) to minimize truncation effects caused by the smaller CBCT volume. Dose distributions on PlanCT and PlanCTFINAL were calculated using the MC codes BEAMnrc/DOSXYZnrc.

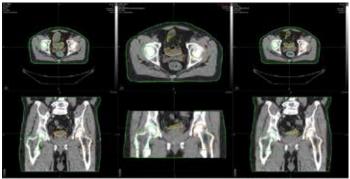

Figure 1. Axial (*top*) and sagittal (*bottom*) views of the PlanCT (*left*) and PlanCT_{DEFORMED} (*center*). The composite image of PlanCT and PlanCT_{DEFORMED} produced PlanCT_{FINAL} (*right*).

Results: Dose volume parameters for the planning target volume (PTV), bladder, rectum, pelvis and both femoral heads are compared in **Table 1**.

Table 1. Difference PlanCT and Plance			calculated wi	th MC using
Plan	Structures	Dmean (%)	Dmax (%)	V95% (%)
	PTV	98.9	103.7	97.7
	Bladder	53.6	102.0	11.6
PlanCT	Rectum	49.8	101.8	8.3
	L Fem Head	19.6	42.1	1.0
	R Fem Head	16.6	46.3	0.5
	PTV	95.3	103.5	65.5
PlanCTFinal	Bladder	48.1	96.1	1.5
(one fraction)	Rectum	58.3	103.5	22.8
	L Fem Head	20.3	45.8	2.7
	R Fem Head	14.9	39.3	0.0

Discussion: Significant differences in dose volume parameters are calculated when using daily CBCTs. Note the large difference in V95% due to inter-fraction prostate movement. Preliminary results highlight the need for more sophisticated QA procedures, including adaptive dose accumulation over the entire course of treatment. This technique is intended to complement daily *in vivo* dosimetry using EPID-based techniques.

SP154 - Developments in Radiation Protection

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP154.1 - Out-of-field radiation dose to critical organs due to radiotherapy for testicular seminoma with modified dog-leg fields: is there a risk for stochastic effects?

Author(s): <u>Michalis Mazonakis</u>¹, Theocharris Berris¹, Efrossyni Lyraraki², John Damilakis¹

¹Department Of Medical Physics, University of Crete, Heraklion/ GREECE, ²Department Of Radiotherapy, University Hospital of Heraklion, Heraklion/GREECE

Purpose: Modern radiotherapy of stage II seminoma involves the use of modified dog-leg fields with reduced dimensions compared to conventional portals. The objectives of this study were to (a) calculate the out-of-field dose to critical organs from irradiation with modified dog-leg fields using a Monte Carlo approach and (b) estimate the associated risk for stochastic effects.

Methods: The Monte Carlo N-particle transport code was used to simulate the head of a linear accelerator generating 6 MV X-rays. The model was validated against in-field dose measurements performed on a water tank and out-of-field thermoluminescent measurements generated on a humanoid phantom. A mathematical phantom representing a typical adult patient was implemented into the Monte Carlo environment. Radiotherapy was simulated with a pair of anteroposterior and posteroanterior modified dog-leg fields covering the para-aortic and ipsilateral iliac lymph nodes. Radiation dose calculations were made for all critical organs that defined by the ICRP publication 103 and located outside the simulated treatment fields. The calculated organ doses were combined with the appropriate risk factors to estimate the probability for developing secondary malignancies and heritable effects.

Results: The measured and calculated in-field radiation doses were in an excellent agreement with a difference of less than 2 %. A small mean difference of 9.6 ± 5.3 % was also found between out-of-field Monte Carlo dose calculations and experimental measurements. Simulated radiotherapy with modified dog-leg fields delivering 30 Gy to the tumor site resulted in an out-of-field organ dose range of 31.4-830.1 mGy. For a testicular cancer patient subjected to radiotherapy at the age of 30 years, the radiation doses received by non-targeted organs may increase the lifetime risk for second cancer development up to 2.2 %. The risk for heritable effects in future generations was estimated to be 0.2 %.

Conclusions: Radiotherapy with modified dog-leg fields may result in a relatively increased risk for second cancer induction. The probability for developing hereditary disorders is low compared to the natural incidence of these effects.

SP154.2 - Peripheral photon dose in organs

Author(s): <u>Beatriz Sanchez Nieto</u>¹, Rodrigo El Far², Leticia Irazola³, José A. Terrón⁴, Francisco Sanchez-Doblado³

¹Instituto De Física, Pontificia Universidad Católica de Chile, Santiago/CHILE, ²Centro De Cáncer, Pontificia Universidad Católica de Chile, Santiago/CHILE, ³Fisiologia Medica Y Biofisica, Facultad Medicina, University of Seville, Sevilla/SPAIN, ⁴Servicio De Radiofísica, Hospital Universitario Virgen Macarena, SEVILLA/SPAIN

There are an increasing number of RT patients who survive for periods comparable/larger than the latent period of a second cancer. Additionally, new techniques provide a better dose conformation at the cost of higher doses in organs outside the treatment field. That makes mandatory to compare the benefits (TCP) and the risks (NTCP and second cancer risks SCR) of the patient exposure. And yet, in spite of the treatment planning systems (TPS) providing accurate calculations of the dose delivered to the target, organs placed at a distance are no considered. Consequently, TPS only generate information regarding tumour control and radiation toxicity of neighbouring organs. The lack of algorithms to estimate equivalent dose to peripheral organs, together with uncertainties on risk factors, make the estimation of SCR not trivial.

Equivalent dose in organs can be calculated as the sum of equivalent doses for each radiation quality. We proposed a methodology to estimate equivalent neutron dose in organs for RT treatments (E>10MV) [1, 2] and developed an algorithm to calculate photon doses (to be submitted) for conformal radiotherapy -3DCRT- and IMRT [3].

The aim was to propound a methodology to calculate the mean absorbed photon dose in peripheral organs for individuals from a point-based algorithm requiring steadily available patient parameters.

Organs' lengths for individuals are calculated by using a scale factor (patient's/Cristy phantom's lengths). It is assumed that the mean organ photon dose is the integral of doses along the organ as follows:

$$Dose_{organ,\gamma} = \frac{1}{L_{organ}} \int_{x_{organ}}^{x_{organ}+L_{organ}} Dose(\varepsilon, f, z, x') dx'$$

L is the organ lenght and X the distance from the most cranial point to isocenter. Our model [3] stablished an expression for point dose calculation as the sum of the transmission and leakege (constant) and a second exponential term depending on the distance to a virtual scattering source (calculated from the isocenter depth –z- and x'). The fitting parameters, obtained for 3DCRT treatments, were modified to account for other treatment efficiencies (\mathcal{E} = prescription dose/ MU) and field sizes, both relatives to 3DCRT. This algorithm was built into Matlab through a Graphical User Interface and was validated [4] and used for calculations on how moving from 3DCRT to IMRT may result in an increase in peripheral organ doses [5].

From equivalent dose in organs, SCR estimations can be made for comparison to epidemiological data on induced RT cancer rates.

SP154.3 - Gamma Radiation Dose-Response Relationship of Human Thyroid Follicular Cells

Author(s): <u>Shyamal R. Chakraborty</u>¹, Arun K. Deb¹, Md. M. Uddin², Md. M. Rahman³

¹Department Of Physics, University of Chittagong, Chittagong/ BANGLADESH, ²Department Of Radiotherapy, Chittagong Medical College and Hospital, Chittagong/BANGLADESH, ³Department Of Radiotherapy, Sylhet M A G Osmani Medical College Hospital, Sylhet/BANGLADESH

Introduction: Thyroid gland is sensitive to gamma irradiation. Thyroid follicular cells produce the hormones T3 (triiodothyronine) and T4 (tetraiodothyronine or thyroxine) which play vital role in our lives. During radiotherapy (Co-60 teletherapy) in head-neck region, patients' thyroid gland is exposed to high level gamma irradiation. The exact dose on thyroid depends upon the tumor site, stage and overall total radiotherapy dose.

Aim of the work: In this research, an attempt had been made to find the relationship between gamma radiation dose to thyroid gland and the consequent response of its follicular cells.

Methodology: A total of one hundred and eighty head-neck cancerous patients of Chittagong Medical College hospital and Sylhet MAG Osmani Medical College Hospital who had to be treated with radiotherapy (⁶⁰Co) were selected in the present research. The patients' hormones T3, T4 and TSH (Thyroid Stimulating Hormone or thyrotropin) had been measured six times for each patient. The measurement times of which were before the beginning of their radiotherapy course, immediately after the radiotherapy, six weeks after the radiotherapy, twelve weeks after the radiotherapy, six months after the radiotherapy and finally twelve months after the radiotherapy for individual patients.

Results and Discussion: Thyroid follicular cells' response had been estimated by the percent of decrease in secretion of hormones T3 and T4 in spite of increased secretion of TSH by the pituitary gland. Graphs had been plotted by keeping the dose to thyroid (from 0 to 66 Gy) of patients (due to head-neck cancer) as abscissa and the percent of reduction of T3 and T4 hormones after one year of completion of radiotherapy as ordinate. For T3 hormone, the most fitted graph had been found to be an exponential one satisfying the equation, $y = y + Ae \cdot x/b$ where, y0, A and b are constants. The analyses had been done by the software OriginPro 7.5. For the T4 hormone, similar graph and equation had been found with slightly different parameters. For TSH, the corresponding relation had been found to be somewhat linear. No significant response had been observed unto twelve weeks after the completion of radiotherapy. At six months after the completion of radiotherapy, significant change in hormone levels had been observed. However at one year after the completion of radiotherapy course, drastic change in hormone levels had been observed. The more the level of exposure to thyroid, the more reduction in hormone T3 and T4 levels had been observed. For the exposure level of 66 Gy, graphs had also been plotted to find the role of time in the manifestation of radiation-response (reduction in the levels of T3 and T4) of thyroid follicular cells. Linear relations had been observed for T3 and T4 and for that 365 days time period.

$\ensuremath{\mathsf{SP154.5}}$ - Aligning the ALARA principle with FFF treatment modalities

Author(s): <u>Stephen Sawchuk</u>, Craig Lewis Physics And Engineering, London Regional Cancer Program/Western University, London/ON/CANADA

The recent popularity of flattening filter free (FFF) treatment beams featuring high dose rates has created some new radiation safety considerations. The softer FFF beams are less penetrating than their counterpart flattened beams (FF) of the same nominal energies. Thus in replacing FF treatment units the existing shielding is usually

adequate.¹ However, higher dose rates available for FFF beams can present radiation safety issues depending on workload, existing shielding, and occupancy factors. We report such a case for our first Varian TrueBeam linac. Ultimately, the ALARA principle is used to justify the modification of shielding to reduce the instantaneous dose rate (IDR)²beyond one primary barrier.

A Varian TrueBeam featuring four energy modes of 6-MV and 10-MV with FF and FFF was to replace its decommissioned predecessor, a Varian 21EX 6MV and 10 MV accelerator. The shielding design and previous radiation survey for the existing treatment bunker was analyzed to assess radiation safety for the new unit, focusing on beam quality, elevated dose rates, and an increased workload. This led to modifications of one existing primary barrier to reduce the IDR. The calculated IDR beyond this barrier for the FFF quality beam at the highest dose rate was 41 mSv / h, above the threshold for a controlled area at 25 mSv / h.¹⁻³ Thus extra shielding was required because of the increase in the dose rate from 6 Gy / minute to 24 Gy / minute at 100-cm SAD, not because of beam quality for the 10MV FFF beam.

A lead wall approximately 1 TVL thick covering this projected field plus margin was constructed at the primary barrier. Radiation survey results using an ion chamber survey meter yielded 28 mSv / h and 7.7 mSv / h for the unmodified and modified barriers respectively. Corresponding calculations were 41 mSv / h and 5.7 mSv / h.

The room beyond the modified primary barrier is an adjacent treatment bunker and thus already a controlled area with the appropriate posting of radiation warning signage. Because the IDR without barrier modification was high, it was reasonable to reduce the exposure for that room by adding the shielding. Thus we used the ALARA principle to further protect our staff.

We have modified a primary barrier for a treatment unit with a FFF beam with high dose rate capabilities. The ALARA principle was used to justify reducing the exposure to further protect staff. The increased exposure was due to the increase in maximum dose rate even though the FFF beams are softer and less penetrating. Hypothetically, situations can arise from a combination of workload, occupancy factors, and existing shielding that not only could cause increases in IDRs, but also the annual equivalent doses. Thus care should be taken in shielding design to deal with the high dose rates.

SP155 - Characterization of Detector Systems for Therapy Dosimetry: Part 3

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP155.1 - Ferrous - methylthymol blue - gelatin gel dosimter with improved auto-oxidation stability Author(s): Kalin I. Penev, Kibret Mequanint

Chemical And Biochemical Egnineering, University of Western Ontario, London/CANADA

The ferrous sulfate - methylthymol blue - gelatin (FMG) dosimeter is a recently-developed modification of conventional ferrous xylenol orange - gelatin (FXG) dosimeter that allows optical scanning with red light (615 - 635 nm), as opposed to amber light (580 - 590 nm). Scanning at the higher wavelength is beneficial as: optical scatter in the gelatin matrix decreases, and these wavelengths can be used for other optical dosimeters, allowing for simpler scanner design. It has previously been shown that the dose sensitivity and diffusion for both FMG and FXG are similar due to equivalency of the signal generation processes. Radiation-induced oxidation of ferrous iron (Fe²⁺) in the acidified gel produces ferric iron (Fe³⁺) in proportion to the delivered dose; and an intensely-coloured complex is formed between Fe³⁺ and either xylenol orange (XO) or methythymol blue (MTB). Unfortunately both gels are prone to autoxidation. We propose decreasing the auto-oxidation in FMG gels by adding phenanthroline-type ligands.

In preliminary experiments 5-nitro-1,10-phenanthroline (Nn) and bathophenanthrolinedisulfonic acid (BD) were tested as stabilizing agents for Fe2+ with MTB in sulfuric acid (SA) solutions at 25 to 40 mM SA. Heating at 72 °C for one hour was used in lieu of a longitudinal study of autoxidation. Relative to Nn, the addition of BD led to higher optical density and, unexpectedly, lower autoxidation protection. Therefore, Nn was selected for the follow-up in-gel tests. The gels were prepared with 5% (w/v) gelatin, 25 or 35 mM SA, 0.1 mM Fe²⁺, 0.1 mM MTB or XO and 0 or 0.3 mM Nn. Table 1 presents a subset of the results, given as the optical density (OD) at the respective wavelength of maximum absorbance (λmax) for each composition. Generally, FMG gels exhibited slightly higher autoxidation than the corresponding FXG gels, and the dose response (Δ (OD)/Gy) dropped with addition of Nn. At least one gel composition (in bold) had a very stable, low background optical density and adequate dose response. Unfortunately the diffusion coefficient was relatively high but addition of glyoxal (5 mM) decreased the diffusion by 10% without significantly affecting the sensitivity and stability (results not shown). In our opinion this FMG composition provides a viable alternative to FXG gels dosimetry.

SP155.2 - The dosimetric property of TLD2000 thermoluminescent dosimeter

Author(s): <u>Nan Zhao</u>, Ruijie Yang, Junjie Wang Radiation Oncology, Peking University Third Hospital, Beijing/CHINA

Purpose: To study the dosimetric properties of TLD2000 thermoluminescent dosimeter (TLD), including repeatability, linearity of dose response, energy response and dose rate effect.

Materials and Methods: 1300 TLD2000 TLDs were read out after exposure to a dose of 1 mGy of 65 keV x-ray, then were sorted out to have the same sensitivity within ±3.0%. TLDs were irradiated to a dose of 120 MU using 6 MV x-ray then irradiated to the same dose after 24 h. TLDs were irradiated by two 1251 seeds with the same activity for 24 h, and the interval time was 24 h, to study the repeatability of TLDs for 6 MV x-ray and 125I seed. TLDs were irradiated to different doses using ¹³⁷Cs (662 keV γ-ray), ¹²⁵I seed and 6 MV x-ray, to study the dose response of the TLDs. TLDs were irradiated to a dose of 1 mGy using ¹³⁷Cs, 48 keV, 65 keV, 83 keV, 118 keV and 250 keV x-rays, to study the energy response of the TLDs. TLDs were irradiated to a dose of 120 MU using 6 MV x-ray with different dose rates of 37 MU/min, 75 MU/min, 150 MU/min, 300 MU/min and 600 MU/min; TLDs were irradiated to the same dose using three ¹²⁵I seeds with different activities of 0.739 mCi, 0.675 mCi and 0.559 mCi, and the irradiated time were 24 h, 26h 17 min and 31 h 48 min. respectively, to study the dose rate effect of TLDs for 6 MV x-ray and 125 | seed.

Results: 350 TLD2000 TLDs were selected with the sensitivity within $\pm 3.0\%$. The maximum deviations of the repeatability were 2.7% and 4.0% for 6 MV x-ray and ¹²⁵I seed, respectively. The dose response of TLDs for ¹³⁷Cs and ¹²⁵I seed were linear. For 6 MV x-ray, the linear response range were 0.74 Gy-10.0 Gy, beyond 10.0 Gy the dose response became supralinear but proportional to the absorbed dose to TLD. The energy response for 48 keV, 65 keV, 83 keV, 118 keV and 250 keV x-rays, relative to the energy response of ¹³⁷Cs, were 1.25, 1.08, 0.99, 0.91 and 0.96, respectively. There were no dose rate effects in the dose rate range of 37 MU/min to 600 MU/min for 6 MV x-ray and 0.66 cGy/h to 0.87 cGy/h for ¹²⁵I seed.

Conclusions: TLD2000 TLD has good repeatability and linear dose response for ¹³⁷Cs, ¹²⁵I seed and 6 MV x-ray without dose rate effect, but the dose response is energy dependent.

SP155.3 - Application of 2D thermoluminescent dosimetry in QA test of Cyberknife

Author(s): <u>Renata Kopec</u>¹, Krzysztof Slosarek², Jan Gajewski¹, Aleksandra Grzadziel², Maciej Budzanowski¹

¹Institute of Nuclear Physics, Kraków/POLAND, ²Center of Oncology – Memorial Institute, Gliwice/POLAND

A measurement of thermoluminescence consists of increasing of temperature of TL material in a controlled way with simultaneous measurement of emitted light. Measurements of light intensity were up to now based on thermoluminescent (TLD) detectors and were realized almost entirely with use of photomultipliers (PM). In 2005 new specially prepared planar thermoluminescent (TL) reader with CCD camera was developed at the Institute of Nuclear Physics of the Polish Academy of Sciences (IFJ) Kraków, Poland. The ultrasensitive 12-bit monochromatic CCD camera was applied instead of PM. The results from that system are 2-D images of TL lighting. The new system has found a few practical applications. Two-dimensional (2-D) thermoluminescence (TL) dosimetry system was developed and tested by evaluating 2-D dose distributions around radioactive sources for different purposes e.g.: radiotherapy, radiology (1) and individual dosimetry (2). In this work additionally the results of studies on the two-dimensional technique based on the 2D planar foils to Cyberknife QA test are presented. Comparison between results from standard Gafchromic films and TL foils are also presented. To analysis of images gamma index method is applied.

SP155.4 - Towards Optical CT scanning of radiochromic 3D dosimeters in mismatched refractive index solutions Author(s): <u>Kurtis H. Dekker</u>, Jerry J. Battista, Kevin J. Jordan Department Of Medical Biophysics, Western University, London/ ON/CANADA

Introduction: The radiochromic plastic dosimeter, PRESAGE[®] (Heuris Inc., USA), shows promise for 3D radiation dosimetry using optical CT readout, as it offers good optical quality, has linear dose response[1], and is commercially available. Unfortunately, difficulty using oil-based refractive index matching solutions limits widespread clinical use. If lower-viscosity, water-based solutions could instead be used in the optical CT aquarium, this practical barrier could be overcome. Such liquids have a lower refractive index than

PRESAGE®, causing ray-bending and incomplete sampling in CT projections. Computer simulation studies[2], [3], however, show that iterative reconstruction could allow accurate reconstruction of a subvolume of the dosimeter, if the paths of rays through the sample are known. In this study, we present a method to measure ray paths using fiducial marker tracking, along with early results from intentionally mismatched-index scanning using a laser CT system.

Methods: For a fan-beam CT scan of a cylindrical object, with projections about 360°, the fiducial will occlude a given light ray twice. Assuming the rotation angle at each occlusion is known, the path of each ray can be calculated using the cylinder's radius. Using a custom built scanning-laser CT system with a large area detector[4], we scanned a uniform solution phantom made of a transparent teflon cylindrical vessel in an aquarium with a matched refractive index. Inside this vessel, liquid with refractive index 6% higher was used. Since Snell's law of refraction depends on the *ratio* of indices, this experiment simulates the case of a PRESAGE® dosimeter scanned in 60% (by weight) glycerol in water, which we found to be sufficiently low in viscosity for optical CT. The fiducial method was used to measure ray paths in order to re-sort the sinogram into parallel beam geometry, and a basic SIRT[5] algorithm was used for image reconstruction.

Results: The reconstruction shows uniformity within 3% for 84% of the radius, beyond which incomplete radial sampling leads to inaccurate values. The reconstructed attenuation coefficient of 0.342 ± 0.004 cm-1 within this region agreed with a central-axis measurement of 0.34 ± 0.02 cm-1 using the known phantom diameter.

Conclusions: With 6% refractive index mismatching, approximately 85% of the radius of a uniform object was reconstructed within 3% accuracy. This suggests that it should be possible to scan the PRESAGE® solid dosimeter in a 60% glycerol solution and accurately reconstruct the dose map within 85% of the radius. In future work we will image PRESAGE® samples with deposited dose distributions to determine if this approach enables practical clinical dosimetry.

SP155.5 - Development of a Novel Linear Energy Transfer Detector Using Doped Plastic Scintillators and Monte Carlo Simulation

Author(s): <u>Humza Nusrat</u>¹, Geordi Pang², Syed Bilal Ahmad³, Brian Keller⁴, Arman Sarfehnia⁴

¹Department Of Physics, Ryerson University, Toronto/CANADA, ²Imaging Research, Sunnybrook Health Sciences Centre, Department Of Medical Biophysics, University of Toronto, Toronto/ CANADA, ³Physical Sciences, Sunnybrook Research Institute, Toronto/CANADA, ⁴Department Of Radiation Oncology, University of Toronto, Toronto/CANADA

In radiotherapy, absorbed dose is a common quantity used to measure the amount of delivered radiation; however, dose is not a good indicator of actual biological damage. Linear energy transfer (LET) is the energy deposited per unit length along a charged particle's pathway; studies have shown that LET correlates well with relative biological effectiveness. This research seeks to design and develop a portable, clinically-suitable LET detector. According to Birks' law, light output of plastic scintillators is stopping power dependent. This dependency can be varied through doping by various high *Z* elements.

By measuring light output signals of differently doped plastic scintillators at a given point (represented by column vector **S**, where each row corresponds to a different scintillator material), fluence of charged particles of a given LET (represented by column vector ϕ , where each row corresponds to different LET bins) can be unfolded by **S=R*** ϕ , where **R** is system response matrix. Hence, the higher the resolution of LET fluence required (i.e. increased rows of matrix ϕ), the higher the number of distinct scintillating materials that must be used. Moreover, ϕ can only be solved if **R** is invertible, and the unicity of ϕ is given by the rank of matrix **R**.

Monte Carlo GEANT4.10.1 was used to determine optimal doping of polyvinyltoluene (base scintillator) to ensure distinctness of detector response, and invertibility of **R**. Various dopant materials (W, Pb, Mo) at several concentrations (1%, 10%) were simulated, FIG 1A. Preliminary results show doping with 1%Pb caused energy deposited to increase by 8.8%+/-0.07%; for 10%Pb this increased to 41.5%+/-0.07%.

GEANT4 was also used to evaluate **R**; each row represents a differently doped scintillator, each column corresponds to different electron LET. **R** was further corrected for signal loss in various connections used to transfer light from scintillator to PMT (i.e. housing, fiber). This was done experimentally using an integrating sphere and calculating the ratio of light transfer in presence/absence of connection assembly (FIG 1B).

Experimental setup shown schematically in FIG 1C was used to measure light output from scintillating materials. In-house code was written to integrate the PMT signal over time. Initial measurements were done using commercially available undoped polyvinyltoluene scintillator and a 1%Pb-doped scintillator.

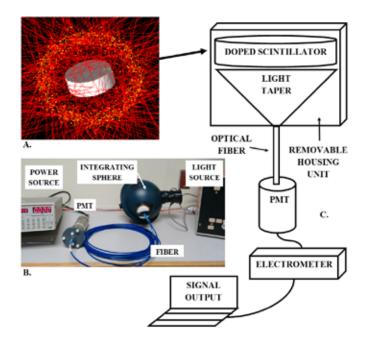

Figure 1: A. Sphere of isotropic mono-energetic electron sources simulated to determine scintillation response of each uniquely doped scintillator to electrons of given LET; B. Setup used to correct **R** for signal loss; **C.**Experimental Setup.

SP155.6 - Reduction of residual signal in LiF:Mg, Cu, P thermoluminescent material.

Author(s): Vinod K. Nelson

Medical Physics, Liverpool & MacArthur Cancer Therapy Centres, Campbelltown/AUSTRALIA

Purpose: LiF: Mg, Ti (TLD-100) is a well-established material for medical dosimetry over the past forty years since its development in the 1960s due to its tissue equivalence, negligible fading over lengthy periods, reasonable radiation sensitivity and relatively low minimum radiation detection level. However recently LiF: Mg, Cu, P has become a popular TL dosimeter in routine applications of personal, environmental and clinical dosimetry due to it's the high sensitivity, almost flat energy response, linear dose response, and the shorter annealing procedures. The main drawback of the LiF: Mg, Cu, P based dosimetry is the significant residual signal due to the presence of a high temperature peak in the temperature range of approximately 270°C - 300°C. Considerable effort has been invested in the development of a LiF: Mg, Cu, P material with a greatly reduced residual signal. However, the integrated processes of sintering and microstructure development in a crystalline compound remain complex even after many years of research. The purpose of this work was to explore the possibility of using a low heating rate and longer TL signal integration time to reduce the residual signal in LiF: Mg, Cu, P (TLD100-H) dosimetry material.

Materials and Methods: TLD100-H material in the form of chips of thicknesses 0.9 mm (thick) and 0.4 mm (thin) were used. The chips were annealed at 240°C for 10 minute after each irradiation and prior to next use. Irradiation was carried out in a solid water phantom at 5 cm depth using 6 MV x-rays. A dose of 0.5Gy was delivered for each irradiation. Three readout cycles were tested, and repeat readouts were carried out immediately after the first readout, using the same parameters. The three heating rates used were 15°C / sec, 10°C/ sec, 5°C/sec and 1°C / sec. The signal was integration time was 30 sec, 60 sec, 60 sec and 300 sec, respectively. The residual signal was calculated as a ratio of first readout TL signal over the second readout TL signal.

Results: The mean residual signal for thick TLD chips was 6.1% and that from thin TLD chips was 7.5% when the heating rate was 15°C/sec. When the heating rate was reduced to 5°C/sec, the mean residual signal for thick TLD chips was 1.9%. For thin chips the residual signal was negligible (<0.1%) when the heating rate was 7°C/sec. At the heating rate of 1°C/sec, the residual signal was practically removed and was less than the background noise of the TLD reader.

Conclusions: The present study shows that a slow heating rate reduces the residual signal in TLD100H dosimeters. The effect is more pronounced in thinner TLD chips. When low dose measurements are performed using TLD100-H material, thin chips with a heating rate of 7°C/sec should be used. A heating rate of 1°C/sec would be ideal for 0.9 mm thick TLD100-H chips; however a heating rate of between 1 and 5 °C/sec would achieve a good balance between low residual signal and a practical overall readout time.

SP155.7 - Application of dose gels in HDR brachytherapy Author(s): Diana Adliene¹, Karolis Jakstas², Neringa Vaiciunaite¹, Jurgita Laurikaitiene³, Reda Cerapaite-Trusinskiene⁴ ¹Physics Department, Kaunas University of Technology, Kaunas/ LITHUANIA, ²Oncology Clinic, Republican Siauliai Hospital, Siauliai/ LITHUANIA, ³Centre Of Mathematics, Physics And Information Technology, Aleksandras Stulginskis University, Kaunas/LITHUA-NIA, ⁴Physics, Mathematics And Biophysics Department, Lithuanian University of Health Sciences, Kaunas/LITHUANIA

Normoxic gels are frequently used in clinical praxis for dose assessment or 3D dose imaging in radiotherapy due to their relative simple manufacturing process, well expressed radiation induced modification of physical properties and well defined spatial shape of the polymerized gel part in the irradiated volume. Normoxic polyacrylamide (nPAG) gels were irradiated in high dose rate (HDR) after loading brachytherapy system MicroSelectron v2 with ¹⁹²Ir source. The source was inserted into 6 Fr catheter which was fixed at the axial position of the gel filled beaker during gel preparation phase. Varying composition and manufacturing process conditions free standing polymerized gel shapes were produced around a catheter as polymerization center. Dose and dose rate related properties of the free standing polymerized gel shapes were evaluated using Raman spectroscopy and were compared to those of in the gel volume located polymerized gel regions of usual nPAG gels. Analysis of the obtained results is provided and possibility to pre-assess special dose distribution in the prescribed irradiation target using these free standing polymerized gels is discussed.

SP155.8 - Practical 3D QA for Radiation Therapy Based on High-Resolution Laser CT of Reusable Radiochromic Polymer-Gel Dosimeters in Dedicated Phantoms

Author(s): Marek Maryanski¹, Liyong Lin², Ali Kassaee², James Kraus², <u>Stephen Avery²</u>

¹MGS Research Inc., Madison/CT/UNITED STATES OF AMERI-CA, ²University of Pennsylvania, Philadelphia/UNITED STATES OF AMERICA

Current quality assurance measurements are not sufficient to detect fine structure errors from complex plans. Treatment delivery methods are becoming more complex with higher doses and fewer fractions. A high resolution technique is needed to account for the subtle errors which combine resulting in a treatment plan which is ultimately inaccurate. Presently water phantoms are used for measuring and determining the dose distribution of radiation produced by a particle beam or photon radiation beam. The standard dosimetry system is comprised of: a water tank, an ionization/diode detector positioned in a fixed position and software used to control the motion of detector and analyze data. It is not possible to use the water tank system for advanced delivery techniques such as Arc Therapy or IMRT. Due to the point-by-point measuring concept this system cannot quantify the effect of modulated beams. 2D detectors such Matrixx or Mapcheck are used for quality assurance measurements but are limited to measuring one plane at a time. This information is adequate for QA test, but with the advancement of treatment planning techniques and treatment machines that deliver highly conformal dose; it's impossible for a 2D detector to capture all the subtleties in the treatment plan. The promise of the clinical benefits of intensity modulated particle therapy (IMPT), for example, will only be achieved by having adequate 3D dosimetry and QA tools. Clinical 3D dosimetry will be critical in keeping pace with the rapid advancements in present day technology.

Our system offers reusable dosimeters which we have demonstrated the feasibility of the signal decay correction and the response signal decay rate; that ranges from hours to days depending on the formulation. The VOLQA[™] software is capable of image reconstruction, DICOM import, 3D registration using orthogonal projections, dose calibration, comparison of measured plans vs calculated plans and automatic generation of the QA summary table. The workflow from end of laser CT scan to QA report is 30 minutes with a dosimetric precision/accuracy of 99.5%/99.0%. There is no quenching effect for proton beams. The system has demonstrated excellent agreement (measurement vs plan) with gamma passing rate above 95% at 2mm/2% acceptance level down to the 50% isodose line. Isotropic spatial resolution ranges from 0.25 to 1 mm with a FOV up to 23 cm. The cost per QA is approximately \$50-\$100.

A practical 3D QA for modern radiation therapy has been developed and tested for clinical QA applications. High resolution and dosimetric accuracy is combined with minimum time required on the part of physics staff. Widespread use in both radiosurgery and particle therapy QA is anticipated. This system has the potential to improve quality assurance of radiation therapy treatment of cancer and other diseases by the introduction of fast, accurate, high-resolution, three-dimensional dosimetry based on laser CT of soft-tissueequivalent polymer dosimeters whose local optical density changes in proportion to local dose. The new technology could potentially be used in acceptance and commissioning testing for all existing treatment modalities.

SP156 - Patient-Specific Modeling and Simulation in Surgery

TRACK 07: SURGERY, COMPUTER AIDED SURGERY, MINIMAL INVASIVE INTERVENTIONS, ENDOSCOPY AND IMAGE-GUIDED THERAPY, MODELLING AND SIMULATION

SP156.1 - A Technique for Prostate Registration by Finite Element Modeling

Author(s): Jianfei Liu¹, <u>Fangsen Cui</u>¹, Zhuangjian Liu¹, Jimin Liu² ¹Engineering Mechanics, Institute of High Performance Computing, A*STAR, Singapore/SINGAPORE, ²Quantiative Image Processing Group, Singapore Biomedical Imaging Consortium, A*STAR, Singapore/SINGAPORE

Magnetic resonance imaging (MRI) targeted and transrectal ultrasound (TRUS) guided needle biopsy is currently the clinical standard routine for diagnosis of prostate cancer. The prostate under TRUS procedure possesses different orientation and shape from its presentation in MRI procedure. Therefore, registration of suspicious tumor sites identified in the MRI images to that of TRUS images is an essential process to ascertain the needling targets during the TRUS procedure. In this paper, an effective technique is proposed to directly transform the prostate geometries from MRI volume to TRUS volume, based on finite element (FE) method and biomechanical models. Both the procedure and the accuracy of this registration method were studied through 2D transformation of prostate axial cross-section. The overall target errors can be reduces to less than 1 mm even for a large deformed prostate.

SP156.2 - Modeling study of neo-aortic root for arterial switch operation: a structural finite element analysis

Author(s): Aike Qiao¹, <u>Zhaoyong Gu</u>¹, Youlian Pan¹, Rongxi Jia¹, Nianguo Dong²

¹Beijing University of Technology, Beijing/CHINA, ²Huazhong University of Science and Technology, Wuhan/CHINA

In order to investigate the influence of sinotubular junction and sinus diameter on the aortic valve closure, numerical simulations were performed. Models of neo-aortic root for arterial switch operation to the patient with complete transposition of the great arteries were established. The 3-dimensional geometry of a reference aortic valve model A, with the aortic annulus diameter (DAA)=9.70mm, the diameters of sinotubular junction (DSTJ)=9.70mm and the sinus diameter (DS)=12.30mm, was built. Then the DSTJ and DS were modified to create four geometric models with different dimensions, named as B(DSTJ=11.60, DS=12.30), C(DSTJ=7.76, DS=12.30), D(DSTJ=9.70, DS=14.76), and E(DSTJ=9.70, DS=9.84). The mechanical behavior of the aortic root on the closing diastolic phase was simulated. The performance of the aortic leaflets was assessed in terms of stress of neo-aortic root, change of the aortic annulus diameter as well as leaflet contact force during closing phase. The reference model A showed a maximum leaflet stress of 96.29kPa. For models B and C, leaflet contact forces are respectively increased by 43.33% and decreased by 10.00% with the sinotubular junction diameter respectively increased by 1.2 times and decreased by 0.8 times compared with reference model A. Compared with model A, leaflet contact forces in models D and E are respectively increased by 6.67% and decreased by 23.33% with sinus diameter respectively increased by 1.2 times and decreased by 0.8 times. It is evident that increasing the sinotubular junction and sinus diameter within a range of 20% can increase the maximum stress and the leaflet contact force for aortic root and vice versa. It may be the reason why neo-aortic valve insufficiency occurs after a long period of time for patients with arterial switch operation.

SP156.3 - Preoperative in silico analysis of atherosclerotic calcification vulnerability in carotid artery stenting using Finite Element Analysis by considering Agatston score Author(s): Sadech Rivahi Alam¹, Umberto Morbiducci¹, Hirovuki

Katano², Kiyoko Yokoyama³, Shady Ali¹, Alberto Audenino¹, Filippo Molinari⁴

¹Mechanical And Aerospace Engineering, Politecnico di Torino, Turin/ITALY, ²Department Of Neurosurgery, Graduate School Of Medical Sciences, Nagoya City University, Nagoya/JAPAN, ³Graduate School Of Design And Architecture, Nagoya City University, Nagoya/JAPAN, ⁴Electronics And Telecommunications, Politecnico di Torino, Turin/ITALY

The role of calcification inside fibroatheroma during carotid artery stenting operation is controversial. Cardiologists face a major problem of "plaque vulnerability" during the placement of both balloon and stent, with stiff plaques containing advanced calcifications that break the arterial wall or give rise to unstable thromboembolic stroke. The aim of this work is to evaluate the role of calcification (in terms of material and mechanical properties) in plague vulnerability and wall rupture and to find plaque maximum resistance before breaking. Image-based models of carotid artery stenting were used and Finite Element Analysis (FEA) was performed to simulate the impact of balloon and stent expansion in the presence of calcified plaques. In detail, a nonlinear static structural analysis was performed on 20 patients acquired using in vivo MDCT angiography. The Agatston Calcium score was obtained for each patient and subject-specific local Elastic Modulus was calculated. The in silico results showed that by imposing maximum ultimate external load of 1.2MPa and 4.2MPa on balloon and stent respectively. average ultimate stress of 55.7±41.2kPa and 171±41.2kPa as well as average Plaque Wall Stress of 19.03±16.05kPa and 64.3±63.3kPa were obtained on calcifications, respectively. Elastic and plastic strain average values of 0.03±0.02 and 0.006±0.01, respectively, were obtained on the calcified plagues after stent expansions. These average data are in good agreement with results obtained by other research groups relative to the values of compressive Elastic Modulus of atherosclerotic plaques and its ultimate stress, strain values after performing carotid artery stenting. Even if our findings are markedly influenced by local geometry and plaque shape, this study enriches the literature in pre-operative prediction of ultimate mechanical parameters in stenting operation to prevent rupture before balloon/stent expansion.

SP156.4 - Biomechanical modeling for foot inversion

Author(s): Junchao Guo¹, Cheng-Fei Du¹, Li Z. Wang¹, Yu B. Fan^{*2} ¹Key Laboratory for Biomechanics and Mechanobiology of Ministry of Education, School of Biological Science and Medical Engineering, Beihang University, Beijing/CHINA, ²National Research Center for Rehabilitation Technical Aids, Beijing 100176, P.R. China, Beijing/ CHINA

Foot inversion was the most common injury of lower limb injury, it seriously affected the foot balance and posture control during standing and walking. The purpose of this study was to describe the rationality of biomechanical modeling for foot inversion. Plantar pressure measurements and foot roentgenogram had been reported. However, direct measurement of the internal tissues stress was difficult. A three-dimensional finite element model of foot inversion was developed to investigate the region of foot inversion injury. Compared with normal foot, the results showed that subtalar joint region was mainly weight-bearing region. Peak von Mises stress of the internal bones was transferred to the lateral longitudinal arch. The simulation in this study would provide the suggestion of therapeutic planning to foot inversion.

SP156.5 - Deformation Method and 3D Modeling of the female body to simulate Core Biopsy procedure

Author(s): Maria Tereza D. Melo, Vinicius P. Da Silva Corrêa, Vladimir F. Nogueira, Victor Hugo L. Goncalves, Henrik D·Oark R. Costa, Lourdes M. Brasil, Jairo Simão S. Melo, Beatriz A. Rodrigues University of Brasília-UnB at Gama-FGA, Brasilia/BRAZIL

Core biopsy is an invasive surgical procedure that collects the tissue samples to be evaluated by an expert. The withdrawal of samples is performed with large-*caliber needles*, attached to a special pistol. It is a technique conducted by an imaging equipment to guide the procedure. Usually consists of ultrasound guided core needle biopsy or stereotactic mammography.

This procedure can be used in the investigation of various diseases and through it, you can identify precise information on the nature of the injury or the degree of impairment of the tissue for diseases. For breast cancer, the results with the biopsy are essential to set an appropriate treatment, and may this be a surgical intervention or not. Thereby, it is guaranteed greater effectiveness in the final results.

Thus, the simulation modeling of surgery and examination has an elastic deformation behavior of human skin through the puncture. It is used physical and mathematical methods to describe computationally this imputed deformation on the skin in a mammary biopsy procedure. Thus, the deformation of Infinite Elements is characterized and justified for such a technique. The method chosen features complex structures with a greater realism, which is ideal for the representation of the breast. And to improve the results obtained on deformation, it is used Fuzzy Logic for the interpretation of the output data.

With the aim of providing the medical students and other health professionals greater dexterity in performing breast biopsy, it was developed the project: 3D Anatomical Atlas Applied to Mama, in order to develop a learning environment using virtual reality precepts. The project is divided into five modules: three-dimensional (3D) modeling, ontological modeling, development of an Intelligent Tutor System (ITS), deformation and pathology. This paper presents the 3D modeling in conjunction with the deformation. The 3D modeling is responsible for creating 3D structures of the female body and its internal composition being used in virtual simulation of surgical procedure Core Biopsy, illustrated by Fig. 1. Thus, professionals can train your skills and, at the same time, using the modeling tools to make them more didactic, so that a student can assimilate the precepts.

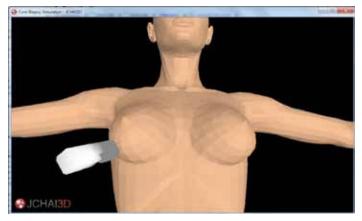

Fig. 1. The simulation of Core Biopsy procedure

SP156.6 - Effects of Band Position on Hemodynamics of Pulmonary Artery: A Numerical Study of Patient-specific Virtual Procedure

Author(s): Jin Long Liu, Wei Min Zhang, Qin Yan, Hai Fa Hong, Jin Fen Liu

Department of Cardiothoracic Surgery, Shanghai Children's Medical Center, Shanghai Jiao Tong University School of Medicine, Shanghai/CHINA

Hemodynamics of pulmonary artery flow after different strategies of pulmonary banding (PAB) was not well understood. By using computer-aided design (CAD), three PAB models were devised and numerical study was done by computational fluid dynamics (CFD). The results indicated that whirling flow was formed in all the PAB models, which is more significant in that with proximal PAB, leading to unbalanced perfusion of lungs. While in distal PAB models, the flow disturbance is relatively mild and unbalanced flow to left pulmonary artery has decreased. Integrated CAD and CFD study can be applied to predict and optimize the surgical outcomes of PAB.

SP156.7 - Experimentally validated Biomechanical Model of in vivo Lung under EBRT considering Diaphragm motion hysteresis

Author(s): Elham Karami¹, Stewart Gaede², Ting-Yim Lee³, Abbas Samani⁴

¹Medical Biophysics, Western University, London/CANADA, ²Department Of Oncology, Western University, London/CANADA, ³Imaging Research Laboratories, Robarts Research Institute, London, ON/CANADA, ⁴Electrical & Computer Engineering, Western University, London/ON/CANADA

Lung cancer is by far the most common cause of cancer death in both men and women. Both small-cell and non-small cell lung cancers are frequently treated with radiation therapy, which is often combined with chemotherapy, surgery or both. However, External Beam Radiation Therapy (EBRT) may lack desirable dosimetric accuracy because of respiration induced tumor motion. Recently, biomechanical modeling of the respiratory system has become a popular approach for tumor motion prediction and compensation. This approach requires reasonably accurate data pertaining to lung geometry, thoracic pressure variation, diaphragm position and tissue biomechanical properties in order to predict tumor motion. However, given the pleural pressure nonuniformity on the lung's surface and contact between the lung, diaphragm and heart, modeling the lung loading is cumbersome. A simple approach frequently used in lung models applies uniform negative pressure on the lung's surface at the end exhalation phase to simulate the inhalation phase [1,2,3]. The negative pressure's magnitude is obtained either from reported pressure-volume curves in the literature or from 4D CT data. Other approaches include modeling the thoracic pressure and diaphragm motion separately [4,5].

To our knowledge, none of the existing lung biomechanical models account for respiratory cycle hysteresis. The lung hysteresis results from surfactant action during inhalation and tissue recoiling during exhalation. In this paper, we present preliminary results obtained from lung 4D CT image processing which indicate that the human diaphragm motion's hysteretic nature. This hysteresis further contributes to the lung hysteresis. To track the diaphragm motion, 22 points located on its surface were tracked in a set of 4D CT images using Free Form Deformable registration. The displacement values in the superior-inferior direction were normalized between 0 and 1 for all the points. The average curve depicted in Figure 1 indicates that the diaphragm motion has similar pattern to the lung compliance curve. These results suggest that, to achieve desirable accuracy with lung biomechanical modeling, this strong diaphragm motion hysteresis should be considered. This was done by modifying the model we presented in [4], leading to significant improvement in tumor motion prediction.

SP157 - Biochips and Blood Analysis

TRACK 08: BIOSENSOR, NANOTECHNOLOGY, BIOMEMS AND BIOPHOTONICS

SP157.1 - On-chip blood Plasma separation using vacuumassisted micropumping for point-of-care application Author(s): Linfeng Xu, <u>Kwang W. Oh</u> Electrical Engineering, SUNY at Buffalo, Buffalo/NY/UNITED STATES OF AMERICA

SMALL (Sensors and MicroActuators Learning Lab), Department of Electrical Engineering, University at Buffalo, The State University of New York (SUNY at Buffalo), Buffalo, New York 14260,

Introduction: To become useful diagnostics tools in global mobile health point-of-care (POC) settings, a disposable biosensor will require further improvement by integration of sample preparation, which has been troublesome due to incorporation of external active valves and pumps [1]. Our approach aims to simplify the on-chip blood plasma separation required to perform specific sensing of biomolecules, all without compromising biosensor functionality. Without any of the requirements of sophisticated equipment or dilution techniques, we could extract the plasma from the whole blood, which is suitable for point-of-care applications. This talk will cover a selected example in the emerging POC applications, such as hemolysis-free on-chip blood plasma separation by using a simple hand-held power-free vacuum-assisted pumping method.

PRINCIPLE/DESIGN: Pneumatic chambers, A and B, are neighbouring with the separation chamber and the dead-end ring channel, respectively, which are physically disconnected each other through a thin air-permeable PDMS wall (separation chamber/PDMS wall/pneumatic chamber A and ring channel/PDMS wall/pneumatic chamber B). Each pneumatic chamber is connected to a hand-held syringe. By pulling the plunger of the hand-held syringe, a vacuum will be generated inside the pneumatic chambers (due to the volume change from 2 uL to 2 mL). This will indirectly withdraw the blood sample in the separation chamber through the are-permeable PDMS wall. Flow rates can be tuned by adjusting the PDMS wall thickness and overlap area between the pneumatic chamber and the separation chamber. Meanwhile, by gravity, blood cells will sediment at the bottom of the separation chamber therefore plasma could be separated from the whole blood. Moreover, phaseguides are employed at the bottom of the separation chambers (1) to prevent air trapping inside the separation chamber and (2) to increase the plasma separation efficiency by avoiding the slide of blood cells that are already sediment down.

EXPERIMENTS/Results: The secret is to indirectly and slowly pump the whole blood into a dead-end chamber/channel embedded with smart microstructures (e.g., phaseguides in order to both enhance the separation efficiency and reduce the separation time) by well-controlled air-diffusion through the thin PDMS wall, due to the syringe-generated pressure difference (atmosphere in the dead-end chamber/channel vs. vacuum in the pneumatic chamber/syringe). This allows fast sedimentation of blood cells and thereby filter-free and hemolysis-free plasma separation. Through the experiments, we found the followings: (1) Pinning time due to the phaseguides was in inverse proportion to the separation efficiency. By adjusting the design parameters of the neck structure in the phaseguides, pinning time could be reduced. (2) The ratio between the height of the phaseguides and the separation chamber was proportional to the separation efficiency. (3) Flow rates were also in an inverse relationship to the separation efficiency. Similar results were also verified by a set of straight channels.

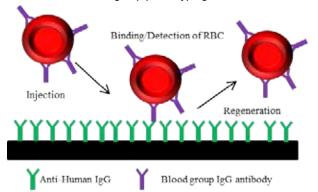

Conclusion: We have investigated a simple hand-held power-free vacuum-assisted pumping method, its application for hemolysis-free on-chip blood plasma separation, and the key parameters that would affect the separation efficiency. The present device is expected to be an effective tool for blood separation, especially for point-of-care applications.

SP157.2 - Multi-Functional Platform for Blood Group Phenotyping using Surface Plasmon Resonance

Author(s): <u>Whui Lyn Then</u>¹, Marie-Isobel Aguilar², Gil Garnier¹ ¹Chemical Engineering, Bioresource Processing Research Institute of Australia (BioPRIA), Monash University, Melbourne/VIC/AUSTRA-LIA, ²Biochemistry, Monash University, Melbourne, Melbourne/VIC/ AUSTRALIA

Accurate and reliable phenotyping of blood groups is of the utmost importance prior to transfusion. Mismatching of incompatible donor and patient blood types could potentially lead to a haemolytic transfusion reaction, which can be fatal. Currently, there are many well established blood typing methods available, such as the column agglutination test (CAT), however methods quantifying these antibody-antigen interactions are limited. This is particularly important to identify and characterize weak interactions between weak subgroup variants, which are often difficult to determine by the naked eye and have the potential to be overlooked. The biosensing system, BIAcore, relies on surface plasmon resonance (SPR) detection to quantify interactions between biomolecules. Previous studies have shown the use of SPR for blood group antigen detection and antibody detection; however, these methods showed poor regeneration and loss of functionality after a single use due to the inability to fully desorb bound material. Each chip (~AUD200) was also limited to a single blood group. A fully regenerable, multi-functional platform for quantitative blood group phenotyping via SPR detection can be achieved by covalently immobilizing an antibody, anti-human IgG, to the chip surface. Anti-human IgG is able to recognize and bind to the Fc region of human IgG antibodies for detection. The surface can therefore be used as an interchangeable platform capable of quantifying the blood group phenotyping interactions between RBCs and IgG antibodies. Much like the Indirect Antiglobulin Test (IAT) used to detect blood groups using IgG antibodies with the CAT, the blood group IgG antibody is incubated with RBCs, and the cells become sensitized, which allows them to bind to the anti-human IgG on the chip surface. This test has potential to guantitatively detect any blood group with a corresponding IgG antibody. A clear distinction between positive and negative results has been achieved using anti-D IgG and reagent red cells, as well as complete regeneration of the antihuman IgG surface. Very little degradation, if any, of the immobilized surface has been observed after over 100 regenerations. Consecutive testing of different blood types has also been successful, allowing multiple blood groups to be detected using a single chip. This multifunctional platform presents potential for quantifying antibody-antigen interactions for blood group phenotyping.

SP157.3 - Harmonic generation microscopy investigation of human pathological samples for automated cancer determination Author(s): <u>Richard Cisek</u>¹, Danielle Tokarz², Ahmad Golaraei³, Serguei Krouglov³, Carolyn Niu⁴, Shingo Sakashita⁴, Ming-Sound Tsao⁴, Sylvia Asa⁵, Brian C. Wilson⁴, Virginijus Barzda³

¹Chemical And Physical Sciences, University of Toronto, Mississauga/ON/CANADA, ²Wellman Center For Photomedicine, Massachusetts General Hospital, Harvard Medical School, Boston/MA/ UNITED STATES OF AMERICA, ³Chemical And Physical Sciences, University of Toronto, Mississauga/CANADA, ⁴Princess Margaret Cancer Centre, University Health Network, Toronto/ON/CANA-DA, ⁵Toronto General Hospital, University Health Network, Toronto/ ON/CANADA

Nonlinear harmonic generation microscopy was used to investigate human pathological samples revealing quantitative differences between tumor and non-tumor regions in the extracellular matrix of several tissues including breast, lung, pancreas and thyroid. During tumor initiation and progression, alterations to the structure of collagen inside the extracellular matrix of different tissues can occur, which can be used for developing new biomarkers in cancer diagnosis. Second harmonic generation (SHG) is a spectroscopic nonlinear optical signal that is sensitive to changes in the ultrastructure of collagen, such as the organization of collagen into fibers, and the distribution of collagen fibers within a femto-liter laser focal volume, and therefore, SHG can be used as a biomarker for cancer diagnosis. The novel technique, polarization-in, polarization-out (PIPO) SHG microscopy was utilized, which is an accurate way to extract the second-order nonlinear optical susceptibility ratio component, $\chi^{(2)}$ $zzz/\chi(^2)zxx$, which is related to the ultrastructure of collagen at each pixel. The PIPO SHG technique requires measuring the SHG intensity at each pixel of the image, at different orientations of the linear polarization of outgoing SHG as a function of the linear polarization orientation of the incident laser radiation. A MATLAB based fitting routine is used to deduce $\chi^{(2)}zzz/\chi(^{2)}zxx$ from the PIPO SHG image stacks, producing a color-coded map consisting of the $\chi^{(2)}zzz/\chi^{(2)}$ zxx value at each pixel. Additionally, the average orientation of the fibers is also deduced at each pixel of the image revealing long range collagen organization in the tissue. The $\chi^{(2)}zzz/\chi^{(2)}zxx$ maps reveal areas of altered collagen structure within tissue sections, and are independent of collagen concentration. Statistically-significant differences in $\chi^{(2)}zzz/\chi^{(2)}zxx$ were found between tumor and nontumor tissues, which varied from organ to organ. Therefore, PIPO SHG microscopy has the potential to be used as a high throughput pathological sample pre-diagnosis system, aiding pathologists in cancer diagnostics. Additionally, PIPO SHG microscopy could also visualize and characterize the structure of collagen in vivo without staining which may aid in the study of collagen-related biological processes such as wound repair.

SP157.4 - Protein Patterning: An investigation on the use of different protein deposition techniques and parameters to transfer proteins onto various surfaces.

Author(s): <u>Kathryn Clancy</u>¹, Dan V. Nicolau²

¹Biomedical Engineering, McGill University, Montreal/QC/CANA-DA, ²Bioengineering, McGill University, Montreal/QC/CANADA

Protein microarrays are used to develop tools in various research areas including drug discovery, diagnosis, and protein-ligand interaction analysis. Their efficacy depends on a well-defined pattern of immobilized proteins that have retained their bioactivity. Protein microarrays are most commonly made via pin or inkjet printing that can lead to spots having uneven protein adsorption within the spotted area. Although automated, these processes have been shown to lead to inaccurate readings. Alternative techniques exist, including microcontact printing (μ CP) with a poly(dimethylsiloxane) (PDMS) stamp that produces protein patterns on surfaces, while maintaining bioactivity for a wide range of proteins.

In previous work we have qualitatively compared the distribution of deposited proteins via pin printing versus μ CP with both flat and pyramid-shaped posts. Here we propose to quantitatively compare these two methods, in addition with inkjet printing, to produce an even fluorescent signal within a defined area. Variation of the protein solution and surface properties, in addition to the deposition method, will also be studied with respect to fluorescent signal production.

Investigation into the experimental parameters used in protein patterning to produce an even protein adsorption pattern will enable reliable assay readings by increasing the signal to noise ratio in printed protein microarrays.

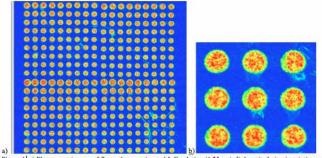

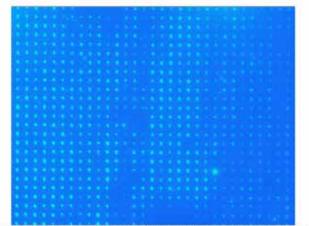

Figure 1] a) Fluorescent images of fluorophore conjugated [gG solution (6.25 μ g/m]) deposited via pin printing onto a 3-(aminopropyl)-tricthoxy silane glass slide with a contact angle of 61.58°, and b) 100% zoomed in image

SP158 - Educational Activities and Training in Medical Physics

TRACK 17: EDUCATIONAL AND PROFESSIONAL ACTIVITIES

SP158.1 - Medical Physics Residencies-101: The What's, Where's, and How's Author(s): <u>Jeff Frimeth</u> Xspect Inc., Toronto/CANADA

Medical Physics residencies serve as an excellent bridge between putting together the didactic knowledge obtained from a graduate program with practical experience in a Medical Physics sub-specialty. Most residency programs are within the Radiation Therapy sub-specialty, although Diagnostic Imaging-based residencies are slowly starting to become more prevalent over recent years. Residency programs prepare one to take a board examination in order to become a Qualified Medical Physicist. The boards which an individual can apply to are the Canadian College of Physicists in Medicine (CCPM) and the American Board of Radiology (ABR). Residencies can be accredited by the Commission on Accreditation of Medical Physics Educational Programs (CAMPEP) body, but this is not essential. Since CAMPEP states minimum requirements to be met in order to ensure adequate coverage of residency program content, there is a continual push for an increase in the number of CAMPEP-accredited residencies. CAMPEP also accredits Medical Physics graduate programs. Enrolling in an accredited graduate program ensures that the individual graduating obtains a minimum standard of didactic knowledge, which will serve him/her for successful completion of a residency program. This talk will serve to inform the individual of how to prepare for applying to a residency program, what one may expect from a residency program, and where one can apply to residency programs. Participants will also be exposed to how one can prepare for taking a board examination, as well as the general scheme of how the board examinations are administered. CAMPEP requirements for residency and graduate programs will also be introduced.

SP158.2 - Education and Clinical Training of Medical Physics in Thailand

Author(s): <u>Anchali Krisanachinda</u>¹, Malulee Tantawiroon², Nisa Chawapun³, Puangpen Tangboonduangjit⁴, Nuntawat Udee⁵ ¹Department Of Radiology, Faculty of Medicine Chulalongkorn University, Bangkok/THAILAND, ²Department Of Radiology, Faculty of Medicine Siriraj Hospital Mahidol University, Bangkok/THAI-LAND, ³Department Of Radiology, Faculty of Medicine, Chiang Mai University, Chiang Mai/THAILAND, ⁴Department Of Radiology, Faculty of Medicine, Mahidol University, Bangkok/THAILAND, ⁵Department Of Radiological Technology, Faculty of Allied Health Sciences, Naresuan University, Phitsanulok/THAILAND

There are 5 education programs for medical physics in Thailand. The first was started in 1972 at Ramathibodi Hospital, Mahidol University. Followed In 1990, the M.S. in Radiological Science program was started at Siriraj hospital, Mahidol University. Then in 2001, the second medical physics program was established at Chiang Mai University. The M.Sc. program in Medical Imaging was started at Faculty of Medicine Chulalongkorn University in 2002. The fifth program has been started at Naresuan University, Phitsanulok in 2014. The major problem in medical physics was the shortage of clinically qualified medical physicists. The situation was improved when IAEA started clinical training for radiation oncology medical physics (ROMP) in 2005, diagnostic radiology medical physics (NMMP) in 2010. **Objective:** To report the education and clinical training of medical physicists in Thailand with the cooperation of Thai Medical Physicist Society (TMPS), the International Atomic Energy Agency (IAEA) and Chulalongkorn University.

Method: All educational programs are two- year program of the didactic lecture, laboratory, on-the- job training, clinical practice and research. The clinical training using IAEA training guides, self assessment, progress report, external visit and external assessment by IAEA experts were obtained under the Regional Cooperative Agreement (RCA) for Asian and Pacific Region. Thai Medical Physicist Society is processing on licensing for qualified clinical medical physicist after the document submission to the committee of Ministry of Public Health.

Results and Conclusions: Even though the number of the medical physicists graduated from all programs is over 300, the lack of qualified medical physicists is still the problem. The success of the ROMP, DRMP and NMMP serves the needs at major university hospitals and the cancer centers. The clinical training was officially accepted by Chulalongkorn University for the Higher Graduate Diploma of Clinical Sciences Program in Medical Physics and started in 2011. The final medical physics education program of Ph.D. in Medical Physics will be started at Chulalongkorn University in August 2015. This program should support the need for medical physicist position in the university.

SP158.3 - Radiation Protection in Medical Imaging and Radiation Oncology

Author(s): Magdalena Stoeva¹, Richard Vetter², Kin-Yin Cheung³, Renate Czarwinski⁴, Francesca Mcgowan⁵ ¹Medical Imaging Dept., Medical University - Plovdiv, Plovdiv/ BULGARIA, ²Mayo Clinic, Rochester/MN/UNITED STATES OF AMERICA, ³Medical Physics & Research, Hong Kong Sanatorium & Hospital, Happy Valley/HONG KONG, ⁴International Radiation Protection Association, Berlin/GERMANY, ⁵CRC Press, Taylor & Francis Group, London/UNITED KINGDOM

Radiation protection is one of the leading and fastest developing areas of medical physics and society as evidenced by the emphasis hospitals and medical organizations are placing on radiation protection culture. The interdisciplinary nature of radiation protection makes it a key discipline in ensuring safety of the public.

Safety and quality assurance in the use of radiation in medicine aims to reduce unnecessary radiation risks while maximizing the benefit. Improvements in quality and safety in radiation medicine require a strong radiation safety culture. To better achieve the goal of strengthening radiation safety in healthcare and better protection of the patients from excessive or unnecessary radiation exposure, a concerted effort by all the role players together with the radiologists, referring practitioners, technologists, professional organizations, international bodies and regulators is essentially needed.

The International Organization for Medical Physics (IOMP) and the International Radiation Protection Association (IRPA) have worked together to produce a book on Radiation Protection in Medical Imaging and Radiation Oncology, intended for use both in countries that have well developed medical and health physics disciplines and in developing countries.

The International Organization for Medical Physics (IOMP) represents over 18,000 medical physicists worldwide and 81 adhering national member organizations. The mission of IOMP is to advance medical physics practice worldwide by disseminating scientific and technical information, fostering the educational and professional development of medical physicists, and promoting the highest quality medical services for patients. The International Radiation Protection Association (IRPA) represents some 18,000 members from 50 associate societies representing 63 countries. IRPA's vision is to be recognized by its members, stakeholders and the public as the international voice of the radiation protection profession in the enhancement of radiation protection culture and practice worldwide

Awareness of the need for emphasis on radiation protection contributes significantly to the safety of healthcare providers, patients, and the public. Contributions are most evident in facility design, in monitoring of personnel and the patient care environment, and in development of procedures and practices for proper handling and limitation of radiation exposure. Medical health physicists are often challenged to maximize protection of personnel while minimizing the cost of resources necessary to keep radiation doses ALARA. Advances in medical health physics will continue to be based on evidence gathered through basic and applied research. Periodic review of the evidence will help medical health physicists to focus on the issues and to advance the science.

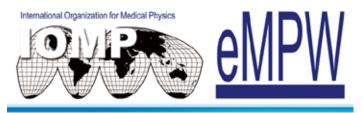

The book Radiation Protection in Medical Imaging and Radiation Oncology, focuses on the professional, operational, and regulatory aspects of radiation protection covering virtually all regions of the world. The theoretical background is complemented by detailed practical sections and professional discussions by the world's leading medical and health physics professionals. Information is well organized into discreet chapters from basic protection to advanced imaging and treatment modalities. This book is a valuable source of information for the medical physicist and related specialties targeting a reading level of MSc and above.

SP158.4 - It's a Medical Physics World! Presenting the Official Bulletin of the International Organization for Medical Physics Author(s): <u>Magdalena Stoeva</u>¹, Virginia Tsapakis², Kin-Yin Cheung³, Slavik Tabakov⁴, Ibrahim Duhaini⁵, Madan Rehani⁶, Anchali Krisanachinda⁷

¹Medical Imaging Dept., Medical University - Plovdiv, Plovdiv/BUL-GARIA, ²Konstantopoulio General Hospital, Athens/GREECE, ³IOMP - Medical Phisics World, York/UNITED KINGDOM, ⁴Medical Engineering And Physics, King's College London, RS/UNITED KING-DOM, ⁵Radiation Oncology, Rafik Hariri University Hospital, Beirut/ LEBANON, ⁶Harvard Medical School and Massachusetts General Hospital, Boston/UNITED STATES OF AMERICA,⁷Department Of Radiology, Faculty of Medicine Chulalongkorn University, Bangkok/ THAILAND

Medical Physics World (MPW) has been the official bulletin of the International Organization for Medical Physics for over 30 years. The first issue of the bulletin was published in 1982 presenting a challenge to the IOMP and the medical physics societies around the world: "... to make 'Medical Physics World' worthy of its title".

Ever since then the IOMP's leading professionals have chaired and contributed to the development of MPW.

Medical Physics World Editors 1982-2015

Prof. Lawrence H. Lanzl

Prof. Colin Orton

Richard L. Maughan

- Dr. Bhudatt R. Paliwal
- Dr. Azam Niroomand-Rad
- Dr. E. Ishmael Parsai
- Dr. Virginia Tsapaki

The last several years mark a great progress in Medical Physics World. The new style and layout introduced in 2012 increased the interest towards MPW not only among our professional society, but also among corporate members and professionals from other disciplines. MPW is now regularly distributed on all major professional events – AAPM meetings, RPM, ICMP, many regional events.

Medical Physics World has always been in-line with IOMP's initiatives and hot topics. Besides providing the regular organizational reports, we have actively supported some of the IOMP's most successful activities – IOMP's 50th anniversary, the foundation of the Medical Physics International Journal (MPI), the International Day of Medical Physics (IDMP) and the formation of the IOMP Women subcommittee (IOMP-W).

During this 3-year period we successfully conducted a dissemination campaign that resulted in MPW's wide recognition among world's leading institutions. The journal is now regularly delivered to the European Congress of Radiology (ECR), the UNESCO International Center for Theoretical Physics (ICTP) and to the US Library of Congress.

The latest achievement of MPW's editorial team is including Medical Physics World in the International Standard Serial Number registrar.

With all the contemporary technology our world turned into an electronic world, so did Medical Physics World. We often call it eMPW now, but we are still devoted to the very first promise "... to make 'Medical Physics World' worthy of its title".

SP158.5 - The new IOMP Professional Journal - Medical Physics International - first results

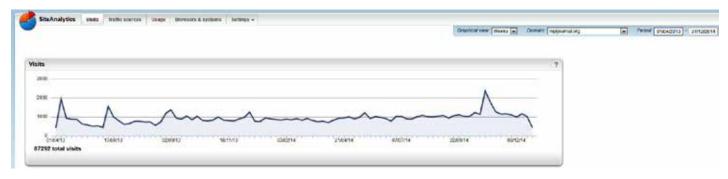

Author(s): <u>Slavik Tabakov</u>¹, Perry Sprawls² ¹Medical Engineering And Physics, King's College London, RS/ UNITED KINGDOM, ²IOMP, Atlanta/UNITED STATES OF AMERICA

The medical physics profession is served by a collection of outstanding journals, each distinguished by its content, method of publication, geographic coverage, and organizational affiliation. The new IOMP journal, *Medical Physics International (MPI)*, joined this group in 2013, filling a specific niche, not as a competitor, but as an active supporter and collaborator with the other journals. MPI is the official journal of the International Organization of Medical Physics (IOMP) and is with fully open access on Internet (www.mpijournal. org), providing information at no cost to the global medical physics community. The mission of MPI is to publish articles that contribute to medical physics education, professional development, communication about international medical physics activities, and to preserve the history and heritage of the profession. The Journal is peer reviewed and publishes also approved abstracts from Medical Physics Conferences.

A distinguishing feature of *Medical Physics International* is that it does not publish manuscripts reporting on research and development. For these we recommend the other established Journals as: *Physics in Medicine and Biology*(the first journal to be designated as an official journal of IOMP in 1969), *Medical Physics, Journal of Applied Clinical Medical Physics* (the AAPM journals), *PhysicaMedica* (the European Journal of Medical Physics) and other regional and national medical physics journals that provide such publication opportunities.

Currently MPI has 4 issues published, which include 260 pages with original papers on education and professional issues, history of the profession, new innovations from the medical physics industry, tutorials and abstracts of PhD theses. Additionally MPI has published 840 pages of approved abstracts from the International Medical Physics Conference ICMP2013 (Brighton, UK) and the International Conference on Radiation Protection in Medicine 2014 (Varna, Bulgaria).

The results are very encouraging - from its first issue MPI Journal has a steady number of about 1000 readers per week (see the statistics attached here). Its web site is designed in a way to allow both download of individual papers and whole PDF issues. Many papers have hundreds of downloads, what is a clear reflection of the need of such a Journal.

SP158.6 - Two First Years of Reuniting, Engaging and Discovering: The Canadian Conference for Undergraduate Women in Physics

Author(s): <u>Madison Rilling</u>¹, Marie-Joël Bergeron-Savard¹, Marie-Eve Boulanger¹, Émily Cloutier¹, Amélie Dumont¹, Chloé Gaudreau¹, Marie-Pier Labonté¹, Jasmine Poirier¹, Carmelle Robert², Brigitte Vachon³

¹Département De Physique, De Génie Physique Et D'optique, Université Laval, Quebec City/QC/CANADA, ²Centre de Recherche en Astrophysique du Québec, Quebec City/QC/CANADA, ³Department Of Physics, McGill University, Montreal/QC/CANADA

A first Conference for Undergraduate Women in Physics was hosted by the University of Southern California in 2006. A few years later, six regional conferences were being held simultaneously and annually throughout the United States [1]. Inspired by this successful model centrally coordinated by the American Physical Society, Mc-Gill University hosted a first Canadian Conference for Undergraduate Women in Physics (CCUWiP) in January 2014, with 54 participants from Ontario and Quebec universities [2]. On 9-11 January 2015, a second, bilingual edition of the CCUWiP was hosted by Université Laval, which welcomed 75 undergraduate students from Eastern Canadian universities [3]. The goal of the CCUWiP is to give undergraduate women studying in a physics-related field the opportunity to experience a professional conference and discover a variety of career paths in academia, industry and health sectors. Moreover, this conference encourages the development of a national network of women in physics and promotes the accomplishments and leadership of women in STEM (Science, Technology, Engineering and Mathematics) fields. In light of having organized the two first Canadian editions, the organizational details involved in providing a student-accessible conference and the typical program of a CCUWiP will be introduced. We will describe the importance of the CCUWiP as a training and career development experience for women at the undergraduate, graduate and professional levels. As a student initiative sponsored by the Canadian Organization of Medical Physicists, the methods of promoting graduate studies, research and careers in medical physics will be highlighted. Finally, based on its success and the growing interest in this conference, we will discuss the future of *Canadian Conferences for Undergraduate Women in Physics* and the potential and efforts in making the CCUWiP an official, annual event.

SP158.7 - Students' perspective on studying online at Heidelberg University, Germany (UHD)

Author(s): <u>Marcel Schaefer</u>¹, Simone Barthold-Beß¹, Jürgen Debus², Lena Gebauer-Hötzel¹, Ina Niedermaier¹, Oliver Jäkel¹, Wolfgang Schlegel¹

¹Dept. Of Medical Physics In Radiation Oncology, German Cancer Research Center (DKFZ) Heidelberg, Germany, Heidelberg/GER-MANY, ²Department Of Radiation Oncology And Radiation Therapy, Heidelberg University Hospital, Heidelberg/GERMANY

Purpose: UHD established two postgraduate MSc programs in Medical Physics. In 2010 the English speaking Master Online "Advanced Physical Methods in Radiotherapy" (APMR) started as first distance learning online program at UHD comprising three mandatory attendance phases (duration from 4-14 days) in Germany during the two years of study. Furthermore, since 2012 the International Master "Clinical Medical Physics" (CMP) is on offer in cooperation with Pontificia Universidad Catolica de Chile (PUC). CMP combines two on-site semesters in Chile taught in Spanish by PUC with a third online semester held in English by UHD. The students terminate their studies with a Master Thesis, written either at PUC or UHD.

After five years' experience in online teaching and learning we would like to present a first result of undertaken evaluations emphasizing on the importance of an ideal curriculum design for postgraduate students working in Medical Physics.

Material and Methods: The CMP program is designed for students from Latin America and it introduces the basics (such as Anatomy and Physiology or Physics of Radiation and Dosimetry) and advanced topics in Medical Physics (such as IMRT or IGRT) to students at the beginning of their professional career. In contrast the APMR program is dedicated to students with a clear background and professional experience in Medical Physics. Thus, it only concentrates on advanced topics such as IMRT, IGRT, Ion Therapy or Advanced Dosimetry and Quality Assurance to educate professionals from all over the world.

The modules of each program adopt the so called "blended learning approach", a combination of online and on-site learning settings. Interactive synchronous online sessions, recorded video lectures and problem based discussions make effective use of emergent internet technologies for its learning objects while offering opportunities to practice skill and network with peers and teachers in hands-on attendance phases at modern radiotherapy facilities in Heidelberg for APMR students and in Chile for CMP participants.

At the end of each semester the students are asked to join formative anonymous online surveys as part of the evaluation system of UHD. Furthermore, during each attendance phase the students have feedback sessions with the program coordinators in order to discuss the last online modules without teachers. This allows students to give positive or even negative feedback in a private and secure setting.

Results: The qualitatively and quantitatively reviewed results of the surveys and the intensive face-to-face discussions represent the students' perspective of the e-learning approaches of both programs and allow us to deepen our understanding of special needs of professionals in the field of Medical Physics. The students reported their satisfaction about the curriculum design in the frame of a permanent supervision by both the teaching and coordinating team.

Conclusion: In conclusion both discussions and survey results helped us to improve our curriculum design. Our continuous modifications seem to be the key for our low drop outs during the last 4-5 years. SP158.8 - Launching of the ASEAN College of Medical Physics Author(s): Kwan Hoong Ng¹, Agnette Perio Peralta², Anchali Krisananchinda³, Djarwani S Soejoko⁴, James Cheow Lei Lee⁵, Nguyen Tan Chau⁶, Freddy Haryanto⁷, Supriyanto Ardjo Pawiro⁴, Chai Hong Yeong¹, Norial Jamal⁸, Marlon Raul Z Tecson⁹, Sakborey Chhom¹⁰ ¹Department Of Biomedical Imaging, Faculty Of Medicine, University of Malaya, Kuala Lumpur/MALAYSIA, 2Center For Device Regulation, Radiation Health, And Research, Food And Drug Administration, Department of Health, Manila/PHILIPPINES, 3Department Of Radiology, Chulalongkorn University, Bangkok/THAILAND, ⁴Physics Department, University of Indonesia, Jakarta/INDONESIA, 5Division Of Radiation Oncology, National Cancer Centre, Singapore/ SINGAPORE, 6Unit Of Pet-ct & Cyclotron, Cho Ray Hospital, Ho Chi Minh City/VIET NAM, 7Department Of Physics, Institut Teknologi Bandung, Bandung/INDONESIA, 8Planning And International Relation Division, Malaysia Nuclear Agency, Bangi/MALAYSIA, 9Medical Physics and Health Physics Services, Inc, Manila/PHILIP-PINES, 10 National Cancer Centre, Calmette Hospital, Phnom Penh/ CAMBODIA

Medical physics is rapidly advancing in the world and the situation is the same in South East Asia. There is an acute need for both qualified and experienced medical physicists to work in hospitals throughout the region.

The Association of Southeast Asian Nations commonly known as ASEAN is a geo-political and economic organization of 10 countries located in Southeast Asia, which was formed on August 8, 1967. The member countries are Brunei, Cambodia, Indonesia, Laos, Malaysia, Myanmar, Philippines, Singapore, Thailand and Vietnam. The motto of ASEAN is "One Vision, One Identity, One Community". Its aims include the acceleration of economic growth, social progress, cultural development among its members, and the promotion of regional peace.

The spirit of ASEAN resonates in the South East Asian Federation of Organizations for Medical Physics (SEAFOMP). The idea of setting up an organization for Southeast Asian medical physics societies was first mooted in 1996. During the International Organization of Medical Physics (IOMP) World Congress at Nice, the formation of SEAFOMP was endorsed by member countries and it was officially accepted as a regional chapter of the IOMP at the Chicago World Congress in 2000. SEAFOMP congresses have been held regularly since its inception and these congresses have stimulated much growth and progress in medical physics in the region.

After a long gestation period, another regional entity, the ASEAN College of Medical Physics, was born in October 2014 at the 12th Southeast Asian Congress of Medical Physics held in Ho Chi Minh City. The founding president of the College is Professor Kwan-Hoong Ng, president-emeritus of SEAFOMP. The secretariat is located in Indonesia.

The vision is to make the ASEAN College of Medical Physics (ACOMP) the premier education and training centre for medical physics in the ASEAN region. To achieve the vision, members will galvanise their talents to develop sustainable activities, and will take advantage of information and communications technologies to achieve their goals.

Some future activities being planned include schools on Monte Carlo simulation, advanced radiation dosimetry, radiation emergency and disaster management, non-ionizing radiation protection, and a project on radiation dosimetric intercomparison.

Finally, official recognition is being sought from international organizations such as the International Organization for Medical Physics (IOMP) and the International Atomic Energy Agency (IAEA). Endorsement and support from these bodies will be an added impetus to the success of the ACOMP.

SP159 - Transport and Physiological Modelling

TRACK 19: BIOPHYSICS AND MODELLING

SP159.1 - Dwarfing Big Data for Oncology Applications: Necessity and Possibilities Author(s): Issam El Naga

Oncology, McGill University, Montreal/QC/CANADA

Learning Objectives:

1) Review of big data applications in radiotherapy.

2) Side effects of integrative approaches

3) Statistical machine learning and decision theory

Title:

Dwarfing Big Data for Oncology Applications: Necessity and Possibilities

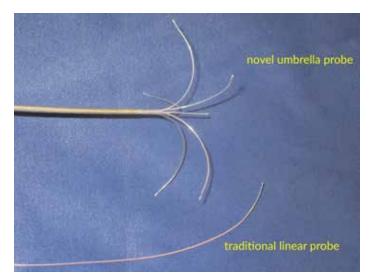

Abstract:

Radiotherapy is a natural resource of big data in terms of large volume, wide variety, fast velocity, and qualitative veracity. A typical radiotherapy treatment scenario can generate a large pool of information that is comprised of patient demographics, radiation dosimetry, multimodality imaging features, and biological markers over a treatment period that can span several weeks. This data constitutes a unique interface between clinical, physical, and biological data interactions. Efforts using commercial and in-house tools are carried out to facilitate data aggregation, sharing, and varying analytics in a secure environment. However, the classical p (variables) >> n (samples) inference problem of statistical learning is challenged in the Big data realm and this is particularly true for oncology applications where p-omics is witnessing exponential growth while the number of cancer incidences has generally plateaued over the past 5-years leading to a guasi-linear growth in samples per patient. Within the Big data paradigm, this kind of phenomenon may yield undesirable effects such as echo chamber anomalies, Yule-Simpson reversal paradox, or misleading ghost analytics. In this presentation, we will discuss these effects as they pertain to radiotherapy and engage small thinking methodologies to counter these effects ranging from classical statistical techniques to modern machine learning approaches. We will particularly discuss the potential and application of semi-supervised learning methods to big data in radiotherapy, in which the data is partially labeled and the techniques occupy some middle ground between supervised learning (all the data are labeled) and unsupervised learning (data is unlabeled) approaches. We will contrast the application of these methods with other big data analytics as promising approaches for radiotherapy outcome prediction and decision support.

SP159.2 - Improved temperature monitoring and treatment planning for loco-regional hyperthermia treatments of Non-Muscle Invasive Bladder Cancer (NMIBC) Author(s): Gerben Schooneveldt¹, Henny P. Kok¹, E.D. Geijsen¹, Fasco Van Ommen¹, Akke Bakker¹, Mattias Westendarp Zanartu², Jean J.M.C.H. De La Rosette², Maarten C.C.M. Hulshof¹, Theo M. De Reijke², Johannes Crezee¹ ¹Radiotherapy, Academisch Medisch Centrum, AMSTERDAM/ NETHERLANDS, ²Urology, Academisch Medisch Centrum, AM-STERDAM/NETHERLANDS

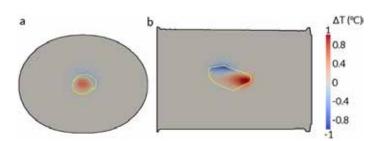

Introduction— Hyperthermia is a cancer treatment that increases the effectiveness of radiotherapy or chemotherapy by heating the tumor area to 41–43°C. Recently, a multi-center phase III randomized clinical trial comparing adjuvant treatment of NMIBC using Mitomycin C with and without loco-regional hyperthermia has started. This invites careful consideration of the bladder as a treatment site. Optimal treatment and quality control requires reliable thermometry and accurate hyperthermia treatment planning. This study aims to improve the current standard in both areas.

Materials and methods— We developed a novel multi-sensor 'umbrella probe' with five thermocouple probes to measure the bladder wall temperature, and a central probe measuring in the bladder center (Fig.1). We extended our treatment planning system with a fluid model computing the convective heat flow within the bladder. The umbrella probe was tested using phantom experiments comparing temperature measurements on the interior and exterior of a porcine bladder placed in tissue equivalent gel, and heated to reach a 4°C temperature rise. The experiments were simulated using both the new convective model and the standard treatment planning system.

Results— The umbrella probe temperature measurements at the interior bladder wall were comparable to temperatures measured on the bladder exterior but differed 0.5°C from temperatures in the bladder center.

The temperature distributions computed by the convective model and by the current treatment planning system showed good agreement within the phantom's gel regions; temperature differences between the models exceeded $\pm 1^{\circ}$ C inside the fluid and in neighboring tissue regions, *i.c.* the bladder wall (Fig.2).

Conclusions— The umbrella probe reliably measures the clinically relevant bladder wall temperature. The convective model is a marked improvement over the current treatment planning system in the region of interest. Explicit modeling of fluids is particularly important when the bladder or its direct vicinity are part of the hyperthermia treatment target area.

SP159.3 - A Full 3D CFD Model Coupled with an Outflow Lumped Boundary and Inflow Total Pressure Formulation to Estimate Human Cardiac Perfusion

Author(s): Iyad Fayssal, Fadl Moukalled, Samir Alam, Robert Habib, Hussain Ismaeel

American University of Beirut, Beirut/LEBANON

There is discordance between the anatomic severities of the coronary narrowing and their corresponding functional significance, i.e. how much this narrowing is truly causing ischemia in the downstream perfused cardiac tissue bed. Fractional flow reserve (FFR) is among the physiological parameters invasively measured to assess the hemodynamic significance of a stenosis during maximal hyperemia with values ≤0.8 indicating vessel at risk for ischemia. Recently, noninvasive prediction of FFR was shown to be possible from noninvasive comprehensive predictive techniques involving computational fluid dynamics (CFD). In this work, a boundary condition formulation is suggested and coupled with a full 3D CFD model to estimate cardiac perfusion. The modeling process starts by truncating the domain of interest at a specific location and separating it from the vascular beds. A lumped dynamic model is considered and coupled to the 3D domain outlet boundary to account for the downstream effects from the vascular bed resulting from truncating the 3D domain. A generalized algorithm is established to handle the dynamic model at the outflow boundary to avoid/damp spurious numerical reflections. On the other hand, the inlet section of the domain is modeled with a total, rather than static, pressure formulation. The developed inflow and outflow boundary formulations coupled to the 3D CFD model allow characterizing the myocardial perfusion of the modeled vessel (i.e. determine the % loss in blood volume flow rate in stenosed arteries). The method is tested on idealized healthy and stenosed arterial branches and single segments under rest and hyperemic conditions. Results have revealed promising indications towards translating the developed methodology into clinical practice.

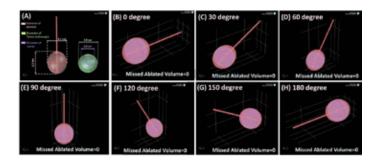

SP159.4 - Simulation Model of Image-Guided Percutaneous Thermal Ablation in the Assessment of Optimal Approach for Complete Tumour Ablation

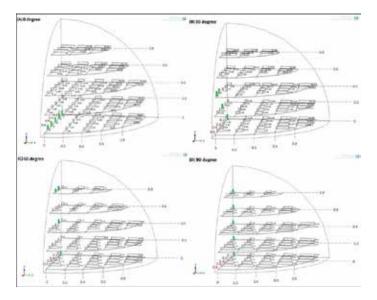

Author(s): Sogol Givehchi, Basri Johan Jeet Abdullah, <u>Chai Hong</u> Yeong

Department Of Biomedical Imaging And University Of Malaya Research Imaging Centre, Faculty Of Medicine, University of Malaya, Kuala Lumpur/MALAYSIA

Purpose: To develop a 3D simulation for imaged-guided percutaneous thermal ablation of the liver tumours based on a geometrical model to investigate the ablation versus tumour volumes with varying needle position and angulations. Materials and **Methods:** This study was carried out using Finite Element Analysis software (Comsol Multiphysics 4.3, COMSOL Inc, USA) to simulate a spherical tumour of 2 cm diameter and a radiofrequency ablation (RFA) needle from the Cool-tip RFA system (Covidien, Massachusetts, USA). Clinical margin of 0.5 cm surrounding the tumour was applied. Common points of intersection of axial, sagittal and coronal planes within the tumour volume were assigned as target sites for needle tip placement. The RFA needle was modeled to pass through the target sites with different angles before advancing it to the edge of the tumour margin. The target sites and the angles of needle insertion were considered as optimal approach if no missed ablation volume was observed within the tumour and its clinical margins.

Result: According to the simulation results, the target site at the epicenter of the tumour was identified as optimal location for needle tip placement despite any variations in needle angulations (Figure 1). Hence, identifying the epicenter of the tumour on the central slice of the axial images is essential for increasing the success rate of complete tumour ablation. Despite the epicenter, complete ablations are also possible by placing the needle tips at several sites as shown in Figure 2.

Conclusion: Complete ablation of the tumour can be constantly achieved by passing the needle through the epicenter of the tumour before advancing it to the edge of the tumour margin, regardless of the angles of the needle insertion. As the needle trajectory deviated from the epicenter, the risk of incomplete ablation increased with increasing angles of insertion.

SP160 - Neuroengineering, Neural Systems / Biophysics And Modelling

PRESIDENTS CALL

SP160.1 - From "Fracking" and "Macrovoids" to the Onset of Cancer Metastasis: A Mechano-Metabolomics Model of a Plausible Fluid-Solid Network Instability in Tumors Author(s): <u>Sai S. Prakash</u>

Chemical & Biomolecular Engineering, Brady Urological Institute, Johns Hopkins University and Medicine, Pikesville-Baltimore/MD/ UNITED STATES OF AMERICA

Based on analogy and inductive reasoning, we postulate that a malignant tumor (carcinoma) grows in size until the "de-percolation" threshold of its encapsulating basement membrane (BM) which undergoes proteolysis during oncogenesis. Typically, BMs are composed of tri-continuous hydrogel networks of collagen-IV, laminin, and interstitial fluid, with connector proteins such as nidogens, and perlecans. The aforementioned threshold is determined by the mechanochemical state of the tumor-membrane complex vis-à-vis its microenvironment and, herein, conjectured to synchronize with the tensile yielding/rupture of the BM. Thereupon, peripheral cells of the tumor undergo epithelial-to-mesenchymal transitions (EMT), becoming motile, and migratory.

We test this postulate by formulating a mathematical model based on continuum fluid-solid mechanics, diffusion, and cell bioenergetics theories. This approach may be characterized as "mechanometabolomics" modeling at the continuum scale and complements genomic, and proteomic approaches. In this model, a prototypical, viscous tumor spheroid grows radially, consuming metabolic nutrients (viz., glucose, oxygen, and lactate) while being constrained by an elastic BM ca. 0.5-2 microns-thick, and a network of linkages of cell adhesion molecules (CAMs), chiefly cadherins and integrins. A fundamental schema "induced" from geology and polymer physics is the fluid-solid mechanical network instability observed in rock formations during hydraulic fracturing (fracking) and during formation of synthetic asymmetric membranes (vis-à-vis large voids), respectively. Polymer physics also furnishes scaling concepts to develop equations of state for cells, and concepts describing cell and tissue rheology via gel poroelasticity theory. Besides, critical perspectives from other recent developments, viz., homeorhetic tumor pressures, mechanotransduction, and symbiotic glucose-lactate metabolism observed in cancer cells, are incorporated, to base the framework on well-grounded physicochemical principles in abiological and/or microbial systems. The nonlinear model is computationally analyzed via Comsol Multiphysics®.

The theoretical simulations (*"in silico* experiments") lucidly support the *a priori* conjecture and are consistent with biological observations of oncogenesis *in vivo*, and physicochemical measurements *in vitro*. Computed stress-strain fields in the tumor microenvironment suggest that proteolyzed BMs, quantified by decreased elastic moduli, participate in aberrant tumor growth dynamics and likely undergo tensile rupture and stress localization-induced cellular detachments, initiating EMTs, and metastasis. Subsequent crack-tip stresses may also shift strains on CAMs from compressive to tensile, suggesting mechanotransduced conformational switches, such as from non-invasive, adherent E-cadherins to invasive N-cadherin phenotypes.

The model also provides a rationale to detect metastatic potential of tumors via a convenient diagnostic imaging tool such as positron emission tomography (PET). PET locates abnormally-high glucose uptake rates in cells and tissues, which are related to the mechanical field evolution of the tumor microenvironment, and thereby, the likelihood of BM rupture. Complementarily, newer techniques that characterize tissue elasticity such as elastography may also be applied in concert with the developed framework.

A major conclusion of this research is that a hallmark of cancer may be a measurable, microscale "physical event" in contrast to nanoscale genomic or proteomic events. Besides proteolysis as a "proximal cause" to rupture, other cancer phenotypes such as higher proliferation rates, softer cells, fractality, etc., can also be incorporated into the model. Experimentation is required to verify the postulate.

SP160.2 - Surface electromyography in quantifying Parkinson's disease and its treatment with deep brain stimulation

Author(s): Saara M. Rissanen¹, Zhe Li², Markku Kankaanpää³, Jian Wang⁴, Olavi Airaksinen², <u>Pasi A. Karjalainen¹</u>

¹Department Of Applied Physics, University of Eastern Finland, Kuopio/FINLAND, ²Department Of Physical Medicine And Rehabilitation, Kuopio University Hospital, Kuopio/FINLAND, ³Department Of Physical Medicine And Rehabilitation, Tampere University Hospital, Tampere/FINLAND, ⁴Department Of Physical Education, Zhejiang University, Hangzhou/CHINA

Parkinson's disease (PD) is a progressive neurodegenerative disorder that affects millions of people worldwide. The disease cannot be cured but the motor symptoms can be relieved with medication or with deep brain stimulation (DBS). However, there is a lack of objective and quantitative methods for monitoring PD and the efficacy of its treatment. Finding these objective methods is a global challenge.

Surface electromyography (EMG) and a principal component (PC) -based monitoring method was used here for quantifying PDcharacteristic features in the EMG signals. The aim was to find the most effective combination of EMG signal features for characterizing PD and its treatment with DBS. It was quantified, if the EMG signals of PD patients change into more similar with the signals of healthy subjects with DBS.

Two groups of PD patients (9 patients with DBS ON and OFF, and 22 patients with medication OFF) and one group of healthy subjects (13 age-matched subjects) were measured during isometric contraction of biceps brachii (BB) muscles and during elbow flexion-extension movements. Surface EMGs were recorded from BB muscles. Several parameters were calculated from the EMG signals. The following parameters worked best in discriminating between healthy controls and PD patients: recurrence rate, correlation dimension, sample kurtosis and crossing rate variable of EMG during isometric contraction, and EMG burst frequency, sample kurtosis and recurrence rate of EMG during extension movements. These variables were chosen to form feature vectors for each subject in the PC-based monitoring method. The analysis revealed clear differences in the EMG features between healthy controls and PD patients (see Fig. 1), and also between DBS OFF and ON. In eight out of nine patients, the surface EMG features changed into more similar with the features of healthy controls when the stimulator was switched on.

The results showed that surface EMG is capable of characterizing patients with PD and effects of DBS treatment. Surface EMG is therefore a potential method for monitoring PD and its treatment efficacy objectively and quantitatively.

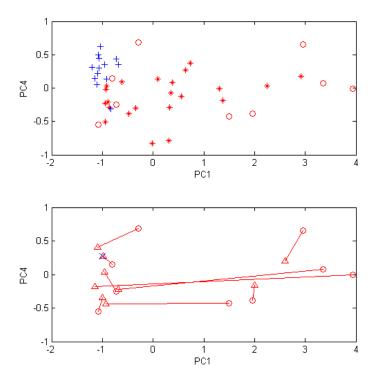

Fig. 1. PCs of 13 healthy controls (+), 22 PD patients with medication OFF (*), and 9 PD patients with DBS OFF (o) in the top figure. The PCs of the 9 PD patients with DBS OFF (o) and ON (Δ) in the bottom figure. The DBS OFF- and ON-states are connected with a line and the center of healthy controls is marked with a cross (x) in the bottom figure.

SP160.3 - A Decade of Experience with Intraoperative Microelectrode Recording in Determining the Subthalamic Nuclie (STN) Deep Brain Stimulation – Lead Positions in 260 Parkinson Diseased Conditions in South India – A Retrospective Study Author(s): <u>Venkateshwarla R. Raju</u>

Biomedical Eng & Neurology & Neurosurgery And, Nizam's Inst of Medical Sciences (NIMS) University & Hospital, HYDERABAD/INDIA

To study the correlation of microelectrode recording with final tract chosen during bilateral STN DBS performed at a specialized centre in South India in 260 Parkinson's disease (PD) Subjects (patients in disease states). In Parkinson's disease there is a decreased dopaminergic output from the substantia-nigra, which changes the firing patterns of many neurons of nuclei (the nucleus). One of the consequences is an increased firing from the neurons of subthalamic nucleus (STN) which by stimulating to the neurons of globuspallidus interna (GPi) causes inhibition of thalamus and cortex causing slowing of voluntary movements. The STN is an almond shaped nuclei located in the midbrain, ventral to the thalamus, and bordered by zona incerta cerebral peduncle, medial lemniscus, SNpr,pc, red nucleus, etc. The simplistic view was supported by the fact that high-frequency current delivered to STN or GPi neurons or other neurons of basal ganglia (BG) which caused their inhibition improved indication of symptoms. It is now known that there is a significant change in the firing pattern and a reorganization of the entire basal ganglia with DBS. A retrospective study was carried out at a tertiary care NIMS - AP State University Super-specialized Hospital with a dedicated movement disorder unit from south India. 260 subjects (patients) with diagnosis of PD as per United Kingdom Parkinson disease society brain bank criteria were included. All the subjects were willing to undergo the procedure and fulfilled the following criteria to be eligible for STN-DBS, i.e., they had a disease

duration of more than 12 years, good response to levodopa, able to walk independently in drug `on` state and had normal cognition. All the PD subjects who were wheel chair or bed bound, had dementia or severe psychiatric disturbances were excluded. Surgery was performed in all by a qualified neurosurgeon. Stereotactic targets were acquired employing a specialized system with a specially designed stereotactic CRW frame which has a luminant MR localizer to directly target points within the STN of brain. The targeting was performed according to Lozano's Technique - 2mm sections are taken parallel to the plane of anterior comissure -posteriror commissure line and at the level with maximum volume of red nucleus, STN is targeted at 3mm lateral to the antereolateral border of red nucleus. The MER itself is not a complete tool to clearly discriminate the optimal target as the line of the DBS lead may not correspond to the axis of the STN. Further the impedance of the microelectrode may vary as they may be influenced by the brain tissue and may not show a clear recording. However, MER definitely confirms the clear position of the electrodes and bolsters the confidence of the neurosurgeons that they are in the target. Further, the availability of MER recording results in a vast data in connection with the functioning on th neurons situated deep in the brain and may help in unraveling the mysteries of the brain. From our experience, we say that MER facilitates selection of the final electrode location in STN DBS.

Microorganisms are widely used in large-scale production of industrial items; therefore the bacterial growth is a key point in this technology development. In this study it is shown a non-chemical growth acceleration system by the stimulation of magnetic field vortex on Escherichia coli (ATCC 9637). It was used a magnetic field intensity from 1.13 to 4.13 mT, it was applied for 6 h, in cycles with five different frequencies: 100, 800, 1500, 2450 and 2500 Hz, in the sinusoidal signal, the sample was a temperature of 37 °C and 150 rpm constant stirring. The results shown that magnetic stimulation has a proliferative effect when the effect when the stimulus is continuous comparing with either intermittent or un-stimulated samples. Growth of Escherichia coli (E. coli) could be altered under magnetic field induces effects. *E.* coli, so these cultures exhibited higher changes in its viability compared to unexposed cells. The increase in rates of microbial growth can accelerate some of the fermentative processes in the food industry, or allow greater obtaining of biomass of producer strains of molecules high biotechnological value as biopolymers, biopharmaceuticals and nanomaterials of biomedical use.

SP160.5 - Electro Magnetic Therapy and Laser in the Chronic Pain Of The Woman.

Author(s): <u>Manuel E. Zuniga</u> Private, INTEGRAL MEDICAL CENTER, GUAYAQUIL/ECUADOR

Introduction: The medical Physics is the application of the physics to the medicine. It is a branch of the multidisciplinary physics. It applies the physical foundations in many therapeutic techniques. Luis Galvani in the century XVIII, scientist and Italian doctor discovered that the muscles and nervous cells were able to produce electricity. In the century XIX he developed himself to electromagnetism based on the relation electricity and human body, being developed thus new contributions to the treatment. These knowledge gave origin to new scientific areas like bio-electromagnetism. German scientific Helmholtz, was the first to demonstrate the electromagnetic action. In the Europe of century XVI, Paracelso used magnets to deal with a variety diseases. Two centuries later Mesmer became famous by treating many disorders with magnets.

OBJECTIVES: To apply the electromagnetic therapy for the chronic pain in the woman. To relieve the pain instantly. To suppress all chronic gynecological such as the pelvic inflammation, pain breasts, headache and others. To offer to well-being and satisfaction in the woman in few minutes.

Methods: Reviewing a meticulous clinical history for the pain. Determining that an organic cause does not exist. Making a careful and detailed physical examination. Determining the cause the pain. Evaluating the scale of pain. Applying the electromagnetic therapy related to laser. Applying (I10 N80) the suitable electrodes, at a frequency of 80 Hz in one weekly session of 2 minutes and for 5 weeks time.Obtaining of pressedmagnetic fields and application of laser in the painful zone.

Results: In more than 20 years of treatment with electro-magnetic therapy and laser, the result for the population of patients was highly satisfactory with 90 % success. We have treated with patient with diagnosis of inflammatory pelvic disease and chronic pain, patients with mastalgia, migraine, fibromialgia, etc., all with excellent results. Patients of all ages that goes from 20 up to 80 years old. With this treatment of electro-magnetic therapy we stimulate the own body with the production of substances with analgesic effect, like the endorfinas and others.

Conclusions: We conclude with the high effectiveness of the electro-magnetic therapy and laser. The therapeutic answer was outstanding and highly satisfactory. Valuing the subjective answer as much as the objective one. Comparing the therapeutic result of the pain before the electro-magnetic therapy and later of its implementation, the suspension of the pain was excellent after. The electro-magnetic therapy is an alternative medicine practice that implies the use of magnetic fields on the human body.

SP161 - Angiography / X-ray Imaging

TRACK 01: IMAGING

SP161.1 - 5D DSA Using Dual Energy Acquisition

Author(s): <u>Gabe Shaughnessy</u>, Charles Mistretta, David Dunkerley, Jordan Slagowski, Michael Speidel Department Of Medical Physics, University of Wisconsin, Madison/ WI/UNITED STATES OF AMERICA

Traditional DSA techniques require the acquisition of mask and fill projections at a single energy. Acquisitions at two energies offer discrimination between materials, allowing a reduction in artifacts associated with misregistration of moving tissue/air interfaces, e.g. bowel gas. We are investigating the application of dual energy projection acquisition to time-resolved volumetric DSA (4D DSA). In the method termed "5D Hybrid DSA", dual-energy projections are acquired from both mask and fill rotations. We utilize a material decomposition algorithm separating high and low kV projections into two basis material projections of lodine, which include bone, and soft tissue. This method serves to isolate the vasculature before being fed into the 4D reconstruction algorithms. The iodine basis images derived from a fill rotation employing fast-kV switching may provide enough data suitable for DSA reconstruction in a variety of applications. Therefore, we propose a "5D Maskless DSA" method which would allow lower total breath hold requirements compared to the usual mask plus fill approach. In a study in a dynamic aneurism phantom it was found that, when care is taken to remove residual bone and soft tissue signal in the iodine basis projections, a maskless dual energy method can provide time-attenuation curves that agree with conventional low energy 4D DSA to within 9% (RMSD). In the Figure, we present the MIPs of a time frame from the 5D DSA reconstructions along with the conventional 4D DSA from the low energy data for comparison. The SNR from the maskless and hybrid methods are competitive with the low energy 4D DSA.

SP161.2 - Investigation of Rhenium-Doped Microsphere-Based Contrast Agents for Diagnostic X-Ray Imaging

Author(s): José Carlos De La Vega¹, Bradford Gill², Katayoun Saatchi¹, Urs O. Häfeli¹

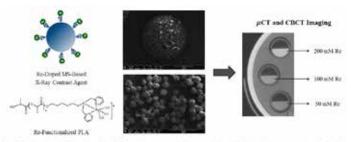

¹Faculty Of Pharmaceutical Sciences, The University of British Columbia (UBC), Vancouver/BC/CANADA, ²Radiation Oncology, BC Cancer Research Centre, Vancouver/BC/CANADA

The administration of iodine-based X-ray contrast agents (XCA) is the gold standard to enhance the contrast of blood vessels and soft tissues in computed tomography (CT). Nonetheless, large and repeated doses are required and severe adverse effects, such as contrast media induced nephrotoxicity and anaphylactoid reactions, occur at an incidence of 3 and 15% with low- and high-osmolarity formulations, respectively. The objective of this study was to overcome these limitations by developing microspheres doped with a radiopaque element, like rhenium. These microspheres could potentially be used to appraise the biodistribution and kinetic degradation of polymeric drug delivery systems.

Since there is a positive correlation between the atomic number and

the linear X-ray attenuation coefficient, rhenium (Z = 75) is deemed to possess superior X-ray attenuation properties than iodine (Z =53). Herein, monosized, biodegradable rhenium-doped microspheres were produced using microfluidic technologies. The size distribution (25.1 ± 2.6 µm, CV = 10.5%) was determined by brightfield microscopy and the external morphology by scanning electron microscopy (SEM). The potential application of this newly developed rhenium-based XCA was evaluated against iohexol, a clinically utilized iodine-based XCA. The formulations were normalized in molar concentration of the radiopaque element. The radiopacity was appraised in an enhanced resolution poly(methyl methacrylate) (PMMA) phantom imaged by micro-CT (µCT), from 50 to 120 kVp, and cone beam CT (CBCT), from 120 to 220 kVp.

This study demonstrated that the variation in radiopacity between rhenium and iodine is dependent upon the applied X-ray tube potential. Owing to the high K-edge of rhenium (71.69 keV) in relation to iodine (33.18 keV), rhenium absorbs high energy photons more efficiently. For instance, it was observed that rhenium displays a greater radiopacity than iodine at high X-ray tube potentials (>80 kVp). Although low and moderate X-ray tube potentials are frequently utilized in clinical practice, the soft region of the X-ray spectrum is absorbed by the patient. Therefore, longer exposure times are required, which contributes to an increase in radiation dose. On the contrary, high X-ray tube potentials require shorter exposure times. As most CT scanners can operate at up to 140 kVp, the utilization of high X-ray tube potentials in clinical practice is feasible. We hypothesize that the use of rhenium as a surrogate of iodine would lead to a reduced radiation dose per scan. Considering these experimental findings, we are currently working on the development of a rheniumdoped microsphere-based XCA with improved functionalities.

Nevel Khemme-Doped Microsphere-Based X-Ray Contrast Agent Characterization and Evaluation. A sample of uniformly-sized microspheres constituted of hitplicely/lumine-functionalized Lpotyfactic acids (PLA) complex with a daminatify microbased core (PLA) OC/A/RE/OD_2) over grednest using microbasific technologies. The microsphere have a micro-sphere information with a highly process aufface. The Yary attention properties of this novel X-ray matting agent wave demonstrated by micro-computed tencography (aCT) and code brane computed tencography (CBCT).

SP161.3 - Theoretical and experimental comparison of image signal and noise for dual-energy subtraction angiography and conventional x-ray angiography

Author(s): <u>Christiane Burton</u>, Ian A. Cunningham The University of Western Ontario, London/CANADA

Cardiovascular disease (CVD) is the leading cause of mortality worldwide. In 2008, it was estimated that 17.3 million people died of CVD, representing 30% of global deaths, and of these deaths 7.3 million are attributed to coronary artery disease. Various techniques are used for imaging blood vessels and assessing the location and severity of arterial narrowings. As an example, digital subtraction angiography (DSA) is a widely used vasculature imaging technique that removes anatomic structures by subtracting an image with only anatomic structures (mask) and a series of images containing the same information with the addition of an iodine injection into the blood stream (contrast). However patient motion can occur during the time gap of several seconds between the mask and contrast images that leads to improper subtraction that may obscure important details of iodinated vessels making DSA largely unsuccessful for cardiovascular imaging. Although software tools are available to

assist with image registration for in-plane translation or rotation motions, respiratory motion, swallowing, uncooperative patients, gas and other involuntary motion remain the primary cause of failed image quality. An alternative method proposed in the 1970's is called dual-energy or energy subtraction angiography (ESA) that could produce iodine-specific images by exploiting the iodine mass attenuation coefficient by combining low and high kV contrast images. The intent for cardiac application is to acquire these low and high images in rapid succession to eliminate motion artifacts. However, it was concluded through a few studies that image quality in terms of iodine signal-to-noise ratio (SNR) for ESA was generally inferior to that of DSA. Despite this conclusion there has never been any direct guantitative comparison of iodine SNR between DSA and ESA. We started our investigation by developing a theoretical model of iodine signal and noise for ESA and DSA. Our theory suggested that ESA can provide iodine-specific images with comparable iodine SNR to DSA for low iodine mass-loadings for similar patient exposures. This result was unexpected, so we validated our theory with an experiment using the same parameters and similar patient exposures and our experimental results showed excellent agreement with theory. These results were encouraging so we expanded our theoretical model to include the effect of additive noise for a detector system. We calculated the additive noise needed to be achieved for a flatpanel cesium iodide detector for ESA and DSA and then compared it to measured additive noise. Our results show excellent agreement and that additive noise is greater at a lower kV. Concurrently we investigated soft-tissue contrast and bone removal. We found that the attenuation properties of soft-tissue and bone are a factor of 5 different using energies for optimal iodine SNR. With gadolinium having a higher k-edge than iodine, and therefore a higher low kV than iodine, this difference narrowed to a factor of 2. We conclude that gadolinium may be an alternative to iodine for removing background structure in ESA. We are currently in the process of developing a fast-kV switcher to demonstrate ESA in real time for cardiac application.

SP161.4 - Some Physical and Clinical Factors Influencing the Measurement of Precision Error, Least Significant Change, and Bone Mineral Density in Dual-Energy X-Ray Absorptiometry Author(s): Jeff Frimeth¹, Eduardo Galiano-Riveros², Dave Webster³ ¹Xspect Inc., Toronto/CANADA, ²Laurentian University, Sudbury/ CANADA, ³Health Sciences North, Sudbury/CANADA

Dual-energy X-ray absorptiometry (DXA) is the standard method of measuring bone mineral density (BMD) at highly trabecular bone, which can be statistically linked to the risk of fracture. For DXA, precision error (PE) and phantom-based accuracy studies are among the most important routine quality control procedures. A precision study was performed at our institution using the International Society for Clinical Densitometry guidelines. Comparing our results with those reported by other investigators, we draw the following general Conclusions: the PE was higher for the spine than the hip, which we attribute to the better geometric reproducibility at the hip. The hypothesis that the DXA calculates BMD relative to water was validated. Whether follow-up measurements are performed by the same technologist on the same day-or different technologists on subsequent days-does not appear to have a clinically significant impact on PE or least significant change (LSC). Mixing beam types (i.e., fan and pencil) may affect lumbar PE and LSC measurements more significantly than those of the hip. The use of a single technologist may reduce the PE for the lumbar spine but appears to increase it for the hip. Restricting the patient population to the female gender has the apparent effect of narrowing the gap between lumbar and hip PE's. Finally, the degree of BMD measurement accuracy can be affected by the type of phantom being used (e.g., European Spine Phantom vs Lunar phantom) and the faults in specific DXA edge detection algorithms.

SP161.5 - Use of Conventional Regional DXA Scans for Estimating Whole Body Composition

Author(s): Mohammad Reza Salamat¹, Amir Hossein Salamat², Mahdi Asgari¹

¹Medical Physics And Biomedical Engineering, Isfahan University Of Medical Sciences, Isfahan/IRAN, ²Isfahan Osteoporosis Diagnosis Center, Isfahan/IRAN

BACKGROUND:

Using soft-tissue composition in conventional regional dual-energy X-ray absorptiometry (DXA) scans of the spine and hip to predict whole body composition (whole-body fat mass, whole-body lean mass and trunk-fat mass) instead of a whole body DXA scan.

Methods:

We identified 143 adult patients who underwent DXA evaluation of the whole body. Anthropometric indices were also measured. Datasets were split randomly into two parts; the derivation set including a sample of 100 subjects, and the validation set including a sample of 43 subjects. Multiple regression analysis with the backward stepwise elimination procedure was used for the derivation set and the estimates were then compared with the actual measurements from the whole-body scans for the validation set. The Ra2 (adjusted coefficient of multiple determination) and SSE (error sum of squares) criteria were applied to compare regression models.

Results:

Using multiple linear regression analyses, the best equation for predicting whole-body fat mass (Ra2= 0. 945) included gender, height, weight, waist circumference (WC), spine fat fraction and hip fat fraction; the best equation for predicting whole-body lean mass (Ra2 = 0. 970) included gender, weight, WC, spine fat fraction and hip fat fraction; and the best equation for predicting trunk-fat mass (Ra2 = 0. 944) included gender, weight, spine fat fraction and hip fat fraction.

Conclusion:

The results of this study show that regional DXA scans of the spine and hip can be used to accurately predict body composition.

SP161.6 - Multiple Energy Synchrotron Biomedical Imaging System- Preliminary Results

Author(s): <u>Bassey Bassey</u>¹, Mercedes Martinson¹, Nazanin Samadi², George Belev³, Cahit Karanfil⁴, Dean Chapman⁵

¹Physics And Engineering Physics, University of Saskatchewan, Saskatoon/CANADA, ²Bimedical Engineering, University of Saskatchewan, Saskatoon/CANADA, ³Experimental Facilities Division, Canadian Light Source Inc., Saskatoon/SK/CANADA, ⁴Physics, Muğla Sıtkı Koçman University, Muğla, Turkey, Kötekli-Muğla/TUR-KEY, ⁵Anatomy & Cell Biology, University of Saskatchewan, Saskatoon/CANADA

The drive to improve and expand the amount of information extracted from various imaging modalities has led to the use of multiple (usually two) x-ray photon energies in computed tomography clinical systems. With the use of a single photon energy, the ability to differentiate soft from hard tissues is a problem which multiple energy imaging can solve. The continuous spectrum available from synchrotron light facilities provides a nearly an ideal source for multiple energy imaging. For living biological subjects a multiple energy system that can extract multiple endogenous or induced contrast materials as well as water and bone images would be ideal. A novel bent Laue single crystal monochromator that has a wide angularly dispersed energy range (polychromator) has been developed to explore the use of multiple energies simultaneously for biomedical imaging at the Biomedical Imaging and Therapy beamline at the Canadian Light Source. Using the 311 reflection from a 511 silicon crystal wafer bent to a radius of 95 cm, the system prepares a 0.5 mm wide focused polychromatic x-ray beam with a spectral range of 27 keV to 43 keV, covering both the iodine and barium K-edges of 33.17 keV and 37.44 keV, respectively. As an example use, test objects with iodine and barium (common contrast agents used in clinical imaging) along with water and bone were imaged and successfully ex-tracted independent quantifiable images of these four materi-als. The biomedical imaging system is presented with emphasis on the polychromator used to prepare the imaging beam.

SP162 - Ultrasound and OCT: Applications

TRACK 01: IMAGING

SP162.1 - Endoluminal Ultrasound Biomicroscopy for in vivo detection of caustic esophagitis in rats

Author(s): Rodrigo D.M. Gomes¹, Rossana C. Soletti², <u>João C.</u> <u>Machado³</u>

¹Post-graduation Program In Surgical Sciences/department Of Surgery, Federal University of Rio de Janeiro, Rio de Janeiro/BRA-ZIL, ²Pharmacy Unit, Centro Universitário Estadual da Zona Oeste, Rio de Janeiro/BRAZIL,³Biomedical Engineering Program/coppe, Federal University of Rio de Janeiro, Rio de Janeiro/BRAZIL

Introduction: the ingestion of caustic substances constitutes a serious public health problem and a pediatric emergency that can lead to serious sequelae. The majority of these accidents occur in the home environment where children ingest cleaning products. Among adults, the caustic ingestion is usually intentional and related to suicide. The most serious complication in the short term following caustic consumption is the esophagus perforation, which can lead to mediastinitis and death. Therefore, a diagnostic technique to evaluate the damage to the esophagus wall is important and endoscopy is primarily employed. Nevertheless, it is a technique that does not provide visualization across the esophagus wall. Recently, a high frequency (40 MHz) minimally invasive imaging ultrasound technique, named endoluminal ultrasound biomicroscopy (eUBM), was implemented to diagnosis small animal digestive diseases. The eUBM has been used successfully in longitudinal studies to followup the growth and differentiation of colon tumors, or even in the diagnostic evaluation of inflammatory lesions in the digestive tract, of small animal models. So far, reports related to the use of eUBM in the evaluation of inflammatory and neoplastic diseases in rat esophagus has not been found.

Objective: to explore the use of eUBM as diagnostic technique at the acute phase of esophageal caustic lesions in rats.

Methods: eight Wistar rats were used and distributed into groups I (injured esophagus) and S (sham), of four rats in each. The animals in group-I received sodium hydroxide (NaOH) at 20%, to cause caustic injury, through a catheter inserted into the distal esophagus while those in group-S received saline. Twenty-four hours after caustic burn induction, the animals in group-I were examined simultaneously through endoscopy and eUBM. Prior to esophagus inspection, the animals were anesthetized with intraperitoneal administration of ketamine (50 mg/kg) and xilazine (5 mg/kg) and thereafter accommodated on an intubating rat platform and intubated. The eUBM system contained an ultrasound mini-probe catheter that rotated 360° around its axis, providing cross-sectional ultrasound images of the esophagus wall. The ultrasound mini-probe was inserted into the accessory channel of a flexible choledochoscope (2.5 mm outer diameter), allowing simultaneous acquisition of endoscopic and eUBM images. During the procedure, the esophagus was irrigated with saline, injected through a flush port on the mini-probe catheter that acted as the ultrasound coupling medium between the transducer and the esophagus wall. After inspection, the esophagus was removed for histological examination.

Results: eUBM images of all animals of group-I presented erosions and ulcers, which had correspondence with histological and endoscopic findings. Additionally, eUBM revealed thickened wall and ulcers reaching up to the esophagus muscle layer, which was not possible to observe from endoscopy. For the animals in group-S, eUBM revealed the esophagus wall without any change, with intact layers. **Conclusion:** eUBM is an imaging method able to accurately assess the acute inflammatory lesions caused by caustic agents in the esophagus of rats.

SP162.2 - To tap or not to tap: A comparison of cranial 3D to 2D ultrasound in extremely preterm neonates with posthemorrhagic ventricle dilation to predict the necessity of interventional ventricular tap

Author(s): <u>Jessica Kishimoto</u>¹, Walter Romano², David S.C. Lee², Sandrine De Ribaupierre², Aaron Fenster¹

¹First Floor Imaging, Robarts Research Institute, London/CANA-DA, ²Western University, London/CANADA

Introduction

Preterm babies are at risk of post-hemorrhagic ventricle dilation (PHVD), which has been linked to brain injury and morbidities such as poor motor coordination and cerebral palsy. PHVD is currently monitored with 2D cranial ultrasound (US), though no consensus has been determined for when interventional surgical therapy is required. Patients with rapid PHVD will require interventions known as 'taps' to remove excess cerebral spinal fluid from the ventricles to prevent further brain injury through excess intracranial pressure. Ventricle volumes (VV) derived from 3D US will be able to distinguish neonates with rapidly increasing VV versus those with stable ventricles.

Methods

The novel 3D US system used in this study has been previously validated in the laboratory through phantom experiments as well as in an *in vivo* study. Neonates with PHVD were enrolled into the present study after informed parental consent following a protocol approved by the REB. Clinical 2D US and 3D US images were acquired within 10 minutes of each other 1-2 times per week throughout the patient's stay in the Neonatal Intensive Care Unit (usually 2-4 months) and analyzed offline. Linear estimates of the ventricles' size (Levene's index (LI), anterior horn width (AHW), third ventricle width (3rd w), and thalamo-occipital distance (TOD)) were measured on the 2D images by a collaborating radiologist. Ventricle volume (VV) was measured from 3D US images by a trained observer and reviewed by a collaborating clinician. Changes in the measurements between subsequent image sets were recorded for each patient.

Results

162 imaging sets were collected from 19 very preterm neonates with PHVD. Strong correlations were found between VV and AHW, 3^{rd} w, and TOD (R²>0.71-0.78), while moderate correlations were found between VV and LI (R²=0.60). No strong correlations were found between changes in ventricle volume and changes in 2D US measurements (R²<0.50). The rate of change in 3D US VV were significant different (p<0.001) between infants requiring an intervention and infants with spontaneously resolved PHVD. No such sig. difference was found using 2D US derived measurements.

Figure 1 a) coronal 2D US image depicting linear measurements used in the study b) segmented 3D US image of a neonate with PHVD

Discussion/Conclusion

While 2D US measurements are reasonable estimates of VV, changes in the measurements are not good indicators of changes in VV. As such, clinicians cannot reliably use changes in 2D US based measurements to determine if a patient has dilating ventricles. This could lead to neonates experiencing dangerous increases in intracranial pressure to have a delay in treatment until more symptoms emerge causing further brain injury. 3D US VV enables better, more

confident monitoring of progressive ventricular enlargement, and seems to predict which patients could require interventional therapy, though a study on a larger cohort would be required to confirm.

SP162.3 - Endoleak and Thrombus Characterization with Dynamic Elastography after Endoleak Embolization following Aneurysm Endovascular Repair

Author(s): Antony Bertrand-Grenier, Fatemeh Zehtabi, Claude Kauffmann, Guy Cloutier, Sophie Lerouge, Gilles Soulez Centre De Recherche Du Centre Hospitalier De L'université De Montréal. Université de Montréal. Montréal/CANADA

PURPOSE

Supersonic Shear Wave Imaging (SSWI) can be used to measure the tissue elasticity in real-time. Our goal is to characterize the mechanical properties of abdominal aortic aneurysm (AAA) after endovascular aneurysm repair (EVAR) in a canine model (endoleaks, thrombus, walls) and compare the results with CT-Scan, Doppler Ultrasound (DUS) and pathologic findings.

METHODS AND MATERIALS

EVAR was done with creation of type I endoleak in 18 aneurysms created in 9 dogs (common iliacs arteries). Two embolization gels, Chitosan (Chi) or Chitosan-Sodium-Tetradecyl-Sulfate (Chi-STS) were injected in the sac to seal the endoleak and promote healing. SSI and Doppler Ultrasound were performed at baseline (implantation, 1-week, 1-month, 3-months) whereas angiography and CTscan were performed at sacrifice. Macroscopic and histopathological analyses were processed to identify and segment five different regions of interest (ROIs): endoleak, fresh or organized thrombus, Chi or Chi-STS. Elasticity modulus values were compared in these ROIs.

RESULTS

At sacrifice, 10 aneurysms had endoleaks, 9 had fresh thrombus, 15 had organized thrombus and 3 were completely sealed. At 3 months, elasticity modulus (in kPa) of 0.1±0.2, 9.2±3.5, 47.3±25.7, 55.9±21.7 and 69.6±29.0 were respectively found in endoleak, fresh and organized thrombus, Chi and Chi-STS regions. Elasticity values of endoleak and fresh thrombus areas were significantly lower than organized thrombus, Chi and Chi-STS areas (p<0.001). Elasticity values of fresh thrombus ranged between 3 and 19 kPa (8.7±3.6 kPa) at 1-week and 30.2±13.8 kPa at 3-months indicating that SSI can evaluate thrombus maturation. Aneurysm with fresh thrombus did not shrink as fast as aneurysm with only organized thrombus.

CONCLUSION

The results show that SSWI was able to characterize thrombus organization, embolization agents and healing over time after endoleak embolization following EVAR. The next objective is to evaluate in clinical study the feasibility and efficacy of this approach.

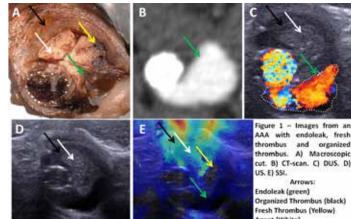

CLINICAL RELEVANCE/APPLICATION, NEW OR **BREAKTHROUGH WORK TO BE PRESENTED**

1. The Supersonic ShearWave Imaging was able to detect endoleak in real-time.

2. This technic has the potential to characterize thrombus organization within the aneurysm sac and in particular fresh thrombus which is associated with endoleak and endotension. The SSWI was able to distinguish fresh thrombus that cannot be detected on CT-scan (actual gold-standard).

3. The SSI can complement conventional DUS in post-EVAR surveil-

lance since the same machine can be used for both examinations. It could reduce the cost, the exposition to ionizing radiation and nephrotoxic contrast agents of surveillance CT-Scan follow up of AAA after EVAR.

SP162.4 - Detecting lipid-rich artery plaque using a handheld photoacoustic imaging device

Author(s): Susumu Hirano¹, Tsuyoshi Shiina¹, Takeshi Namita¹, Kengo Kondo², Makoto Yamakawa³

¹Graduate School Of Medicine, Human Health Sciences, Kyoto University, Kyoto/JAPAN, ²Center For The Promotion Of Interdisciplinary Education And Research, Kyoto University, Kyoto/JAPAN, 3Advanced Biomedical Engineering Research Unit, Kyoto University, Kyoto/JAPAN

Objectives: Carotid atherosclerosic plaque rupture is a cause of brain infarction. To prevent plaque rupture, it is important to detect the lipid-rich vulnerable plaque. However, it is not easy to evaluate such plaque by conventional medical imaging. Photoacoustic imaging is investigated as a novel modality of visualizing the difference of tissue characteristics. We have developed a handheld photoacoustic imaging device and tried to evaluate the possibility to detect lipid-rich artery plaque with it in phantom experiments.

Methods: Carotid artery plaque was modeled by injecting beef fat into a bovine aortic wall. The bovine aorta was submerged in saline. Light of a pulse-laser source is conducted to the measurement cross section of the ultrasound probe by holding a bundle of optical fibers close to the probe. Light at wavelengths of 800-1400nm was irradiated. The photoacoustic signal distribution was measured as photoacoustic images.

Results : In photoacoustic images at wavelengths where lipid absorbs light highly, strong photoacoustic signals were observed from the boundary between fat and the vessel wall. Figure 1 presents the spectrum of photoacoustic signals from the boundary. Although peak wavelengths subtly differ between the above spectra and the absorption spectrum of lipid, the shapes of the spectra are similar. At wavelengths of 1240-1300nm where the lipid spectrum shape differs, the similarity between the photoacoustic spectra and the absorption spectra was evaluated by calculating the correlation coefficient. As shown in Fig. 2, there is high correlation at the boundary between fat and the vessel wall.

Conclusion: The possibility of detecting lipid-rich plaque was confirmed based on an analysis of the photoacoustic spectrum. For future work, there are some issues to consider, such as experiments using more realistic models considering blood, its flow, and subcutaneous tissue; optimization of irradiated light intensity; selection of appropriate wavelength; and signal processing to improve SNR.

SP162.5 - Intersex differences in posterior eye chamber by spectral optical coherent tomography

Author(s): Karina Maciejewska, Iwona Pajonk, <u>Zofia Drzazga</u> Medical Physics, A Chelkowski Institute of Physics, University of Silesia, Katowice/POLAND

Optical coherent tomography (OCT) is a modern, non-invasive interferometric imaging technique. In our research, it was used to scan retina in young, healthy group of students in order to investigate the intersex differences in the structures of retina layers and its elements. 24 healthy eyes with normal vision were examined using SOCT Copernicus HR device. SOCT scans were conducted for a fovea of retina and in region of optic disc with the use of 3D, Asterix and Circle modes. In general, 120 measurements were performed. In obtained scans, the distance between RPE (retina pigment epithelium) and choroid was smaller in women than in men group, what seems to be the reason of a thinner retina in women. Analysis of optic disc revealed significantly higher rim area in women group than in men, but a little lower cup/disc ratio. These findings may be of a great importance in diagnosis glaucoma and other eye diseases when comparing intersex results.

SP162.6 - Longitudinal Analysis of 3D Pre-Term Neonatal Ventricle Ultrasound Images

Author(s): <u>Wu Qiu</u>, Jing Yuan, Jessica Kishimoto, Sandrine De Ribaupierre, Aaron Fenster

Robarts Research Institute, University of Western Ontario, London/ CANADA

Intraventricular hemorrhage (IVH) is a major cause of brain injury in preterm neonates. Measuring ventricular dilatation or shrinkage quantitatively is an important step in monitoring patients and evaluating treatment options. 3D ultrasound (US) has been developed to monitor ventricle volume as a biomarker for ventricular dilatation and deformation. Ventricle volume as a global indicator, however, it does not allow for the precise analysis of local ventricular changes, which could affect specific white matter bundles, such as in the motor or visual cortex, and could be linked to specific neurological problems often seen in this patient population later in life. In this work, we report a spatial-temporal nonlinear registration approach, which is applied to analyze the detailed local changes of the ventricles of preterm neonates with IVH from 3D US images. In particular, we employ a novel sequential convex/dual optimization to efficiently extract the optimal spatial-temporal deformable, which simultaneously optimizes the sequence of 3D deformation fields. The experiments with four patients with 4 time-point images for each patient showed that the proposed spatial-temporal registration approach accurately and efficiently recovered the longitudinal deformation of the ventricles from 3D US images, generating a Dice similarity coefficient (DSC) of 81.0%±2.2%, a the mean absolute surface distance (MAD) of 0.5±0.5 mm and a maximum absolute surface distance (MAXD) of 3.0±2.1 mm by comparing the registered follow-up image with corresponding baseline image. The obtained results suggests that the proposed approach may be potentially used to analyze the change pattern of cerebral ventricles of IVH patients, their response to different treatment options, and to elucidate the deficiencies that a patient will have later in life.

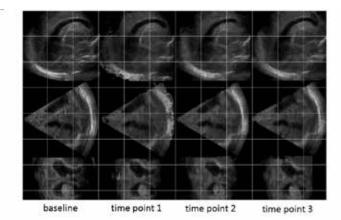

Figure 1. An example of registration results of 3D ventricle US images of an IVH neonate. 1 - 4 columns: baseline, registered images at time points 1-3. The first - third row: sagetal, coronal, and transvers view.

Table 1. Registration results of 4 patient images (4 time points each patient) in terms of DSC, MAD, and MAXD (p1-p4; patient ID), represented as the mean ± standard deviation.

SP162.7 - Breast Invasive Ductal Carcinoma Assessed by Conventional Ultrasound and Contrast-Enhanced Ultrasound in Different T-Stages

Author(s): <u>Yanchun Zhu</u>¹, Zhiyuan Wang², Yaoqin Xie¹ ¹Institution Of Biomedical And Health Engineering, Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shenzhen/CHINA, ²Department Of Ultrasound, Hunan Cancer Hospital, Changsha/CHINA

BACKGROUND: Accurate assessment of tumor size is necessary when selecting patients for breast-conserving surgery. There was little evidence of an association between conventional Ultrasound (US) and Contrast-enhanced US (CEUS) in predicting T stage of Breast Invasive Ductal Carcinoma (BIDC).

OBJECTIVE: The purpose of this study was to explore the value of CEUS in measuring the size and predicting T stage of BIDC.

Methods: Conventional US and CEUS were performed before pathology examinations by using a Siemens-Acuson S2000 scanner. One hundred and six patients confirmed with nodules of BIDC were included in the study. Person's correlations, linear regression and Wilcoxon signed-rank test were used to evaluate the relationship between two methods.

Results: Among 106 nodules, there were 16 nodules in T1 stage, 71 nodules in T2 stage and 19 nodules in T3 stage. The results show that CEUS consistently enlarge tumor size measurement: the width differences were 3.11 ± 1.34 mm, 3.91 ± 1.78 mm and 3.16 ± 2.56 mm for T1, T2 and T3 stages, respectively; and depth differences were 1.96 ± 1.13 mm, 2.47 ± 1.19 mm and 2.34 ± 1.77 mm for T1, T2 and T3 stages, respectively. As shown in Figure 1, significant correlations were observed between size measurements of US and CEUS (width measurement: r = 0.908, r = 0.925 and r = 0.927 for T1, T2 and T3 stages respectively; depth measurement: r = 0.959, r = 0.971 and r = 0.976 for T1, T2 and T3 stages respectively; all P < 0.001). Linear regression models similar among different T stages.

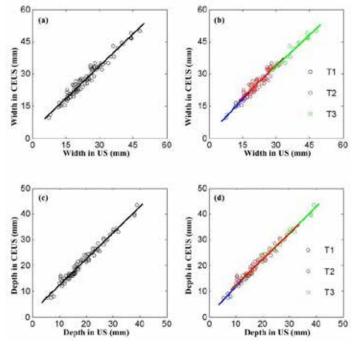

Figure 1. Comparison of CEUS and US measurements of all subjects and subjects with different T-stages.

Conclusions: In conclusion, this study suggests that larger size measured by CEUS than US. CEUS is a useful method for measuring the size and predicting the T stage of BIDC.

SP162.8 - Comparison of ultrasound systems in scoliosis measurement

Author(s): <u>Maggie Hess</u>¹, Daniel Borschneck², Gabor Fichtinger³, Tamas Ungi¹

¹School Of Computing, Queen's University, Kingston/CANA-DA, ²School Of Medicine, Queen's University, Kingston/CANA-DA, ³School of Computing, Queen's University, Kingston/ON/ CANADA

Introduction:

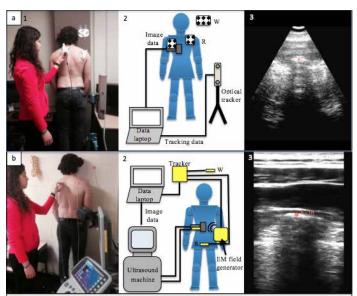

Idiopathic scoliosis is the most frequent spinal deformation presenting as a spatial deviation from the medial vertebral line. It is diagnosed in early adolescence and monitored until adulthood when surgical correction may happen. Patients are monitored by X-ray imaging every 3-6 months, exposing them to aggregating ionizing radiation, which increases the risk of cancer. Tracked three-dimensional ultrasound imaging allows for risk-free and accurate measurement of spinal curvature (Ungi et al. Ultrasound Med Biol, 2014). In this work, we compared the utility of inexpensive portable ultrasound with more expensive stationary ultrasound in spinal curvature measurement.

Methods:

An open-source tracked ultrasound based scoliosis measurement platform (Ungi et al. Ultrasound Med Biol, 2014) was utilised. This system is based on the SlicerIGT (www.SlcierIGT.org) open source environment that allows for seamless swapping among tracking devices and ultrasound scanners without requiring any programming or engineering development work. Two configurations of this system (Figure 1a) were compared: Interson USB ultrasound (Interson Corp, Pleasanton, CA, USA) with optical MicronTracker Hx60 (Claron Technology Inc., Toronto, ON, Canada); and Sonix Touch (Ultrasonix, Richmond, BC, Canada) with electromagnetic Ascension M180 (Ascension, Milton, VT, USA). In both configurations, a reference marker was attached to the patient and to the wall to compensate for gross body motion during ultrasound scanning. The intrinsic accuracy of SlicerIGT with both optically and electromagnetically tracked ultrasound was previously analyzed (Lasso IEEE TBME, 2014). This work focused on ultrasound image utility. Three human volunteers were scanned downward from the 7th cervical vertebra along the thoracic and lumbar regions. Two physicians experienced in spine ultrasound evaluated the visibility and clarity of the tip of transverse process. the anatomical feature that is necessary for curvature measurement.

Results and Conclusions:

For both physicians, in all patients and in all vertebras, the transverse process tip (N=102) was clearly visible with both Interson and Ultrasonix, without failure. In the hands of these two experienced physicians, the Interson and Ultrasonix scanners were functionally identical for the purpose of scoliosis measurement. The Interson scanner costs only \$3,500. The optical and electromagnetic trackers cost about the same. The complete system with Interson, Micron tracker and laptop computer easily fits into a backpack. Altogether this configuration offers a highly portable, inexp ensive and risk-free solution for ultrasound-based scoliosis monitoring and it may also open the way for scoliosis screening and be adopted in chiropractic care.

SP163 - Primary Dosimetry Standards

TRACK 05: DOSIMETRY AND RADIATION PROTECTION

SP163.1 - Candidate Technologies for Next-Generation Dosimetry Standards Author(s): <u>Ronald Tosh</u>

Radiation Physics Division, NIST, Gaithersburg/MD/UNITED STATES OF AMERICA

Primary standard instruments are broadly understood to be capable of realizing the unit of a physical quantity directly, according to its definition from basic physical principles, and because of their fundamental role in the calibration chain ideally possess the highest attainable accuracy and precision permitted by the state of the art. Because of its highly complex interactions with matter, however, ionizing radiation poses special challenges for its metrology and for the establishment of primary standards in which the measurand and the resulting units of measurement can be readily abstracted from the target material and physical attributes of the radiation source. This poses certain difficulties for advancing the state of the art in the quest for candidate technologies on which to base next-generation primary standards.

The extent to which this situation has inhibited the migration of technological advances from allied fields into radiation metrology may be difficult to ascertain, but is suggested by the resemblance of present-day water calorimeters to the earliest prototypes, developed decades ago, in which radiation-induced temperature rise is measured with thermistor probes sealed in a glass vessel. Heat transfer and scattering perturbations attributable to these components are well understood, however even when correction factors are readily obtainable the resulting instrument is still limited for use at fixed depth in static, flat radiation fields.

Remote detection of temperature rise by use of light or ultrasound is well established in non-destructive testing, but its use here, to detect the temperature field in an irradiated volume would seem to offer distinct advantages for the dosimetry of certain nonstandard beams and, more generally, for spatial mapping of dose distributions within matter. At NIST, both ultrasonic and optical techniques have been developed and exploited for high precision thermometry of water for purposes of radiotherapy-level dosimetry. In the case of ultrasound, work proceeds along two general lines, development of an imaging array for obtaining dose distributions in water and specialized studies with fewer transducers investigating detection limits and strategies for recovering faint signals. Parallel work using lasers in place of the ultrasound has yielded therapy-level dose measurements in both water and PMMA, and, via the use of sensitive interferometric techniques, shows considerable promise for exceeding the thermal sensitivity achievable with existing calorimetry systems.

Realization of an imaging calorimeter based on light or ultrasound remains a distant goal, however, with many technical hurdles yet to overcome, and thus work also continues on ways to adapt and improve thermistor-based systems for new primary standards for radiotherapy beams, and, most recently, for CT beams. A prototype calorimeter with thermistor beads embedded in a polystyrene core has been used in a HDPE phantom subjected to therapy-level radiation from a clinical accelerator and diagnostic-level radiation from a CT imaging system. With further refinements, the anticipated instrument would provide a calorimetry response to dose spanning over 3 orders of magnitude for beam energies ranging from keV to MeV, potentially making the system a portable "universal" primary reference standard that only requires electrical calibration of the thermistors.

SP163.2 - Absorbed dose to water measurements in a clinical carbon ion beam using water calorimetry

Author(s): Julia-Maria Osinga¹, Steffen Greilich², Oliver Jäkel³, Ulrike Ankerhold¹, Achim Krauss¹

¹Department Of Dosimetry For Radiation Therapy And Diagnostic Radiology, Physikalisch-Technische Bundesanstalt (PTB), Braunschweig/GERMANY, ²Division Of Medical Physics In Radiation Oncology, German Cancer Research Center (DKFZ), Heidelberg/ GERMANY, ³Heidelberg Ion-Beam Therapy Center (HIT), Heidelberg/GERMANY

Introduction: Until now, dosimetry of heavy ions with ionization chambers has not reached the same level of accuracy as dosimetry of conventional high-energy photons. The standard uncertainty associated with carbon ion dosimetry is about a factor of 3 higher as compared to high-energy photons [1]. This is mainly caused by the limited knowledge of the so-called kQ,Q0 factor, which corrects for the different response of the ionization chamber to the actual user beam quality Q (here: 12C) compared to the reference beam quality Q0 (here: 60Co). A significant discrepancy between fluence- and ionization-based dose measurements in carbon ion beams was shown in a previous study [2], which could indicate an inaccurate kQ,Q0 factor. The kQ,Q0 factor is, up to now, determined by calculations based on cavity theory and Monte-Carlo transport simulations and asks for experimental verification. This can be done by use of a primary standard for absorbed dose to water that allows for a direct calibration of the chamber in the user beam quality Q. Therefore, a project was initiated to perform absolute absorbed dose to water measurements in carbon ion beams by water calorimetry [3] to determine the kQ,Q0 factor with a lower standard uncertainty.

Materials and Methods: The water calorimeter measurements at HIT had to be adjusted to the specific conditions, namely (1) the irradiation with a pulsed beam using the raster-scan method and (2) the off-isocenter position of the calorimeter. Therefore, a number of investigations were required prior to the calorimetric measurements to determine and optimize the beam parameters at the measurement position complying with the following requirements: Firstly, the irradiation time needs to be as short as possible to minimize heat conduction effects occurring during the calorimetric measurements. At the same time, a homogenous and reproducible dose distribution is necessary to achieve a low standard uncertainty in the subsequent calorimetric measurements. To perform the corresponding investigations, a water-equivalent slab phantom was designed to mimic the real measurement condition of the calorimeter offering high flexibility in measurement set-ups. Based on the optimal beam parameters found, a series of measurements (>100) with the water calorimeter and two Farmer-type ionization chambers were performed in the entrance channel of a 430 MeV/u carbon ion beam.

Results: Current results of the calorimetric and ionometric measurements performed over a time period of 6 months, including the experimental determination of associated correction factors as well as calculations of the induced heat transport effects for the water calorimeter, will be presented. Further, a preliminary estimation of the currently investigated kQ,Q0 factor for both ionization chambers will be given.

Conclusion: We investigated optimized irradiation conditions enabling accurate calorimetric measurements in a scanned carbon ion beam. The latest results indicate that the experimental determination of the corresponding kQ,Q0factor for ionization chambers with a relative standard uncertainty below 1 % is achievable.

SP163.3 - Results from the on-going key comparison BIPM. RI(I)-K6 : What have we learned ? Author(s): <u>Susanne Picard</u>, David T. Burns BIPM, Sevres cedex/FRANCE

Results from the on-going key comparison BIPM.RI(I)-K6 : What have we learned ?

Susanne Picard¹ and David Burns²

Bureau International de Poids et Mesures

Pavillon de Breteuil - 92312 Sèvres cedex - France

The BIPM is presently carrying out a series of comparisons of absorbed dose to water, *Dw*, in accelerator beams of National Metrology Institutes. For this purpose, the BIPM developed a primary standard graphite calorimeter [1, 2] designed to be transported to the institutes for measurements in accelerator photon beams. The aim is to validate national primary standards by determining their degree of equivalence, published in the BIPM online key comparison database [3].

The BIPM standard has been successfully transported to the NRC (Canada), PTB (Germany), NIST (USA), LNE-LNHB (France), AR-PANSA (Australia) and the NPL (UK), where comparisons in the accelerator photon beams of each institute have been carried out, as well as with the VSL (Netherlands) [5 – 12]. Future comparisons are planned, notably for the NMIJ (Japan), NIM (China), KRISS (Korea), ENEA (Italy), METAS (Switzerland) and the MKEH (Hungary).

A closer study of the first comparisons in this series is made. Monte Carlo calculations have been carried out for 17 different beam qualities allowing the prediction of Monte Carlo coefficients for future comparisons. Accumulated calorimeter measurement data serve as a basis for quality control, and may give an indication of spectral dependence. Accumulated ionometric and calorimetric data have also been used for a determination of *W*air (the mean energy required to create an ion pair in dry air) and *I*g (the mean excitation energy for graphite) for these beams [13]. The degrees of equivalence are discussed and the results are compared to other comparisons made for the same quantity.

The authors are grateful to their colleagues at the NRC, PTB, NIST, LNE-LNHB, ARPANSA, NPL and the VSL for their participation.

SP163.4 - Absorbed dose-to-water primary standard and traceability system for radiotherapy in China Author(s): <u>Kun Wang</u>, Sunjin Jin, Jian Zhang National Institute of Metrology, Beijing/CHINA

The absorbed dose-to-water was measured both by ionization and calorimetry method at radiotherapy dose levels in China. A graphite ionization chamber, based on the cavity theory and combined with Monte Carlo simulation, was developed to measure absorbed dose to water for Co-60 gamma radiation. With Townsend compensation method to achieve ionization current measurement, using EGSnrc package for graphite cavity ionization chamber to simulate water perturbation parameter, measured the ion recombination and radial inhomogeneity correction factor, the combined standard uncertainty to measure absorbed dose to water for Co-60 was 0.37%.

The standard based on a water calorimeter is designed to operate in Co-60 and megavoltage photon beams from a linear accelerator. The water calorimeter operated at 4 °C to eliminate the problems associated with convection in water phantoms at room temperature. A low-noise temperature measurement circuit was able to resolve temperature differences at the μ K level. With the bath and Peltier cooling system, the temperature of water phantom is stable at (4±0.0001) oC. Using the cylindrical sealed glass vessel and bead thermistor of 10 k Ω , in the H2-saturated high pure water system, the resistance was measured by Wheatstone AC bridge. After calibrating thermistor and bridge separately, absorbed dose to water is absolutely measured with the combined standard uncertainty of 0.38%.

NIM participate in the comparison organized by Asia-Pacific Regional Metrology Programme (APMP), the differences with the reference value in APMP.RI (I)-K4 comparison was 0.04%, NIM finally had the ability for the traceability of absorbed dose to water.

The primary standard of water absorbed dose for photon radiation from 4 MV to 25 MV will be established and achieve the traceability of water absorbed dose for radiation therapy. This new standard will significantly reduce the uncertainty of ion chamber calibrations for Chinese radiotherapy centers and open up new areas of research for the NIM.

SP163.5 - Design of an MRI-compatible water calorimeter for use in an integrated MRI-Linac and Gamma-Knife

Author(s): <u>Niloufar Entezari</u>¹, Davis Ly², James Renaud³, Arman Sarfehnia⁴

¹Department Of Physics, Ryerson University, TORONTO/ON/CANA-DA, ²Department Of Engineering, University of Waterloo, Waterloo/ ON/CANADA, ³Medical Physics Unit, McGill University, Montréal/ CANADA, ⁴Department Of Radiation Oncology, University of Toronto, Toronto/CANADA

Purpose: The aim of this work is to present numerical design and optimization of a portable water calorimeter appropriate for dual use in an integrated MRI-linac and Gamma-Knife[®], based on the

concept of 4°C stagnant water calorimetry. In calorimetry, dose to water(*D*w) is measured based on the principle that energy absorbed in a sensitive volume is completely converted to temperature rise(ΔT) using specific heat capacity of medium *cP*,*D*=*cP** ΔT **k*ht, where *kht* is heat transfer correction and compensates for heat gain or loss at point of measurement due to conductive and convective effects.

Methodology: The calorimeter dimensions, constrained by the size of an MRI-linac bore and Gamma-Knife collimator ring, were numerically optimized to maximize thermal stability. Several materials were investigated to be used for the calorimeter body, and thermal insulation.

A comprehensive numerical optimization study of four different calorimeter designs was undertaken using a commercial finite element method software package by accurately modeling heat transport inside a given geometry(FIG 1). For each design, thermal stability of system in presence of minor ambient thermal fluctuations was evaluated.

To study the effects of possible coolant temperature fluctuations (circulating in calorimeter to keep it at 4° C), several simulations were performed in which the temperature of coolant was kept either constant, slowly increasing, or fluctuating at a given frequency. The long term drift(48h) was simulated, and *k*ht due to seven consecutive irradiation runs by a high energy beam was calculated.

Results and **Conclusions:** The calorimeter was designed to be used in upright position in MRI-linac with the radiation beam incident from the top, while it is rotated 90 degrees for use in Gamma-Knife. In the latter case, its semi-spherical end is placed at the isocenter of Gamma-Knife collimator ring, providing a constant depth of measurement for every incident beam angle.

Due to MRI-compatibility requirements, the calorimeter is to be rapid prototyped/built entirely out of plastic. Among all insulation materials tested, solid state aerogel-based insulation resulted in highest performance and thermal stability.

kht was found to be 1.002 ± 0.014 , 0.984 ± 0.013 , 0.986 ± 0.029 , 1.002 ± 0.013 (k=1) for designs in FIG1a-d respectively. The design in Fig.1d was chosen for prototyping, as it demonstrated the greatest long term stability (0.36μ K/hr).

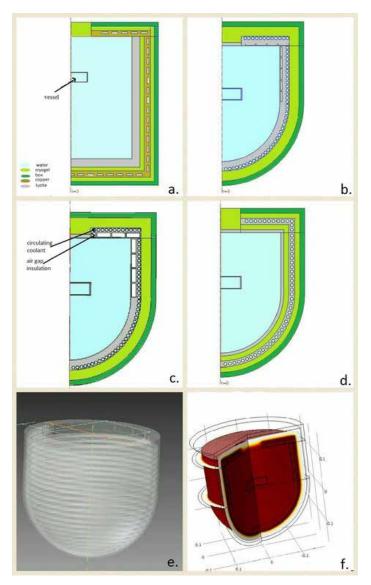

Fig. 1: Four calorimeter designs investigated in this work (a to d); A rendering of coolant passageway inside the calorimeter wall (e). Simulated temperature distribution inside calorimeter design depicted in FIG1(c) following 48 hours drift (f).

SP163.6 - On the practical use of calorimetry for routine absolute dosimetry in the radiotherapy clinic

Author(s): <u>James Renaud</u>¹, Arman Sarfehnia², Jan Seuntjens¹ ¹Medical Physics Unit, McGill University, Montréal/CANADA, ²Department Of Medical Physics, Sunnybrook Health Sciences Centre, Toronto/ON/CANADA

Purpose: The aim of this work is to describe the construction, development, and modes of operation of a small-scale graphite calorimeter probe (GPC) conceived for use as an absolute dosimeter in the radiotherapy clinic (Patent No. PCT/CA2013/000523).

Similar in size and shape to a 0.6 cm³ cylindrical ionization chamber, the GPC has been designed to help meet the clinical need for accurate reference dosimetry in nonstandard radiation fields.

Materials and Methods: Based on a numerically optimized design obtained in previous work (Fig. 1), a functioning prototype with embedded active thermal control capable of quasi-adiabatic and isothermal operation was constructed in-house.

In quasi-adiabatic mode, the radiation-induced temperature rise is measured in the sensitive volume (*i.e.* the core) while the outermost portion of the device is thermally stabilized by a software-based temperature controller. In isothermal mode, the entire device is subject to active thermal control and the quantity of interest in the electrical power necessary to maintain a stable temperature while irradiated.

An experimental characterization of the GPC repeatability, linearity, and dose rate dependence while operated in quasi-adiabatic mode was carried out in a water-equivalent phantom, under reference conditions, in a 6 MV photon field. Similarly, a characterization study of the GPC's isothermal mode was conducted by simulating radiation fields of various dose rate (0.5 - 11.8 Gy/min) and duration (10 - 180 s) by means of electrical power dissipation.

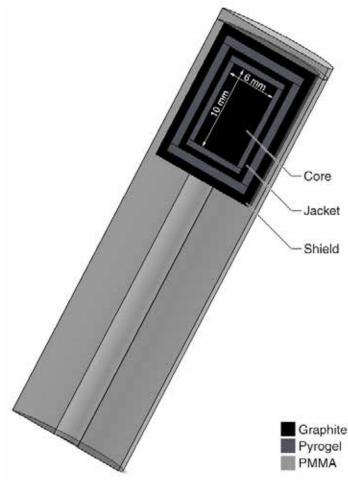

Fig 1. An isometric cutaway view of the GPC

Results: For the quasi-adiabatic mode, a epeatability of 0.4% was established (n = 64), linearity was characterized by an adjusted R^2 value of 0.9996 (n = 40), and no statistically-significant dose rate dependence was observed.

For isothermal mode, differences between expected and actual GPC response ranged between 0.3 - 1.4%, and in general, agreement was superior for longer irradiations with dose rates greater than 2 Gy/min.

Discussion and Conclusions: This proof of concept points to the feasibility of operating the GPC in both quasi-adiabatic and isothermal mode for the purpose of absolute clinical dosimetry. As expected from a calorimeter, the GPC is characterized experi-

mentally (quasi-adiabatic) and through simulation (isothermal) by a strong linear response and relative dose rate independence.

Plans to experimentally verifying the isothermal mode of operation by showing self-consistency between the two modes are underway. Further comparison against other reference class dosimeters in standard and non-standard fields are to follow.

SP164 - Adaptive Radiation Therapy (ART)

TRACK 06: NEW TECHNOLOGIES IN CANCER RESEARCH AND TREATMENT

SP164.1 - Real-time dose reconstruction for adaptive radiation therapy

Author(s): <u>Martin F. Fast</u>, Cornelis Philippus Kamerling, Peter Ziegenhein, James L. Bedford, Simeon Nill, Uwe Oelfke Joint Department Of Physics, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London/UNITED KINGDOM

Currently dose reconstruction can only be conducted after the treatment fraction due to its computational cost and missing real-time data interfaces. In future, real-time treatment interventions such as dynamic multi-leaf collimator (dMLC) tracking will require on-line dose reconstruction to ensure target coverage and organ-at-risk (OAR) sparing.

To facilitate this study, we have implemented on-line dose reconstruction by connecting our software for delivery & tracking (DynaTrack) and for dose calculation & planning (DynaPlan) through a TCP/IP network. DynaTrack is interfaced to our research Elekta Synergy linac/Agility MLC and controls treatment delivery and dMLC tracking via a real-time tracking interface. Actual MLC apertures and (simulated) target positions are reported to DynaPlan every 40 ms and 20 ms respectively. DynaPlan then relies on a set of pre-calculated dose influence matrices (Dij) with 5x5 mm² bixel resolution generated in research RayStation using its singular value decomposed pencil beam algorithm to calculate the actually delivered dose. To investigate the impact of dMLC deliveries on dose distributions, we generated two plans in Pinnacle: a lung patient (RTOG 1021, 54 Gy, 3 Fx, 15-beam, PTV 34 cm³) and a prostate patient (RTOG 0938, 36.25 Gy, 5 Fx, 7-beam, PTV 104 cm³). The dose was accumulated onto a voxel resolution of 1.95x1.95x3 mm³ (lung) and 2.3x2.3x1.5 mm³ (prostate). Three treatment scenarios were evaluated: a static delivery (no motion, no tracking), a conventional delivery (motion, no tracking), and an adaptive delivery (motion, tracking). Two motion trajectories were used to propagate the PTV contour within the planning CT (assuming static OARs).

We successfully implemented truly on-line dose reconstruction for experimental treatment deliveries on a linac. The dose reconstruction was updated at 25 Hz and took \leq 30 ms (prostate) and \leq 20 ms (lung) per MLC aperture. Dijdata of up to 1 GB per beam segment was handled at a memory throughput of \leq 43 GB/s on a single workstation computer. The reconstructed dose distributions (see table) highlight the fact that target dose can be safely recovered using dMLC tracking for these patients and motion conditions.

Real-time dose reconstruction is technologically feasible without compromising on resolution or accuracy. This is an important milestone towards the implementation of on-line replanning for adaptive radiation therapy and dose-guided dMLC deliveries. Future work will assess the impact of the motion model on the dose and use collapsed-cone Dij data for lung patients.

SP164.2 - Evaluation of unified intensity-modulated arc therapy (UIMAT) for the treatment of head-and-neck cancer

Author(s): <u>Michael Macfarlane</u>¹, Douglas Hoover², Eugene Wong³, Jerry J. Battista², Nancy Read⁴, David Palma¹, Varagur Venkatesan⁴, Alex Hammond⁴, Jeff Z. Chen⁴

¹Department Of Medical Biophysics, Western University, London/ CANADA, ²Department Of Oncology, Western University, London/ CANADA, ³Department Of Physics & Astronomy, Western University, London/CANADA,⁴London Regional Cancer Program, London Health Science Center, London/ON/CANADA

Purpose: Recently our group developed a unified intensity-modulated arc therapy (UIMAT) technique which combines IMRT and VMAT optimization and delivery in a single arc [1]. In this current study, we evaluated the potential benefit of UIMAT for the radiation therapy of complex head-and-neck cancers.

Method: A retrospective planning study was performed on 20 headand-neck cases (13 treated clinically with VMAT and 7 with IMRT). These cases were re-planned using our UIMAT technique and the results were compared with the clinically delivered plans. Plans were assessed in terms of target coverage, target conformity, and sparing of organs at risk. The feasibility of plan delivery was verified with an ArcCheck phantom and a Varian TrueBeam linear accelerator operating in clinical mode.

Results: When compare to VMAT or IMRT alone, UIMAT plans maintained target coverage and conformity while significantly reducing the mean doses to organs at risk. This trend is summarized in Table 1. A comparison of dose-volume histograms between VMAT and UIMAT plans is also shown in Figure 1. In addition to its dosimetric advantage, UIMAT plans can be delivered with the same level of efficiency as VMAT.

Conclusion: Compared with IMRT or VMAT alone, UIMAT appears to offer dosimetric advantages for the radiation therapy of head-and-neck cancers.

SP164.3 - A Hybrid IMRT/VMAT Technique for the Treatment of Nasopharyngeal Cancer

Author(s): <u>Nan Zhao</u>, Ruijie Yang, Yuliang Jiang, Suqing Tian, Fuxin Guo, Junjie Wang

Radiation Oncology, Peking University Third Hospital, Beijing/CHINA

Purpose: This study is to investigate a Hybrid IMRT/VMAT technique which combines intensity modulated radiation therapy (IMRT) and volumetric modulated arc therapy (VMAT) for the treatment of nasopharyngeal cancer (NPC).Methods:2 full arcs VMAT (2ARC-VMAT), 9-field IMRT (9F-IMRT) and Hybrid IMRT/VMAT plans were created for 10 patients with NPC. The Hybrid IMRT/VMAT plans were combination of 1 full arc VMAT (Hybrid-VMAT) and 7-field IMRT (Hybrid-IMRT). The dose distribution of planning target volume (PTV) and organs at risk (OARs) for Hybrid IMRT/VMAT was compared with 9F-IMRT and 2ARC-VMAT. The monitor units (MUs) and treatment delivery time were also evaluated. Results: For PTV70 and PTV59.4, the Hybrid IMRT/VMAT technique significantly improved target dose conformity compared with 9F-IMRT (0.62 vs 0.47, p=0.01; 0.64 vs 0.58, p=0.01) and 2ARC-VMAT (0.62 vs 0.43, p=0.00; 0.64 vs 0.60, p=0.01). For PTV54, the Hybrid IMRT/VMAT technique improved target dose conformity compared with 9F-IMRT (0.69 vs 0.63; p=0.00). The near maximum dose (D2%) and mean dose of mandible in Hybrid IMRT/VMAT were 5.2% (p=0.00) and 4.2% (p=0.03) lower than 9F-IMRT plans, respectively. The mean dose of TMJ, temporal lobe and unspecified tissue for Hybrid plans were 12.8% (p=0.00), 11.4% (p=0.01) and 4.0% (p=0.02) lower than 9F-IMRT plans, respectively. The V30 of right and left parotids for Hybrid plans and VMAT plans were 34.7% vs 35.7% (p=1.00) and 36.1% vs 37.1% (p=1.00), respectively. The mean dose of TMJ, D2% of mandible for Hybrid plans and 2ARC-VMAT plans were 37.4 Gy vs 39.3 Gy (p=0.34) and 63.7 Gy vs 64.7 Gy (p=0.06), respectively. Conclusions: Hybrid IMRT/VMAT technique can be a viable radiotherapy technique with better plan quality.

SP164.4 - Interactive real time adaptation of IMRT treatment plans

Author(s): <u>Cornelis Philippus Kamerling</u>¹, Katrin Welsch¹, Peter Ziegenhein¹, Simeon Nill¹, Jamie Mcclelland², Uwe Oelfke¹ ¹Joint Department Of Physics, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London/UNITED KINGDOM, ²Centre For Medical Image Computing, Dept. Of Medical Physics And Bioengineering, University College London, London/ UNITED KINGDOM

Recently we introduced a software platform for IMRT treatment planning based on a sequence of local dose adaptations. These are facilitated by direct interaction of the planner with the graphical representation of the patient dose in a real-time feedback loop. Here we report on an extension of this interactive dose shaping (IDS) software for adaptive radiotherapy based on daily cone beam CTs (CBCTs).

The developed workflow consists of five essential components as indicated in figure 1. All related algorithms are integrated with our research TPS Dynaplan and optimized for speed to comply with the interactive planning paradigm. To facilitate deformable image registration (1a), the NiftyReg (UCL, London, UK) package was integrated.

As an example for the performance of the implemented workflow we report its application for a prostate patient aiming to re-establish the initially planned dose (based on planning CT) on a new patient geometry observed on a CBCT in fraction 5. The center-of-mass shift from PTV and rectum were 5.3 and 4.4mm respectively, mainly in posterior direction. The PTV dose prescription was 67Gy. Dose quality indicators were evaluated for (i) initial plan on initial geometry, (ii) initial plan on new geometry, (iii) adapted plan on new geometry and are reported in table 1. The recovered target dose indicates a successful restoration of the initially planned dose. The slightly higher rectum dose is the result of the decreased distance between PTV and rectum. The computations were performed on a low-end Intel i7 desktop PC with an image processing runtime of 2min, dominated by image registration (1a) with 84s. IDS recovery (5a) took 5s.

This work provides a first proof of concept study for the integration of an ART therapy workflow into an IDS TPS. Further validation aiming to optimize the image processing parameters and IDS recovery performance is in progress.

SP164.5 - A Hybrid IMRT/VMAT technique for the treatment of non-small cell lung cancer

Author(s): <u>Nan Zhao</u>, Ruijie Yang, Junjie Wang, Xile Zhang Radiation Oncology, Peking University Third Hospital, Beijing/CHINA

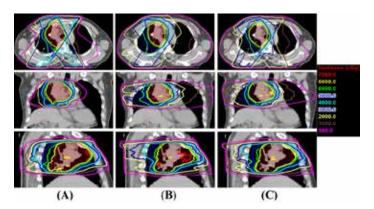

Purpose: To investigate a Hybrid IMRT/VMAT technique which combines intensity modulated radiation therapy (IMRT) and volumetric modulated arc therapy (VMAT) for the treatment of non-small cell lung cancer (NSCLC).

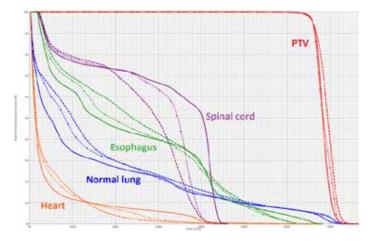

Methods and Materials: 2 partial arcs VMAT, 5-field IMRT and Hybrid IMRT/VMAT plans were created for 15 patients with NSCLC. The Hybrid IMRT/VMAT plans were combination of 2 partial arcs VMAT and 5-field IMRT. The dose distribution of planning target volume (PTV) and organs at risk (OARs) for Hybrid IMRT/VMAT was compared with IMRT and VMAT. The monitor units (MUs) and treatment delivery time were also evaluated.

Results: Hybrid IMRT/VMAT significantly improved the target conformity and homogeneity compared with IMRT and VMAT. The V30 of normal lung for hybrid plans was significantly lower than IMRT plans (17.7% vs 18.7%; p<0.05) and VMAT plans (17.7% vs 18.4%; p<0.05). The V5, V10, V30 and mean lung dose (MLD) of normal lung for hybrid plans were 5.1%, 7.7%, 3.8% and 3.9% lower than those for VMAT plans, respectively (p<0.05). The maximum dose of spinal cord for hybrid plans was 5.6 Gy lower than that for IMRT plans (p<0.05). The dose received by esophagus and heart for

hybrid plans were significantly lower than those for IMRT plans. The mean delivery time of IMRT, VMAT and hybrid plans were 280 s, 114 s, and 327 s, respectively. The mean MUs needed for IMRT, VMAT and hybrid plans were 933, 512, and 737, respectively.

Conclusions: The Hybrid IMRT/VMAT technique significantly improved the target conformity and homogeneity compared with IMRT and VMAT. It reduced V5, V10, V30 and MLD of normal lung compared with VMAT, and protected the OARs better with fewer MUs compared with IMRT. Hybrid IMRT/VMAT technique can be a viable radiotherapy technique with better plan quality.

SP164.6 - Offline adaptive VMAT - feasibility study using planning CT deformed electron density mapping on daily CBCT to estimate parotid dose volume relationship.

Author(s): Ayyalusamy Anantharaman', <u>Vellian Subramani</u>², V.S Subramanian¹, Gandhi Arun³, Shanmugam Thirumalai Swamy³, Murugesan Kathirvel³, Ilamurugu Arivarasan³ ¹Research And Development Centre, Bharathiar University, Coimbatore/INDIA, ²Radiation Oncology, All India Institute of Medical Sciences, New Delhi/INDIA, ³YASHODA HOSPITAL, HYDERABAD/ INDIA

Aim:

To evaluate the parotid dose volume relationship in offline Adaptive Volumetric Modulated Arc therapy by using deformable mapping of planning CT electron density values on daily CBCTs.

Methods and Materials:

Daily CBCTs were acquired for 10 head and neck patients undergoing rapid arc treatments. The Smart Adapt system was used to deform the planning CT to the daily CBCTs, obtaining the anatomical information of the day with the electron density values of the planning CT. The deformed contours were checked for any discrepancies and Rapid Arc plans were calculated with fixed MUs on the deformed CTs. Based on the calculated plans, a cumulative DVH was generated and the variation in the parotid volume and the delivered mean doses of parotids were analyzed.

Results:

There was shrinkage of parotid volumes during the course of the treatment. In this study, the observed maximum, minimum and mean parotid volume reduction were 52%, 13% & 29% respectively. The mean dose of parotids varied from -3.6% to 17% from the planned doses. The parotid volume and dose variation for 10 patients are shown in the table below. It was observed that for parotids closer to high dose regions a small volume shrinkage causes a remarkable increase in mean dose due to more of the parotid volume inside the high dose region. Whereas for parotids closer to low risk nodal regions, there is no significant change in mean dose even for a volume shrinkage of 30%. Parotid mean doses were less than the planned doses for two patients due to shrinkage along craniocaudal direction also.

PATIENT	VOLU	ME (%)	MEAN C	OSE (%)
PATIENT	LEFT	RIGHT	LEFT	RIGHT
1	52	44	17.1	7.4
2	30	14	0.5	4.6
3	31	41	7.5	7.3
4	13	15	4.8	-2.8
5	18	25	13.9	0.8
6	29	32	-3.6	9.8
7	27	25	1.2	9.1
8	19	15	6.7	5.2
9	23	35	8.1	10.3
10	21	18	6.3	2.5

PAROTIDS VOLUME DOSE COMPARISON

Conclusion:

The results from the study showed that it is clinically feasible to estimate the parotid shrinkage and the delivered dose - volume relationship in VMAT using planning CT electron density mapping on daily CBCTS.

SP164.7 - Plan Optimization for a Lung Patient on a Parallel Linac-MR System

Author(s): <u>Daniel Tamagi</u>, Brad Warkentin, Amir Keyvanloo, B Gino Fallone, G. Colin Field

Medical Physics, Cross Cancer Institute, Edmonton/CANADA

Purpose: In a hybrid Linac-MR system, the magnetic field of the MRI produces a Lorentz force on charged particles that affects dose deposition. The resulting effects on patient dose distributions are expected to be most significant in low density regions such as lung, where the mean free paths of electrons and positrons are longer. This study uses a simplified (three-beam) Stereotactic Body Radiation Therapy treatment plan for a lung patient to investigate the importance of these dosimetric perturbations in the fluence optimization and dose calculation stages of the treatment planning process.

Methods: Modified versions of the EGSnrc Monte Carlo codes

BEAMnrc and DOSXYZnrc were used to generate patient-specific beamlets in 1) the absence of a magnetic field, and 2) in the presence of a magnetic field (either 0.56T or 1.5T) oriented parallel to the beam. These beamlets were imported into a research version of the RayStation TPS (RaySearch Laboratories, Sweden), and were used: 1) to perform "forward" dose calculations of unmodulated beams, and 2) to optimize fluence patterns for modulated beams. Forward calculations using the kernels for 0T, 0.56T and 1.5T were performed for MLC shaped fields and were compared to determine the dosimetric effects of the magnetic field. The RayStation fluence optimization software was used to determine fluence patterns for each of the 3 fields to achieve clinical goals. MATLAB code was written to compare these optimized fluence patterns as a function of magnetic field strength. A forward calculation was performed for these optimized fluence patterns and the resulting dose distributions were compared for the 3 magnetic fields.

Results: As a function of magnetic field strength, fewer Monitor Units (max % differences of -0.9% for 0.56T, and -2.4% for 1.5T compared to 0T) were required to achieve equivalent target coverage, due to the confinement of scattered electrons by the magnetic field. We also observed more lung sparing (Mean dose of 0.8% less for 0.56T, and 9.5% less for 1.5T compared to 0T) as a function of magnetic field strength due to the scattered electron confinement, and the reduced MU's. With identical optimization objectives, percent differences for fluence elements were within +-5% between the 0T and 0.56T optimizations, but were as large as 60% for some elements between the 0T and 1.5T. We found that optimizing the fluence without the magnetic field being considered resulted in worse target coverage (D5 % differences of 0.2% and 2.6% for 0.56T and 1.5T respectively compared to 0T). This effect is clinically negligible for the 0.56T case, but was more significant at 1.5T.

Conclusion: Our study suggests that modeling the magnetic field during fluence optimization and during the forward dose calculation is significant at 1.5T, but is clinically negligible at 0.56T. Our study also indicated that equivalent target coverage (compared to a conventional linac) can be achieved with better sparing of lung if the magnetic field is modeled during forward planning and fluence optimization. These results are for a lung patient with a simplified 3 beam treatment plan. More investigation is needed.

SP165 - EEG

TRACK 09: BIOSIGNAL PROCESSING

SP165.1 - A Fully Unsupervised Clustering on Adaptively Segmented Long-term EEG Data

Author(s): <u>Vaclav Gerla</u>¹, Elizaveta A. Saifutdinova¹, Vaclav Kremen¹, Michal Huptych¹, Vladimir Krajca², Lenka Lhotska¹ ¹Department Of Cybernetics, Czech Technical University in Prague, Prague/CZECH REPUBLIC, ²Department Of Biomedical Technology,

Czech Technical University in Prague, Kladno/CZECH REPUBLIC

Several new procedures for efficient processing of long-term EEG recordings has been validated on long-term comatose EEG data. The proposed solution is based on the use of cluster analysis over a set of various features derived from adaptively segmented EEG data. Special attention was given to utilization of clinically relevant information from multichannel EEG data. Methods for validation of the cluster analysis results were implemented and tested. Suggested algorithms speeds up a subsequent evaluation of the data and simplify a tedious and time-consuming work of neurologists or sleep technicians, making the evaluation more objective, and represent results in an understandable form.

SP165.2 - A Real-Time Clustered MUSIC algorithm for the ocalization of synchronous MEG/EEG source activity

Author(s): Christoph Dinh¹, Matti S. Hämäläinen², <u>Daniel Baumgar-</u> ten¹, Jens Haueisen³

¹Institute Of Biomedical Engineering And Informatics, Technische Universität Ilmenau, Ilmenau/GERMANY, ²Athinoula A. Martinos Center For Biomedical Imaging, Massachusetts General Hospital -Massachusetts Institute of Technology - Harvard Medical School, Charlestown/MA/UNITED STATES OF AMERICA, ³Biomagnetic Center, Clinic For Neurology, Jena University Hospital, Jena/GER-MANY

Magnetoencephalography (MEG) and Electroencephalography (EEG) provide millisecond temporal resolution and are thus ideally suited for real-time monitoring of brain activity. Among various inverse algorithms mapping sensor space measures to sources in the brain, spatio-temporal dipole fitting methods such as MUSIC (Multiple Signal Classification) and RAP-MUSIC (Recursively Applied and Projected MUSIC) have demonstrated superior ability in the localization of a restricted number of independent sources. However, these methods are computationally extensive and commonly applied for offline data analysis subsequent to the measurement.

We propose a novel Real-Time Clustered MUSIC algorithm (RTC-MUSIC) that makes use of the advantages of the well-established MUSIC algorithm but can be applied to real-time data streams during the measurement. For this purpose, regional cortical activity is represented by a small number of dipoles based on a cortical atlas and a k-means algorithm, thus considerably reducing the size of the gain matrix. The computation of the subspace correlations between dipole pairs is highly parallelized. Moreover, performance optimization is achieved by employing Powell's Conjugate Gradient Method [26] as the search algorithm to find the best dipole source combination without performing a brute-force calculation of all dipole correlations.

Our results show that the gain matrix clustering improves the condition of the underlying inverse problem. In addition, the reduction of the gain matrix to the most representative dipoles considerably reduces the computational effort. Performance optimization in RTC- MUSIC yields a further reduction of the required calculation steps by approximately 50 % for the same number of dipoles, sensors and independent sources, respectively, compared to the MUSIC algorithm. Moreover, the number of computational steps is exponentially decreasing with the number of parallel cores employed for the calculation.

Applying our novel RTC-MUSIC algorithm to single trial MEG data from an auditory task reveals similar localization precision compared to the original MUSIC algorithm. The real-time performance of our algorithm was confirmed in measurements with the Elekta Neuromag[®] MEG system.

We conclude that our novel RTC-MUSIC algorithm with gain matric clustering allows for real-time localization of correlated sources of neuronal activity. It copes with the low SNR of single trial data and considerably reduces the computational time compared to MUSIC.

SP165.3 - Spatial harmonics for compressive sensing in electroencephalography

Author(s): Uwe Graichen¹, Christina Salchow¹, Daniel Strohmeier¹, Patrique Fiedler¹, Roland Eichardt¹, <u>Jens Haueisen²</u> ¹Institute Of Biomedical Engineering And Informatics, TU Ilmenau, Ilmenau/GERMANY, ²Institute Of Biomedical Engineering And Informatics, Ilmenau University of Technology, Ilmenau/GERMANY

Magnetoencephalography (MEG) and electroencephalography (EEG) provide information on brain function with a high temporal resolution. Recent developments in EEG allow for ubiquitous recording using dry electrodes. However, multichannel dry electrodes still suffer from higher channel dropouts compared to standard wet EEG.

We propose a new technique for interpolating EEG channels based on compressive sensing (CS). The complete signal is reconstructed from an incomplete set of measurements via convex programming. An adapted, convex optimization problem was designed to solve the interpolation problem. EEG is neither sparse in the canonical basis in the original time domain nor sparse in transformed time domains. Therefore, current CS algorithms cannot achieve good recovery quality. Consequently, we propose compressive sensing in the spatial domain. We use our recent spatial harmonic analysis (SPHARA) to decompose measured data obtained with a dry 97-channel EEG cap. SPHARA is based on the Eigenanalysis of the discrete Laplace-Beltrami operator defined on a triangular mesh. It allows a spatial Fourier analysis of the spatial potential distribution of EEG data. Pattern reversal visual evoked potentials (VEP) were measured using the dry electrode cap and a commercial amplifier (RefaExt, ANT B.V., Enschede, The Netherlands) for four healthy male volunteers. Channel dropouts were simulated for an increasing number of channels: 5, 10, 15, 20, 25, 30, 40 and 50%. Both, randomly chosen channels and channel patches were considered.

Our proposed method is able to interpolate randomly chosen dropout channels up to 50% of the total number of channels. Channel patches could be interpolated for dropout channels up to 20% of the total number of channels. Figure 1 shows two examples of reconstructed VEPs of one volunteer after 20% channel dropout for a frontal and an occipital patch. The SPHARA based interpolation was compared to k-Nearest Neighbors (kNN) and a spherical spline interpolation. Spherical spline interpolation performed significantly worse to kNN and SPHARA for randomly chosen channels and channel patches. kNN performed similar to SPHARA for randomly chosen channels but worse for larger channel patches.

In conclusion, we proposed a new compressive sensing technique for the interpolation of missing EEG channels. Moreover, this interpolation approach allows transformations between different EEG montages.

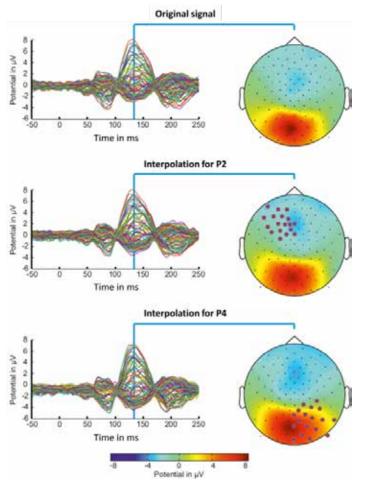

Figure 1: Original VEP signal (top row), SPHARA interpolation of frontal patch (P2) of 20% dropout channels (middle row), and SPHARA interpolation of occipital patch (P4) of 20% dropout channels (bottom row). The position of the dropout channels is indicated by violet filled circles.

Torres-Muller² ¹Electrical Engineering, Federal University of Espirito Santo, Vitoria/ BRAZIL, ²Electrical Enginnering, Federal University of Espirito Santo, Vitoria/BRAZIL, ³Ryerson University, Toronto/CANADA, ⁴Department Of Electrical And Computer Engineering, Ryerson University, Toronto/CANADA

Background:

This paper compares performance of two popular feature extraction methods, namely, multivariate synchronization index (MSI) and canonical correlation analysis (CCA) methods, for their use in a compressive sensing (CS)-based Steady-State Visual Evoked Potential (SSVEP) brain-computer interface (SSVEP-BCI) system. A person with severe motor disability would focus his/her visual attention on a bilateral visual stimulus generated on a computer screen, Meanwhile, the SSVEP-BCI system can be applied by performing various signal processing operations including EEG signal acquisition, application of CS, EEG signal reconstruction, feature extraction, and visual stimulus-frequency recognition. The MSI and CCA methods can be used to estimate respective features from the signals reconstructed using a CS algorithm. Simulation results indicate that the classification performance offered by the MSI method for the signals reconstructed using a CS algorithm, with compression ratio (CR) of up to 75%, remains at par with that for the original uncompressed signals. Whereas, the classification performance offered by the CCA method is reduced after the application of CS. Therefore, the MSI method can be more suitable for designing CS-based low-power wireless sensors for the acquisition of EEG signals in the SSVEP-BCI systems.

Method:

Five male subjects (29.8 \pm 2.17 years) participated in this study. Initially, signals from three occipital channels (O1, O2 and Oz) were extracted. Signals were compressed using CS with CR of 75%. Compressed signals were reconstructed using the -RLS, -RLS, and BSBL-BO algorithms. In the pre-processing stage, the data were segmented and windowed with window lengths (WL) of 1 s and 4 s, each one with an overlap of 50%. Then, the Common Average Reference (CAR) and band-pass filter in the range 3-60 Hz were applied. The CCA and MSI methods were applied independently, and the classification performance was evaluated.

Results and Conclusion:

The comparison of performance (mean and standard deviation) was tested in 50 repetitions of reconstructed Electroencephalographic (EEG) signals averaged for 5 subjects and different windows length. Finally, these results were also compared with the original EEG signals. From the results, we can see that generally the higher the window length of the data, the higher is the precision. As it can be noticed for all cases tested, the MSI technique surpassed that of CCA. The results regarding the reconstructed signals were slightly closer to the original signal: \approx 72 % (WL = 1 s) and \approx 85% (WL = 4s). The three reconstruction algorithms showed results very similar to each other. For the proposed system, the MSI method can offer acceptable performance for high CR. The proposed system offers faithful detection performance and is suitable for the design of lowpower wearable wireless electrodes. By using the stimulus frequency based on the MSI method, it is demonstrated that the proposed system can offer acceptable performance for a high CR compared to CCA technique. Consequently, the power-consumption in wireless EEG can be significantly reduced.

SP165.5 - Multi-way based Source Localization of Multichannel EEG signals Exploiting Hilbert-Huang Transform

Author(s): <u>Saeed Pouryazdian</u>, Soosan Beheshti, Sridhar Krishnan Electrical And Computer Engineering, Ryerson Univeristy, Toronto/ CANADA

Background: Electroencephalogram (EEG) non-invasively measures the electrical potential at the scalp arising primarily from synchronous neuronal activity of the brain cells. EEG is high-dimensional and it is known that the processing of information by the brain is reflected in dynamical changes of the electrical activity in time, frequency, and space. Study of brain's physiological, mental and functional abnormalities requires methods that can describe these variation of EEG signals in time and frequency and space in a localized and quantitative way. Localization of the electrical activity of brain has been an active area of research known as EEG source localization. Methodology: EEG source localization is an ill-posed problem which in case of matrix (two-way) analysis forces us to add specific constraints, which may not be physiologically meaningful. Multi-way (tensor) analysis, on the other hand, is desirable in a sense that it's unique under mild condition and no such constraints are required. Parallel Factor Analysis (PARAFAC) is a well-known and common multi-way model in high-dimensional data modeling context. Temporal, Spatial and Spectral information of the multichannel EEG are used here to generate a three-way Time-Frequency-Space EEG tensor. The required Time-Frequency (TF) plane for generation of EEG tensor is provided through TF representation of each

EEG channel. Continues Wavelet Transform (CWT) is conventionally used in literature which suffers from the lack of ability to exactly localize a single oscillatory event in time and frequency contemporarily. Motivated by the high-resolution capability of Hilbert-Huang Transform (HHT) in both temporal and spectral domain and its data dependent and adaptive nature, here we use HHT for TF representation. HHT consists of a combination of Empirical Mode Decomposition (EMD) and Hilbert Transform (HT). EMD is a fully data-driven technique for decomposing a non-stationary time series into a set of oscillatory and spectrally localized components called Intrinsic Mode Functions (IMFs). HT of the extracted IMFs, that reveals the non-stationarity of a signal through the computation of the instantaneous frequency and the instantaneous amplitude, is the second step of HHT. Furthermore, EMD-based TF representation enables us to embed the detrending of EEG signals by simply removing the corresponding IMFs. Results and Conclusion: Events in EEG can be uniquely characterized by a set of temporal, spectral and spatial signatures which their outer product makes a rank-one tensor. In a PARAFAC model, the observed EEG tensor is decomposed as a linear combination of rank-one tensors, each of them corresponding to an EEG event. Simulation results show that multi-way analysis of EEG greatly improve separation and localization of overlapping events in EEG and furthermore, the extracted signatures using PARAFAC decomposition of HHT-based EEG tensor, exploiting the merits of HHT, are more localized compared to CWT-based tensor analysis by having a higher Gini Index, which is used for measuring the sparsity and the concentration of energy in a signal. Removal of low frequency trends in EEG signal is essential and failure to do so can result in masking of the event of interest. Detrending of EEG is effectively embedded in HHT-based multi-way analysis.

SP166.1 - Enhanced Transcutaneous Electrical Nerve Stimulation (eTENS): A Novel Method of Achieving Posterior Tibial Nerve Stimulation Therapy for Overactive Bladder Author(s): <u>Paul Yoo</u>

Institute Of Biomaterials And Biomedical Engineering, University of Toronto, Toronto/CANADA

Overactive bladder (OAB) is characterized by symptoms of urinary urgency, frequency, and incontinence that can significantly affect quality of life. Posterior tibial nerve stimulation (PTNS) is an emerging therapy for OAB, where clinical efficacy has been shown as comparable to drugs and sacral nerve stimulation. PTNS therapy is delivered as periodic (e.g., weekly) stimulation sessions that result in improved bladder symptoms over a period of 12 weeks. While early studies attempted to use conventional transcutaneous electrical nerve stimulation (TENS) for providing OAB therapy, percutaneous stimulation using needle electrodes was subsequently found to provide significantly greater therapeutic effects. Despite the improved therapeutic outcomes however, percutaneous stimulation requires a trained clinician to deliver therapy and also entails repeated visits to the clinic. Furthermore, recent PTNS trials identify long-term compliance to therapy as a significant limiting factor for patients (i.e., annual drop-out rate > 12 %).

As a potential solution, we present a novel method of electrically stimulating peripheral nerves. Called enhanced transcutaneous electrical nerve stimulation (eTENS), this method achieves neural activation by coupling a conventional TENS electrode with an electrically-passive element placed in close proximity to the target nerve. Using computational software (Comsol Multiphysics + Matlab), we implemented the eTENS system in a model of the rat posterior tibial nerve (PTN). The electrically passive element was modeled as a nerve cuff placed around the PTN trunk; while the TENS electrode was depicted as a monopolar electrode located on the skin surface. The level of neural activation achieved by current passing through the TENS electrode was quantitatively approximated by the activating function, i.e., the second spatial difference of the extracellular potential along myelinated PTN fibers (diameter = 10 μ m).

The results of our computational simulations showed that neural excitability by surface stimulation – as predicted by the activating function – increased significantly when the target nerve was instrumented with an electrically-passive implant (e.g., nerve cuff). When compared to the case with "no implant", our model predicted that the eTENS system can achieve activating function values that were up to 6.4 times greater. These results, in turn, suggest that electrical activation of a target nerve can be achieved with stimulation amplitudes 0.15 times lower than that required by conventional TENS. Our computational model further shows that this enhancement in neural excitability depends on several key factors: physical dimensions and conductivity of the passive implant, depth of the target nerve from the skin surface, and relative alignment of the passive implant with the surface electrode.

The results of our computational study support the idea of enhancing the effectiveness of TENS by coupling the stimulus with an electrically-passive element. We have characterized the role of individual model parameters with respect to neural excitability, and have thereby identified key design parameters critical for testing the eTENS system in vivo. Further long-term implant studies are required for clinical translation in OAB patients.

SP166.2 - Decreasing Upper Extremity Demands During Sitting Pivot Transfers for Individuals with Spinal Cord Injury by **Utilizing Functional Electrical Stimulation**

Author(s): Stephanie N. Bailey¹, Scott W. Slivka², Lisa M. Lombardo1, Kevin M. Foglyano1, Ronald J. Triolo3

¹Motion Study Laboratory, Louis Stokes Cleveland Department of Veterans Affairs Medical Center, Cleveland/UNITED STATES OF AMERICA, ²Department Of Physical Therapy, Cleveland State University, Cleveland/UNITED STATES OF AMERICA, 3Departments Of Orthopaedics And Biomedical Engineering, Case Western Reserve University, Cleveland/UNITED STATES OF AMERICA

INTRODUCTION

The sitting pivot transfer (SPT) is a functional task performed by individuals with spinal cord injuries (SCI) that requires quick, intense forces on the upper extremities (UEs). Performed an average of 15-20 times/day [1], this repetitive task could be a contributing factor to the prevalence of secondary shoulder pathologies that develop in this population. Implanted functional electrical stimulation (FES) systems have been utilized in individuals with SCI to improve mobility, however, have not been evaluated in the ability to improve SPTs by reducing the demand to the UEs.

METHODS

A single subject performed SPTs between a standard wheelchair (WC) and modified chair, placing one hand on the WC armrest and the other on the seat of the chair, similar to the work of Desroches et al [2]. Using a Vicon MX system (Oxford UK) at 100 Hz, kinetics were recorded using an in-chair force plate, one in the floor, and a load cell attached to the armrest of the WC (AMTI, Watertown MA). Trials were randomized between two conditions: volitional and with stimulation to both quadriceps. The quasi-static peak and average moments were calculated about both shoulder joints during the lift pivot phase of SPTs. Paired t-tests (p<0.05) were performed to determine if there was a difference between stimulation conditions.

RESULTS AND DISCUSSION

There were many significant (p<0.05) decreases in average and peak moment about both shoulders when using stimulation (Table 1), which shows that both the leading and trailing limb can benefit from this transfer technique.

Table 1: Decreased Moments during SPT when using Stimulation com- pared to Volitional								
	Average Moment (Nm)			Peak Moment (Nm)				
	Mean	Mean StDev p-value			StDev	p-value		
WC to Chair (n=6)								
Leading UE (L)	17.77	5.00	0.014	30.47	9.96	0.038		
Trailing UE (R)	18.70	4.86	0.009	12.97	4.68	0.064		
Chair to WC (n=12)								
Leading UE (R)	26.84	3.44	<0.001	33.25	3.31	<0.001		
Trailing UE (L)	23.76	3.51	<0.001	28.00	7.04	0.007		

Table 1. D ~ ^ ^ بأسريام مغم ODT مار ، 04:

Future research should focus on an improved set up that is able to detect moment during each phase of the SPT as well as including additional participants with various levels of paralysis to validate findings.

CONCLUSIONS

Utilizing FES in the lower extremities during SPTs has potential to decrease the moment about the shoulder joint bilaterally by shifting a portion of theweight-bearing to the lower extremities.

SP166.3 - Design of Orthotic Mechanisms to Control Stand-to-Sit Maneuver for Individuals with Paraplegia

Author(s): Sarah R. Chang¹, Mark J. Nandor², Kevin M. Foglyano³, Maria Lesieutre², Rudi Kobetic³, Ronald J. Triolo³ ¹Department Of Biomedical Engineering, Case Western Reserve University, Cleveland/UNITED STATES OF AMERICA, ²Department Of Mechanical Engineering, Case Western Reserve University, Cleveland/UNITED STATES OF AMERICA, 3Motion Study Laboratory, Louis Stokes Cleveland Department of Veterans Affairs Medical Center, Cleveland/UNITED STATES OF AMERICA

Individuals with paraplegia can use functional neuromuscular stimulation (FNS) to accomplish sit-to-stand, standing, and standto-sit maneuvers. Stand-to-sit (STS) requires eccentric contractions or lengthening of the active guadriceps muscle. However, eccentric contractions are not well controlled with FNS due to a lack of feedback to the extensor muscles during the maneuver. STS using only FNS results in large impact forces at initial contact with the seating surface, high accelerations at the impact, high knee angular velocities, and a heavy reliance on the upper limbs [1]. In this study, we design and evaluate two different orthotic approaches for controlling the stand-to-sit transition.

A hydraulic hip-knee coupling mechanism was designed to lock, unlock, or couple the ipsilateral hip and knee motion of a hip-knee ankle orthosis. Fluid flow is directed between cylinders at the hip and knee joints, where hip flexion causes the hip cylinder rod to extend and move fluid into the rod side of the knee cylinder, forcing the knee cylinder to retract. The blind sides of the cylinders are connected to move fluid from the knee cylinder blind side into the hip cylinder blind side during movement. A mechanical transmission is used to convert the retraction of the knee cylinder rod to a knee flexion moment. Since the ipsilateral hip and knee will be coupled, individuals with paraplegia can control their hip angle via the upper limbs and thereby control their knee angle.

A hydraulic knee damping mechanism was designed to lock, unlock, or damp knee motion for a hip-knee ankle orthosis. Fluid flow is modulated between rod and blind sides of the knee cylinder through a proportional valve. When the proportional valve is fully closed, the knee cylinder is unable to move and locks the knee. When the proportional valve is partially open, the knee cylinder provides a damping force to help slow the knee angular velocity during knee flexion of STS.

Both mechanisms are undergoing bench testing to ensure safety of the device before clinical evaluation in able-bodied volunteers and

subjects with paraplegia. The hip-knee coupling mechanism provides a consistent 1:1 coupling ratio, where one degree of hip flexion results in one degree of knee flexion. The 1:1 ratio will achieve hip-knee angle relationships as seen in able-bodied STS maneuvers and provide a way to better control the STS for individuals with paraplegia. The damping created by the proportional valve mechanism is in the process of being characterized in bench testing. The mechanisms will be implemented in STS maneuvers for recipients of implanted neuroprostheses with spinal cord injury to quantify the extent to which the mechanisms assist in reducing the impact force on the seating surface and in controlling the STS maneuver.

SP166.4 - Improved Peripheral Nerve Recording with a Small Form-Factor Nerve Cuff Electrode: A Computational Study Author(s): Parisa Sabetian, Paul Yoo University of Toronto, Toronto/CANADA

Electrical nerve stimulation has been successfully used to treat a wide range of neurological disorders (e.g., epilepsy, obstructive sleep apnea) by surgical implantation of nerve cuff electrodes. However, very limited progress has been made in the using these electrodes as part of closed-loop controlled neuroprosthetic systems. The current literature indicates that poor signal-to-noise ratio (SNR) of the recorded neural signal as one of the primary limitations of using nerve electrodes to measure peripheral nerve activity. To this end, we investigated the feasibility of improving signal fidelity by optimizing the design of a small form-factor, bipolar nerve cuff electrode.

A computer model - which combined the use of finite element software (Comsol Multiphysics) and Matlab - was implemented to simulate single fiber action potentials (SFAP) recorded by either a pseudo-tripolar or bipolar nerve cuff electrode. Our simulations showed that the inter-electrode distance (hence, the total length of the nerve electrode) significantly affects the peak-to-peak value (Vpp) of the simulated SFAP. The pseudo-tripolar electrode showed a 17.5-fold increase in Vpp as the cuff length was increased from 7mm to 33mm; whereas the bipolar configuration resulted in a 2-fold increase as the cuff length increased from 7mm to 20mm. Interestingly, at nerve cuff lengths below 13 mm, the Vpp of the SFAP recorded by the bipolar electrode was larger than that of the pseudotripolar electrode. Our model also revealed that the edge length (distance between the outer electrode contact and the edge of the insulating nerve cuff) had a significantly greater effect on the Vpp of SFAPs recorded from bipolar electrodes than that with a pseudotripolar electrode: 80% vs. 1% increases, respectively. Furthermore, simulations involving external noise sources and electrically-shielded nerve cuff electrodes showed dramatic (up to 99%) increases in the SNR of the recorded neural activity.

Concomitant experiments in 12 anesthetized rats confirmed our computational study. By recording stimulation-evoked compound nerve action potentials (CNAPs) from the sciatic nerve, we compared the Vpp value of the CNAP obtained from 3 electrode configurations: pseudo-tripolar (cuff length = 11 mm), bipolar (type A, inter-electrode distance=7 mm), and bipolar (type B, inter-electrode distance=3 mm). The type A (bipolar) electrode yielded the largest Vpp signal, which was 18% and 29% greater than pseudo-tripolar and type B electrodes, respectively. In 5 experiments, we also showed that electrically shielding the nerve electrode with a highly conductive material significantly increased the SNR by up to 65%.

The preliminary results of this study suggest that modifications to conventional nerve cuff electrodes can have significant effects on the fidelity of recorded neural signals. Both computational and experimental data suggest that design variable such as the edge length, inter-electrode distance and the presence of external shielding markedly improve the SNR. Further work is needed to test these ideas under more realistic conditions, such as spontaneous neural activity in either acute or long-term implant studies.

SP166.5 - Effect of stimulation on non-erect postures with a standing neuroprosthesis

Author(s): <u>Brooke Odle</u>¹, Musa L. Audu¹, Raviraj Nataraj², Ronald J. Triolo¹

¹Biomedical Engineering, Case Western Reserve University, Cleveland/UNITED STATES OF AMERICA, ²Orthopaedics, Case Western Reserve University, Cleveland/UNITED STATES OF AMERICA

Neuroprostheses can enable individuals with spinal cord injury stand erect from otherwise seated positions in the wheelchair [1]. To prevent collapse, current systems stiffen the lower extremities through continuous supramaximal activation of the knee, hip and trunk extensors. This approach does not allow for modulation of stimulation to enable users assume other than erect postures except by pulling or pushing against the continuously activated muscles with the arms. We hypothesized that appropriate changes in stimulation to ankle and hip muscles would decrease upper extremity effort exerted on a support device with changing posture. Preliminary experiments were performed to determine effects of altering stimulation on standing postures for one recipient of an implanted neuroprosthesis with motor and sensory complete paraplegia.

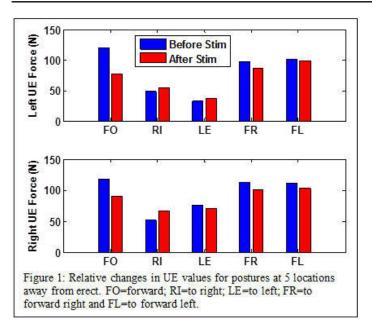

The limits of the postures achievable with upper extremity effort on a walker were defined with constant stimulation as the subject leaned as far as possible from erect in five different directions: forward, left, right, and diagonal (forward-right and forward-left) while center of pressure (CoP) at the extreme leaning positions were recorded. A subject-specific musculoskeletal model was used to generate optimal muscle activations required to maintain postures at the five extreme positions using inverse dynamics. Muscle activations were scaled to the threshold and saturation level pulse-widths (PWs) for each of the stimulated muscles. With real-time visual feedback, subject later adjusted her standing posture to move her CoP from erect to each of the 5 locations from the first experiment. After stabilizing at the new posture, stimulus levels were adjusted to coincide with the optimal values for the new CoP location as computed from inverse dynamics while the UE forces exerted on the instrumented walker were measured.

UE effort reduced by about 30% between left and right in the fore-aft direction and between 5%-10% in the diagonal directions (Figure 1). A relative increase (mean 20% between left and right UEs) was noted for movements to extreme left/right directions. The preliminary results indicate the potential for reducing UE forces (especially toward the forward direction) when optimal stimulus levels are applied. Future experiments will involve repeated trials on additional subjects. The ability to vary stimulus levels would enable users of standing neuroprostheses to vary their postures in a task-dependent manner to undertake activities of daily living which would otherwise be impossible from an erect posture.

SP166.6 - Automatic Detection of Destabilizing Wheelchair Conditions for Modulating Actions of Neuroprostheses to Maintain Seated Posture

Author(s): Anna Crawford¹, Musa L. Audu¹, <u>Ronald J. Triolo²</u> ¹Louis Stokes VA Medical Center, Cleveland/UNITED STATES OF AMERICA, ²Department Of Orthopaedics, Case Western Reserve University, Cleveland/UNITED STATES OF AMERICA

The number of wheelchairs users and thus wheelchair related accidents in the United States is growing. There are an estimated 100,000 wheelchair related accidents a year in the United States, primarily resulting from tips and falls1. Constant stimulation of the otherwise paralyzed core hip and trunk muscles can stabilize seated posture and return users to and maintain erect sitting positions in response to applied disturbances^{2,3}. The goal of this study is to automatically predict and detect potentially destabilizing conditions encountered by wheelchair users to control the actions of a neuroprosthesis to prevent falls and improve manual propulsion efficiency by appropriately modulating stimulation. Wireless inertial measurement units consisting of tri-axial acceleration and gyroscopic sensors⁴ were applied above the right caster of the wheelchair frame and on the sternum of 4 individuals with low cervical to low thoracic spinal cord injuries. Subjects propelled over level ground, ascended and descended 5 and 10 degree ramps, negotiated sharp turns and simulated rough terrain consisting of closely spaced and loosely spaced rumble strips, and completed simulated collisions such as sudden stops and a curb drop. A Vicon motion capture system acquired signals from the wireless sensors and tracked the position of both the wheelchair and user for use as a gold standard for detecting the each event and classifying each maneuver. Sensor data were exported and processed in Matlab. Mean and standard deviations of features including individual components and resultant magnitudes of the accelerometer and goniometer signals at the onset and during, and the steady state propulsion leading up to or following each event were calculated for each trial. Distinctly different signatures of feature values were observed for each event which could be incorporated into a generalized classifier for discrete event detection. For example, the gyroscopic data in forward and lateral directions and the component of acceleration in the anterior-posterior direction as well as the resultant acceleration were most sensitive to discriminating sudden stops from other states. Construction and verification of a wireless inertial measurement based wheelchair event classifier to control a neuroprosthesis to modulate stimulation in an appropriate manner to maintain seated stability and optimal performance is ongoing.

SP166.7 - Selecting Upper Extremity Command Signals to Modulate Electrical Stimulation of Trunk Muscles during Manual Wheelchair Propulsion

Author(s): Kyle P. Tepe¹, Stephanie N. Bailey², <u>Ronald J. Triolo²</u> ¹Biomedical Engineering, Case Western Reserve University, Cleveland/OH/UNITED STATES OF AMERICA, ²Motion Study Laboratory, Louis Stokes Cleveland Department of Veterans Affairs Medical Center, Cleveland/UNITED STATES OF AMERICA

Introduction

Manual wheelchair propulsion (MWCP) is known to be mechanically inefficient. Shoulder pain is frequently reported by manual wheelchair users after paralysis due to spinal cord injury (SCI)¹. Neuroprostheses employing functional neuromuscular stimulation (FNS) can reactivate paralyzed muscles controlling the pelvis and torso while sitting². Low-level constant stimulation to stiffen the hips and trunk can improve mechanics of MWCP over level surfaces and at comfortable speeds³. We hypothesize that synchronizing activation of the hip and trunk flexor and extensor muscles with the MWCP cycle is necessary to improve efficiency in more challenge tasks like ramps and sprints. This study evaluated the suitability of upper extremity (UE) electromyographic (EMG) activity as a command signal to appropriately time stimulation with the stroke cycle.

Methods

A 38-year-old female with a T3 SCI (AIS A) was instructed to push her own wheelchair while on a treadmill in a V-Gait virtual reality environment (Motek Medical, Amsterdam, the Netherlands). Wireless EMG (Delsys, Natick MA) from eight bilateral UE muscles was acquired synchronously with pushrim kinetics (SmartWheel, OutFront, Mesa AZ). Threshold-based detection of total pushrim force was used to define individual MWCP cycles and distinguish contact (push) from recovery phases⁴. At least 50 MWCP cycles were obtained at self-selected, fast (+20%) and slow (-20%) speeds. EMG data during individual propulsion cycles were obtained using synchronized SmartWheel data, normalized in length, and averaged across all cycles.

Muscles were qualitatively classified as contact or recovery phase muscles based on their activity over the cycle. Signal strength was quantified by calculating the statistical range of each ensemble average for each condition. Relative timing of the strongest and most consistent signals with respect to contact and recovery phase transitions were considered optimal candidates for command sources for an implanted neuroprosthesis.

Results

Right pectoralis major and right posterior deltoid muscles exhibited the largest statistical ranges and were best correlated with contact and recovery phases, respectively, for all propulsion conditions. Performance of a classification algorithm using this combination of muscles to detect contact and recovery states of wheelchair propulsion is currently being quantified in preparation for clinical testing of an EMG-based neuroprosthesis control system to modulate stimulation appropriately with the propulsion cycle and determine its effect on MWCP efficiency during challenging real-world conditions.

TRACK 12: MEDICAL DEVICES

SP167.1 - Medical Devices

Author(s): <u>Aaron Fenster</u> Imaging Research, Robarts Research Institute, London/ON/CANADA

The continuous advances in technology and software, as well as their widespread use in diagnosis and treatment has provided new and transformative capabilities to physicians. The past 3 decades have witnessed revolutionary advances with the development and optimization of PET, CT, MRI and ultrasound imaging for diagnosis of a wide range of diseases. The next few decades are likely to bring advanced technologies to surgical and minimally invasive interventional methods to treat diseases. Advanced robotic systems have already had an important impact on surgical procedures as demonstrated by the da Vinci robotic system. While advanced tools and visualization software are continuing to be developed for robotic aided open surgical systems, many innovations are still required for image-guided minimally-invasive (i.e., percutaneous) interventional systems.

Many researches and companies have been focusing on developing a variety of novel robotic, navigation, guidance and visualization systems to be used for specific surgical/interventional indications. For example, revolutionary systems have been developed to be MR compatible (i.e., operate within or near an MR scanner), allowing accurate, precise and reliable minimally invasive MR-guided interventions such as prostate biopsy and therapy. Other systems have been developed that use 3D ultrasound fused with MR or CT images to guide biopsy and interventional tools. This approach makes use of the high quality images provided by MR and CT for identification of the targets together with the real-time ultrasound guidance of the interventional tools into the body. Examples of this type of systems include 3D ultrasound with MR fusion to guide prostate biopsy, as well as 3D ultrasound fused with CT images to guided focal ablation of liver tumors using radio-frequency or microwave energy delivery systems.

Innovations in robotics/mechatronics coupled to advanced software tools have resulted in complex and crowded surgical and therapy rooms. Thus, innovators have been developing a variety of virtualreality guidance and navigation technologies making use of optical and electro-magnetics navigation systems. These systems are being developed and used in neuro-surgery as well as for focal liver tumor ablation. In addition, manipulation of tools and the complex set of images has required innovation in non-touch control as viewing and manipulating of tools and image display through use of a mechanical device such as a mouse, keyboard or touchscreen are problematic, requiring the physician to break the sterile field during surgery. Additionally, the surgeon's hands are likely covered in bodily fluids, which could interfere with use of these devices. Thus, gesture-based systems allowing 3D control through real-time highcontent virtual reality navigation would permit complex functions to be controlled without touching mechanical devices.

Clearly, we are in the middle of possibly the next revolution for medical imaging devices, which promise to integrate robotics, advanced software, virtual realty navigation with a variety of therapy/surgical tools. In this paper, we will focus on a survey of image-guided surgical/interventional medical devices and the potential direction this field will take over the next decade.

Learning Objectives:

1) Chllenges facing developers of image-guided intervemtion devices

2) Current state of medical devices used in image-guided intervention.

3) Opportunities for development of new and transformative medical devices used in image-guided intervemtion.

SP167.2 - Dielectric Properties of Urine for Diabetes Mellitus and Chronic Kidney Disease between 0.2 GHz and 50 GHz Author(s): <u>Hua Nong Ting</u>¹, Peck Shen Mun¹, Teng Aik Ong², Yip Boon Chong³, Kwan Hong Ng⁴

¹Department Of Biomedical Engineering, University of Malaya, Kuala Lumpur/MALAYSIA, ²Department Of Surgery, University of Malaya, Kuala Lumpur/MALAYSIA, ³Damansara Specialist Hospital, Petaling Jaya/MALAYSIA, ⁴Department Of Biomedical Imaging, University of Malaya, Kuala Lumpur/MALAYSIA

This paper investigates the dielectric properties of urine among normal subjects, subjects with diabetes mellitus (DM) and subjects with chronic kidney disease (CKD) at microwave frequency between 0.2 GHz and 50 GHz. The measurements were conducted using openended coaxial probe at room temperature (25° C), 30° C and human body temperature (37° C). Statistical significant differences in dielectric properties were observed across temperatures among normal, DM and CKD subjects. Significant differences were reported across subject groups at 25° C, 30° C and 37° C respectively.

SP167.3 - Intraoperative Bioelectrical Impedance Measurement for Assisting Segmental Renal Artery Clamping Partial Nephrectomy

Author(s): Jun Du¹, <u>Yu Dai²</u>, Qing Yang¹, Jianxun Zhang² ¹Tianjin Medical University Cancer Institute and Hospital, Tianjin/ CHINA, ²Institute of Robotics and Automatic Information System, Nankai University, Tianjin/CHINA

Critical procedures of segmental renal artery clamping partial nephrectomy (SACPN) includes segmental renal artery (SA) discrimination and ischemic area identification. Due to limitations of intraoperative ultrasonography, novel technique to facilitate SACPN is being needed. The aim of this paper is to explore whether intraoperative bioelectrical impedance spectroscopy (EIS) assessment could facilitate SACPN. Five domestic pigs were included in present study. The noninvasive electrical impedance sensor we developed consists of two stainless steel spherical electrodes, which are used to measure impedance spectra over the frequency range of 200 kHz to 5 MHz. EIS of renal artery and renal vein were assessed. After SA clamping, EIS of ischemic area, nonischemic area and ischemicnonischemic boundary of kidney were examined. In porcine model, EIS of renal artery is significantly higher than renal vein (p<0.05). After SA clamping, EIS of ischemic area was significantly higher than nonischemic area (p<0.05). In addition, EIS of ischemic-nonischemic boundary was between that of ischemic and nonischemic area. The experimental results proved that the intraoperative EIS assessment could possibly facilitate SACPN through SA discrimination and renal ischemic area identification.

SP167.4 - Renal Volume Estimation by Ultrasound Parallel Scanning for Polycystic Kidney Disease Follow-up Author(s): <u>Franco Simini</u>¹, Mauro Sitrin¹, Esteban Arrua¹, Diego Tobal², Luciana Urruty¹, Oscar Noboa² ¹Núcleo De Ingeniería Biomédica, Universidad de la República, Montevideo/URUGUAY, ²Nephrology Department, Universidad de la República, Montevideo/URUGUAY

Renal size provides information for the diagnosis and prognosis of kidney diseases. Volume measurement is usually based on ellipsoid calculations derived from Ultrasound (US) imaging. Complex pathologies such as Polycystic Kidney Disease (PKD) require images obtained with contrast media or ionising radiations (X Rays), not suitable due to toxicity and radiation effects. We have developed NEFROVOL, a low cost, noninvasive solution to reconstruct renal structure and to estimate its volume, using parallel US scans (Figure 1)

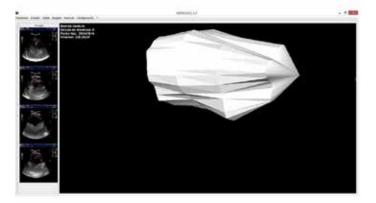

Figure 1: 3D reconstruction of a sweet potato. Four US scans are shown at the left and a view of the solid in the centre.

Parallel and equidistant kidney sections are obtained using a cutaneous Grid. The set of 4 to 8 scans are processed by the Volumetric Pixel Method (VPM) after each kidney layer was obtained with the Layered Convex Hull Method (LCHM), keeping both the precision of the VPM and the speed of LCHM.

Patient	Cuts	Dimensions	Real NEFROVOL		Difference %	
1	3	10.74x4.99x6.56	184.08	138.05	-25	
2	3	9.30x4.56x6.41	129.85	164.01	21	
3	4	11.84x5.04x5.49	171.39	172.76	1	
4	3	10.35x3.73x5.50	111.18	109.0	-2	

Table 1 Test of NEFROVOL measuring KIDNEYS of volunteers

Tests on geometric solids, fruit and patients yield estimates within 13%, 17% and 25% of the real volume, respectively. The volume of normal kidneys can be measured by conventional ellipsoidal formula and agrees with NEFROVOL calculation in patients 3 and 4. Transplanted patient 1 and volunteer patient 2 show larger differences: up to 25% of the volume.

NEFROVOL generates standard electronic medical record documents (single measurement or trend), and is compatible with 3D printing by generating STL files.

NEFROVOL addresses the problem of 3D reconstruction of organs from US scanner images, adding the estimation of volume for follow up purposes. Despite the low precision, NEFROVOL can be of used to monitor kidney volume increase, which is the goal of the research. Better precision will be addressed by including intermediate parallel scans.

SP167.5 - Can Removal of Middle Molecular Uremic Retention Solutes be Estimated by UV-absorbance Measurements in Spent Dialysate?

Author(s): <u>Kai Lauri</u>¹, Merike Luman², Jana Holmar¹, Ruth Tomson¹, Sigrid Kalle¹, Jürgen Arund¹, Fredrik Uhlin³, Ivo Fridolin¹ ¹Department Of Biomedical Engineering, Technomedicum, Tallinn University of Technology, Tallinn/ESTONIA, ²Centre Of Nephrology, North-Estonian Medical Centre, Tallinn/ESTONIA, ³Department Of Nephrology, University Hospital, Linköping, Linköping/SWEDEN

The objectives of this study were: (1) to compare removal of the middle molecular (MM) and small uremic retention solutes; (2) to investigate if MM removal can be assessed by UV-absorbance at the wavelength of 297 nm dur-ing various dialysis treatment modalities. Seven uremic patients, four females and three males, mean age 58.1±8.7 years, were included into the study during 28 chronic hemodialysis sessions. A parameter, reduction ratio (RR) in percentage, was calculated for a small uremic retention solute urea, for a MM retention solute beta2-microglobulin (B2M), and for UV-absorbance at the wavelength of 297 during different dialysis modalities: conventional hemodialysis (HD), high flux hemodialysis (HF-HD), and postdilutional online hemodiafiltration (HDF) with different parameter settings. Achieved results were compared regarding mean values and SD, and by systematic and standard errors (BIAS±SE). It was found that RR is similar for small and MM uremic retention solutes in case of dialysis modality with the highest convective transport, HDF (78.9±8.1% for urea and 78.1±6.8% for B2M, N=7). Moreover, RR of small uremic retention solutes can be estimated with sufficient accuracy by UV-absorbance at 297 nm in the spent dialysate for all modalities (BIAS±SE: 1.7±4.0%, N=28), and for MM uremic retention solutes only for HDF (BIAS±SE: 1.1±7.1%, N=7). The results should be confirmed by appropriate kinetic modeling in the next studies.

Keywords— Middle molecules, uremic toxins, beta2-microglobulin, uremic retention solutes, urea, dialysis, UV-absorbance.

SP167.6 - Discrimination of prostate tissue with a combination of Raman spectroscopy and tactile resonance technology Author(s): <u>Olof Lindahl</u>¹, Morgan Nyberg², Ville Jalkanen³, Kerstin Ramser¹, Börje Ljungberg⁴, Anders Bergh⁵

¹Centre For Biomedical Engineering And Physics, Umeå University, Umeå/SWEDEN, ²Engineering Sciences And Mathematics, Luleå University of Technology, Luleå/SWEDEN, ³Applied Physics And Electronics, Umeå University, Umeå/SWEDEN, ⁴Surgical And Perioperative Sciences, Urology And Andrology, Umeå University, Umeå/SWEDEN, ⁵Medical Bioscience, Pathology, Umeå University, Umeå/SWEDEN

Prostate cancer (PCa) is the most common cancer in men in Europe with 416 700 new cases reported in 2012 and in the USA with an estimate of 233 000 new cases for 2014. The most prevalent curative treatment for PCa is radical prostatectomy (RP). In Europe, RP made up 59 % of the curative treatments in 2000 and in the USA about 70 000 men were offered RP in 2003. The standard procedure after RP is to examine the resected prostate histologically. One important examination is the evaluation of tumour cells in the surgical and the anatomical margins (PSM) since there is an increased risk of PCa recurrence if tumour cells are found at the surgical margin. A new dual-modality probe has been developed for prostate cancer detection by us. The probe combines two methods, a tactile resonance sensor that measures the tissue stiffness modality, and Raman spectroscopy, that measures the molecular content. Together the two methods are the basis for the dual-modality probe and a hypothesized method intended for detecting PSM during radical prostatectomy. The idea is that the surgical margin, i.e. the surface, of the prostate is to be scanned to locate stiffer areas using the stiffness modality of the combined instrument. Harder nodules are an indication of tumour presence but also of stiff benign structures,

such as prostate stones. The Raman spectroscopy modality would then be applied at these locations to discern the boundaries between cancerous and non-cancerous stiff tissue.

The aim of this study was to evaluate the ability of the combined probe to discriminate different tissue types in fresh human prostate slices ex vivo.

The results from four human prostates show that the tactile resonance modality was able to discriminate significantly between two different tissue types: soft epithelial tissue and stiff stroma (p < 0.05). The Raman spectra exhibited a strong fluorescent background at the current experimental settings. However, stroma could be discriminated from epithelia by integrating the value of the spectral background. Combining both parameters resulted in 100% sensitivity and 91% specificity.

We conclude that the results indicates that the two modalities together increase the sensitivity and specificity and are promising for further development of an instrument and method for discriminating prostate tissues and thus also cancer that is the final goal.

SP167.7 - Appropriate Medical Devices for Low Resource Settings: Electronically Controlled Gravity-Feed Intravenous Infusion Set

Author(s): <u>Philippa N. Makobore</u>¹, Paul Niyitanga¹, Simon Ssekitoleko¹, Robert Ssekitoleko², Peter Rolfe³

¹Instrumentation Division, Uganda Industrial Research Institute, Kampala/UGANDA, ²Ugandan Maternal and Newborn Hub, Kampala/UGANDA, ³School Of Electrical Engineering And Automation, Harbin Institute of Technology, Harbin/CHINA

ABSTRACT

Background

Despite an improvement in the reduction of the Infant Mortality Rate (IMR), 45/1000 as of 2012 down from 54/1000 in 2009, Uganda continues to lag far behind target for achieving the Millennium Development Goals. Children continue to die from preventable diseases such as pneumonia and diarrhoea which contribute to nearly 40% of the IMR. The majority of neonates and infants with pneumonia, diarrhoea and malaria often present in advanced disease stages; hence requiring intravenous fluid and/or drug delivery. Unfortunately, existing infusion sets are not tailored to the needs and resources of Uganda. Medical equipment surveys in Low and Middle Income Countries (LMICs) show that equipment needed for neonatal and infant care are imported and in short supply largely due to high cost. It is also invariably poorly maintained, and is often rendered nonfunctional or potentially hazardous by users. Furthermore, electrically operated devices are usually unable to withstand prevailing intermittent power supply.

Method

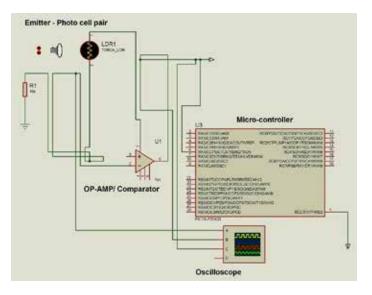

The Electronically Controlled Gravity-Feed Intravenous (ECGI) Infusion Set has been designed to overcome the deficiencies of existing intravenous therapy systems by providing an easy to use, cost effective plug-on intravenous administration monitoring and control system. Additional features will include occlusion detection, high and low drip rate alarm settings and visual readout of the drip rate all provided for on a microcontroller platform. The power supply will be characterized by a hybrid battery charging bed (solar and electrical mains). Implementation will be executed using Proteus software, preliminary prototyping with bread boards and finally Printed Circuit Board (PCB) development.
